(b) The galvanised steel sheets used in manufacture shall comply with AS 1397 for steel base grade G250

and a minimum coating Class of Z600.

(c) Where specified, the pipes and drainage units shall be given a protective coating over the steel, after assembly of a coal tar epoxy paint or equivalent as approved by the Superintendent, to a thickness of 400 microns.

(d) Field cut ends shall be carefully wire brushed to remove any scale followed immediately by two coats of zinc-rich organic primer complying with AS/NZS 3750.9 or two coats of inorganic zinc silicate paint complying with AS/NZS 3750.15.

(2) Helical lock-seam corrugated steel pipe

(a) Helical lock-seam corrugated steel pipe shall be supplied in accordance with AS 1761 and AS 1762 and shall be of the class and size as shown on the drawings.

(b) The galvanised steel sheet used in manufacture shall comply with AS 1397 for steel based grade G250 and a minimum coating Class of Z600.

(c) Unless otherwise approved by the Superintendent, no part of the pipe shall incorporate steel strips which have been joined by welding. Field cut ends shall be carefully wire brushed to remove any scale followed immediately by two coats of organic zinc-rich primer complying with AS/NZS 3750.9 or two coats of inorganic zinc silicate paint complying with AS/NZS 3750.15. Pipes and coupling bands shall be given a protective hot-dip coating of bitumen on both sides to AASHTO standard M190 or equivalent as part of the process of manufacturing.

(3) Bolted steel pipes, pipe arches and special shapes

(a) Bolted steel pipes, pipe arches and special shapes shall be supplied in accordance with AS 2041 and shall be of the class and size as shown on the drawings. The corrugated pipe or plate shall be hot-dip galvanised on both sides after fabrication in accordance with the requirements for coating thickness and mass for articles in AS/NZS 4680.

(b) Also, after assembly, all bolted steel pipes, pipe arches and special shapes shall be given a protective coating on the outside of the steel plate, of a coal tar epoxy paint complying with AS 3887 or equivalent paint approved by the Superintendent. Invert plates shall be coated on the outside before they are placed on the pipe bed. The plate surface shall be cleaned and degreased with a cleaning solution recommended by the protective coating manufacturer. The protective coating shall be applied to give a uniform minimum dry thickness of 400 microns. Any coating damaged shall be recoated by first cleaning any grease, mud or other foreign matter from the affected area. The area shall then be recoated so that the minimum dry thickness of the coating is 400 microns.

(4) Materials and surface treatment of steel pipes and pipe arches

All steel pipes and pipe arches will require an Engineer's certification that the pipe materials and surface treatments are adequate to provide for installation and in-service loading, as well as corrosion protection for a satisfactory design life of 100 years, unless indicated otherwise on the drawings. Such certification shall address the chemistry of the soil, groundwater, stream and backfill material as specified SC6.4.6.6.4(5).

(5) Materials against steel structures

(a) The severity of corrosive attack on steel structures will depend on the pH value and electrical resistivity of the soil surrounding the structure and the pH value of the water in the stream.

(b) Besides meeting the normal requirements of the bedding, selected backfill materials and the materials used for embankment construction above the steel structures and within a horizontal distance from the structure equal to the height of the filling over the structure, the pH and resistivity limits as shown in Figure SC6.4.6.6.2 will determine the level of corrosion protection required.

(c) Notwithstanding the height of fill, embankment material within 6m of the structure shall conform to these requirements.

(d) The pH and electrical resistivity of the material shall be determined in accordance with AS 1289.4.3.1 and AS 1289.4.4.1.

(e) The Contractor shall nominate the sources of the various materials and submit documentary evidence

from a NATA registered laboratory that the representative samples conform to the requirements of this clause and the protective treatment provided. The samples shall be pre-treated if necessary so as to represent the condition and grading when compacted and in service.

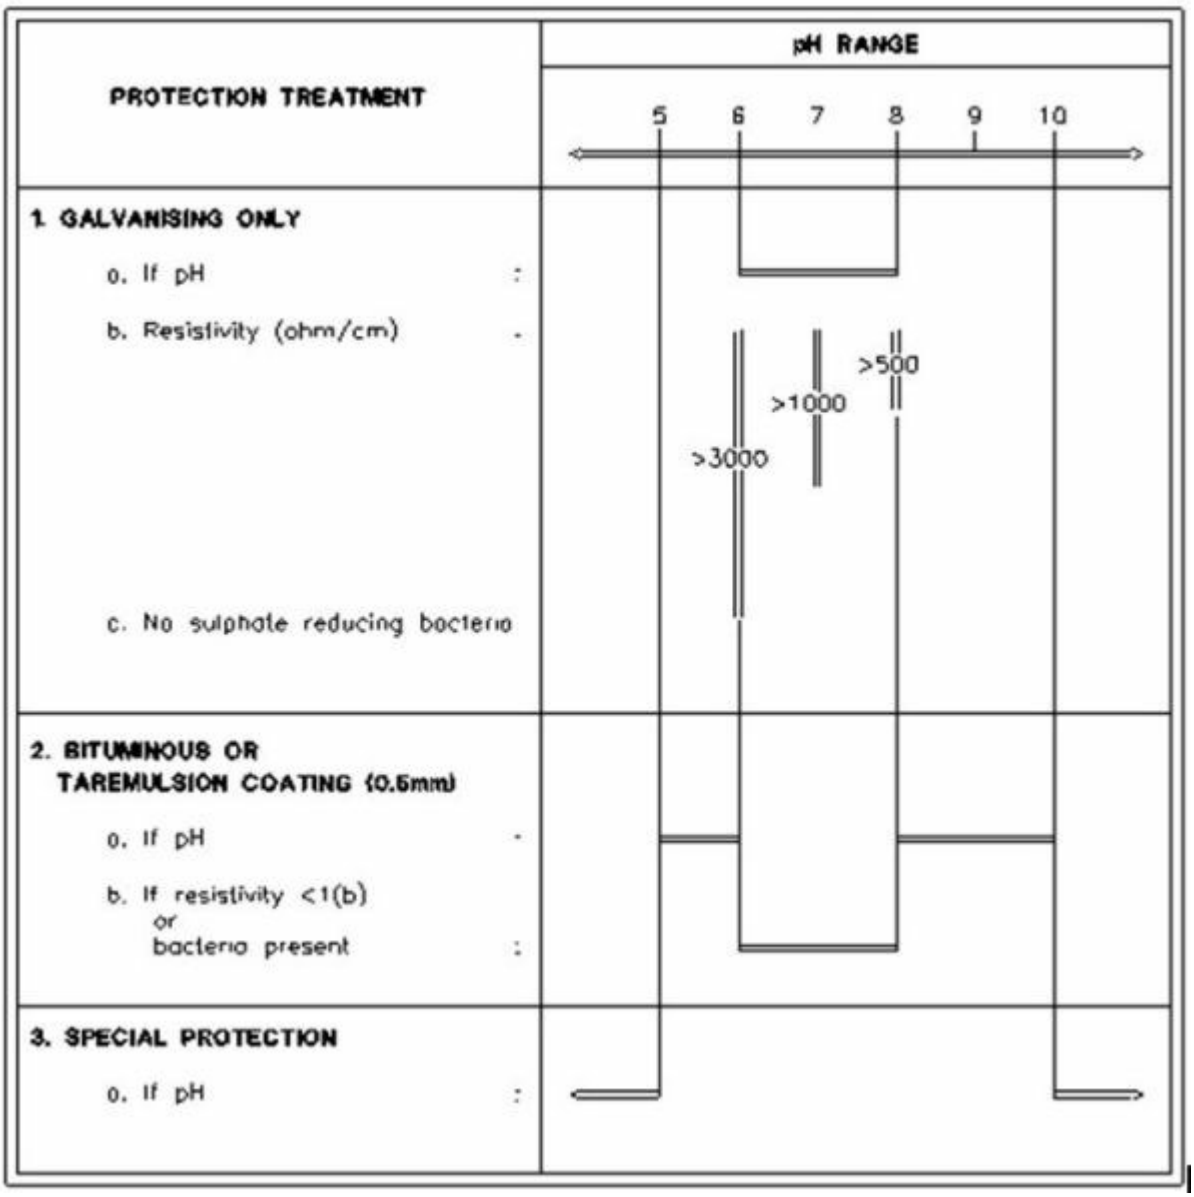

Figure SC6.4.6.6.2 Corrosion protection requirements for steel structures

(6) Excavation and foundation preparation

(a) Unless otherwise indicated on the drawings or approved by the Superintendent, the formation shall be completed to subgrade level and the pipes then installed in the normal trench condition.

(b) The trench shall be excavated to a level 75mm below the design invert and for a minimum width of 600mm on each side of the structure.

(c) Where unsuitable material, as determined by the Superintendent, is encountered at the foundation level, it shall be removed to a depth approved by the Superintendent. The additional excavation shall be backfilled with material complying with, selected material as per SC6.4.6.10 Earthworks (construction).

(d) Where rock is encountered at the foundation level, the foundation shall be excavated for an additional depth of 250mm, or 0.25 times the structure width, whichever is the lesser and for a width equal to the width of the structure. The additional excavation shall be backfilled with material complying with, and compacted to, the requirements for HS3 pipe support as specified in SC6.4.6.6.3 3(b).

(7) Bedding

Bedding shall meet the requirements of SC6.4.6.6.3(3)(f). The thickness of uncompacted bedding material

between the foundation and the outer surface of corrugation shall not be less than 75mm. The uniform blanket of loose material which provides the minimum 75mm thick bedding, shall be placed on the shaped, compacted selected material foundation to allow the corrugations of the structure invert to bed in and become filled with the material.

(8) Installation

(a) General
The assembly of all corrugated steel pipes and pipe arches as well as helical lock-seam corrugated steel pipes shall be carried out in accordance with the manufacturer's recommendations. These recommendations shall be submitted to the Superintendent before assembly or laying of the culverts is commenced.

If deemed necessary after consultation with the manufacturer, temporary bracing of corrugated steel pipes or pipe arches shall be carried out in accordance with the manufacturer's recommendations.

(b) Joints
Corrugated steel pipes or pipe arches shall be joined in accordance with the manufacturer's recommendations and AS 2041.

Where helical-lock seam corrugated steel pipes are to be joined, both ends of the join shall be rerolled with four annular corrugations of pitch 68mm. Coupling of the re-rolled ends shall be made in accordance with AS 1761 by using semi-corrugated bands. Rubber ring joint seals shall be used in conjunction with the coupling bands except where specifically indicated otherwise in the drawings.

All joints or lap joints in pipes or pipe arches (excluding rubber ring joint coupling bands) shall be covered with strips of non-woven geotextile material, of minimum 250mm width and of minimum mass 270 grams per square metre in accordance with the requirements for geotextile in SC6.4.6.20 Subsoil, foundation and pavement drains, to prevent loss of sand backfill or bedding into the pipe.

(9) Backfill

(a) Compaction of the material in the side support and overlay zones shall comply with the requirements of clause SC6.4.6.6.3(5) except that the required relative compaction in the side support and overlay zones shall be 95 per cent (AS 1289.5.4.1 standard compaction). Backfill shall be placed around the steel pipe or structure, to a minimum dimension equal to the pipe width, on both sides.

(b) All material shall be compacted in layers not exceeding 150mm compacted thickness. Each layer shall be compacted to the relative compaction specified before the next layer is commenced.

(c) At the time of compaction, the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content which, unless otherwise approved by the Superintendent, is neither less than 60 per cent nor more than 95 per cent of the apparent optimum moisture content, as determined by AS 1289.5.4.1 (standard compaction).

(d) The remainder of the trench to the underside of the subgrade, or selected material zone as specified in SC6.4.6.10 Earthworks (construction), shall be backfilled with material satisfying the requirements for embankment material as defined in SC6.4.6.10 Earthworks (construction). Where excavation is approved through the selected material zone, the section of trench within the select material zone shall be backfilled with selected material as defined in SC6.4.6.10 Earthworks (construction).

(e) The Contractor shall check the shape of the culvert during backfilling to ensure that on completion of backfilling, the vertical and horizontal centreline dimensions of the pipe or structure shall not vary from the manufacturer's specified dimensions by more than plus or minus 2 per cent for pipes and pipe arches.

(10) Invert protection of corrugated steel pipes and pipe arches

(a) Where shown on the drawings, the invert of corrugated steel pipes and pipe arches shall be protected using sprayed concrete.

(b) The sprayed concrete shall be placed to a thickness of not less than 100mm over the crest of the

corrugations and to a width such that the bottom third of the pipe circumference is covered symmetrically about the invert of the pipe.

(c) All foreign material shall be removed from the surface to be protected. Where corrosion has occurred all loose scale shall be removed.

(d) The production, application and curing of sprayed concrete shall be in accordance with sub-section SC6.4.6.28 Minor concrete works.

(e) The sprayed concrete shall be reinforced with a fabric of hard drawn steel wire 4mm diameter with 200mm square mesh. The fabric shall be securely supported at a central location within the sprayed concrete by non-metallic supports.

(f) Laps in fabric shall be 300mm and a cover of 50mm of sprayed concrete shall be provided to the fabric at all edges.

(g) Immediately after placement of the sprayed concrete, all free water shall be removed and the surface coated with cement slurry.

(h) No water shall be allowed to flow over the surface of the sprayed concrete for twenty-four hours after the placement of sprayed concrete.

SC6.4.6.6.5 UPVC pipes

(1) Materials

(a) Unplasticised PVC (UPVC or similar material) Pipes and Fittings shall be manufactured in accordance with AS/NZS 1254 and shall be of the type and size as shown on the drawings. Where pipes with extreme external diameter are equal to or greater than 450mm (375mm nominal internal diameter) are proposed, a separate approval from the Superintendent and council is required.

(b) Embedment material in the bedding, side support and overlay zones shall be in accordance with bed and haunch zone material in SC6.4.6.6.3(3).

(c) Trench backfill material shall satisfy the requirements for embankment material as defined in SC6.4.6.10 Earthworks (construction).

(2) Excavation and bedding

(a) Unless otherwise indicated on the drawings or approved by the Superintendent, the formation shall be completed to subgrade level and the pipes then installed in the normal trench condition.

(b) Figure SC6.4.6.6.3 and Table SC6.4.6.6.2 indicate the dimensions of bedding and backfilling for pipes laid in trench conditions and embankment conditions, unless otherwise indicated on the drawings.

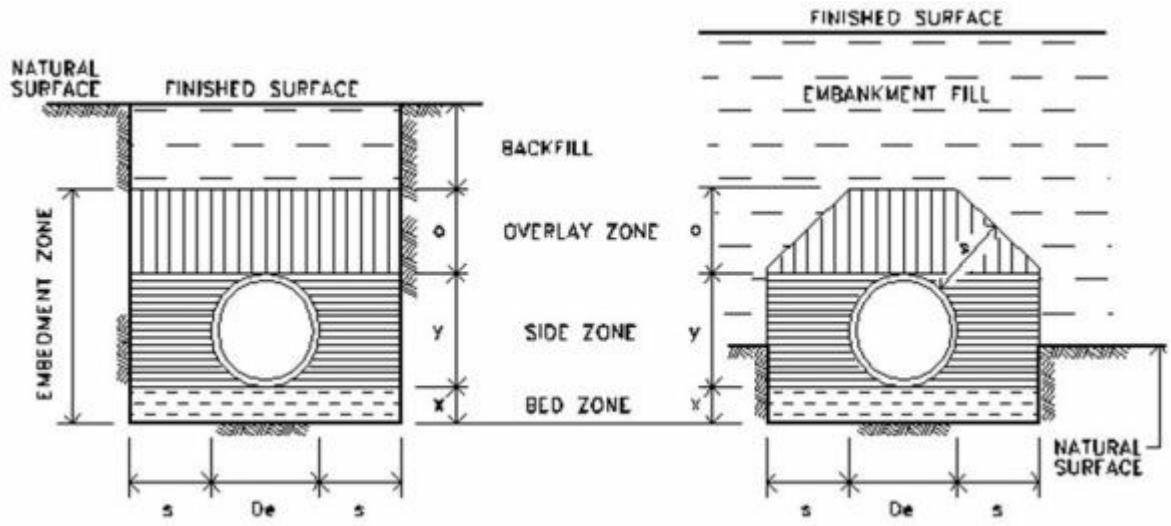

Figure SC6.4.6.6.3 Pipe installation conditions

Table SC6.4.6.6.2 Trench and embedment dimensions

Extreme External	Minimum Dimensions (mm)			
Dia (De)mm	x	s	o	y
[3]75≤150	75	100	100	Pipe dia.
>150≤300	100	150	150	Pipe dia.
>300≤450	100	200	150	Pipe dia.

Note—Where multiple pipes are laid side by side, the minimum distance between the pipes shall be dimension "s" for the larger of adjacent pipes.

(c) Bedding zone material shall be placed and compacted in accordance with the requirements in Table 5.5 of AS/NZS 2566.2.

(3) Installation

(a) Embedment of the UPVC pipe shall be in accordance with the requirements of AS/NZS 2566.2 and to the dimensions shown in Figure SC6.4.6.3.

(b) Pipe laying shall be in accordance with Part 7 of AS 2032 and solvent-cement pipe jointing shall be in accordance with Part 3 of AS 2032. Jointing may be performed with the pipes either in the trench or at ground level. All pipes, or jointed pipelines, shall be lowered into the trench without being dropped. Pipelines shall be placed so that joints are not strained.

(4) Backfill

(a) Compaction of the material in the side support and overlay zones shall comply with the requirements of SC6.4.6.6.3(5) for HS3 support type.

(b) All material shall be compacted in layers not exceeding 150mm compacted thickness. Each layer shall be compacted to the relative compaction specified before the next layer is commenced, or compacted in one operation by saturation and vibration to achieve a minimum Density Index as specified in Table 5.5 of AS/NZS 2566.2 – Buried Flexible Pipelines – Installation.

(c) At the time of compaction, the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content, which, unless otherwise approved by the Superintendent, is neither less than 60 per cent nor more than 95 per cent of the apparent optimum moisture content, as determined by AS 1289.5.4.1 (standard compaction).

(d) The remainder of the trench to the underside of the subgrade, or selected material zone as specified in SC6.4.6.10 Earthworks (construction), shall be backfilled with material satisfying the requirements for embankment material as defined in SC6.4.6.10 Earthworks (construction). Where excavation is approved through the selected material zone, the section of trench within the select material zone shall be backfilled with selected material as defined in SC6.4.6.10 Earthworks (construction).

SC6.4.6.6.6 Limits and tolerances

The limits and tolerances for materials and product performance related to the various clauses in this sub-section are summarised in Table SC6.4.6.6.3 Summary of Limits and Tolerances below:

Table SC6.4.6.6.3 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
	Culvert Position	± 10mm	SC6.4.6.6.2(1)
	(a) Grade Line	± 6mm	
	(b) Grade line <0.5%		
	(c) Horizontal Alignment	± 50mm	SC6.4.6.6.2(1)
	Bedding		
	(a) Bed and Haunch Zone Compaction	Table 5 – Bedding factors for Working Dead Loads (U, H and HS Supports) of AS/NZS 3725	SC6.4.6.6.3(3)

Backfill - Concrete Pipes (a) Side and Overlay Zone Compaction	Table 5 – Bedding factors for Working Dead Loads (U, H and HS Supports) of AS/NZS 3725	SC6.4.6.6.3(5)

SC6.4.6.7 Precast box culverts

SC6.4.6.7.1 Introduction

(1) Scope

(a) This sub-section covers the installation of precast concrete box culverts and should be read in conjunction with sub-section SC6.4.6.4 Stormwater drainage.

(b) The work to be executed under this Specification consists of:

(i) preparation of foundations;

(ii) provision of bedding;

(iii) construction of base slabs;

(iv) installation of precast culvert units;

(v) headwalls and wingwalls;

(vi) backfilling against structures;

(vii) provision and removal of coffer dams; and

(viii) excavation of inlet and outlet channels.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

(2) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.10 Earthworks (construction)
SC6.4.6.4 Stormwater drainage
SC6.4.6.9 Open drains
SC6.4.6.12 Flexible pavements
SC6.4.6.28 Minor concrete works

(b) Australian Standards:
AS1597.1 - *Precast reinforced concrete box culverts - Small culverts*
AS1597.2 - *Precast reinforced concrete box culverts - Large culverts*
AS/NZS ISO 9001:2008 - *Quality management systems - Requirements.*

(c) Other:
Austroads, *Guide to Geotextiles*
Department of Transport and Main Roads
MRTS05 - *Unbound Pavements*
MRTS24 - *Manufacture of precast concrete culverts*

SC6.4.6.7.2 Materials

(1) Culvert units, link and base slabs

(a) The supply and testing of precast reinforced concrete box culvert units, link and base slabs shall be in accordance with AS1597 with the following alterations or additional requirements:

(i) proof load testing must be arranged by the Contractor in batches as specified in either AS1597.1 or AS 1597.2 as appropriate;

(ii) proprietary lifting anchors must be provided in the culvert units, link and base slabs;

(iii) delivery and unloading is the Contractor's responsibility; and

(iv) the supplier must implement and maintain a Quality System in accordance with ISO 9001 to ensure materials, manufacture and proof load testing conform to the appropriate Standards.

(b) A conformance certificate, to AS1597 must be submitted to the Superintendent at least 3 working days prior to dispatch.

(c) Each unit must be marked at time of manufacture with:

(i) type and size;

(ii) casting date;

(iii) manufacturer's name; and

(iv) inspection pass and date.

(2) Handling, delivery and storage

(a) Ensure adequate equipment and load shifting machineries are available for safe handling and unloading.

(b) Upon delivery of precast units, ensure that the following criteria have been achieved:

(i) 70% of the minimum concrete strength;

(ii) small culvert units: Cured to AS 1597.1 clause 2.6.3; and

(iii) large culvert units: Cured to AS 1597.2 clause 2.7.

(c) Prior inspection of the stored precast box culvert units is to be undertaken for dimensional accuracy and defects following delivery. Results of the inspections must show that the units conform to the following:

(i) small culvert unit: To AS 1597.1; and

(ii) large culvert unit: To AS 1597.2.

(3) Concrete

The concrete and reinforcement for cast-in-situ base slabs shall comply with sub-section SC6.4.6.28 Minor concrete works.

(4) Selected backfill

The quality of selected backfill shall comply with the requirements in AS 1597.2, or alternatively comply with the requirements of side/overlay zone materials in Table SC6.4.6.6.1 *Bedding material grading limit* of sub-section SC6.4.6.6 Pipe drainage.

(5) Ordinary backfill

Ordinary backfill is material obtained from culvert excavations, cuttings and/or borrow areas which are in accordance with the requirements for the upper 0.3 m of embankment construction as detailed in SC6.4.6.10 Earthworks (construction).

SC6.4.6.7.3 Construction

(1) Coffer dams

(a) At some sites it may be expedient for the Contractor to construct a coffer dam. The construction of coffer dams shall be the responsibility of the Contractor.

(b) Coffer dams shall be sufficiently watertight to prevent damage of the concrete by percolation or seepage through the sides, and shall be taken sufficiently below the level of the foundations to prevent loosening of the foundation materials by water rising through the bottom of the excavation. Coffer dams shall be adequately braced and shall be so constructed that removal will not weaken or damage the structure.

(c) A coffer dam may be constructed to the actual size of the reinforced concrete invert slab and used as side forms for the concrete. The details of the coffer dam and formwork, and the clearances proposed shall be subject to the approval of the Superintendent, but the Contractor shall be responsible for the successful construction of the work.

(d) Coffer dams which have tilted or have moved laterally during sinking, shall be righted or enlarged to provide the clearances specified. This work will be at the Contractor's expense.

(e) No timber or bracing shall be left in the concrete or in the backfill of the finished structure. Coffer dams, including temporary piles, shall be removed at least to the level of the invert after completion of the

structure. Upon completion of works, remove coffer dams, including temporary piles, at least to the level of the culvert invert after completion of the structure. Ensure that no material associated with the coffer dam or dewatering can enter the culvert.

(2) Excavation

Excavation shall be carried out in accordance with the provisions in sub-section SC6.4.6.4 Stormwater drainage.

(3) Foundations

(a) Rock foundations shall be neatly excavated to the underside of the mass concrete or selected fill bedding shown on the drawings. All minor fissures shall be thoroughly cleaned out and refilled with concrete, mortar or grout. All loose material shall be removed.

(b) Where rock is encountered over part of the foundation only, or lies within 300mm below the underside of the mass concrete or selected fill, all material shall be removed to a depth of 300mm below the mass concrete or selected fill for the full width of the foundation over the length where the rock is encountered. This additional excavation shall be backfilled with ordinary backfill material.

(c) Over-excavation or uneven surfaces shall be corrected with mass concrete so as to provide a uniform surface at least 50mm above the highest points of rock.

(d) Earth foundations shall be finished to line and level to the underside of bedding shown on the drawings. Care shall be taken to avoid disturbing material below this level.

(e) All soft, yielding or unsuitable material shall be removed and replaced with ordinary backfill material as directed by the Superintendent and backfilled in accordance with sub-section SC6.4.6.4 Stormwater drainage.

(4) Bedding

(a) Cast-in-situ base slabs

No bedding material shall be placed until the foundations have been inspected and approved by the Superintendent.

Bedding shall be either mass concrete or lightly bound paving material which complies with the requirements of at least a Type 3, Subtype 3.3 material as defined in the Specification MRTS05 (04/11), whichever is shown on the drawings.

Mass concrete bedding blinding layer shall be 20 mpa compressive strength and shall not be less than 50mm thick over any point in the foundation. It shall be laid to the line and level of the underside of the base slab to a tolerance of ±10mm in level and ±50mm in line. The bedding shall be finished to a smooth surface. Where longitudinal gradients are less than 0.5 per cent, concrete blinding layers shall be installed with +/- 6mm of the grade line.

(b) Precast base slabs

Precast base slabs, U-shaped culvert units and one piece culvert units shall be supported on a bed zone of selected backfill of minimum compacted depth 150mm in accordance with AS 1597.2.

If suitable compaction of the trench subgrade cannot be achieved, it will be the responsibility of the developer to recommend an alternate solution to council to achieve the desired bearing capacity for the structure prior to construction.

(5) Cast-in-situ base slabs

(a) Cast-in-situ base slabs shall be constructed to the dimensions shown on the drawings and in accordance with the requirements of sub-section SC6.4.6.28 Minor concrete works. The invert levels shall be within -10mm to +10mm of the design level, grade 5mm in 2.5m (1 in 500) and plan position ±50mm. Where longitudinal gradients are less than 0.5 per cent cast insitu base slabs shall be installed within +/- 6mm of the grade line.

(b) Recesses or nib walls to accommodate the walls of the precast crown units shall be formed in the base

slab to the dimensions shown on the drawings.

(6) Installation of precast units

(a) Precast units shall not be installed until the base slab has attained a minimum compressive strength of 20 MPa.

(b) Precast crown units shall be placed on a bed of mortar either on the slab or in the recesses in the base slab. Any gaps between the side walls and the sides of the recesses shall be packed with cement mortar. Lifting holes and butt joints between units shall be packed or sealed with cement mortar or grout or flexible joint filler.

(c) Before placement of top slabs on U-shaped units or link slabs on adjacent crown units, the bearing areas of the supports shall be thoroughly cleaned and covered with a bed of mortar of minimum thickness 5mm after placement of precast unit.

(d) Lifting anchor recesses shall be filled to the surface with cement mortar.

(e) In the case of multi-cell culverts, a nominal 50mm gap shall be provided between adjacent cells. This gap shall be filled with cement mortar or grout.

(f) All mortar joints shall be protected from the sun and cured in an approved manner for not less than 48 hours.

(g) All external surfaces of vertical joints between precast crown units, shall be covered full length, and minimum 100mm width, with strips of denso tape or similar as an alternative to joint filling.

(7) Backfill

(a) All bracing and formwork shall be removed prior to backfilling. Prior to backfill placing, present to the Superintendent for inspection all seals, joints and levels.

(b) Selected backfill shall be placed in the side zones of the box culverts and wingwalls, and to a depth of 300mm in the overlay zone of the culverts, in layers with a maximum compacted thickness of 150mm in accordance with the backfilling and compaction requirements of AS 1597.2. Alternatively cohesionless materials can be compacted in one operation by saturation and vibration to achieve a minimum Density Index of 70. The remainder of the excavation shall be backfilled with ordinary embankment fill in accordance with SC6.4.6.10 Earthworks (construction).

(c) Backfill shall be placed against wingwalls, headwalls and retaining walls in accordance with SC6.4.6.28 Minor concrete works.

(d) Backfill layers shall be placed simultaneously on both sides of the culvert with a maximum 600mm level difference to avoid differential loading. Backfilling and compaction shall commence at the wall and proceed away from it.

(e) Where the slopes bounding the excavation are steeper than 4:1, they shall be cut in the form of successive horizontal terraces of at least 1m width before the backfill is placed.

(8) Excavation of inlet and outlet channels

(a) Excavation of inlet and outlet channels shall be carried out as shown on the drawings and shall extend to join the existing stream bed in a regular manner as detailed SC6.4.6.9 Open drains.

(9) Construction loading on culverts

(a) Construction vehicles and plant shall not pass over the culvert until 28 days after the casting of the base slab or until the cylinder compressive strength of the base slab concrete has reached 32 MPa.

(b) Construction vehicle loads on culverts for various design fill heights shall be in accordance with AS 1597.2.

SC6.4.6.7.4 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.7.1 Summary of Limits and Tolerances below:

Table SC6.4.6.7.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Spec Clauses
1.	**Mass Concrete Correction**		
	a) Over highest points of rock	50mm	SC6.4.6.7.3(3)
2.	**Mass Concrete Bedding**		
	a) Level	± 10mm	SC6.4.6.7.3(4)
	b) Level where grade line <0.5%	+/- 6mm	
	c) Line	± 50mm	SC6.4.6.7.3(4)
3.	**Culvert Location**		
	a) Invert Level	±10mm	SC6.4.6.7.3(5)(a)
	b) Invert where grade line is <0.5%	+/- 6mm	
	c) Grade	5mm in 2.5m (1 in 500)	SC6.4.6.7.3(5)(a)
	d) Plan Position	±50mm	SC6.4.6.7.3(5)(a)

SC6.4.6.8 Drainage mats

SC6.4.6.8.1 Introduction

(1) Scope

(a) The purpose of this policy sub-section is to provide standards advice and guidelines for the use and installation of drainage mats.

(b) Drainage mats shall be constructed where and as shown on the drawings or as directed by the Superintendent.

(c) This sub-section should be read in conjunction with SC6.4.6.21 Subsurface drainage.

(d) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in the SC6.4.5 Supervision and construction guidelines

(2) Terminology

Type A drainage mats	are intended to ensure continuity of a sheet flow of water under fills, to collect surface seepage from a wet seepage area or for protection of vegetation or habitat downstream of the road reserve where a fill would otherwise cut the flow of water.
Type B drainage mats	are constructed to intercept water which would otherwise enter pavements by capillary action or by other means on fills and to intercept and control seepage water and springs in the floors of cuttings.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section one as follows:

SC6.4.6.21 Subsurface drainage
SC6.4.6.20 Subsoil, foundation and pavement drains

(b) Australian Standards:

AS 1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio.*

(4) Order of construction

(a) Type A drainage mats shall be constructed after the site has been cleared and grubbed and before commencement of embankment construction.

(b) Type B drainage mats shall be constructed after completion of the subgrade construction and before construction of the pavement.

SC6.4.6.8.2 Construction

(1) Type A mats

(a) Type A drainage mats shall be constructed under embankments as and where shown on the drawings or as directed by the Superintendent.

(b) After the embankment foundation has been trimmed and any necessary trench drains installed, a geotextile complying with the requirement of SC6.4.6.21 Subsurface drainage, shall be laid on the embankment foundation. The area of geotextile laid shall be sufficient to cover the area of the Type A drainage mat and an additional amount for enclosing the sides of the drainage mat after the filter material has been placed. Laps of minimum width of 500 mm shall be provided at each join in the geotextile.

(c) Type C filter material or Type D filter material, as shown on the drawings or as determined by the Superintendent, shall be placed on the geotextile and compacted to the satisfaction of the Superintendent. The minimum thickness of the compacted filter material shall be 300 mm plus an allowance for the expected consolidation of the embankment foundation under the embankment load or 500 mm if the amount of the expected total consolidation of the embankment foundation is not known.

The filter material shall be placed in two or more layers so that no layer, when compacted, has a thickness greater than 250 mm.

(d) After completion of placement and compaction of the filter material, geotextile shall be placed on top of and around the sides of the filter material so that the filter material is completely enclosed by geotextile. The geotextile shall be secured in such a manner as to prevent movement of the geotextile by wind or by construction plant placing subsequent layers of filter material or earth filling over the drainage mat.

(e) An additional layer of geotextile shall be placed on the drainage mat under the base of any rock facing which may be placed as part of the embankment construction. The additional layer of geotextile shall extend beyond the outside and inside faces of the bottom layer of rock.

(f) Care shall be taken not to damage the geotextile during the construction of the drainage mat or during placement of subsequent layers of filter material, earth filling or rock facing. Any geotextile so damaged shall be repaired or replaced by the Contractor to the satisfaction of the Superintendent. The cost of repairing or replacing such damaged geotextile shall be borne by the Contractor.

(g) Type A drainage mats shall extend 2 m beyond the toes of embankments and such extensions shall be covered by a 300 mm thick layer of Type C filter material or Type D filter material, as determined by the Superintendent. This protective layer shall be placed immediately after completion of construction of each drainage mat.

(h) Outlets from Type A drainage mats may be surface outlets at the toes of embankments or piped outlets connected to other drainage systems. Where piped outlets are constructed they shall conform to the requirements of SC6.4.6.21 Subsurface drainage.

(2) Type B mats

(a) Type B drainage mats shall be constructed in cuttings as and where shown on the drawings or as directed by the Superintendent. Type B drainage mats shall be constructed for the full width of cuttings and for the pavement width in other locations.

(b) After the subgrade material has been compacted and trimmed, a geotextile complying with the requirements of SC6.4.6.21 Subsurface drainage, shall be laid on the subgrade. Laps of minimum width of 500 mm shall be provided at each join in the geotextile.

(c) Slotted thick walled unplasticised PVC pressure pipe complying with AS 1477, shall be laid on the geotextile at a distance of 200 mm from and parallel to the longitudinal edges of the drainage blanket as shown in the drawings. Details of slot sizes and spacings are shown in SC6.4.6.20 Subsoil, foundation and pavement drains.

(d) Type A filter material shall be placed on the geotextile and compacted to achieve a relative compaction, determined by AS 1289.5.4.1, of at least 100 per cent (standard compaction). Alternatively, the Superintendent may approve the use of a coarser filter material having a maximum particle size of 75 mm and a maximum D90/D10 ratio of three.

(e) The thickness of the compacted filter material shall be as shown on the drawings or as directed by the Superintendent. If the required thickness of compacted filter material is greater than 250 mm, the filter material shall be placed in two or more layers so that no layer, when compacted, has a thickness greater than 250 mm.

(f) After completion of placement and compaction of the filter material, geotextile shall be placed on top of and around the sides of the filter material so that the filter material is completely enclosed by geotextile. The geotextile shall be secured in such a manner as to prevent movement of the geotextile by wind or by construction plant placing pavement layers over the drainage mat.

(g) Outlets from Type B drainage mats shall conform to the requirements of SC6.4.6.21 Subsurface drainage.

Table SC6.4.6.8.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Filter Material**		
	(a) Layer thickness	250 mm max	SC6.4.6.8.2(1) SC6.4.6.8.2(2)
	(b) Compaction (Relative) Type A filter material	100% Standard	SC6.4.6.8.2(2)
2.	**Type B Mats**		
	(a) Design level at top of mat	+0, -40 mm	SC6.4.6.8.2(2)

SC6.4.6.9 Open drains

SC6.4.6.9.1 Introduction

(1) Scope

(a) This policy sub-section provides standards, advice and guidelines for the construction, lining and protection of all types of open drains including the construction of rock filled wire mattresses and gabions associated with stormwater drainage infrastructure.

(b) This sub-section should be read in conjunction with SC6.4.6.4 Stormwater drainage, and other drainage sub-sections as applicable:

(i) SC6.4.6.6 Pipe drainage;

(ii) SC6.4.6.5 - Drainage structures; and

(iii) SC6.4.6.7 Precast box culverts.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

Editors note - A reference to drawings is a reference to construction drawings.

(2) Terminology

Open drains	are all drains other than pipe and box culverts and include catch drains, contour drains, diversion drains, table drains, batter drains, swales, channels, gutters and kerb and channel.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:

SC6.4.6.4 Stormwater drainage
SC6.4.6.6 Pipe drainage
SC6.4.6.5 Drainage structures
SC6.4.6.21 Subsurface drainage
SC6.4.6.28 Minor concrete works
SC6.4.6.7 Precast box culverts
SC6.4.6.26 Landscaping

(b) Australian Standards:

AS 1141.22 - *Wet/dry strength variation*
AS 1289.5.4.1 - *Compaction control test – Dry density ratio, moisture variation and moisture ratio*
AS 1289.5.7.1 - *Compaction control test Hilf density ratio and Hilf moisture variation (rapid method)*
AS 2758.4 - *Aggregate for gabion baskets and wire mattresses*
AS 2876 - *Concrete kerbs and channels (gutters) – Manually or machine placed*
AS/NZS 4534 - *Zinc and zinc/aluminium-alloy coatings on steel wire.*
AS/NZS 4680 - *Hot-dip galvanized (zinc) coatings on fabricated ferrous articles*

(c) Other:

Austroads, *Guide to Pavement Technology, Part 4B – Asphalt (AGPT04B)*
Austroads, *Guide to Pavement Technology, Part 4G – Geotextiles and Geogrids (AGPT04G)*
ASTM International, ASTM A975 - *Standard specification for double-twisted hexagonal mesh gabions and revet mattresses (metallic coated steel wire or metallic coated steel wire with PVC coating)*
International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

SC6.4.6.9.2 Unlined open drains general

Open drains shall be designed and constructed in accordance with the relevant clauses in Chapter 9 of QUDM 2013. Locate and construct open drains to avoid recharging groundwater, a shallow water table and salinity degradation of

adjacent land.

Any unsuitable material must not be used for the bed and banks of the drain and must be removed from the site. Where a tree is marked for preservation, any drain must be diverted around it with sufficient clearance to avoid damage to the tree's root system.

Where open drains pass through private property, drainage easements of sufficient width to contain the flow and vehicular access for maintenance must be provided and registered as an encumberance on the title of the land through which the drain passes.

Prior to works commencing, temporary drainage measures must be implemented in accordance with the requirements of Best Practice Erosion and Sediment Control.

(1) Types

Catch drains shall be provided above the top and at the toe of embankments as part of the construction of the adjacent roadway. The edges of catch drains shall be positioned not less than 2 m from the tops of cuttings or the toes of embankments nor more than is necessary to maintain the fall of the drains unless otherwise approved.

Minor diversion and contour drains shall be constructed where shown on the construction drawings. Minor diversion drains shall have the same capacity as the nearest pipe culvert on the line of the drain unless otherwise approved by the Superintendent.

Table drains, swales and depressed medians shall be constructed to the line and level shown or calculated from the drawings. Their construction is deemed to be part of the earthworks.

(2) Inlet, outlet and diversion drains shall extend to join the existing stream bed and be of sufficient size to accommodate the design flows from the upstream catchment. The drain shall be excavated to the full width of the structure and care must be taken to ensure the stream bed can accommodate the additional flow with only minimal disturbance.

(3) Construction material excavated from drains shall be placed on the lower sides of the drains and formed as banks with slopes graded in accordance with QUDM Third edition 2013 – Provisional. This material shall be compacted in accordance with AS 1289.5.4.1 and shall be not less than 95 per cent for standard compactive effort.

The Contractor shall ensure that none of the activities associated with the work disturbs any watercourse outside the site. Any excavation below the level of the natural channel shall be backfilled with suitable material compacted to a density equal to and compatible with that existing naturally.

Any excess material shall be legally and responsibly disposed of by the Contractor.
Unlined drains and areas adjacent to open drains shall be treated and revegetated immediately after the drains are complete, in accordance with SC6.4.6.26 Landscaping.

SC6.4.6.9.3 Lined open drains general

(1) The Contractor must only use proprietary products which are suited to the terrain and have been approved for use by council. This would include the use of

(a) organic fibre and vegetation mats installed in accordance with the manufacturer's instructions;

(b) rock filled wire mattresses; or

(c) concrete where there is insufficient width to accommodate the required water way area, or the flow velocity in the drain will exceed the non-scouring velocities or where the trail is likely to be used as a bikeway of footpath during dry periods. Lining shall conform to the profile of the drain and shall be provided as soon as possible after forming the drain.

Before placing any lining material, the foundation material shall be shaped and compacted to not be less than 95 per cent for standard compactive effort as determined by AS 1289.5.7.1 or AS 1289.5.4.1

This section does not include kerb and channel.

(2) Concrete lining

Concrete lining for open drains shall be cast-in-situ or sprayed concrete supplied and placed to a minimum thickness of 100 mm measured at right angles to the surface of the lining in accordance with sub-section SC6.4.6.28 Minor concrete works.

Polyfibres must not be used in marine environments, or where there is risk of fibres escaping into the environment, without approved controls to capture loose polyfibre strands.

Weepholes shall be provided in the concrete at intervals of 2 m spacing with non-horizontal elements or as determined by the Superintendent.

Contraction joints in concrete lining, consisting of narrow transverse and vertical grooves, 5-10 mm in width, 20 mm deep, shall be formed neatly in the surface of the freshly placed concrete at intervals of 3 m unless otherwise specified by the Superintendent.

Expansion joints shall be placed at intervals not more than 15 m with a minimum width of 15 mm and shall consist of preformed jointing material of bituminous fibreboard or alternate approved material and shall be of sufficient depth to fill the joint.

(3) Stone pitching

Stone pitching shall consist of sound durable rock not less than 100 mm thick, properly bedded on approved loam or sand and mortared to present a uniform surface. The exposed surface of each stone or block shall be generally flat and not less than 0.05 square metres in area. Spaces between adjacent stones or blocks shall not exceed 20 mm in width.

(4) Batter drains

Batter drains shall be constructed using either half round steel pipes or precast nestable concrete units as shown and detailed on the drawings.

The units shall be installed in carefully excavated and template controlled trench to produce an even rim line of +0 mm to –50 mm from the batter line at the underside of topsoil.

Any over excavation and undulations in the batter line shall be backfilled and both sides of the drain compacted over the full length to form a firm shoulder against the rim of the batter drain.

When topsoil is placed it shall be tapered over a width of 1 m to zero thickness at the rim of the drain. Both sides of the drain shall then be turfed for minimum width of 1 m and pinned down as provided in SC6.4.6.26 Landscaping.

(5) Proprietary products

Unless shown on the drawings, proprietary products may only be used with the approval of the Superintendent. Where specified, they must be used strictly in accordance with the manufacturer’s instructions.

SC6.4.6.9.4 Rock filled wire mattresses and gabions general

(1) Prior to installation of rock filled wire mattress or gabion excavate so the mattresses finish flush and level with the surrounding ground. Rock-filled wire mattresses and gabions shall be placed at the locations shown on the drawings. Installation shall be in accordance with the manufacturer's instructions. A geotextile, as shown on the drawings, shall be placed between the wire cage and the material being protected.

Foundations of floors of gabions should ideally be within cut material, however if in fill areas or embankments then material must be compacted in layers not greater than 150 mm thick, to a relative compaction of 95 per cent when tested in accordance with AS 1289.5.4.1, for standard compactive effort.

(2) Materials

For wire mattresses and gabions, the galvanising requirements for wire of circular cross section cited in this Clause as "heavily galvanised", shall comply with the coating mass requirements for round wire, Class W10, in AS/NZS 4534. The contractor must submit for approval the type of mattress/gabion proposed along with confirmation of compliance to ASTM A975 and a schedule of installation locations.

(a) Gabions

The gabions shall be of the sizes shown on the drawings and fabricated of woven heavily galvanised wire mesh and PVC coated where specified on the drawings. Each gabion shall be divided by diaphragms into cells whose length shall not be greater than the width of the gabions plus 100 mm. Gabions shall have a nominal mesh size of 80 mm x 100 mm and body wire shall be a minimum diameter of 2.7 mm heavily galvanised with an additional thickness of 0.4 mm PVC coating where specified on the drawings. The minimum core diameters of heavily galvanised selvedge wire and lacing wire shall be 3.4 mm and 2.2 mm respectively.

(b) Wire mattresses

Unless specified otherwise, the wire mattresses shall be supplied in units having dimensions of 6 m x 2 m x 230 mm, and shall be cut to suit areas as shown on the drawings. The mattresses shall be divided by diaphragms into cells of length not exceeding 600 mm. Unless otherwise specified, they shall be fabricated of woven heavily galvanised wire and PVC coated where specified on the drawings.

Mattresses shall have a mesh size of 60 mm x 80 mm and body wire shall be a minimum diameter of 2.0 mm heavily galvanised with an additional minimum thickness of 0.4 mm PVC coating where specified on the drawings. The minimum core diameters of heavily galvanised selvedge wire and lacing wire shall be 2.7 mm and 2.2 mm respectively.

(c) Geotextile

A chemically and biologically stable geotextile with a minimum strength rating (G) of 1350 and minimum mass of 180 grams per square metre, in accordance with Guide to Pavement Technology Part 4G Geotextiles, shall be used.

Samples, manufacturer's specification and instructions on installation shall be submitted to the Superintendent seven days before the intended use of geotextile.

(d) Rock Fill Material

The rock fill shall consist of clean hard rock complying with the requirements of AS 2758.4.
Rock fill for gabions shall have particle sizes between 100 mm and 250 mm. Rock fill material should be placed by hand and only when approved by the superintendent shall they be placed using a suitable mechanical device to ensure fill is tightly packed with a minimum of voids. Fill material shall be levelled off 25 mm to 50 mm above the top of the mesh to allow for settlement.
When the mattress is on a slope, rock fill material shall be placed into the units starting from the low end. Units shall be filled slightly overfull by 25 mm to 50 mm to allow for settlement and to provide an even tight and smooth surface of the required contour.

(3) Assembly and erection

Before laying out the gabions or wire mattresses, geotextile shall be placed on the founding material and against any surface that will be in contact with either drainage course or earth backfill.

Adjust the position of the diaphragms so that the sides hinge up on the thicker wire woven in the mesh. Lace the gabion boxes along all diaphragm points and edges at to all adjacent boxes. Internal bracing wires 4 per metres at 330 mm centres to prevent distortion. Face bracing wires 4 per metres of face.

Ensure star pickets are either driven or cut off level with the top of the mattress.

After tying diaphragms and adjacent units of mattresses/gabions on all three adjacent corners(rear, floor and front face), leave top edge untied to allow for securing along with the lid section. The end corners of wire mattress/gabion tied sections shall be firmly tied after galvanised star pickets are driven and stretched in place a minimum of 900 mm into the surrounding ground in the final location at one end.

Carefully secure the opposite end of the gabions without damaging or distorting the dimensions of the units to a

suitable mechanical device and apply a stretching force to the assembled mattress/gabion section to be filled. Whilst under tension, secure each corner of each unit using galvanised star pickets driven into foundation ensuring each unit is stretched tight in all directions.

(4) Filling

Fill whilst the gabion boxes are under tension. Place the rocks at the front face and other exposed faces by hand to produce a neat face free of excessive bulges, depressions and voids.

Redistribute the filling materials by hand to ensure that all diaphragm compartments are fully filled to produce a neat and level top surface. Overfill by 25 to 50 mm to allow for subsequent settlement.

Mechanical filling equipment may be used with caution ensuring to protect any PVC or galvanized coatings from abrasion. Release the tension on the mattress/gabion boxes only when fully laced so as to prevent any slackening.

The upstream edge of wire mattresses shall be folded down into a trench of minimum depth 300 mm and filled with rock fill. This edge shall be tied to star pickets.

Final lacing should be undertaken as soon as practicable after filling particularly if there is a storm or flood expected. Stretch lids tightly over the filling and lace down securely. The works should be inspected upon completion of lacing.

SC6.4.6.9.5 Summary of limits and tolerance

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.9.1 below.

Table SC6.4.6.9.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Open Drains - General**	Grade - QUDM 2013 Table 9.5.2	SC6.4.6.9.2(3)
	(a) Grading		
	(b) Depth	Based on hydraulic capacity of the channel	SC6.4.6.9.2
	(c) Freeboard	QUDM 2013 table 9.3.1 & Fig 9.8	SC6.4.6.9.2
	(d) Channel Side Slopes	QUDM 2013 Section 9.5.3	SC6.4.6.9.2(3)
	(e) Compaction	>95% (standard compaction)	SC6.4.6.9.2(3)
2.	**Open Drains - Lining**	>95% (standard compaction)	SC6.4.6.9.3(1)
	(a) Compaction of Foundation		
3.	**Stone Pitching**	>100mm thickness	SC6.4.6.9.3(3)
	(a) Rock Dimensions		
	(b) Exposed Surface Area	>0.05 sq m	SC6.4.6.9.3(3)
	(c) Spaces between Stones	<20mm width	SC6.4.6.9.3(3)
4.	**Batter Drains**	+0, -50 from batter line	SC6.4.6.9.3 (4)
	(a) Rim line		
5.	**Kerb and channel**		
	(a) Compaction of foundation	To AS 2876	SC6.4.6.9.3(6)
	(b) Level of gutter surface	Level ≤ ±6mm of design level	SC6.4.6.9.3(6)
	(c) Alignment	Level ≤ ±50mm of design alignment	
	(d) Surface uniformity	Deviation of kerb and channel surface from 3m straight edge ≤5mm	SC6.4.6.9.3(6)
	(e) Contraction Joints		
	(i) Area	≥50% of CS area	SC6.4.6.9.3(6)
	(ii) Groove Width	≥5mm	SC6.4.6.9.3(6)
	(f) Expansion Joint Interval	at all gully pits and associated structures	SC6.4.6.9.3(6)
	(g) Backfill behind Kerb		
	(i) Layer thickness	≤150mm	SC6.4.6.9.3(6)
	(ii) Compaction	>95% (standard compaction)	SC6.4.6.9.3(6)

Item	Activity	Limits/Tolerances	Clause
6.	**Rock Fill for Gabions and Wire Mattresses**	>100kN	SC6.4.6.9.4(2)(d)
	(a) Wet Strength		
	(b) Wet/Dry Strength variation	<35%	SC6.4.6.9.4(2)(d)
	(c) Particle size for Gabions	>100mm <250mm and preferably not greater than 200 mm	SC6.4.6.9.4(2)(d)
	(d) Fill Level	>25mm <50mm above top of mesh	SC6.4.6.9.4(2)(d)
	(e) Particle size for Wire Mattresses	Between 75 mm and two-thirds of the mattress thickness, or 250 mm, whichever is the lesser	SC6.4.6.9.4(2)(d)
7.	**Erection of Gabions and Wire Mattresses**	Depth in ground >900mm Spacing <1m	SC6.4.6.9.4(3)
	(a) Star pickets for ties		
	(b) Trench Depth for upstream edge	Depth >300mm	SC6.4.6.9.4(3)

SC6.4.6.10 Earthworks (construction)

SC6.4.6.10.1 Introduction

(1) Scope

(a) This sub-section provides standards, advice and guidelines for earthworks and associated construction, including:

(i) removal of topsoil;

(ii) all activities and quality requirements associated with site regrading, the excavation of cuttings, the haulage of material and the construction of embankments to the extent defined in the drawings and sub-section;

(iii) removal and replacement of any unsuitable material;

(iv) any spoil or borrow activities associated with earthworks; and

(v) any additional processing of selected material for the selected material zone.

(b) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section one as follows:

SC6.4.6.30 Control of traffic
SC6.4.6.11 Clearing and grubbing
SC6.4.6.4 Stormwater drainage

(b) Australian Standards:

AS1141.11 - *Soil classification test – Determination of the particle size distribution of a soil – Standard method of analysis by sieving*
AS1289.3.3.1 - *Calculation of the plasticity index of a soil.*
AS1289.5.1.1 - *Determination of the dry density/moisture content relation of a soil using standard compactive effort.*
AS1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio.*
AS1289.5.7.1 - *Compaction Control Test Hilf density ratio and Hilf moisture variation (Rapid Method).*
AS1289.6.1.1 - *Determination of the California Bearing Ratio of a soil - Standard laboratory method for a remoulded specimen.*
AS1289.7.1.1 - *Soil reactivity tests – Determination of the shrinkage index of a soil*
AS2187.0 - *Explosives - Storage, transport and use - Terminology*
AS2187.1 - *Explosives - Storage, transport and use - Storage*
AS2187.1 - *Explosives - Storage, transport and use - Use of explosives*

(c) QLD Government Legislation:

Environmental Protection Act 1994
Environmental Protection (Noise) Policy 2008
Explosives Act 1999
Explosives Regulation 2003
Sustainable Planning Act 2009
Work Health and Safety Act 2011

(d) Other:

International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

Workplace Relations Ministers' council, *Australian Code for the Transport of Explosives by Road and Rail*
MRTS55 Use of Explosives in Roadworks

(3) Natural surface and earthworks materials

(a) Natural surfaces

The Contractor must verify the accuracy of the model by field surveys. If the Contractor considers any areas of the model not to be representative of the approved plans, the Contractor shall give not less than seven days' notice, prior to commencement of Works to the Superintendent to allow checking. If the subsequent check survey reveals the ground model to be incorrect, any plans that are affected are to be resubmitted for approval.

(b) Earthworks materials

The Contractor shall be responsible for any assumptions made by the contractor in relation to the nature and types of the materials encountered in excavations and the bulking and compaction characteristics of materials incorporated in embankments.

The estimated quantity for general earthworks at any cutting includes all types of materials which may be encountered in the cutting.
Where material from excavations is acceptable for use in embankments, but the Contractor elects to:

(i) spoil it; or

(ii) use it for the Contractor's own purposes; or

(iii) use it as a source of pavement materials; or

(iv) construct embankments with dimensions in excess of those specified.

and a deficiency of material for embankment construction is thereby created, the Contractor shall make good that deficiency from sources of material meeting the quality requirements specified in clause SC6.4.6.10.6(2). The cost of making good such deficiency of material shall be borne by the Contractor.

(4) Protection of earthworks

The Contractor's responsibility for care of the Works shall include the protection of earthworks.
The Contractor shall install effective erosion and sedimentation control measures in accordance with accepted *Best Practice Erosion and Sediment Control* procedures, prior to commencing the earthworks, and shall maintain these control measures for the duration of the contract.

Details of the proposed sediment and erosion control measures and procedures are to be documented by a suitably qualified person in accordance with council's soil and sediment erosion control standards. The proposed measures and procedures are to be approved by council prior to implementation on site.

Adequate drainage of all working areas shall be maintained throughout the period of construction to ensure run-off of water without ponding, except where ponding forms part of a planned erosion and sedimentation control system.

When rain is likely or when work is not proposed to continue in a working area on the following day, precautions shall be taken to minimise ingress of any excess water into earthworks material. Ripped material remaining in cuttings and material placed on embankments shall be sealed off by adequate compaction to provide a smooth tight surface.

Should insitu or stockpiled material become wet as a result of the Contractor not providing adequate protection of earthworks, the Contractor shall be responsible for replacing and/or drying out the material and for any consequent delays to the operations.

(5) Setting out of earthworks

Before earthworks operations commence and after survey controls are in place, batter profiles shall be established by the Contractor and the necessary pegs driven at 25m intervals, at each cross section shown on the drawings or at each change in batter slope, whichever is the lesser. The chainage/station, offset from-control line and slope distance to finished surface level, shall be clearly marked on each peg.

The batter profiles shall be repositioned by the Contractor at each change in the slope of the batter and at

intervals of not more than 5m of vertical height.

All pegs and batter profiles shall be maintained in their correct positions. Additional pegs and profiles may be required to suit the Contractor. These shall not be painted with the same colours used for the specified setting out pegs and stakes.

The position and extent of all transitions from cuttings to embankments and foundations for shallow embankments shall be marked with clearly labelled stakes in accordance with Clauses SC6.4.6.10.3(5) and SC6.4.6.10.6(3).

(6) Stockpile sites

The Contractor shall obtain the written consent of the Superintendent to the use of any stockpile site which is not shown on the drawings. Proposals in this regard shall be submitted at least three working days before stockpiling is due to commence and shall specify the maximum dimensions of the proposed stockpile.

Any clearing and grubbing required for these sites shall be carried out in accordance with SC6.4.6.11 Clearing and grubbing. Temporary erosion and sedimentation control measures shall be taken in accordance with *Best Practice Erosion and Sediment Control.*

Restoration of stockpile sites following completion of the work shall be carried out in accordance with IECA *Best Practice Erosion and Sediment Control.*

SC6.4.6.10.2 Removal of topsoil

(1) Scope

Topsoil is surface soil which is reasonably free from subsoil, refuse, clay lumps and stones.

Removal of topsoil from any section of the Works shall only commence after erosion and sedimentation controls have been implemented and when clearing, grubbing and disposal of materials have been completed on that section of the works in accordance with relevant parts of *Best Practice Erosion and Sediment Control* and SC6.4.6.11 Clearing and grubbing.

Topsoil throughout the length of the Work shall be removed and stockpiled separately clear of the Work with care taken to avoid contamination by other materials. The work shall include the following:

(a) Cuttings

Removal of the topsoil to a depth quoted in SC6.4.6.10 Attachment A Earthworks supplementary information, or as directed by the Superintendent.

(b) Embankments

Removal of topsoil over the base of embankments up to the depth below the natural surface quoted in SC6.4.6.10 Attachment A Earthworks supplementary information, or as directed by the Superintendent. For those embankments or sections of embankment where the height of embankment from natural surface to underside of pavement is less than two metres, topsoil which is deeper than the depth quoted in SC6.4.6.10 Attachment A Earthworks supplementary information shall be removed to its full depth as directed by the Superintendent.

(c) Other locations

Removal of topsoil as directed by the Superintendent.

(2) Topsoil stockpiles

The maximum height of stockpiles shall not exceed 2.5m and the maximum batter slope shall not exceed 2h:1v.

Topsoil stockpiles shall not contain any timber or other rubbish and shall be trimmed to a regular shape.

Keep topsoil and underburden stockpiles separate.

Stabilise stockpiles and batters that will remain bare for more than 28 days by covering with mulch or anchored

fabrics or seeding with sterile grass.

Establish sediment controls around unstabilised stockpiles and batters. Locate stockpiles away from drainage lines, at least 10m away from natural waterways and where they will be least susceptible to wind erosion.

To minimise erosion, stockpile batters shall be track rolled or stabilised by other means acceptable to the Superintendent.

Where seeding of stockpiles to encourage vegetation cover is specified, such work shall be carried out in accordance with SC6.4.6.26 Landscaping.

SC6.4.6.10.3 Cuttings

(1) Scope

Construction of cuttings shall include all operations associated with the excavation of material within the limits of the batters including benching, treatment of cutting floors and transition from cut to fill.

(2) Excavation

Materials encountered in cuttings shall be loosened and broken down as required so that they are acceptable for incorporation in the Works. In this regard, the Contractor's attention is drawn to clauses SC6.4.6.10.5 Unsuitable material, SC6.4.6.10.6(1) Scope and SC6.4.6.10.6(2) Embankment material.

Cuttings shall have batter slopes as shown on the drawings or as redetermined by the Superintendent on the basis of site inspection and investigation during the excavation.

The tops of all cuttings shall be neatly “rounded”.

In all cuttings, undulations in the general plane of the batter shall not be permitted except that batters may require progressive flattening at the ends of cuttings due to the presence of less stable material.

Cut faces shall be cleaned of loose or unstable material progressively as the excavation proceeds.

Where, after the removal of topsoil as specified in clause SC6.4.6.10.2(1) Scope, material of variable quality or moisture content is encountered, the Contractor shall adjust his excavation methods to ensure blending of the materials, to obtain material meeting the requirements of clause SC6.4.6.10.6(2) Embankment material.

(3) Batter tolerances

If the Contractor excavates the batter beyond the batter slope line and the tolerance applicable thereto, the Superintendent may authorise a minor change in the general slope of the batter to suit the convenience of

the Contractor, but such a change shall not be regarded as a redetermination of the batter slope under clause SC6.4.6.10.3(2) Excavation. Alternatively the Contractor shall submit details of the material and/or methods proposed to restore the specified slope and stability of the batter for the Superintendent's approval.

For batters steeper than 1:1, if any section of the batter up to a height of 3m above the table drain level has been over excavated beyond the tolerance limit specified, the Superintendent may direct that the batter be restored to the average batter slope using randomly mortared stone. The stone shall be similar to the sound rock in the cutting and the mortar shall be coloured to match the colour of the rock.

The tolerances for the excavation of batters, measured at right angles to the design grade line, are given in Table SC6.4.6.10.1 Excavation tolerances for batters.

Table SC6.4.6.10.1 Excavation tolerances for batters

Location	Tolerance (mm)	
	Slope 1:1 or flatter	Steeper than 1:1
Toe of batter and level of table drain	+ 0 - 150	+ 0 - 200
2m above table drain and higher	+ 300 - 300	+ 300 - 600
Between level of table drain and 2m above table drain	pro rata basis	pro rata basis

Note—tolerances are measured normal to the batter surface with (+) measured towards the roadway.

(4) Benching in cuttings

Cut batters shall be benched as shown on the drawings to provide drainage and erosion control. Notwithstanding the tolerances permitted under clause SC6.4.6.10.3(3) Batter tolerances, bench widths shall not be less than those shown on the drawings.

Benches shall be maintained and cleaned of loose stones and boulders regularly throughout the Contract period. The cost of such maintenance and cleaning of benches shall be borne by the Contractor.

(5) Subgrade of cuttings

The subgrade of cuttings shall be excavated, parallel to the designed grade line, to a designed subgrade level. The subgrade must then be trimmed to a level of not more than +0mm, -50mm from the designed subgrade level. Prior to ripping or removal of the cut material, the Contractor shall determine the CBR of the material in at the subgrade level in accordance with AS1289.6.1.1, Plasticity Index AS1289.3.3.1 and Shrink-Swell Index AS1289.7.1.1. Sufficient tests shall be taken to represent all the various materials which may exist within the subgrade.

Adequate sampling and testing shall be undertaken to satisfy all necessary requirements to verify the intended pavement design. Where the Superintendent considers that any underlying material is unsuitable for pavement support, the Superintendent may direct that it be removed in accordance with clause SC6.4.6.10.5 Unsuitable material.

The Contractor shall rip or loosen all material in the subgrade to a minimum depth of 200mm below the designed subgrade level for the width of the selected material zone (or subbase layer, where no selected material zone), including areas of rock. The maximum dimension of any particles in the ripped or loosened zone shall not exceed 150mm.

After recompaction, the subgrade within cuttings shall be re-trimmed parallel with the finished wearing surface so that their levels do not vary more than +0mm, -50mm from the designed subgrade level. It shall be recompacted in accordance with Clause SC6.4.6.10.7(1).

Horizontal tolerance – the width of the cutting at subgrade level for support of the pavement shall not be less than that specified.

Prior to placing any subsequent layers over the completed subgrade level, the Contractor shall present the completed surface to the Superintendent for inspection. The Contractor shall verify as part of the quality system that the completed surface has achieved full conformance with all respects to relevant specifications.

In placing subsequent layers, the Contractor shall use equipment and techniques to avoid surface heaving or other damage to the subgrade surface.

(6) Transition from cut to fill

After the removal of topsoil and before the excavation of any cutting commences the contractor shall survey and mark the position of the intersection line between cutting and embankment occurring at the underside of

the selected material zone or pavement subbase.

The contractor is to ensure that the transition from cut to fill is undertaken in accordance with best practice geotechnical procedures and guidelines.

SC6.4.6.10.4 Blasting general

(1) When explosives are permitted to be used by council, the contractor shall obtain all necessary licences from the appropriate authorities, and shall comply with all government and council regulations relating to transport, storage, handling and the use of explosives and also to the rules set out in AS2187.1 and AS2187.2. The transport of explosives shall be in accordance with the *Australian Code for the Transport of Explosives by Rail and Road. The requirements of the Explosives Act 1999* and *Explosives Regulation 2003* and Local laws, if applicable, shall be complied with.

The contractor shall be liable for any accident, damage or injury to any person, property or thing, resulting from the use of explosives.

Before the start of blasting operations, the contractor, in the presence of the superintendent, shall conduct a dilapidation survey to determine and record the existing condition of all structures likely to be affected by any blast.

The survey shall include all structures including public utilities within 500m of any blast but shall be extended where the maximum instantaneous charge proposed is likely to produce peak particle velocities greater than allowable at structures more remote from a blast site. A written report of the survey, supported by photographs where necessary, together with a list of any existing defects in the structures, shall be submitted to the owner of each structure, to the superintendent and council before blasting commences.

The contractor shall advise the superintendent of the proposed maximum instantaneous charge and the contractor's validation of the adequacy of the proposed structural survey at least three working days before the survey is due to commence. The superintendent may direct amendments to the scope of the survey as a result of blast monitoring during the work. All costs associated with the surveys and reports shall be borne by the contractor.

Before each blasting operation, the contractor shall submit to the Superintendent written details of the proposed blasting procedure including the quantity and type of explosive to be detonated, the blasting pattern to be used and measures proposed to limit noise and to ensure that vibration from blasting does not adversely affect nearby structures.

Ground vibration caused by blasting shall not exceed the values of peak particle velocity listed in Table SC6.4.6.10.2 Limiting peak particle velocity.

Table SC6.4.6.10.2 Limiting peak particle velocity

Point of Potential Damage (within 1 km of blasting site)	**Peak Particle Velocity**
Completed and cured bridge structures or sub‐structures (e.g. completed abutment).	25mm/sec
Bridgeworks and structural retaining walls under construction.	20mm/sec
Residential premises, schools, hospitals and other buildings.	5mm/sec (with 10% not to exceed 10 mm/sec)
Buildings or monuments of historical significance.	2mm/sec

The contractor shall advise all residents within a radius of 1km, by letter drop before blasting operations

commence, of the likely times, frequency and duration of blasting and precautions being taken to ensure that damage to property will not result.

Unless otherwise approved, blasting operations shall be confined to the periods Mondays to Fridays (excluding public holidays), 9am to 3pm.

When blasting operations are being carried out, precautions shall be taken relating to the safety of persons and animals and the road shall be closed to traffic and the appropriate signs erected in accordance with the sub-section SC6.4.6.30 Control of traffic. A standard warning procedure such as that given in the AS2187.2 shall be established and observed at all times.

(2) Presplitting

Where presplitting is carried out the spacing of presplit drill holes shall not exceed 750mm centre to centre.

(3) Blasting records

The Contractor shall maintain accurate records of each blast showing the details listed below:

(a) date and time of blast;

(b) location, number and diameter of holes loaded;

(c) depth of each hole loaded;

(d) inclination of holes;

(e) maximum and minimum burden;

(f) types of explosives used;

(g) charge distribution in each hole;

(h) maximum instantaneous charge;

(i) delay periods and sequence;

(j) total amount of charges in the blast; and

(k) length and type of stemming in each hole.

The records shall be prepared as holes are loaded and signed by the Powder man. A copy shall be provided to the Superintendent on the day of the blast.

(4) Control of air blast over-pressure

This clause shall apply only where a noise sensitive location exists within 1km of the blasting site.

The Contractor's attention is drawn to the recommendations given in the *Environmental Protection (Noise) Policy 2008* or as amended - for the reduction of air blast over-pressure.

The noise emanating from blasting operations shall not exceed an over-pressure level of 115dB (linear peak) at any noise sensitive location (such as residential premises, schools or hospitals). Up to 10 per cent of the total number of blasts may exceed this value provided a level of 120dB is not exceeded at any time.

The Contractor shall arrange for the monitoring of air blast over-pressure to ensure compliance with the specified limits. All monitoring shall be carried out by personnel possessing current NATA registration for such monitoring. All test results shall be reported on NATA endorsed test certificates which shall include a clear statement as to compliance or non-compliance with the requirements of this sub-section. In general, a monitoring location will be near the perimeter of the noise sensitive location at the point closest to the maximum charge. The Contractor shall submit a copy of the monitoring record to the Superintendent.

In the event that the measured air blast over-pressure exceeds the specified limits, the Contractor shall suspend further blasting work and shall submit to the Superintendent proposals detailing any additional steps and precautions the Contractor shall take to ensure that for any future blast, the limiting over-pressure shall not be exceeded. The Contractor shall not resume any blasting until such proposals have been submitted.

(5) Control of ground vibration

The Contractor shall arrange for the monitoring of ground vibrations to ensure compliance with the peak particle velocity limits shown in Table SC6.4.6.10.2 Limiting peak particle velocity. All monitoring shall be carried out by personnel possessing current NATA registration for such monitoring. All test results shall be reported on NATA endorsed test certificates which shall include a clear statement as to compliance or non-compliance with the requirements of this part of the sub-section. In general a monitoring location shall be near the perimeter of the structure or building at the point closest to the maximum charge. The Contractor shall submit a copy of the monitoring record to the Superintendent.

To minimise the risk of peak particle velocity limits being exceeded, the Contractor shall develop a blasting site relationship between peak particle velocity, distance and blasting charge.

For the first blast, monitors shall be set up at not less than five points at varying distances away from the blasting site. The Maximum Instantaneous Charge for the first blast shall not exceed that calculated from the following formula:

$$MIC = 0.5\left[\frac{D}{\left[\frac{PPV}{1140}\right]^{-0.625}}\right]^2$$

where MIC = Maximum Instantaneous Charge in kilograms
D = Distance in metres from charge to the point of potential damage
PPV = limiting peak particle velocity from Table SC6.4.6.10.2.

A log-log (base 10) graph of measured peak particle velocity (vertical axis) versus Scaled Distance (horizontal axis) shall be plotted, where

$$\text{Scaled Distance} = \frac{D}{\sqrt{MIC}}$$

The mean regression line shall be obtained by the least squares method.

For subsequent blasts, the MIC and other aspects of blast design may be adjusted provided that further ground vibration monitoring is undertaken and the mean regression line redetermined to demonstrate that peak particle velocity limits are not exceeded. The Contractor shall make the regression line plots available to the Superintendent, if so requested.

SC6.4.6.10.5 Unsuitable material

Unsuitable material is that occurring below the designed floor level of cuttings and below the nominated depth for stripping topsoil beneath embankments, which the Superintendent deems to be unsuitable for embankment or pavement support in its present position. Unsuitable material also includes material in cuttings which the Superintendent deems to be unsuitable for embankment construction.

Such material shall be excavated to the extent directed by the Superintendent. Material removed as unsuitable, as directed by the Superintendent, shall be incorporated in embankments in accordance with SC6.4.6.10.6(2) Embankment material or spoiled in accordance with clause SC6.4.6.10.6(13) Spoil.

After removal of the unsuitable material, the floor of the excavation shall be re-presented to the Superintendent for inspection, prior to backfilling with replacement material, to determine whether a sufficient depth of unsuitable material has been removed. Prior to placing replacement material the excavated surface shall be compacted in accordance with SC6.4.6.10.8(1) Compaction and moisture requirements.

The unsuitable material which has been removed shall be replaced with material from cuttings, or with material borrowed in accordance with clause SC6.4.6.10.6(14) Borrow, of the quality specified in clause SC6.4.6.10.6(2).

Embankment materials. Replacement material is deemed to form part of embankment construction. It shall be placed in accordance with clause SC6.4.6.10.6(5) Placing Fill for embankment construction and compacted in accordance with clause SC6.4.6.10.8(1) Construction management.

Reworking or replacing any material which the Superintendent deems to have become unsuitable because of inappropriate construction activities shall be borne by the Contractor.

Excavate and dispose of all contaminated material in an environmentally responsible manner including the following:

(1) assay material uncovered on-site prior to disposal. If the wastes include putrescibles wastes, then also analyse leachate and landfill gases;

(2) excavate material in a manner which avoids off-site environmental problems;

(3) seal remaining contaminated material or wastes, where only part of the tip has been excavated, to ensure than there is no off-site effect now or in the future;

(4) transport odorous wastes in covered vehicles; and

(5) dispose of contaminated material in a landfill licensed to take the type of contaminated material or wastes uncovered.

SC6.4.6.10.6 Embankment construction

(1) Scope

Embankment construction includes all operations associated with the preparation of the foundation areas on which fill material is to be placed, the placing and compacting of approved material within areas from which unsuitable material has been removed in accordance with clause SC6.4.6.10.5 Unsuitable material, the placing and compacting of fill material and of materials of specified quality in nominated zones throughout the Works and all other activities required to produce embankments as specified to the alignment, grading and dimensions shown on the drawings. It also includes any pre-treatment such as breaking down or blending material or drying out material containing excess moisture.

(2) Embankment material

Material for embankment construction shall be obtained from the cuttings within the Works in accordance with clause SC6.4.6.10.3(2) Excavation supplemented by borrow in accordance with clause SC6.4.6.10.6(14) Borrow and from other sources as approved by the Superintendent if necessary. The material shall be free of tree stumps and roots, clay, topsoil, steel, organic material and other contaminants and shall be capable of being compacted in accordance with clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The work shall be programmed so that material of the quality specified in clause SC6.4.6.10.6(5) Placing fill for embankment construction and SC6.4.6.10.6(9) Selected material zone for the upper zones of the formation is available when required.

(3) Foundations for embankments

(a) Following removal of topsoil in accordance with clause SC6.4.6.10.2 Removal of top soil, the embankment foundation area shall be made available for inspection by the Superintendent.
Where the Superintendent considers that any underlying material is unsuitable, the Superintendent may direct that it be removed and replaced in accordance with clause SC6.4.6.10.5 Unsuitable material.

(b) Foundations for Shallow Embankments
Shallow embankments are those embankments of a depth less than 1.0m from the top of pavement to natural surface. After removal of topsoil the Contractor shall survey and work out the extent of the area of shallow embankments.

Material in the foundations for shallow embankments which does not meet the requirements specified in SC6.4.6.10 Attachment A Earthworks – supplementary information, shall be deemed unsuitable in

accordance with clause SC6.4.6.10.5 Unsuitable material and shall be replaced by material of the specified quality.

Foundations for shallow embankments shall be prepared for embankment construction after removing topsoil and unsuitable material, by loosening the material exposed to a depth of 200mm, adjusting the moisture content of the loosened material and compacting as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements. The Contractor shall use equipment and techniques to minimise surface heaving or other foundation damage.

(c) Other embankments

For all other embankments the foundation shall be prepared by grading and levelling the general area, adjusting the moisture content where necessary and compacting the top 200mm as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The bridging layer shall consist of free-draining granular material with or without geofabric interlayer as specified on the drawings. The granular material shall be end-dumped and spread in a single layer and in sufficient depth to allow the passage of earthmoving equipment with minimal surface heaving. The compaction requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements shall not apply to the bridging layer.

A bridging layer may also be employed, subject to the approval of the Superintendent, where ground water or seepage is encountered in the foundation area or where the Contractor demonstrates that it is impracticable to achieve the degree of compaction specified for the foundation in clause SC6.4.6.10.8(1) Compaction and moisture requirements. A bridging layer shall not be acceptable if its proximity to the pavement is likely to affect the pavement design. As an alternative to a bridging layer, approval of a working platform created by the chemical stabilisation of in situ material to conform with sub-section SC6.4.6.19 Stabilisation may be required.

(4) Hillside embankments

Where embankments are to be constructed on or against any natural slopes or the batters of existing embankments, the existing slope or batter, if it is steeper than 4 horizontal to 1 vertical in any direction, shall be cut in the form of horizontal terraces over the whole area to be covered by new filling. The existing slope or batter shall be stepped in successive terraces, each at least 1m in width, the terraces to be cut progressively as the embankment is placed. Wherever possible terraces shall coincide with natural discontinuities. Subsoil drainage may be required in some instances. Material thus excavated shall be compacted as part of the new embankment material.

(5) Placing fill for embankment construction

The methods of excavation, transport, depositing and spreading of the fill material shall be selected so as to ensure that the placed material is uniformly mixed.
The embankment shall be constructed so as to derive its stability from the adequate compaction of the fine material embedding the large rock pieces rather than mechanical interlock of the rock pieces. The fine material shall be compacted to meet the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements.

Fill material for embankment construction shall be placed in layers parallel to the grade line and compacted in accordance with clause SC6.4.6.10.8(1) Compaction and moisture requirements. The layers shall be of uniform compacted thickness not exceeding 200mm, except that where more than 25% by volume of the filling consists of rock with any dimension larger than 150mm, the Superintendent may approve an increase in the compacted layer thickness to 300mm, provided that the relative compaction specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements is attained.

The maximum dimension, measured in any direction, of rock pieces in the fill material for embankment construction shall not exceed two-thirds of the approved compacted layer thickness. Any larger rock pieces shall be reduced in size for incorporation in the embankment layers.

Rock material shall be broken down and evenly distributed through the fill material, and sufficient fine material

must be placed around the larger material as it is deposited to fill the voids and produce a dense, compact embankment. Where the Superintendent considers insufficient fine material is present to fill the voids, additional fine material shall be obtained from other places in the work or by a change in the method of winning fill material.
Stony patches with insufficient fine material to fill the voids shall be reworked with additional fine material being blended in to achieve a dense, compact layer.

In placing embankment layers, the Contractor shall use equipment and techniques to avoid surface heaving or other damage to the foundations and underlying embankment layers.
After compaction, embankment material in the zone(s) below the selected material zone (or subbase layer, where no selected material zone) shall have a CBR value not less than that quoted in and for the depth(s) specified in SC6.4.6.10 Attachment A Earthworks Supplementary Information.

For the purpose of this clause, the CBR value of the material shall be determined by Test Method AS1289.6.1.1.

The Contractor shall be responsible for determining suitable sources of material and for any processing to satisfy these quality requirements.

(6) Embankment batters

The batter slopes shown on the drawings represent the estimated requirements for the expected types of materials, and may be subject to redetermination by the Superintendent according to the Superintendent's assessment of the materials encountered.

When completed, the slope of embankment batter shall conform to those shown on the drawings and conform to the following tolerances:

(a) for a vertical distance to 1m below the shoulder, no point on the completed batter to vary from the specified slope line by more than 150mm when measured at right angles to the slope line;

(b) at distances greater than 1m vertically below the shoulder, no point on the completed batter to vary from the specified slope line by more than 300mm when measured at right angles to the slope; and

(c) in no case is the edge of the formation at the underside of the pavement to be nearer to the roadway than shown on the drawings and the batter slope at no point be steeper than the specified slope.

However, in no case shall the edge of the formation at the underside of the pavement be nearer to the roadway than shown on the drawings.
Undulations in the general plane of the batter shall not be permitted.

(7) Rock facing of embankments

Where shown on the drawings, embankment batters (including embankments at bridge abutments) shall be provided with a facing of clean, hard, durable rock.

The rock facing shall be built up in layers ahead of each layer of filling. Rock may be placed by hand or plant but shall be placed in such a manner that its least dimension is vertical and that mechanical interlock between the larger stones occurs. Any rock deposited in the rock facing which has an excess of fine material surrounding it shall be removed together with the excess fine material and replaced.

The Contractor shall adjust its working methods and programme the work so as to obtain hard and durable rock of the specified dimensions as it is required. The space between larger batter rocks shall be filled with progressively smaller rocks to form a 'graded filter' which prevents the leaching out of fines from the fill material but which does not overfill the voids between larger rocks, or cause the larger rocks to lose contact with one another. Fine material shall not cover the outside of the rocks on the face of the batter.

The Contractor shall exercise extreme caution whilst placing the rock facing. Where embankment material is placed above other roads in use the outer rock layer shall be placed in such a manner as to prevent spillage down the batter.

The Contractor shall ensure that, under no circumstances, could any rock be dislodged and roll onto any adjacent roadway or track in use.

(8) Trimming tops of embankments

The tops of embankments shall be trimmed parallel to the designed grade line at levels equal to the finished surface level less the thicknesses of pavement courses and the selected material zone.

The tops of embankments at these levels shall be compacted to meet the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements and trimmed so that they do not vary by more than ±50mm from the calculated level. The width of the embankment at subgrade level shall not be less than that specified.

Prior to placing any subsequent pavement layers over the completed top of embankment filling, the contractor shall present the completed surface to the superintendent for inspection. The contractor shall verify as part of the quality system that the completed surface has achieved full conformance with all respects of the relevant specifications.

(9) Selected material zone

A selected material zone must be provided in accordance with the following quality requirements:

(a) it shall be free from stone larger than 75mm maximum dimension and have no less than 50% passing the 19mm AS sieve;

(b) a CBR value not less than the specified in SC6.4.6.10 Attachment A Earthworks Supplementary Information for the fraction passing AS 19mm sieve; and

(c) Plasticity Index of 15 maximum.

If chemical stabilisation is specified these requirements must apply to the selected material immediately prior to incorporating the stabilising agent.

The Contractor shall use working methods to yield material for the selected material zone by breaking down oversize rock or by other means, including processing through a crusher, to ensure that the resulting material conforms to the requirements of this clause.

The Contractor shall ensure that any material encountered of the quality specified for the selected material zone shall be either placed directly in the selected material zone or stockpiled at locations approved by the Superintendent for future use by the Contractor in the selected material zone until at least sufficient material is reserved to complete the selected material zone over the whole work. Should the Contractor fail to conserve material of the specified quality, the Superintendent may direct that material of equivalent quality be provided.

The selected material zone shall be placed and compacted in layers with the compacted thickness of each layer not exceeding 150mm. The selected material shall be homogeneous and free from patches containing segregated stone or excess fines. There shall be no areas containing material which does not comply with the specified requirements of this clause and compaction shall be as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The top of the selected material zone shall be compacted and trimmed parallel with the designed grade line at a level equal to the finished surface level minus the thickness of pavement layers adopted. The tolerances for the trimmed levels are given in SC6.4.6.10 Attachment A Earthworks – Supplementary Information.

Prior to placing any subsequent pavement layers over the completed select material zone surface, the Contractor shall present the completed surface to the Superintendent for inspection. The Contractor shall verify as part of the quality system that the completed surface has achieved full conformance with all respects of relevant Specification.

(10) Fill adjacent to structures

For the purpose of this clause, structures shall include bridges, precast and cast-in-situ box culverts and

retaining walls. Fill adjacent to other culverts and drainage structures to be provided in accordance with SC6.4.6.4 Stormwater Drainage, SC6.4.6.6 Pipe Drainage, SC6.4.6.7 Precast Box Culverts and SC6.4.6.5 Drainage Structures.

No filling shall be placed against structures, retaining walls, headwalls or wingwalls within 21 days after placing of the concrete, unless the walls are effectively supported by struts to the satisfaction of the Superintendent, or when the contractor can demonstrate that 85% of the design strength of the concrete has been achieved. This includes concrete in bridge decks and fill placement that impacts the position, stability and serviceability of bridge deck member bearings.

(11) Treatment at weepholes

Drainage adjacent to weepholes shall be provided by either a layer of broken stone or river gravel consisting of clean, hard, durable particles graded from 50 mm to 10 mm such that:

(a) the maximum particle dimension shall not exceed 50mm; and

(b) no more than 5% by mass shall pass the 9.5mm A.S. sieve.

The broken stone or river gravel shall be continuous in the line of the weepholes, extend at least 300mm horizontally into the fill and extend from 200mm below to at least 450mm vertically above the level of the weepholes, where practicable.

Alternatively the Contractor may provide a synthetic membrane (geotextile) of equivalent drainage characteristics. It shall be stored and installed in accordance with Manufacturer's instructions. The use of a synthetic membrane (geotextile) shall be subject to the Superintendent's approval.

(12) Selected backfill

(a) Selected backfill shall be placed adjacent to structures in accordance with Table SC6.4.6.10.3 Selected backfill, width and height. The selected backfill shall consist of a granular material having a maximum dimension not exceeding 50mm and a Plasticity Index, determined by AS1289.3.3.1, neither less than 2 nor more than 12.

Table SC6.4.6.10.3 Select backfill, width and height

Structure Type	Selected Backfill	
	Width	Height
Bridge abutments	2m	H
Cast-in-situ Box Culverts and Precast Culverts	H/3	H + 300mm
Corrugated Steel Pipes and Arches	0.5m	H + 500mm
Retaining Walls	H/3	H

(Where H = height of structure)

The selected backfill shall be placed in layers, with a maximum compacted thickness of 150mm. Layers shall be placed simultaneously on both sides of box culverts to avoid differential loading. Compaction shall start at the wall and proceed away from it, and shall meet the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The existing embankment slope behind the structure shall be cut in the form of successive horizontal terraces, each terrace being at least 1m in width, and the selected backfill shall be placed in accordance with clause SC6.4.6.10.6(5) Placing fill for embankment construction.

Where a bridge deck is being concreted adjacent to an abutment, no filling shall be placed against the abutment within 21 days after placing concrete in the bridge deck, unless approved by the Superintendent.

In the case of spill-through abutments, rocks shall not be dumped against the columns or retaining walls but shall be built up evenly by individual placement around or against such structures.

In the case of framed structures, embankments at both ends of the structure shall be brought up simultaneously, the difference between the levels of the embankments at the respective abutments, shall not exceed 500mm.

(13) Spoil

Spoil is surplus material from excavations which is not required to complete the Works as specified or other material from excavations whose quality the Superintendent deems to be unacceptable for incorporation in the Works.

Where there is surplus material the Superintendent may direct that flatter batter slopes be provided on embankments which have not been commenced, and/or direct that the excess material be used in the uniform widening of embankments, the surface of which shall be shaped so as to provide a tidy appearance and effective drainage. The surplus material shall be spread and compacted as specified in clauses SC6.4.6.10.6(5) Placing fill for embankment construction and SC6.4.6.10.8(1) Compaction and moisture requirements for material in embankments.

Alternatively, spoil shall be disposed of in the manner and at locations approved by the Superintendent within the specified working area for the Works or be removed and disposed of off site by the Contractor. Surplus material so deposited shall be compacted as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements for material in embankments or to such lesser extent as may be approved by the Superintendent.

(14) Borrow

Borrow will only be authorised by the Superintendent if, in constructing cuttings and embankments to the batter slopes specified or directed by the Superintendent or in providing materials of the quality specified, and not by reason of excess widening of embankments or wastage by the Contractor of material of the quality specified in clauses SC6.4.6.10.6(2) Embankment material, SC6.4.6.10.6(7) Rock facing of embankments, SC6.4.6.10.6(8) Trimming tops of embankments or SC6.4.6.10.6(10) Fill adjacent to structures, there is an overall deficiency in either the quantity or the quality of material required to complete the Works.

Where borrow material is required to complete the Works as specified, the location of borrow sites shall be as approved by the Superintendent, and the quality of material shall be acceptable to the Superintendent in accordance with clauses SC6.4.6.10.6(2) Embankment material, SC6.4.6.10.6(7) Rock Facing of Embankments or SC6.4.6.10.6(10) Fill Adjacent to Structures as appropriate. The edges of borrow sites must be no closer than 3m from any fence line, or edge of excavation or embankment. Adequate clearance shall be provided for the construction of catch drains. Borrow sites shall have drainage outlets acceptable to the Superintendent, cut batter slopes not steeper than 4h to 1v, and shall be left by the Contractor in a tidy and safe condition (i.e. stabilising disturbed areas).

For borrow within the defined working area for the Works as specified, site preparation shall be in accordance with SC6.4.6.11 Clearing and grubbing and clause SC6.4.6.10.2 Removal of top soil. Restoration of borrow sites shall be carried out by Contractor in accordance with Best Practice Erosion and Sediment Control.

If borrow material is obtained by uniformly widening a cutting, the requirements of Clauses SC6.4.6.10.3(2) Excavation, SC6.4.6.10.3(3) Batter tolerances and SC6.4.6.10.3(5) Treatment of floors of cuttings as to the redetermination of batter slopes, the trimming of batters and the compaction of floors of cuttings respectively shall apply to the borrow area.

The Contractor shall be responsible for obtaining any permits required for entry on land and for the payment of any royalty for such borrow material. The Contractor shall also comply with any requirements of the *Planning Act 2016* – as amended, Townsville City Plan, Local laws and land owners, as appropriate.

SC6.4.6.10.7 Acid sulfate soils

(1) Objective

To minimise disturbance to areas of potential acid sulphate soils (PASS) and/or actual acid sulphate soils (ASS). If disturbance of PASS/ASS cannot be avoided, appropriate treatment is required to minimise the

potential for environmental harm.

PASS and ASS are soils that have the potential to generate acid through oxidation of iron sulphides when exposed to air. ASS and PASS are generally found in coastal areas, and generally in soils at an elevation of 5m AHD or lower.

(2) References

Dept of Environment and Resource Management, *Nov 2002*
Queensland Acid Sulfate Soil Technical Manual Soil Management Guidelines
State Planning Policy
EF006: Daily Dredging Checklist Form
CE020: Regulated Waste Transport Procedure
QAF004 Incident, Hazard, Improvement reporting form

(3) Safety requirements

Works shall comply with provisions of the Work Health and Safety Act 2011 and subsequent regulations. Personnel are responsible for their own Personal Protective Equipment (PPE) and the safety of the surrounding workplace during works.

Care is to be taken when using hydrogen peroxide, including gloves and eye protection.

(4) Environmental Requirements

Compliance with Environmental Protection Act 1994 and subordinate legislation.
Compliance with *Queensland Acid Sulfate Soil Technical Manual Soil Management Guidelines*
Compliance with the State Planning Policy.
Compliance with all other environmental legislation.
Compliance with TCC Environmental Policy.

(5) Equipment and materials

Testing should be undertaken by a suitably qualified laboratory.

(6) Method

(a) Identifying ASS/PASS on site

The following points can assist in determining if soil has a likelihood of containing ASS/PASS. Affirmative answers to the following questions may indicate the presence of ASS/PASS. Field observations and tests should be complemented by laboratory testing.

(i) Is the site elevation 5m AHD or less?

(ii) Are mangroves, she-oaks or melalueca species (i.e. paper barks) present on site?

(iii) Is there other vegetation that is stunted or dying?

(iv) Does the soil have a dark grey to grey appearance?

(v) Is there a rotten egg smell (hydrogen sulphide) to disturbed soil?

(vi) Is there a mottled-yellow mineral present in the soil (Jarosite)?

(vii) Is there water bodies nearby that have a very clear blue-ish appearance, or does it appear to be reddish (rust) in colour?

(viii) Is the pH of the excavated sediment, or water, below 4?

(b) Managing and treating ASS and PASS

(i) Determine if works can be undertaken without disturbing ASS/PASS material.

(ii) If ASS/PASS is to be disturbed as a result of project activities then undertake testing to determine the severity of the potential acidification and extent of ASS/PASS material.

(iii) ASS/PASS material excavated on site must either be treated on site or transported to a treatment location. A treatment pad should be set up as per the *Queensland Acid Sulfate Soil Technical*

Manual, Soil Management Guidelines.

(iv) ASS material should be transported as regulated waste as it has the potential to be generating acid while exposed to the atmosphere.

(v) All treatment of PASS/ASS must be undertaken in compliance with the *Queensland Acid Sulfate Soil Technical Manual, Soil Management Guidelines.*

(vi) ASS/PASS treatment must be undertaken as per the laboratory recommendations.

(c) Corrective/Emergency Actions

If PASS and/or ASS are identified through site inspection and confirmed through lab testing, follow procedure outline in (6) above.

If corrective actions are identified, an Incident, Hazard, Improvement Report is to be completed and subsequent review of this procedure undertaken in accordance with these guidelines.

(d) Waste Control

Treat PASS and ASS in accordance with guidelines (State Policy)

Ensure wastes generated as a result of field testing or work activities are disposed of correctly.

(e) Responsibilities

(i) Site foreperson/works controller is responsible for:

(A) monitoring and testing soils; and

(B) Minimising disturbance to PASS/ASS.

(ii) The Environmental Engineer is responsible for ensuring any environmental non-compliances are reported.

(iii) The Executive Manager Engineering Services is responsible for:

(A) notifying relevant personnel of changes to this procedure; and

(B) delivering training to personnel (if required).

(f) Monitoring and reporting

The foreperson will monitor and test soils prior to commencement of works and record results of field tests on daily dredging checklist.

SC6.4.6.10.8 Compaction and quality control

(1) Compaction and moisture requirements

In areas listed below, all layers shall be uniformly compacted to not less than the relative compaction specified before the next layer is commenced. Each layer of material shall be trimmed prior to and during compaction to avoid bridging over low areas. A smooth surface shall be presented at the top of each layer.

(a) The following areas shall be compacted to provide a relative compaction, determined by AS1289.5.1.1 using AS1289.5.4.1 or AS1289.5.7.1 for standard compactive effort, of not less than 95%.

(i) each layer of material replacing unsuitable material as detailed in clause SC6.4.6.10.5 Unsuitable material

(ii) each layer of material placed in embankments, up to 300mm from the top of the sub-grade;

(iii) fill placed adjacent to structures up to 300mm from the top of sub-grade;

(iv) material in unsealed verges and within medians up to the level at which topsoil is placed;

(v) spoil (excluding unsuitable material); and

(vi) all other areas except those where a higher relative compaction is specified.

Unsuitable material shall be stockpiled as directed by the Superintendent and compacted by track rolling.

(b) The following areas shall be compacted to provide a relative compaction of not less than 97% as determined by AS1289.5.1.1 using AS1289.5.4.1 or AS1289.5.7.1 for standard compactive effort:

(i) foundations for shallow embankments;

(ii) foundations other than shallow embankments;

(iii) the whole area on the floors of cuttings;

(iv) each layer of the embankment or cutting within 300mm from the top of sub-grade;

(v) each layer of the selected material zone as specified in clause SC6.4.6.10.6(9) Selected material zone;

(vi) any areas of material of specified quality which may be shown on the drawings or specified elsewhere behind kerbs and/or gutters or adjacent to rigid pavements; and

(vii) the fill material placed adjacent to structures as specified in clauses SC6.4.6.10.6(10) Fill adjacent to structures and SC6.4.6.10.6(12) Selected backfill in each layer within 300mm from the top of the sub-grade.

Where the vertical alignment design is such that a substantial portion of the road is required to be built at or close to the natural surface, cut the prepared subgrade to a depth below natural surface of less than 0.5m. Approval is required when shallow cutting conditions occur, the specified transition from cut to fill may be modified such that the depth of terrace excavation at the transition from cut to fill is reduced from 900mm to 250mm.

Treat the floor of shallow cutting as specified in clause SC6.4.6.10.3(5) Treatment of floors of cuttings and clause SC6.4.6.10.3(6) Trasition from cut to fill and compact to provide a relative compaction of not less than 100% for a depth of 200mm determined by AS1289.5.4.1, for standard compactive effort.

At the time of compaction the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content which, unless otherwise approved by the Superintendent, is within the range set out in SC6.4.6.10 Attachment A Earthworks Supplementary Information of the optimum moisture content as determined by AS1289.5.1.1 or AS1289.5.7.1. Material which becomes wetted up after placement shall not be compacted until it has dried out so that the moisture content is within this range. The drying process may be assisted by aeration, or where approved by the Superintendent, by the use of hydrated or quick lime. Alternatively the Contractor may transport the wet material to a stockpile site for drying out and later use as fill material. If there is insufficient moisture in the material for it to be compacted as specified, water shall be added. The added water shall be applied uniformly and thoroughly mixed with the material until a homogeneous mixture is obtained.

Compaction shall be undertaken to obtain the specified relative compaction for the full depth of each layer in embankments and for the full width of the formation over the entire length of the work. Compaction shall be completed promptly to minimise the possibility of rain damage.

Any material placed by the Contractor that has attained the specified relative compaction but subsequently becomes wetted up so that the moisture content is greater than the apparent optimum, determined by AS1289.5.4.1, shall be dried out and uniformly recompacted to the required relative compaction in accordance with this clause before the next layer of material is placed. Alternatively, the Contractor may remove the layer of wetted material to a stockpile site for drying and later re-use.

(2) Test locations

The specified compaction and moisture tests shall be taken at the random test locations established in each lot in accordance with the specified minimum testing frequency. Prior to testing the Contractor shall work the lot to ensure uniform moisture content and compaction of all material within the lot.

The test(s) then taken shall be considered to represent the total volume of material placed within the lot.

Where the Superintendent considers that the material which is present has not achieved uniformity required by this clause or clause SC6.4.6.10.6(5) Placing fill for embankment construction, the Superintendent may take or

direct further testing. The Superintendent shall nominate the area represented by the additional testing.

If such testing confirms that material not conforming to the Specification, the Contractor shall carry out remedial work as necessary to achieve conformance to the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements.

(3) Deflection monitoring

Following completion of the formation to the underside of the selected material zone in accordance with clause SC6.4.6.10.6(3) Foundations for embankments and SC6.4.6.10.6(5) Placing fill for embankment construction, completion of the selected material zone in accordance with clause SC6.4.6.10.6(9) Selected material zone and SC6.4.6.10.3(5) Treatment of floors of cutting, the Contractor shall make the work available in lots, for the Superintendent or council to carry out deflection monitoring.

A lot for deflection testing shall consist of a continuous length of formation, in compliance with council requirements, and a single carriageway width which is generally homogeneous with respect to material and appearance. The contractor shall identify the boundaries of each lot with stakes clearly labelled to the satisfaction of the Superintendent.

Prior to the release of the lot, a proof roll is to be performed with a single drive axle truck with an axle load of 8.2 t covering all lanes of carriage way including parking bays having no evident movement.

(4) Widening of formation

Road shoulders and formation shall be widened to accommodate footpaths, guard fence, streetlight plinths, emergency telephone bays and vehicle standing areas as shown on the drawings.

(5) Subgrade testing and treatment

Refer to SC6.4.4.2.4

SC6.4.6.10.9 Summary of limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.10.4 Summary of limits and tolerances below.

Table SC6.4.6.10.9 Summary of limits and tolerances

Item	Activity	Limits/Tolerances
1.	**Batter Slopes**	± 300mm
	a) Excavation	
	b) Embankment	± 300mm
2.	**Subgrade**	Parallel to designed grade line. Tolerance is to be within +0mm - 50mm of the levels specified.
	Vertical Tolerance	
	Horizontal Tolerance	The width of the cutting at subgrade level for support of the pavement shall not be less than that specified on the drawings or documentation.
3.	**Tops of Embankments**	Parallel to the designed grade line. Tolerance is to be within, ±50mm from the levels specified
	Vertical Tolerance	
	Horizontal Tolerance	The width of an embankment at subgrade shall not be less than that specified on the drawings or documentation.
4.	**Selected Material**	SC6.4.6.10 Attachment A: Earthworks – Supplementary Information

Note—tolerances are measured at right angles to design surfaces.

SC6.4.6.10.10 Attachment A: Earthworks - supplementary information

Clause	Description	Value
SC6.4.6.10.2(1)	The depth below natural surface up to which the removal and measurement of top soil shall apply: (a) Cutting area; and (b) Embankment area	75mm
SC6.4.6.10.3(5)	Minimum CBR value in cutting floors used for design of pavement	3%
SC6.4.6.10.6(3)	Requirements of material in foundations for shallow embankment Moisture Content - within the range of 60% to 90% of optimum	
SC6.4.6.10.6(5)	Upper Zones of Formation and SC6.4.6.10.6 (9) Select Material Zone Material within each zone shall have a CBR value of not less than the following, under the nominated test conditions:	

Location	Minimum CBR Value	Depth	Nominated Soaking Period (Days)
a. Select Material Zone	10	200	4
b. Material below Selected Material Zone to 1.5 metre from top of pavement	3	N/A	4

SC6.4.6.10.6(9) Construction tolerances for selected material zones is to be ±50mm of the designed grade and crossfall profile

SC6.4.6.10.8(1) Moisture content of material placed in embankments:

(a) Material in upper zones of formation - within the range of 60% to 90% of optimum

(b) All other embankment material - within the range of 60% to 90% of optimum

SC6.4.6.11 Clearing and grubbing

SC6.4.6.11.1 Introduction

(1) Scope

This sub-section provides standards, advice and guidelines for the clearing of all vegetation, both living and dead, all minor man-made structures (such as fences and livestock yards), all rubbish and other materials, including the chipping of the crowns of trees and the branches of shrubs, and the grubbing of trees stumps from the area. The work also includes the disposal, in accordance with clause SC6.4.6.11.3(2) Chipping of cleared vegetation and SC6.4.6.11.3(3) Disposal of materials, of all materials that have been cleared and grubbed.

(2) General requirements

Site works shall take all measures to prevent damage to existing underground and overhead utility services.

Before commencing earthworks, locate and mark existing underground services in the areas to be affected by the works including clearing, excavating and trenching.

All existing utilities, natural landscape features, including natural rock outcrops, natural vegetation, trees to be preserved, soil and watercourses are to remain undisturbed.

Explosives shall not be permitted to be used in clearing, grubbing or other demolition activities.

Editor's note—DIAL 1100 BEFORE YOU DIG is a free service, from anywhere in Australia, through which underground pipes and cables are located (possible within two working days). For more information go to the Dial 1100 Before you Dig website.

SC6.4.6.11.2 Clearing

(1) Clearing operations

The area within the limits of clearing shall be cleared of all vegetation, both living and dead, all minor man-made structures (such as fences and livestock yards), all rubbish and other materials which, are unsuitable for use in the works with the exception of certain trees marked for preservation. The contractor shall plan clearing operations such that wherever possible, clearing is carried out progressively and only the minimum area of land is left disturbed at any time.

The contractor shall give the superintendent written notice of seven days of the intention to clear any area of the work. The superintendent shall mark or indicate to the contractor the trees that shall be preserved. The contractor shall arrange for an inspection by an authorised council officer and shall obtain council's approval to proceed with clearing and grubbing. The contractor must conform to the requirements of SC6.4.5.2(18) when protecting identified trees and bushland within or adjacent to the construction site.

The erection of structures, excavation and filling, changes to soil profiles, stockpiling of spoil, storage of other materials and driving or parking of any vehicle or machinery within 4m of the trunks of trees to be retained shall not be permitted unless they form part of the works as approved by the council.

The Contractor shall plan all operations to ensure that there is no damage to any trees outside the limits of clearing specified or directed by the Superintendent. No growing trees shall be destroyed or damaged by the Contractor other than those specified and those indicated by the Superintendent.

Any tree remaining within the road reserve but outside the limits of clearing which is, in the opinion of the Superintendent, unsound and likely to fall upon the roadway shall be cleared and disposed of in accordance with clause SC6.4.6.11.3(2) Chipping of cleared vegetation, subject to prior approval of council.

If directed by the Superintendent, any branch, which overhangs the road formation, shall be cut back to within 0.5 m of the tree trunk and disposed of in accordance with clause SC6.4.6.11.3(2) Chipping of cleared vegetation.

(2) Fallen timber and tree damage

Every precaution shall be taken to prevent timber from falling onto private property. The Contractor shall dispose of any timber that has fallen onto private property or produce written consent from the property owner to its remaining there.

The cost of disposal of such fallen timber shall be borne by the Contractor. Prior to entering the private property, the Contractor shall obtain consent from the Superintendent and the property owner. Damage of any kind, including damage to trees, fencing, occurring during clearing operations shall be made good by the Contractor. The cost of making good such damage shall be borne by the Contractor. Any damage to trees or vegetation which in councils opinion, will require its removal, is to be in rectified in accordance with SC6.4.5.2.1(19)(d).

SC6.4.6.11.3 Grubbing

(1) Grubbing

All trees and stumps, on or within the limits of clearing, unable to be felled and removed by the clearing methods used by the Contractor shall be removed by grubbing.

Grubbing operations shall be carried out to a depth of 0.5m below the natural surface or 1.5m below the finished surface level, whichever is the lower.

Holes remaining after trees and stumps have been grubbed shall be backfilled promptly with sound material to prevent the infiltration and ponding of water. The backfilling material shall be compacted to at least the relative density of the material existing in the adjacent ground.

(2) Chipping of cleared vegetation

The Contractor shall produce a wood-chip mulch derived from crowns of trees and branches of shrubs cleared under this sub-section. The wood-chip mulch produced shall be stockpiled for subsequent use or for use at other locations as appropriate.

The wood-chip mulch shall be produced from branches having a maximum diameter of 100mm and the chipped material produced shall not have two orthogonal dimensions exceeding 75mm and 50mm.

(3) Disposal of surplus materials

Unless otherwise specified elsewhere, all surplus materials cleared and grubbed in accordance with this sub-section shall either be removed from the site or used for landscaping within the site in accordance with the approved plans and any conditions set by council.

Unless otherwise approved by council in writing, disposal of timber and other combustible materials by burning shall not be permitted.

SC6.4.6.12 Flexible pavements

SC6.4.6.12.1 Introduction

(1) Scope

This policy sub-section provides standards, advice and guidelines for the supply, spreading, compaction and trimming of base and subbase courses of flexible pavements.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

Editor's note—A reference to drawings is a reference to construction drawings.

(2) Pavement structures

Flexible pavement material types and layer thicknesses must be as per design requirements.

(3) Activity plan

Prior to commencement of work, the Contractor must provide the Superintendent a Pavement construction plan and detail the following activities:

(a) allocation of plant and personnel for the contract period;

(b) work programming to meet the constraints of all inspection points; and

(c) prepare and submit a Pavement construction plan for the flexible base and subbase construction consistent with the drawings and subject to direction by the Superintendent. Include the following:

(i) a time based program;

(ii) a drawn sectional plan showing lots and sequence;

(iii) site availability, assumptions on weather, plant and materials;

(iv) a list of activities requiring approvals or notification of local authorities, statutory bodies, and local residents; and

(v) off-site storage of plant, personnel and maintenance facilities.

(4) Inspection, sampling and testing

Inspection, sampling and testing of the pavement must be undertaken by the Contractor in accordance with the requirements of this sub-section before, during and after the construction of the pavement. Testing must be carried out by a NATA registered laboratory with appropriate accreditation and suitably qualified personnel.

The Contractor must provide the Superintendent with written notice when testing is being carried out and copies of all test reports for approval to proceed.

Field density tests must be carried out in accordance with AS 1289.5.3.1, or, with the Superintendent's concurrence, with a Nuclear Density Meter in accordance with Clause SC6.4.6.12.6(3).

(5) Terminology

Base material	materials designated as Base are of a suitable quality that form the uppermost structural element of a pavement and on which the surfacing may be placed.
Bound material	bound material incorporates binder/s to produce structural stiffness (UCS > 1.5MPa at 28 days in accordance with TMR Test Method Q115).

Flexible pavement	a flexible pavement consists of a base and a subbase constructed of unbound granular materials or modified material, obtaining its load spreading properties from intergranular pressure, mechanical interlock and cohesion between the particles of the pavement material.
Modified material	modified material incorporates small amounts of stabilising binder to improve the properties of the material without significantly affecting structural stiffness. A modified material must have sufficient stabilising binder to achieve a UCS range of 0.8MPa - 1.5MPa at 28 days in accordance with TMR Test Method Q115.
Subbase material	materials designated as Subbase are laid on the subgrade (or selected material), below the base, either for the purpose of making up additional pavement thickness, to prevent intrusion of the subgrade into the base, or to provide a working platform.
Unbound material	unbound materials are granular materials with no significant capacity to resist tensile stresses.

(6) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.16 - Sprayed bitumen surfacing
SC6.4.6.19 - Stabilisation
SC6.4.4.2 - Pavement design

(b) Queensland Department of Transport and Main Roads specifications:
MRTS05 - Unbound Pavement

(c) Queensland Department of Transport and Main Roads Test Methods:
Q142A - Dry Density - Moisture Relationship (Standard Compaction).
Q115 - Unconfined Compressive Strength of Compacted Materials.
Q701 - Benkelman Beam Deflections.

(d) Australian Standards:

AS 1141.14 *- Particle shape, by proportional calliper*
AS 1141.22 *- Wet/dry strength variation*
AS 1289.3.1.1 *- Determination of the liquid limit of a soil - Four point Casagrande method*
AS 1289.3.3.1 *- Calculation of the plasticity index of a soil*
AS 1289.3.6.1 *- Determination of the particle size distribution of a soil - Standard method of analysis by sieving*
AS 1289.3.6.3 *- Determination of the particle size distribution of a soil - Standard method of fine analysis using a hydrometer*
AS 1289.5.1.1 *- Determination of the dry density/moisture content relation of a soil using standard compactive effort*
AS 1289.5.3.1 *- Determination of the field density of a soil - Sand replacement method using a sand-cone pouring apparatus*
AS 1289.5.4.1 *- Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS 1289.5.8.1 *- Determination of field density and field moisture content of a soil using a nuclear surface moisture - density gauge - Direct transmission mode*
AS 1289.6.1.1 *- Determination of the California bearing ratio of a soil - Standard laboratory method for a remoulded specimen*
AS 5101.4 *- Methods for preparation and testing of stabilized materials. Method 4: Unconfined compressive strength of compacted materials*

SC6.4.6.12.2 Materials

(1) General

The Contractor must submit details of all constituents of the proposed base and subbase materials, including sources of supply and the proposed type and proportion of any binder including targeted 28 days unconfined compressive strength (UCS). These details must be submitted to the Superintendent, supported with test results from a nominated NATA registered laboratory confirming that the constituents comply with the requirements of this sub-section.

If the proposed base or subbase is a bound material, the Contractor must submit a completed SC6.4.6.19 Attachment A Stabilisation mix design contained in the sub-section SC6.4.6.19 Stabilisation.

No material may be delivered until the Superintendent has approved the source of supply.

If, after the Contractor's proposals have been approved, the Contractor wishes to make changes in any of the material constituents the Contractor must inform the Superintendent in writing of the proposed changes. No delivery of material produced under the altered proposal must take place without the approval of the Superintendent.

At least 2 weeks before placement of the material on site, the Contractor must submit a Certificate from a laboratory with appropriate NATA registration demonstrating and stating that the unbound material or the mix and its constituents comply with the requirements of this sub section.

Ongoing testing of materials during delivery and construction must be undertaken on samples taken from the site.

(2) Unbound base and subbase

Base materials must comply with the requirements of type 2.1 materials as per clause 7.2 of MRTS05, grading B or C.

Sub-base materials must comply with the requirements of type 2.3 materials as per clause 7.2 of MRTS05, grading B or C.

Lower sub-base must comply with the requirements of type 2.4 materials as per clause 7.2 of MRTS05, grading B or C.

Unbound materials, including blends of two or more different materials, must consist of granular material which does not develop significant structural stiffness when compacted. Material produced by blending must be uniform in grading and physical characteristics.

(a) **Surface Evenness**

Townsville City Council reserves the rights to carry out the necessary test procedure and supply results to the Contractor.

(b) **Layer Thickness**

Unbound pavement material must be laid at a minimum thickness of 125mm and a maximum thickness of 250mm.

(c) **Longitudinal Joins**

Longitudinal joins for paving runs for the top layer of the base courses must be aligned to coincide with the position of the traffic lane markings, except where approved otherwise in writing by the Superintendent.

(d) **Segregation**

Segregation is the uneven distribution of particle sizes. The construction process must minimise segregation. There must be no visible signs of segregation on each lot. Samples must be taken from each lot to check that segregation of the material in the lot has not occurred. Additional samples must be taken from any areas which show visible signs of segregation. Each sample must be tested in accordance with Test Method Q103A.

(3) Lime modified base and subbase materials

Modification of unbound base and subbase materials to meet the requirements of clause SC6.4.6.12.2(2) Unbound base and subbase by the addition of hydrated lime or quicklime is subject to approval by the Superintendent and to the additional requirements of this clause. After modification, the material must meet the requirements of clause SC6.4.6.12.2(2) Unbound base and subbase.

Modification of materials must be by means of blending either hydrated lime through a stationary mixing plant or by hydrated lime or quicklime utilising in-situ operations.

Material requirements of hydrated lime and quicklime must be in accordance with sub-section SC6.4.6.19 Stabilisation.

The method of incorporating lime through the stationary mixing plant must ensure that the lime is mixed uniformly through the material.

In-situ operations must be in accordance with sub-section SC6.4.6.19 Stabilisation.

The proportion of lime must be not less than 1.5% nor more than 4% by mass. The material prior to lime treatment must contain no added pozzolanic material.

The lime treated material must yield an unconfined compressive strength not exceeding 1MPa, when tested in accordance with Test Method Q115 where sampling is undertaken within 24 hours of adding the lime and testing is after 28 days curing.

(a) **Curing Final Layer**

Moist curing process has the potential to "wash" the cementitious paste from the upper surface, which leaves an unbound, non-cohesive, soft pavement matrix with high embedment potential for the subsequent sealing aggregate. Therefore, wherever possible the completed pavement should not be moist cured within 48 hours of placing. Moist curing must be carried out using equipment fitted with spray jets that deliver water to the pavement as a fine mist. The use of conventional spray bars or high pressure water nozzles with large aperture sprays holes will not be permitted. Conventional bituminous surface curing may be used within 48 hours.

(4) Bound base and subbase materials (Including Modified Material)

Bound material for a UCS>1.5MPa (28 days) to be used as subbase generally or base layer may be supplied as a pugmill quarry product with stabilising agent and laid using a paving machine or grader laid. Alternatively it may be produced by the in-situ stabilisation of natural or blended gravel where stabilisation is undertaken by mobile plant at the site.

Prior to stabilisation, the layer to be stabilised must meet the appropriate requirements for subbase material.

Material requirements for the stabilising agent must be in accordance with sub-section SC6.4.6.19 Stabilisation.

The stabilisation process must meet the requirements of sub-section SC6.4.6.19 Stabilisation.

The unconfined compressive strength (UCS) of the material after 28 days curing as determined by Test Method Q115 must be not less than 2.5MPa for stabilised pavements and not less than 0.8MPa for modified pavements. Sampling and test specimen compaction of the material must be undertaken within one hour of the incorporation of the stabilising agent.

The maximum period (working time) between mixing cement with the gravel material and the completion of compaction must be 3 hours. Council reserves the rights to reject the work if working time is not achieved and the material must be removed from site.

(a) **Surface Evenness**

Townsville City Council reserves the rights to carry out the necessary test procedure and supply results to the contractor.

(b) **Layer Thickness**
Bound pavement material (including Modified Material) must be laid at a minimum thickness of 150mm and a maximum thickness of 250mm. If bound layers are placed with a paving machine, Council may approve thinner layers.

(c) **Longitudinal Joins**
Longitudinal joins for paving runs for the top layer of the base courses must be aligned to coincide with the position with the traffic lane markings, except where approved otherwise in writing by the Superintendent.

(d) **Segregation**
Segregation is the uneven distribution of particle sizes. The construction process must minimise segregation. There must be no visible signs of segregation of the material in the lot has not occurred. Additional samples must be taken from any areas which show visible signs of segregation. Given the presence of cement additive in the material, the relevant test for segregation must be as specified in AS 1289.3.6.1.

(e) **Curing Final Layer**
Moist curing process has the potential to “wash” the cementitious paste from the upper surface, which leaves an unbound, non-cohesive soft pavement matrix with high embedment potential for the subsequent sealing aggregate. Therefore, the completed pavement must not be moist cured within 48 hours of placing. After 48 hours, moist curing must be carried out using equipment fitted with spray jets that deliver water to the pavement as a fine mist. The use of conventional spray bars or high pressure water nozzles with large aperture sprays holes will not be permitted. Conventional bituminous surface curing may be used within 48 hours.

SC6.4.6.12.3 Delivery, stockpiling and processing of pavement material

(1) Delivery to site
Materials must be supplied sufficiently damp to avoid segregation and loss of fines during transit.

(2) Stockpiling of unbound materials
Stockpile sites must be located as shown on the drawings or as approved by the Superintendent.

Stockpile sites, which must be cleared of all vegetation and extraneous matter, must be shaped to form a crown so as to be free draining and compacted over the whole area to provide a relative compaction, determined by AS1289.5.4.1 for standard compactive effort, of not less than 95%.

Stockpiles and stockpile sites must be maintained so as to prevent the stockpiled materials from becoming intermixed or contaminated with foreign material.

The total height of any stockpile must not exceed 3m.

Stockpiles must be of uniform shape with side slopes neither steeper than 1.5h to 1v nor flatter than 3h to 1v.

The worked face of any stockpile must be the full face of the stockpile. The stockpiled material must be maintained at a moisture content sufficiently damp to avoid loss of fines.

At the completion of the works, stockpile sites must be cleared of all surplus material and left in a clean and tidy condition.

(3) Delivery of modified or bound materials
Modified or bound materials must be delivered in vehicles fitted with covers of canvas or other suitable material to prevent loss of moisture during transport.

The time between mixing and conveyance by delivery trucks to the site, must be such as to allow incorporation into the works including trimming and compaction within the nominated field working period.

Each truck load of bound material must be identified by delivery dockets, indicating the time and date of mixing and registration or fleet number of the delivery truck, and such dockets must be made available to the Superintendent at the point of delivery.

Bound materials must comply with the requirements of sub-section SC6.4.6.19 Stabilisation.

SC6.4.6.12.4 Spreading pavement materials

The contractor must present the underlying layer to the Superintendent prior to placement of subsequent layers and must ensure that moisture content of the underlying layer does not exceed 90% of the laboratory optimum moisture content as determined by AS1289.5.1.1. If the underlying layer has become rutted or mixed with foreign matter, it must be corrected to comply with this Sub-section before spreading of the next layer of pavement.

Where the underlying layer was constructed by the Contractor, or where the Contractor's activities caused the underlying layer constructed by others to become non-complying with this sub-section, correcting the underlying layer to comply is the responsibility of the Contractor.

Each layer of material must be deposited and spread in a concurrent operation and, after compaction, the finished surface levels on the base and subbase courses must be within the permitted tolerances stated in Clause SC6.4.6.12.6(6)(c) Levels and surface trim without subsequent addition of material. The thickness of each compacted layer must be neither less than 125mm nor more than 250mm for all pavement layer types, unless otherwise approved by the Superintendent.

At all work boundaries in bound materials the Contractor must provide vertical faces to provide for transverse and longitudinal joints.

When spread for compaction processes the moisture content of the unbound and bound base materials must be in the range of 60-90% and subbase materials must be in the range of 75-100% of laboratory optimum moisture content in accordance with AS1289.5.1.1.

Bound materials with UCS > 1.5MPa (28 days) must not be spread with a self-propelled paver when the ambient air temperature in shade is either below 5°C or above 35°C. Where the materials are to be spread outside the required ambient air temperature range, the Contractor must submit a work proposal to the Superintendent for approval.

SC6.4.6.12.5 Compaction

(1) General requirements

Each layer of the base and subbase courses must be uniformly compacted over its entire area and depth to satisfy the requirements of relative compaction set out in clauses SC6.4.6.12.6(3) Relative compaction and SC6.4.6.12.6(4) Compaction requirements and acceptance.

On sections of pavement with one way crossfall, compaction must begin at the low side of the pavement and progress to the high side. On crowned sections, compaction must begin at the sides of the pavement and progress towards the crown. Each pass of the rollers must be parallel with the centreline of the roadway and uniformly overlap each preceding pass. The outer metre of both sides of the pavement must receive at least two more passes by the compaction plant than the remainder of the pavement.

At locations where it would be impracticable to use self propelled compaction plant, the pavement material must be compacted by alternative hand operated plant approved by the Superintendent.

Watering and compaction plant must not be allowed to stand on the pavement being compacted.
If any unstable areas develop during rolling, the unstable material must be rejected. The rejected material must be removed for the full depth of the layer, disposed of and replaced with fresh material in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses. This operation will be at cost to the Contractor.

The placement of subsequent layers must not be allowed until the requisite testing has been completed and the test results for each layer have been accepted by the Superintendent and correct curing times for bound

layers has been attained.

Any unbound material in a layer that has attained the specified relative compaction but subsequently becomes wetted up must be dried out and, if necessary, uniformly recompacted and trimmed to meet the specified density requirements and level tolerances.

(2) Curing of bound materials
The curing of the surface layer of a lot must commence after compaction is completed and must be in accordance with the SC6.4.6.19 Attachment A Stabilisation mix design.

The stabilised work must be protected against rapid drying out by keeping it continuously wet or damp during the period prior to the provision of a subsequent layer or the application of a prime or primer-seal. Also refers to the requirements of SC6.4.12.2 (5) (e) Curing of final layer.

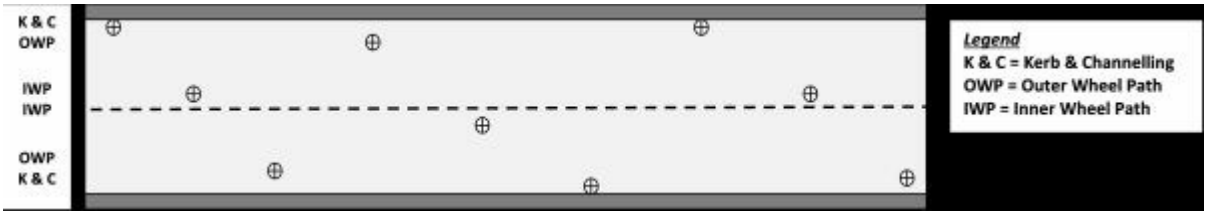
SC6.4.6.12.6 Acceptance of compaction

(1) Lots for acceptance
Acceptance of work, as far as compaction is concerned, must be based on density testing of the work in lots. A lot must be nominated by the Contractor, but must conform to the following:

(a) cover only a single layer of work which has been constructed under uniform conditions in a continuous operation and not crossing any transverse construction joints; and

(b) for unbound materials, it may equal a day's output using the same material.

(2) Compaction assessment
The Superintendent must assess compaction for each lot based on arranged test locations for in-situ dry density testing in line with the following diagram. The intention is that one in every three density tests must be positioned against the inner line of the kerb and channel on either side. This arrangement must be repeated or truncated as appropriate depending on the number of tests required per lot.



Similar arrangement must be adopted for roads with no kerb and channel or edge constraint, with the test locations at the edge shifted to the OWP position. A random arrangement for test locations at intersection is acceptable, provided that one in every three density test is positioned along the inner kerb and channel / edge line.

The Contractor must arrange for testing to assess compaction on the basis of a pro rata testing frequency of 10 tests per 5,000sqm with a minimum of three tests per lot.

The elastic rebound deflection must be taken as the maximum deflection in accordance with Test Method Q701 utilising the Benkelman Beam or equivalent. The average maximum deflection for any lot must not exceed 1mm, and the co-efficient of variation (CV) in recorded deflections must not exceed 30%.

Measurements must be taken at the rate of 4 per 1,000sqm, with a minimum of ten measurements per lot.

Proof rolling must be undertaken with the use of a single drive axle truck with a rear single axle/dual wheels load of 8.2t or tandem rear axle/dual wheels carrying a load of 13.8t. Proof rolling cover all lanes of the carriage way including parking bays and must show no evident movement.

(3) Relative compaction
The relative compaction of pavement material at each location tested for in-situ dry density must be calculated

in accordance with AS 1289.5.4.1 as follows:

Relative Compaction (per cent) = $\frac{\text{In-situ dry density}}{\text{Comparative dry density}} \times 100$

Note—the comparative dry density must be the maximum dry density determined in the laboratory.

The council Superintendent may approve some or all of the in-situ dry density testing to be carried out with a single probe Nuclear Density Meter in the direct transmission mode in accordance with AS 1289.5.8.1. Council reserves the right to request additional testing at the discretion of the Inspector.

Each day that material is produced for placement in a layer or layers, a sample of the material must be taken by the Contractor for maximum dry density testing to represent that day's production.

For unbound layers, the sample must be tested in accordance with AS 1289.5.1.1 to determine the maximum dry density (standard compactive effort) for the material.

For bound layers the sample must be tested within two hours after the addition of stabilising agent to the mix in accordance with Test Method Q142A to determine the maximum dry density (standard compactive effort) for the material. This test method must also be used to determine the standard optimum moisture content.

The maximum dry density so determined must be used as the comparative dry density in relative compaction calculations for all like material from that lot or day's production placed in a single layer of work whichever is the lesser.

(4) Compaction requirements and acceptance

All compaction test results must exceed the minimum requirements in accordance with:

(a)	Unbound pavement	MRTS05
(b)	Insitu stabilised subgrade using lime	MRTS07A
(c)	Insitu stabilised pavement using cement	MRTS07B
(d)	Insitu stablised pavement using foam bitumen	MRTS07C
(e)	Plant mixed stabilised pavement	MRTS08

(5) Reworking of rejected unbound layers

Lots or areas of pavement that have been rejected in regard to compaction must be reworked before resubmission for compaction assessment.

Material that has become degraded, segregated or otherwise reduced in quality by reworking must be rejected. The rejected material must be removed, disposed of and replaced with fresh material complying with this Sub-section in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses. When a lot or area of pavement is resubmitted for compaction assessment, testing must be carried out in accordance with clauses SC6.4.6.12.6(2) Compaction assessment and SC6.4.6.12.6(3) Relative compaction.

All corrective work must be carried out by the Contractor before the resubmission of a lot for compaction assessment, including rewatering, rerolling, removal and replacement of material as well as reworking. All costs associated with corrective work carried out before the resubmission of a lot for compaction assessment, including rewatering, rerolling, removal and replacement of material as well as reworking must be borne by the Contractor. Reworking of rejected modified or stabilised material is not accepted.

(6) Tolerances

(a) General

The tolerances stated are the acceptable limits of departure from the dimensions shown on the drawings, which may occur during construction.

Areas for assessment of conformity with tolerance requirements must be divided into lots and presented to the Superintendent together with survey reports covering line and level.

(b) Width

At any cross section without kerb and /or guttering channel or a dish drain, and for pavement layers extending under the kerb and channel or dish drain/or guttering , the horizontal dimension measured from the design centre line to the edge of the constructed pavement surface must be neither less than 50mm less than the dimension nor more than 300mm greater than the dimension shown on the drawings.
The average width of the layer determined from measurements at three sites selected at random by the Superintendent over any 200m road length, or part thereof, must be not less than the specified width.

(c) Levels and surface trim

The levels of the finished surface of the top of the unbound subbase course must not vary from the design levels by more than ±15mm.

Level tolerances at the top of the unbound base course must not exceed those stated above for subbase. In addition, where kerb and channel exists or is being constructed, the level of the top of the base course adjacent to the kerb and channel must not vary by more than ±5mm from the lip level of the gutter minus the design thickness of the wearing surface.

The design level of the top of the subbase course must be determined from the design level of the finished road surface less the thickness of the base course and the wearing course, including an allowance for any flush seal layer in the pavement design.

The pavement surface after trimming and immediately prior to sealing must be of a quality such that the deviation under a 3m straight edge placed in any direction does not exceed 12mm. Measurements for conformance must be taken in accordance with the maximum lot size and minimum test frequencies in SC6.4.5 Construction management.

(7) Action on rejection

(a) Unbound materials

A lot that has not complied with the requirements for width or level tolerance as set out in clauses SC6.4.6.12.6(6)(b) Width and SC6.4.6.12.6(6)(c) Levels and surface trim respectively must be rejected except as otherwise provided in this clause. Rejected lots must be removed, disposed of and replaced with fresh material in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses.

Notwithstanding the above, where the rejected lot can be corrected by further trimming, the Superintendent may allow the surface to be corrected without complete removal and replacement with fresh material. Such trimming must be undertaken in a manner that produces a uniform, hard surface and must be achieved by cutting only without filling. After any such cutting, the level tolerances in clause SC6.4.6.12.6(6)(c) Levels and surface trim must apply.

The required surface correction or replacement work ordered in accordance with this clause including removal of material, disposal and supply and transport of replacement material, must be borne by the Contractor.

(b) Bound materials

An area of bound material that has not complied with the requirements for width or level tolerance as set out in clauses SC6.4.6.12.6(6)(b) Width and SC6.4.6.12.6(6) Levels and surface trim respectively must be rejected except as otherwise provided for in this clause. Rejected areas must be removed, disposed of and replaced with fresh material in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses.

The removal and disposal of rejected material and its replacement with fresh material must be borne by the Contractor.

Notwithstanding the above, the Superintendent may allow the Contractor to rectify the area in the following cases:

(i) Where the cause for rejection is under clause SC6.4.6.12.6(6)(c) Levels and surface trim, the course is a subbase course and rejection is due to departures from design level being too far below the design level, the Contractor may increase the thickness of the base course to make up such deficiency in thickness.

(ii) Where the cause for rejection is under clause SC6.4.6.12.6(6)(c) Levels and surface trim, the course is a subbase course and rejection is due to departures from design level being too far above the design level, the Contractor may propose a regrading of the design level of the base course, to allow for its design thickness to be laid, up to a maximum of 20mm above the original design level. Approval by the Superintendent must be subject to the following requirements:

(A) the rate of change of grade from the original finished design surface level must be less than 3mm per metre;

(B) the regrading must not interfere with the proper design functioning of the drainage system;

(C) the regrading must not interfere with levels at the property boundary, or increase or decrease footpath or footpath crossover levels or grades beyond council's allowable design limits; and

(D) the regrading must not interfere with clearances.

(iii) Where the cause for rejection is under clause SC6.4.6.12.6(6)(c) Levels and surface trim, the course is a base course and rejection is due to departures from design level being too far above the design level, the Contractor may propose a regrading of the design level of the base course. Approval by the Superintendent is subject to the requirements of this clause in (ii) above.

(8) Removal and replacement of rejected courses
Sections of work that have been rejected by the superintendent are to be removed from the work site and replaced with fresh material.

Any rejected pavement sections are to be removed and replaced over the full length of the rejected lot for a minimum length of 20m of the pavement layer. Any damage to underlying or abutting layers or structures must be made good by the Contractor using methods approved by the Superintendent.

The Superintendent may approve removal for less than the full width as constructed if the cause of the rejection of the work can be isolated transversely to the Superintendent's satisfaction. In this case, the new longitudinal cold joint must be formed and located along the centreline of the road pavement.
After removal of rejected base or subbase course material, the section must be presented for inspection by the Superintendent before replacement work is commenced.

Materials used as replacement materials, and the subsequent spreading, compaction, trimming, curing and testing of the replacement materials, must comply with the requirements of this sub-section.

The removal, replacement and correction of base and subbase courses required under this clause must be the responsibility of the Contractor in respect of delays caused by such removals, replacements and corrections must be borne by the Contractor.

All costs associated with the corrective work must be borne by the Contractor.

(9) Maintenance before completion of wearing surface
Following the Superintendent's acceptance of any section of the work, the Contractor must maintain the prepared surface of the base in the condition specified for acceptance until the wearing surface is completed. The preparation work must be carried out in a manner which will promote the adhesion of the bituminous material to the surface of the pavement. Preparation work must include:

(a) Removal of all foreign and loose material from the surface; and

(b) Light watering on dry and dusty surface

Ball Penetration testing on inner and outer wheelpaths must be carried out on all pavements before application of bituminous material. Where a ball penetration result exceeds 4.0mm the surface must not be sprayed until Council is advised and approval to proceed granted.

The base course of sections of the accepted work must be covered with a primerseal over the full width of pavement in accordance with sub-section SC6.4.6.16 Sprayed bitumen surfacing within 7 days of the date of the acceptance of such sections, unless otherwise approved by the Superintendent.

Should the pavement condition deteriorate before the application of the primerseal and consent to proceed with the bitumen surfacing work is withdrawn by the Superintendent, the Contractor must re-prepare the pavement and re-present the pavement for inspection by the Superintendent.

The maintenance and re preparing areas of the deteriorated pavement is the responsibility of the Contractor.

The Contractor must maintain adequate drainage of the pavement, and remove any ponded water within 12 hours of its creation if free drainage cannot be achieved, prior to the completion of the wearing course.

SC6.4.6.12.7 Opening pavement to traffic

General requirements

For unbound pavement layers, construction plant and vehicles not involved in the current construction or testing of the work must not be permitted to use the pavement until the primerseal has been applied, unless otherwise approved.

For bound pavement layers, construction plant and vehicles not involved in the current construction or testing of the work should not use the pavement until the primerseal has been applied and seven days have elapsed since placement of the base. In any case only vehicles registered for legal road usage and loaded within legal limits will be allowed to use the pavement.

SC6.4.6.12.8 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.12.1 below.

Table SC6.4.6.12.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Stockpile Sites**	(i) Relative Compaction >97% (ii) Stockpile height <3m (iii) Stockpile batter <1.5:1 and >3:1	SC6.4.6.12.3(2) SC6.4.6.12.3(2)
2.	**Spreading Pavement Materials**		
	(i) Compacted Layer Thickness	≥150mm (modified material) ≥125mm (unmodified material) ≤250mm (all material)	SC6.4.6.12.4
3.	**Compaction Acceptance**		
	Minimum value of all calculated relative compaction results	All compaction test results must exceed the minimum referenced requirements	SC6.4.6.12.6(4)
4.	**Width of Pavement**	-50mm to +300mm of dimensions on drawings	SC6.4.6.12.6(6)(b)
	(i) Design centre-line to edge of constructed pavement		
	(ii) Average Width	The average width determined from 3 random sites over any 200m road length, or part thereof, must be not less than the specified width.	SC6.4.6.12.6(6)(b)
5.	**Surface Level**		
	(i) Subbase levels	<± 15mm from design level	SC6.4.6.12.6(6)(c)
	(ii) Base levels	<± 15mm from design level	SC6.4.6.12.6(6)(c)

(iii) Base levels adjacent to kerb and channel	<±5mm from the lip levels of adjacent gutter minus design thickness of wearing surface.	SC6.4.6.12.6(6)(c)
(iv) Shape	Deviation from a 3m long straightedge on base surface immediately prior to sealing must be less than 12mm	SC6.4.6.12.6(6)(c)
(v) Ball Penetration	>4.0mm	SC6.4.6.12.6(9)

SC6.4.6.13 Asphaltic concrete

SC6.4.6.13.1 Introduction

(1) Scope

(a) This policy sub-section provides standards, advice and guidelines for the production and placing of asphalt including the supply of materials, sampling, testing and any other operations necessary to provide asphalt. The extent of the policy sub-section includes:

(i) manufacture/supply of the production mix;

(ii) provision of a testing laboratory;

(iii) preparation of the surface on which asphalt is to be placed;

(iv) transport of asphalt;

(v) laying and compaction of asphalt; and

(vi) sampling and testing.

(b) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note—A reference to drawings is a reference to construction drawings.

(2) Plant

The Contractor must provide all the plant, equipment and labour necessary for carrying out the work in accordance with this sub-section.

All plant and equipment used on the work must be in accordance with the submitted quality documentation and kept in good operating condition. The Contractor must not use in the work any plant or equipment demonstrated to be faulty in operation so as to effect the product quality or unsafe in operation as assessed by the Superintendent.

All plant must be registered and insured as appropriate to its use on a public road and must comply with statutory environmental regulations.

(3) Protection of services and road fixtures

The Contractor must take all necessary precautions to prevent asphalt or other material used on the work from entering or adhering to gratings, hydrants or valve boxes, access chamber covers, bridge or culvert decks and other road fixtures. Immediately after the asphalt has been spread the Contractor must clean off or remove any such material as directed by the Superintendent and leave the services and road fixtures in a condition satisfactory to the Superintendent.

(4) Control of traffic

The Contractor must provide for traffic control in accordance with the requirements of sub-section SC6.4.6.30 Control of traffic while undertaking the work.

The Contractor must take all necessary steps to avoid or minimise delays and inconvenience to road users during the course of the work but without compromise to the safety of the road users or employees.

(5) Work records

Particulars of the work performed must be recorded by the Contractor on the Asphalt Work Record at SC6.4.6.13 Attachment A Asphalt Work Record or as per the Contractor's own procedures where equivalent. The Contractor must complete the Asphalt Work Record, which must be countersigned by the Superintendent each day as a true record of the work performed.

Delivery dockets stating the mass of each truck load of asphalt must be attached to the Asphalt Work Record.

(6) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections:

SC6.4.6.30 - Control of traffic

(b) Australian Standards:

AS 1141.11	*- Particle size distribution by dry sieving*
AS 1141.14	*- Particle shape, by proportional calliper*
AS 1141.17	*- Voids in dry compacted filler*
AS 1141.18	*- Crushed particles in coarse aggregate derived from gravel*
AS 1141.22	*- Wet/dry strength variation*
AS 1141.42	*- Pendulum friction test (PAFV)*
AS 1160	*- Bitumen emulsions for the construction and maintenance of pavements*
AS 2008	*- Residual bitumen for pavements*
AS 2150	*- Hot mix asphalt*
AS 2734	*- Asphalt (hot-mixed) paving - Guide to good practice*
AS 2758.5	*- Asphalt aggregates*
AS 2891.1	*- Sampling of Asphalt (AS2891.1.1 Methods of Sampling and testing asphalt Loose asphalt)*
AS 2891.3.1	*- Bitumen content and aggregate grading - Reflux method*
AS 2891.5	*- Determination of stability and flow - Marshall procedure*
AS 2891.8	*- Voids and density relationships for compacted asphalt mixes*
AS 2891.10	- Water and volatile oils content

(c) Queensland Department of Transport and Main Roads Specifications:

MRTS17	*- Bitumen*
MRTS18	*- Polymer Modified Binder*
MRTS21	*- Bituminous Emulsion*
MRTS30	*- Dense Graded and Open Graded Asphalt*

(d) Austroads:

AGPT03-2009 *Guide to Pavement Technology Part 3 – Pavement surfacings*
AGPT04B-2007 *Guide to Pavement Technology Part 4B - Asphalt*

SC6.4.6.13.2 Materials

Materials and mix ingredients must be in accordance with MRTS30. Binder must be in accordance with MRTS17 and polymer modified binder in accordance with MRTS18.

SC6.4.6.13.3 Asphalt mix design

(1) Approved mix

The supply only of an approved mix in accordance with MRTS 30.

The Contractor may not make any changes to the approved mix, or constituent materials without the prior written approval of the Superintendent.

Notwithstanding any approval given by the Superintendent to a proposed asphalt mix, the Contractor is responsible for producing asphalt which satisfies all requirements of this policy sub-section.

Asphalt produced in the plant and delivered to the site must be known as the "production mix".

(2) Production

(a) Asphalt production must comply with the requirements of MRTS30.
The Superintendent, upon provision of notice to the asphalt supplier or the supplier's representative, must have access to the mixing plant for purposes of inspection to verify production procedures and the supplier's compliance with the Contractor's Quality Management Manual and Project Quality Plan. The Superintendent must have the right to declare any non-conformance and be entitled to request correction

of either the Contractor's Quality Management Manual or the Project Quality Plan or both.

(b) Storage of asphalt
Asphalt may be stored in an insulated storage bin prior to delivery. Asphalt which has been stored for more than twenty four hours or is below the minimum temperature specified must not be used. Binder manufacturer's instructions must be followed when polymer modified asphalt is stored.

(c) Contractor's laboratory
The Contractor must maintain and operate an appropriately registered NATA testing laboratory at or near the mixing plant to control the quality of the asphalt produced.

The Contractor will make the laboratory available for inspection by the Superintendent at any time during the course of the works.

All documented test results must be submitted to the Superintendent for inspection and approval in a format and to a timetable suitable to the Superintendent.

The Contractor is responsible for taking samples and must supply all facilities, equipment and labour for that purpose. The samples must be taken by the Contractor.

(d) Frequency of sampling
For the purpose of testing production mix the Contractor must sample production lots at the minimum frequencies set in MRTS30. This testing frequency requirement must apply to each asphalt mix type. The test results must be related to production intervals with samples representing the full lot of production of the relevant mix for the production interval.

Test results from this production control sampling are acceptable as representative of deliveries made under this contract subject to the traceability of production from specific production intervals to the location at the paving site.

Such traceability shall include registration of lot number and time of production on the delivery docket system. The size of any production lot shall be limited to production from a 12 hour "shift".

Sampling shall be performed in accordance with Test Method Q301. Samples shall be identified so as to allow traceability of the mix to the paving site. Each sample or sample portion as appropriate sampled as a referee sample shall be stored in an airtight container labelled so as to be traceable to the job and paving site location.

Testing required shall be arranged by the Contractor at an appropriately registered NATA laboratory. Test reports will be made available to the Superintendent as soon as they are available and always within 7 days of delivery of material.

Dense graded asphalt that does not include modified bitumen may include a proportion of RAP up to but not exceeding 20% by mass. The resultant asphalt shall meet all requirements for the Nominated Mix.

The RAP to be utilised shall be nominated by source and/or stockpile. Testing of the Nominated Mix shall include RAP sampled from the stockpile and of similar physical properties as that to be utilised for the contract. Any change in RAP supply shall be brought to the attention of the Superintendent prior to proposed usage in asphalt under this contract.

(3) Delivery
The bodies of haulage trucks shall be kept clean and coated with a thin film of an approved release agent to prevent asphalt sticking to the body of the truck. Any surplus release agent shall be removed before loading.

During transport asphalt shall be covered with a canvas or other suitable cover which is held down securely.

When transported to site until delivery to the hopper, the mix must be covered with a heavy duty canvas or similar waterproof cover which shall overlap the sides of the truck body by at least 250mm and shall be tied down securely. The bodies of all trucks shall be suitably insulated.

Delivery of the asphalt shall be at a uniform rate within the capacity of the spreading and compacting equipment.

The mass of all truck loads of asphalt shall be measured on a registered weighbridge.

(4) Placing

Placing of asphalt shall not be permitted when the surface of the road is wet or while rain appears imminent, or when cold winds chill the asphalt to such an extent that, in the opinion of the Superintendent, spreading and compaction will be adversely affected. The Superintendent may order work to cease temporarily on account of adverse weather, unsatisfactory pavement surface condition, or other circumstance which the Superintendent feels may adversely affect the subsequent operations.

(5) Preparation of pavement

The existing surface shall be dry, clean and free from any loose stones, dirt and foreign matter. The surface shall be swept beyond the edge of the proposed asphalt layer by at least 300mm. Any foreign matter adhering to the pavement and not swept off shall be removed by other means. Any areas significantly affected by oil contamination shall be cleaned to the satisfaction of the Superintendent.

Surface preparation shall be in accordance with AS 2734. Thermoplastic linemarking or other linemarking, where indicated necessary by the Superintendent will be removed prior to paving. Raised pavement markers shall be removed prior to paving.

The Contractor, when paving over existing road pavement, shall be responsible for the recording of lane marking positions including the extent of barrier line. After paving the Contractor will mark up the pavement to re-establish such positions using conventions agreed with the Superintendent and to a standard adequate to allow accurate re-establishment of line marking.

The Contractor shall repair any damage to the existing pavement surface caused by the Contractor's activities. Affected areas designated by the Superintendent shall be removed and reinstated to the Superintendent’s satisfaction.

A corrector course shall be used to correct irregularities in an existing surface and/or modify the shape of an existing surface. Any surface depressions greater than 25mm in depth and any uneven surface shall be brought to the general level of the surrounding pavement/deck surface. Where a corrector course is used to modify the shape of an existing surface, the course shall be laid to the reduced levels and/or shape specified in the documents.

The Contractor shall mark out, in the presence of the Superintendent, the areas where corrector course is to be applied and shall not lay corrector course prior to receiving acceptance of the proposed areas from the Superintendent.
The asphalt in these patches shall be compacted to comply with the general level of the existing surface to the Superintendent’s satisfaction.
Back filling and stress absorbing fabric strips is to be carried out in accordance MRTS30 where indicated on the drawings or directed by the superintendent.
Preparation of the prepared surface is to be to the satisfaction of the Superintendent. Subsequent inspection and Superintendent’s approval of surface condition shall be required prior to the release of the hold point.

(6) Tack coat

Only on multiple courses shall tack coat be used between each course unless directed otherwise by the Superintendent. The whole of the area to be sheeted with asphalt shall be tack coated with a light and even coat of bitumen emulsion. Bitumen emulsion shall comply with the requirements of MRTS21.

The bitumen emulsion shall be applied at a rate of between 0.1 litres per square metre and 0.2 litres per square metre of undiluted bitumen unless otherwise specified.

The bitumen emulsion shall be applied by a mechanical sprayer with spray bar. Where the areas to be sprayed are small, irregular or inaccessible to mechanical sprayers, such areas shall be tack coated by hand spraying or brushing.

The bitumen emulsion may be warmed or diluted with water to facilitate spraying. Adequate time shall be allowed for the emulsion to break before asphalt is laid. Over application of tack coat, due to surface depressions, shall be removed or dispersed by brushing.

All contact surfaces of kerbs and other structures and all cold joints shall be coated with a thin uniform application of tack coat.

Care shall be taken to ensure that bitumen emulsion is not sprayed on, or allowed to coat, any services or exposed fixtures including concrete kerbs, guardfence or bridge handrails. Appurtenances susceptible to overspray shall be protected with suitable paper.

When trucks or other vehicles are likely to move from tack coated areas onto adjacent finished surfaces, the Superintendent may require that the finished surfaces be suitably protected from carryover of bituminous material.

In locations of heavy pedestrian traffic, such as shopping areas, the Contractor shall take appropriate precautions in accordance with sub-section SC6.4.6.30 Control of traffic to keep pedestrians off tack coated areas.

(7) Laying

(a) Paver
The paver(s) shall be expected to have a minimum spreading capacity of 50t of asphalt per hour and be capable of spreading a width of at least 3.7m to the requirements of this sub-section. It shall be expected to have automatic screed control operated from joint matching shoe, fixed line, travelling straight edge or levelling beam. The Contractor shall provide the Superintendent with notice of proposed pavers without these capabilities and obtain Superintendent's agreement to their use.

(b) Laying operations
The work shall be so arranged as to keep the number of joints, both longitudinal and transverse to a minimum.

The paver shall operate at a uniform speed and the delivery of asphalt shall match the output of the paver such that continuous laying of asphalt is achieved.

When laying asphalt in echelon the distance between pavers shall be such that the temperature of the asphalt at the edge of the asphalt laid by the advance paver is not less than 80 °C by the time the following paver matches the longitudinal joint.

In the event of faulty operation of the paver causing irregularities in the spread asphalt, work shall cease until the fault is rectified.

Unless otherwise approved by the Superintendent, asphalt shall not be spread by hand behind the paver. Workers shall not stand or walk on the hot surface until compaction has been completed except where necessary for correction of the surface.

The Superintendent may approve spreading asphalt by hand for minor correction of the existing surface and in areas inaccessible to mechanical pavers.

Asphalt shall not be placed when the surface of the pavement is wet or while rain appears imminent.

AS 2734 shall constitute a valid reference of good practice for asphalt laying practice.

(c) Laying temperature

Weather restrictions and minimum asphalt temperatures at the time of discharge into the paver shall be in accordance with MRTS30. Measurement may be made by calibrated infra-red thermometers when accepted by both Contractor and Superintendent.

The Superintendent may reject that part of any truck load which contains lumps of cooled asphalt which are liable to affect the quality of the finished surface.

The laying temperature shall be measured in the paver hopper. A suitable stem type thermometer readable and accurate to within plus or minus 2 °C with a range from at least 0 °C to 200 °C shall be used. The stem shall be inserted into the asphalt to a depth of approximately 200mm at a location at least 300mm from the side of the paver. The average of two readings shall be adopted as the temperature of the mix. Measurements of asphalt and road surface temperatures and wind velocity to comply with this Clause shall be recorded on the Asphalt Work Record Sheet.

(d) Level control

The minimum controls for level set out below shall be used. Additional controls may be necessary to obtain the required finished pavement properties.

Corrective courses shall be automatically controlled by programmed computer control of the paver, joint matching shoe or stringline sensor. Where the correction is only minor, the Superintendent may allow the use of levelling beams at least 10m long.

Intermediate courses shall be automatically controlled by programmed computer control of the paver or a joint matching shoe.

The wearing course shall be controlled by levelling beams at least 10m long and, as required by the Superintendent or a joint matching shoe. When identified in the Project Quality Plan and/or approved in writing by the Superintendent, small areas (as defined) may be paved as wearing course without the use of levelling beam to achieve target levels.

(e) Layer thickness

The compacted thickness of each course shall be as shown on the drawings. A course may comprise one or more layers. The nominal compacted layer thickness shall be in accordance MRTS30.

(8) Joints

(a) General

The location of longitudinal and transverse joints shall be as approved by the Superintendent and at the spacing nominated in the drawings. All joints shall be compacted and finished with a smooth, planar surface coinciding with, and being of similar appearance to the remainder of the layer.

(b) Longitudinal joints

An automatically controlled joint matching device shall be used to control the levels of adjacent runs. Care shall be taken to provide positive bond between adjoining runs. Longitudinal joints shall be:

(i) continuous and parallel;

(ii) coincident within 150mm of line of change in crossfall;

(iii) offset by at least 150mm from joints in underlying layers;

(iv) located away from traffic wheel paths; and

(v) located beneath proposed traffic linemarkings in the case of a wearing course.

Work shall be arranged to avoid longitudinal joint faces being left exposed overnight.

When pavers are laying asphalt in echelon, the hot joint so produced shall be constructed by leaving an uncompacted strip approximately 150mm wide along the edge of the first run, and after the adjoining run has been spread, both sides of the joint shall be rolled simultaneously.

A joint shall be considered “cold” when the temperature of the asphalt has dropped below 60ºC for dense graded mix. Cold joints will require tack coating.

(c) Transverse joints

When the end of the asphalt layer has cooled due to disruption of the work, or when resuming work on the next day, a transverse joint shall be formed.

Transverse joints shall be at right angles to the direction of laying. They shall be staggered by at least 1m between successive layers and between adjacent runs.

Runs shall end either against a timber bulkhead to ensure a straight vertical, well compacted edge or by feathering out and compacting. In the latter case, before continuing the run the feathered material shall be cut back to a line where the full layer thickness exists. The surface shape of the end of the run shall be checked by a straight edge to locate the line of cut. The end of the previous run shall be lightly tack coated before the laying of the next run proceeds.

When the asphalt layer is required to join and match the level of an existing pavement surface, bridge deck or other fixture, sufficient of the existing material shall be cut out to achieve the minimum layer thicknesses requirements.

SC6.4.6.13.4 Compaction

(1) Plant and equipment

The proposed compaction fleet and rolling pattern shall be adequate to achieve the specified compaction and finish.

The minimum number of rollers used for compaction of asphalt laid at various rates should be as shown in Table SC6.4.6.13.1 Minimum roller combinations for compaction.

For compaction of confined areas or patching works a small vibrating roller, or hand operated vibrating compactor acceptable to the Superintendent shall be used.

Table SC6.4.6.13.1 Minimum roller combinations for compaction

ASPHALT OUTPUT	ALTERNATIVE ROLLER COMBINATION		
	Dense Graded Asphalt		
Tonnes per hour per paver	Static Steel	Steel Vibrating	Pneumatic Tyred
Up to 45	1	-	1
	-	1	1
45 to 85	1	-	2
	-	1	1
85 to 120	1	-	3
	2	-	2
	-	2	1
Above 120	As for 85 to 120 plus additional rollers as determined by Compaction Trials		

Note— 1. At the discretion of the Superintendent, the minimum number of rollers may be decreased for layer thicknesses in excess of 60mm.

2. Additional pneumatic tyred rollers to those specified may be required for backrolling asphalt.

(2) Dense graded asphalt

(a) Initial rolling

Initial rolling shall be carried out using steel rollers. Vibratory steel rollers may be used, but they shall be operated in the static mode for the first pass. On deep lift asphalt, pneumatic tyred rollers may be used.

Initial rolling shall commence as soon as possible after laying has commenced. Rollers shall be operated as close as possible to the paver.

The transverse and longitudinal joints and edges shall be compacted first.

The minimum asphalt temperature at the commencement of rolling shall be as detailed in MRTS30.

(b) Secondary rolling
Secondary rolling shall immediately follow initial rolling. In secondary rolling, static steel rollers or pneumatic tyred rollers shall be used. The tyre pressures of pneumatic tyred rollers should equal or exceed 550 kilopascals.

Rolling shall commence at the longitudinal joint side of the run.

Secondary rolling shall be completed before the mix temperature falls below 80 °C.

(c) Final rolling
Final rolling shall be carried out by a pneumatic tyred roller to eliminate all roller marks and to produce a uniform finish. If secondary rolling has been carried out with a pneumatic tyred roller, a steel roller may be used for final rolling instead of the pneumatic tyred roller specified.

Final rolling shall be completed before the asphalt temperature falls below 60 °C.

(3) Acceptance criteria for compaction
The acceptance for compaction shall be on a lot by lot basis where each day's work in one layer is generally one lot. Any defective areas which show cracking, bony material or exhibiting excessive binder shall be excluded from the lot and shall be rectified by the Contractor before being tested.

When directed by the Superintendent the Contractor shall arrange for the determination of the relative compaction of the lot by either of the following methods:

The acceptance for compaction on a lot shall be on the basis of characteristic value of relative compaction in accordance with MRTS30.

(4) Finished pavement properties
Each course of asphalt shall be finished parallel to the finished surface of the wearing course.

(5) Thickness
The thickness of asphalt shall be specified and/or measured in one of the following ways:

(a) No finished surface levels specified
When asphalt is placed over an existing pavement in one or more courses and no corrective course is applied, the calculated average compacted thickness of each course shall be in accordance with the course thickness specified in the Drawings and tolerances indicated in MRTS30.

(b) Finished surface levels specified
When asphalt is placed to specified levels, vertical tolerances and thicknesses shall be in accordance with MRTS30.

(6) Shape
The surface shall not deviate from the bottom of a 3m long straightedge laid in any direction by more than 5mm.

(7) Removal and replacement of rejected material
The sections of work that have been rejected under the preceding clauses of this sub-section or as otherwise determined by the Superintendent shall be removed within 15 days from the work and replaced with fresh asphalt mix material corresponding in grade and quality to that material specified in the Approved Mix unless otherwise approved by the Superintendent.

If removal of the single nonconforming pavement strata is impossible, the affected area as determined by the Superintendent shall be removed to subbase or subgrade depth as appropriate to provide a smooth level

surface on which to found the reinstated base and/or subbase course.

The perimeter of the nonconforming area shall be prepared in accordance with the practice pertaining to longitudinal and transverse cold joints (AS 2734).

In rejected sections the material is to be removed over the full length of the affected area except that a minimum length of 5m and a minimum width equal to the paver width shall be removed.

The Superintendent shall have the right to alter the constitution, quality, grading, or other parameters of the "reinstatement pavement" if it is felt that reconstruction of the affected area with the Approved Mix would produce nonconforming pavement as a result of non-continuous pavement structure.

After removal of the rejected base or subbase course the area shall be made available to the Superintendent for inspection and approval to proceed with the works. Superintendent inspection and approval is required prior to release of hold point.

All materials used in the reinstatement of the nonconforming area shall comply with the requirements of this sub-section unless otherwise directed by the Superintendent.

SC6.4.6.13.5 Limits and tolerances

The limits and tolerances applicable to the various clauses of this sub-section are summarised in Table SC6.4.6.13.2 below:

Table SC6.4.6.13.2 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	Materials and mix ingredients and manufacture	AC Asphalt - MRTS 30 and current TMR supplementary specifications. Bitumen - MRTS 17 Polymer modified binder - MRTS 18	SC6.4.6.13.2
2.	**Preparation of Pavement** (a) Cleaning of Surface	>300mm beyond the edge of proposed layer	SC6.4.6.13.3(1)
3.	**Tack Coat** (a) Bitumen Emulsion	Application Rate > 0.10 and < 0.20 litres per square metre	SC6.4.6.13.3(1)
4.	**Laying** (a) Paver Capacity	>50 tonnes asphalt per hour	
	(b) Spread Width	>3.7m	
	(c) Laying in Echelon	Distance between pavers is such that temperature of asphalt at edge (or laid by leading paver) is >80˚C when following paver matches the longitudinal joint.	
	(d) Laying Temperature		
	(i) Dense Grade AC	As per MRTS30	
	(e) Level Control	>10m length	SC6.4.6.13.3(7)(d)
	(i) Levelling Beam for Corrective Course		
	ii) Levelling Beam for Wearing Course	>10m length	SC6.4.6.13.3(7)(d)
	(f) Course and Layer Thickness	Nominal size mix and compacted layer thickness as per MRTS30.	
5.	**Longitudinal Jointing** (a) Change in Crossfall	Within 150mm of line of change.	
	(b) Where Underlying Layers	Offset at least 150mm from joints in underlying layers.	
6.	**Transverse Jointing** (a) Where Underlying Layers	Stagger to be >1m between successive layers and adjacent runs.	

Item	Activity	Limits/Tolerances	Clause
7.	**Compaction**	Initial Rolling:	SC6.4.6.13.3(2)(c)
	(a) Dense Graded Asphalt	To be commenced before asphalt temperature falls below 115ºC for layer ≤40mm. Refer to MRTS30	
		Secondary Rolling:	SC6.4.6.13.3(2)(d)
		Tyre pressures on pneumatic rollers to be≥550kPa.	
		Rolling to be completed before the asphalt temperature falls below 80ºC.	
		Final Rolling:	SC6.4.6.13.3(2)(d)
		Rolling to be completed before asphalt temperature falls below 60ºC.	
	(b) Acceptance Criteria for Compaction	On bases of characteristic value of relative compaction as per MRTS30 AC7 90% AC10 90% AC14 91% (92% > 50mm) AC20 93%	SC6.4.6.13.3(4)
8.	**Finished Pavement**	Max. compacted thickness tolerance as for	
	(a) Thickness	Table 12.3.3.2 of MRTS30 AC7 ± 5mm AC10 ± 5mm AC14 ± 7mm Where finished surface levels are specified, thickness and level shall comply with requirements of MRTS30. Reduced level primary tolerance ± 10mm.	
	(b) Shape	Shall not deviate from bottom of 3m straight edge by more than 5mm	SC6.4.6.3(6)

SC6.4.6.14 Mass concrete sub-base

SC6.4.6.14.1 Introduction

(1) Scope

This policy sub-section provides standards advice and guidelines for the construction, by mechanical or hand placement of mass concrete sub-base including trial sections and sub-grade beams.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note—A reference to drawings is a reference to construction drawings.

(2) Thickness and levels of subbase

The sub-base thickness and levels shall be as per design requirement.

(3) Provision for base slab anchors

During construction of the sub-base, in advance of concrete base construction the Contractor shall make provision to permit construction of base slab anchors at the locations and to the dimensions shown on the design. Excavation of material, trimming of trenches, compacting of the bottom of the trench, disposal of surplus material and construction of the concrete anchors shall be carried out in accordance with sub-sectionSC6.4.6.15 Plain and reinforced concrete base as part of the concrete base construction.

(4) Reference and source documents

Documents referenced in this Sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:

SC6.4.6.15 - Plain and reinforced concrete base

SC6.4.6.28 - Minor concrete works.

(b) Australian Standards:

AS1012.1 - *Sampling of fresh concrete*

AS1012.3.1 - *Determination of properties related to the consistence of concrete - Slump test*

AS1012.4.2 - *Determination of air content of freshly mixed concrete - Measuring reduction in air pressure in chamber above concrete*

AS1012.8 - *Method of making and curing concrete – Compression and indirect tensile test specimens*

AS1012.8 - *Method of making and curing concrete – Flexure test specimens*

AS1012.9 - *Determination of the compressive strength of concrete specimens*

AS1012.13 - *Determination of the drying shrinkage of concrete for samples prepared in the field or in the laboratory*

AS1012.14 - *Securing and testing cores from hardened concrete for compressive strength*

AS1141.11.1 - *Particle size distribution – Sieving method*

AS1141.14 - *Particle shape, by proportional calliper*

AS1141.22 - *Wet/dry strength variation*

AS1160 - *Bitumen emulsions for the construction and maintenance of pavements*

AS1379 - *Specification and manufacture of concrete*

AS1478.1 - *Chemical admixtures for concrete, mortar and grout – Part 1: Admixtures for concrete*

AS2758.1 - *Concrete aggregates*

AS3582.1 - *Supplementary cementitious materials for use with portland and blended cement - Flyash*

AS3799 - *Liquid membrane-forming curing compounds for concrete*

AS3972 - *General purpose and blended cements*

(c) Other:

Austroads, *Guide to Pavement Technology Part 4G: Geotextiles and Geogrids*

SC6.4.6.14.2 Materials for concrete

(1) Cement

Cement shall be Type GP Portland cement or Type GB blended cement complying with AS3972. Cement shall be from a source approved under the Queensland Government's State Purchasing Policy.

When submitting details of the nominated mix in accordance with clause SC6.4.6.14.4(1) General the Contractor shall nominate the brand and source of the cement. On approval of a nominated mix by the Superintendent, the contractor shall use only the nominated cement in the work.

Documentary evidence of the quality and source of the cement shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

If the Contractor proposes to use cement which has been stored for a period in excess of three months from the time of manufacture, the Superintendent may require a retest to ensure the cement complies with AS3972, before the cement is used in the work.

Cement shall be transported in watertight containers and shall be protected from moisture until used. Caked or lumpy cement shall not be used.

(2) Flyash

Flyash shall be from a source approved under the Queensland Government's State Purchasing Policy. The use and the quality of flyash shall comply with AS3582.1.

When submitting details of the nominated mix in accordance with clause SC6.4.6.14.4(1) General, the Contractor shall nominate the powerhouse source of the flyash. On approval of a nominated mix by the Superintendent, the Contractor shall use only flyash from the nominated powerhouse.

Documentary evidence of the quality and source of the flyash shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

(3) Water

Water used in the production of concrete shall be potable, free from materials harmful to concrete or reinforcement, and be neither salty nor brackish.

(4) Admixtures

Chemical admixtures and their uses shall comply with AS1478.1. Admixtures shall not contain calcium chloride, calcium formate, or triethanolamine or any other accelerator. Admixtures or combinations of admixtures other than specified below shall not be used. An air entraining agent may be included in the mix. If an air entrainer is used, the air content of the fresh concrete shall comply with Clause SC6.4.6.14.3(5) Air content.

Fresh concrete with an air content not complying with Clause SC6.4.6.14.3(5) Air content shall be rejected.

During the warm season (October to March inclusive), a lignin or lignin based ("ligpol") set retarding admixture approved by the Superintendent, shall be used to control slump within the limits stated in Clause SC6.4.6.14.3(4) Consistency. The dosage shall be varied to account for air temperature and haul time in accordance with the manufacturer's recommendations. A copy of the NATA endorsed Certificate of Compliance with AS1478.1 shall be submitted to the Superintendent, together with the proposed `dosage chart' in accordance with SC6.4.6.14.4(1) General.

If the Contractor proposes to vary the admixture between the warm and cool seasons such variation shall constitute a proposed change to an approved mix for the purposes of Clause SC6.4.6.14.4(2) Variations to approved mixes.

When submitting details of the nominated mix in accordance with Clause SC6.4.6.14.4(1) General, the Contractor shall nominate the proprietary source, type and name of each admixture to be used. Documentary evidence of the quality shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

(5) Aggregates

(a) General

(i) When submitting details of the nominated mix in accordance with clause SC6.4.6.14.4(1) General, the Contractor shall nominate the sources of aggregate to be used and shall submit details of the geological type of each aggregate.

(ii) Aggregates shall all pass the 37.5mm AS sieve and shall comply with AS2758.1 in respect of bulk density, water absorption (maximum 5%), material finer than 75 micrometres, impurities and reactive materials. The proportion of misshapen particles (2:1 ratio) determined by AS1141.14 shall not exceed 35%.

(iii) When submitting details of the nominated mix, the Contractor shall submit to the Superintendent a NATA Certified Laboratory Test Report on the quality and grading of the aggregate proposed to be used. The grading shall be known as the "Proposed Grading".

(iv) If the Contractor proposes to blend two or more aggregates to provide the Proposed Grading the Test Reports for each constituent material shall be submitted separately and the Superintendent advised of the proportions in which the various sizes and constituents are to be combined. The aggregate from each source and the combined aggregate shall comply with the requirements of this clause.

(v) All aggregate used in the production of concrete shall be clean, hard, durable rock fragments free from the inclusion of mineral salts, oils, organic matter or other materials deleterious to the performance of concrete.

(b) Grading

(i) The grading of the combined aggregate used in the work, determined by AS1141.11, shall not deviate from that of the proposed grading by more than the amounts shown in Table SC6.4.6.14.1 Aggregate grading deviation limits.

Table SC6.4.6.14.1 Aggregate grading deviation limits

Australian Standard Sieve	Maximum Deviation Per Cent Passing by Mass of Total Sample
37.5mm	-5
19.0mm	+ or -10
4.75mm	+ or -10
1.18mm	+ or -5
600mm	+ or -5
150mm	+ or -2

(c) Durability

Any fraction of any constituent and any fraction of combined aggregate shall conform to the following requirements:

(i) Wet Strength AS1141.22 Shall not be less than 50kN; and

(ii) 10 per cent Fines Wet/Dry Variation AS1141.22 Shall not exceed 35%.

(d) Storage

(i) Storage and handling facilities shall be such as to prevent the aggregates becoming intermixed or mixed with foreign materials, and to prevent segregation occurring.

(ii) The area surrounding the storage facilities and mixing plant shall be so constructed that delivery vehicles, loaders and trucks shall not be capable of introducing foreign matter to the aggregates at any time. If foreign matter is introduced or the area reaches a condition where, in the opinion of the

Superintendent, foreign matter may be introduced to the aggregates, production of concrete and delivery of materials shall cease until the condition is corrected to the satisfaction of the Superintendent.

SC6.4.6.14.3 Quality requirements of concrete

(1) Cement and flyash content
When a cement and flyash blend is nominated the minimum acceptable range is 40 – 75% by mass of the total cementitious material (cement and fly ash) in accordance with AS3582.1.

(2) Compressive strength
The compressive strength of concrete shall be determined in accordance with AS1012.9. The minimum compressive strength at 7 days shall be 4MPa and at 28 days shall not be less than 5MPa for flyash blended cement. The maximum compressive strength at 28 days shall be less than 15MPa, with the exception that where the nominated mix demonstrates a 28 day shrinkage less than 400 microstrains, then the concrete achieving a strength less than 20MPa shall be accepted.

(3) Shrinkage
The drying shrinkage of the nominated mix, determined by AS1012.13 shall not exceed 450 microstrain after 21 days air drying. The drying shrinkage at the nominated slump plus 10mm shall be taken as the average of the reading or readings within 5% of the median of the three readings obtained in accordance with AS1012.13.

(4) Consistency
The Contractor's nominated slump, determined in accordance with AS1012.3.1, shall be neither less than 25mm nor more than 40mm for mechanically placed concrete and shall be neither less than 50mm nor more than 65mm for hand placed concrete. The compactibility index range shall be between 60 and 80 in accordance with AS1012.3.4.

(5) Air content
If an air entraining agent is used, the air content of the fresh concrete, determined in accordance with AS1012.4.2, shall be neither less than 3% nor more than 7% when discharged from the transport vehicle ready for placement.

SC6.4.6.14.4 Design and control of concrete mixes

(1) General
The Contractor shall submit, for approval by the Superintendent, details of the concrete mix or mixes and the materials, including source, to be used for each of mechanically placed and hand placed subbase, including nominated slump and moisture condition of the aggregates (oven dry, saturated surface dry, or other specified moisture content) on which the mix is based. Each such mix shall be known as a “nominated mix”.

The Contractor shall provide a Certificate from a laboratory with appropriate NATA registration stating that each nominated mix and its constituents meet the requirements of this Specification. All relevant test results shall accompany the Certificate. All phases of any particular test must be performed at one laboratory. The certificate shall confirm that the required testing has been carried out in the twelve month period before the date of submission to the Superintendent.

In the tests supporting the above certification, the compressive strength gain curve shall be submitted showing the compressive strengths at ages 3, 7, 10 and 28 days determined in accordance with AS1012.9. Each of the results shall be based on three specimens of concrete produced from a batch of the nominated mix. The compressive strength shall be the average of individual results within 1MPa of the median.

These details shall be submitted at least 21 days before using the nominated mix in the work.

(2) Variations to approved mixes
The Contractor shall not make any changes to the approved mix, its method of production or source of supply

of constituents without the prior written approval of the Superintendent.

Where changes to an approved mix are proposed, the Contractor shall provide details of the nominated mix and materials, in accordance with clause SC6.4.6.14.4(1) General. If the variations to the quantities, qualities or sources of the constituents in the approved mix are less than 10kg for Portland cement, 20kg for other cementitious material and 5% by mass for each other constituent, except admixtures, per yielded cubic metre of concrete, the superintendent may approve the changes without new trials being carried out.

Notwithstanding these tolerances, the minimum cement content shall be 90kg per yielded cubic metre of concrete, the minimum flyash content shall be 100kg per yielded cubic metre of concrete.

SC6.4.6.14.5 Conformance for concrete strength and thickness

(1) Concrete cylinders

(a) Test specimens

Test specimens for determining the compressive strength of concrete shall be standard cylinders complying with AS1012.8.1. The Contractor shall supply a sufficient number of moulds to meet the requirements for the frequency of testing specified in this clause and shall also arrange for a laboratory with appropriate NATA registration to conduct the sampling of fresh concrete and the making, curing, delivery and testing of specimens. Copies of test results shall be forwarded to the Superintendent.

Samples of concrete for testing shall be taken in accordance with AS1012.1. The selection of the batches to be sampled shall be taken randomly. The specimens shall be moulded from each sample so that they are as identical as practicable.

The method of making and curing specimens shall be in accordance with AS1012.8.1 with compaction by internal vibration.

The Contractor shall mark the specimens for identification purposes.

Specimens shall be inspected, capped and crushed in accordance with AS1012.8.1 and AS1012.9.

(b) Frequency of moulding of test specimens

Test specimens shall be moulded as follows:

(i) For the determination of the compressive strength at twenty eight days:

- For each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens

(ii) For the determination of the compressive strength at seven days:

- For each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens

(iii) For the determination of compressive strength for any early testing as deemed necessary by the Contractor:

- For each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens

A lot is defined as a continuous pour of up to 50 cubic metres of concrete placed in the subbase.

(2) Compressive strength of concrete

(a) General

The compressive strength of the concrete represented by a pair of specimens moulded from one sample shall be the average compressive strength of the two specimens.
At the time of approving the mix design, the Superintendent shall nominate whether 7 day or 28 day compressive strength or both shall be the acceptance criteria for strength.

(b) Adjustment of test compressive strength for age of specimen

Should any specimen be tested more than 28 days after moulding the equivalent 28 day compressive strength shall be the test compressive strength divided by the factor applying to the age of the specimen at the time of the test shown in Table SC6.4.6.14.2 - Concrete age conversion factors.

For intermediate ages the factor shall be determined on a pro rata basis.

Table SC6.4.6.14.2 Concrete age conversion factors

Age of Specimen at time of test (days)	Factor
28	1.00
35	1.02
42	1.04
49	1.06
56	1.08
70	1.10
84	1.12
112	1.14
140	1.16
168	1.18
196	1.20
224	1.22
308	1.24
365 or greater	1.25

(c) Conformance for compressive strength
If the compressive strength of test cylinders for any lot is less than the criteria specified in Clause SC6.4.6.14.3(2) Compressive strength, the lot represented by the test cylinders shall be removed and replaced.

In case of non-conformance the Contractor may request permission of the Superintendent to core the in situ subbase for testing of the actual compressive strength to represent the particular lot. The locations for testing shall be nominated by the Superintendent. Such locations may be determined by the use of a nuclear density meter, or any alternative method. Testing shall be carried out at the request of the Contractor. Subbase concrete failing to reach the required in situ compressive strength shall not be retested for at least 72 hours after the determination of the value of the in situ compressive strength.

(3) Specimens cut from the work

(a) Specimens cut from the work shall be tested in a NATA registered laboratory nominated by the Contractor. Specimens shall be in the form of cylindrical cores of hardened concrete.

Cores shall be secured, accepted, cured, capped and tested in accordance with AS1012.14 with the following amendments:

(i) The requirement that the concrete shall be at least 28 days old before the core is removed shall not apply. However, concrete must have hardened enough to permit removal without disturbing the bond between the mortar and the coarse aggregate.

(ii) The preferred dimension for cores shall be 100mm diameter but in no case shall the diameter be less than 75mm or two and one half times the nominal size of the coarse aggregate, whichever is the greater.

(iii) When inspected in the uncapped state, cores shall be rejected if any diameter departs by more than 5mm from the mean diameter.

(iv) Cores shall be rejected where the length of the core when ready for capping is less than the diameter. The test strength determined shall be adjusted for form by a factor in accordance with Table SC6.4.6.14.3 Core strength factor.

(v) Wet Conditioning only shall be used.

Table SC6.4.6.14.3 Core strength factor

Length/Diameter Ratio	Correction Factor
2.00	1.00
1.75	0.98
1.50	0.96
1.25	0.93
1.00	0.89

Note—for intermediate form ratios, the factor shall be determined by interpolation.

Core cutting shall be carried out by the Contractor in the presence of and at the locations nominated by the Superintendent. The frequency of coring shall be such that a core is taken to represent each lot or the area of subbase placed between any two consecutive construction joints whichever is the lesser. The lot represented by each core shall be nominated by the Contractor at the time of sampling and duly recorded prior to testing.

Cores shall be despatched to arrive at the testing laboratory within 24 hours of the core being cut from the subbase. Wet curing shall commence within 24 hours of the receipt of the cores.

The cutting and transporting the cores to the testing laboratory and restoring all holes in the subbase shall be the responsibility of the Contractor. The method of restoration shall be approved by the Superintendent.

(4) Acceptance of cored concrete for compressive strength
Concrete shall achieve an in situ compressive strength of 5MPa within 28 days of placement.
If the specimen cut from the subbase reaches 4MPa for in situ compressive strength, base paving may proceed.

(5) Conformance for thickness

(a) General
No thickness measurements will be carried out if the surface of the subbase is within the level tolerances as specified in Clause SC6.4.6.14.7(5)(b) Surface tolerances.
If scabbling is required to achieve the level tolerance limits, the Superintendent may order thickness checks to be carried out. Where the survey ground model of the subgrade is available, subbase thickness shall be calculated from levels taken on a 5m grid on the plan area. Alternatively, the Superintendent may authorise coring and measurement at the edges of the layer. Thickness measurements shall be rounded off to the nearest 5mm.

(b) Thickness below specification
After making due allowance for the tolerances, subbase which is more than 20mm below the theoretical thickness shall be rejected and removed from the site. The removal and disposal from the site shall be the responsibility of the Contractor.

Subbase which is 20mm or less below the theoretical thickness may be accepted by the Superintendent providing that it represents isolated sections within a lot and such sections comprise less than 10 per cent of the area of the lot.

SC6.4.6.14.6 Productions, transport and consistency of concrete

(1) Production and transport of concrete
At least 3 weeks before commencing work under this sub-section, the Contractor shall submit, for the information of the Superintendent, details of the proposed methods of handling, storing and batching materials for concrete, details of proposed mixers and methods of agitation, mixing and transport.

(2) Handling, storage and batching materials
The methods of handling, storing and batching materials for concrete shall be in accordance with AS1379, with

the following additional requirements:

(a) certificates of calibration issued by a recognised authority shall be made available for inspection by the Superintendent, as evidence of the accuracy of the scales;

(b) cementatious material shall be weighed in an individual hopper, with the cement weighed first;

(c) the moisture content of the aggregates shall be determined at least daily immediately prior to batching. Corresponding corrections shall be made to the quantities of aggregates and water; and

(d) where a continuous type mixer is employed, the components shall be measured by a method of continuous weighing approved by the Superintendent, except for liquids which may be measured by volume or flow rate meter.

(3) Mixers and agitation equipment

Details of proposed mixers and agitation methods shall be in accordance with the plant and equipment sections of AS1379, with the following additional requirement that in Appendix A of AS1379 the maximum permissible difference in slump shall be 10mm.

(4) Mixing and transport

Mixing and transport methods shall be in accordance with the production and delivery sections of AS1379, with the following additional requirements:

(a) The mixer shall be charged in accordance with the manufacturer's instructions.

(b) For the purpose of conducting mixer uniformity tests in accordance with Appendix A of AS1379 on a split drum mixer producing centrally mixed concrete, the whole of the batch shall be discharged into the tray of a moving vehicle. The concrete shall then be sampled from the tray of the vehicle at points approximately 15% and 85% along the length of the tray.

(c) For truck mixed concrete, addition of water in accordance with the batch production section of AS1379 shall be permitted only within ten minutes of completion of batching and within 200m of the batching facilities. The delivery docket must clearly indicate the amount of water added, but in no circumstance shall the water:cement ratio be exceeded. Mixing of the concrete shall be completed at that location.

(d) After addition of the cement to the aggregate, concrete shall be incorporated into the work within:

(i) one and a half hours, where transported by truck mixer or agitator; and

(ii) one hour, where transported by non agitating trucks.

Means of verification, satisfactory to the Superintendent, of the times of addition of cement to the aggregate shall be provided.

The times within which the concrete shall be incorporated into the work may be reduced if the Superintendent considers the prevailing weather, mix type, or materials being used warrant such a change.

(e) The size of the batch in an agitator vehicle shall not exceed the manufacturer's rated capacity nor shall it exceed 80% of the gross volume of the drum of the mixer.

(5) Maximum mixing time

Where by reason of delay, it is necessary to hold a batch in the mixer, mixing may be continued for a maximum of 10 minutes except for split drum mixers where the maximum shall be 5 minutes.

For longer periods, the batch may be held in the mixer and turned over at regular intervals, subject to the time limits specified for incorporation of the concrete into the work not being exceeded.

(6) Consistency

The consistency of the concrete shall be such as to allow the production of a dense, non segregated mass with bleeding limited so as to prevent bleed water flowing over the slab edge under the conditions of placement. If bleed water does so flow, the Contractor shall cease paving until the consistency of the mix is adjusted to prevent flow or the mix is redesigned and approved by the Superintendent. The edge produced shall maintain its

shape and shall not sag or tear.

The Contractor shall provide all equipment, materials and labour for consistency testing and shall carry out tests in the presence of the Superintendent.

The consistency of the concrete shall be checked by use of a slump cone in accordance with AS1012.3.1. The test shall be made on concrete samples obtained in accordance with AS1012.1. The compactibility index range shall be between 60 and 80 in accordance with AS1012.3.4. Check tests shall be done on each truckload of concrete or as directed by the Superintendent.

SC6.4.6.14.7 Placing and finishing concrete subbase

(1) General

At least four weeks before commencing work under this Specification, the Contractor shall submit as part of the Quality Plan, for the information of the Superintendent, full details of the equipment and methods proposed for placing and finishing the concrete subbase together with a paving plan showing proposed paving widths, sequence and estimated daily outputs.

The Contractor shall give the Superintendent 7 days written notice of the intention to commence construction of the subbase on any section of work (including the placement of the trial subbase in accordance with Clause SC6.4.6.14.11.

The surface on which concrete subbase is to be placed shall be clean and free of loose or foreign matter and in damp condition.

Submit the work-as-executed survey of the subgrade to the full extent of the works to the Superintendent for confirmation, and highlight any locations where the actual level is higher than the design levels. If the underlying layer is required to be spray sealed, take levels on the top of the seal and after removal of foreign or loose material such as aggregate. Report levels to the nearest millimetre and survey on 5.0m grid on a plan area. In the case of non conforming levels, locally redesign the pavement levels as directed by the Superintendent.

Concrete shall not be placed either during rain or when the air temperature in the shade is below 5°C or above 38°C.

The temperature of the concrete placed in the work shall be neither less than 10°C nor more than 32°C.

(2) Rate of evaporation

When the value of Rate of Evaporation, determined from the graph in Figure SC6.4.6.14.1 Rate of evaporation, exceeds 0.5kg per square metre per hour the Contractor shall take precautionary measures, satisfactory to the Superintendent, for the prevention of excessive moisture loss. If, in the opinion of the Superintendent, such precautionary measures prove to be unsatisfactory, the Contractor shall cease work while the evaporation rate is in excess of 0.50kg per square metre per hour.

Should the Contractor elect to use an evaporation retarder to prevent excessive moisture loss, application shall be by fine spray after all finishing operations, except minor manual bull floating, are complete.

The Contractor shall be responsible for measuring and recording concrete temperature and wind velocity at the point of concrete placement, and for continuously measuring and recording air temperature and relative humidity daily, at the site throughout the course of the work. The Contractor shall provide and maintain all equipment and shall provide suitable personnel necessary for all such measuring and recording.

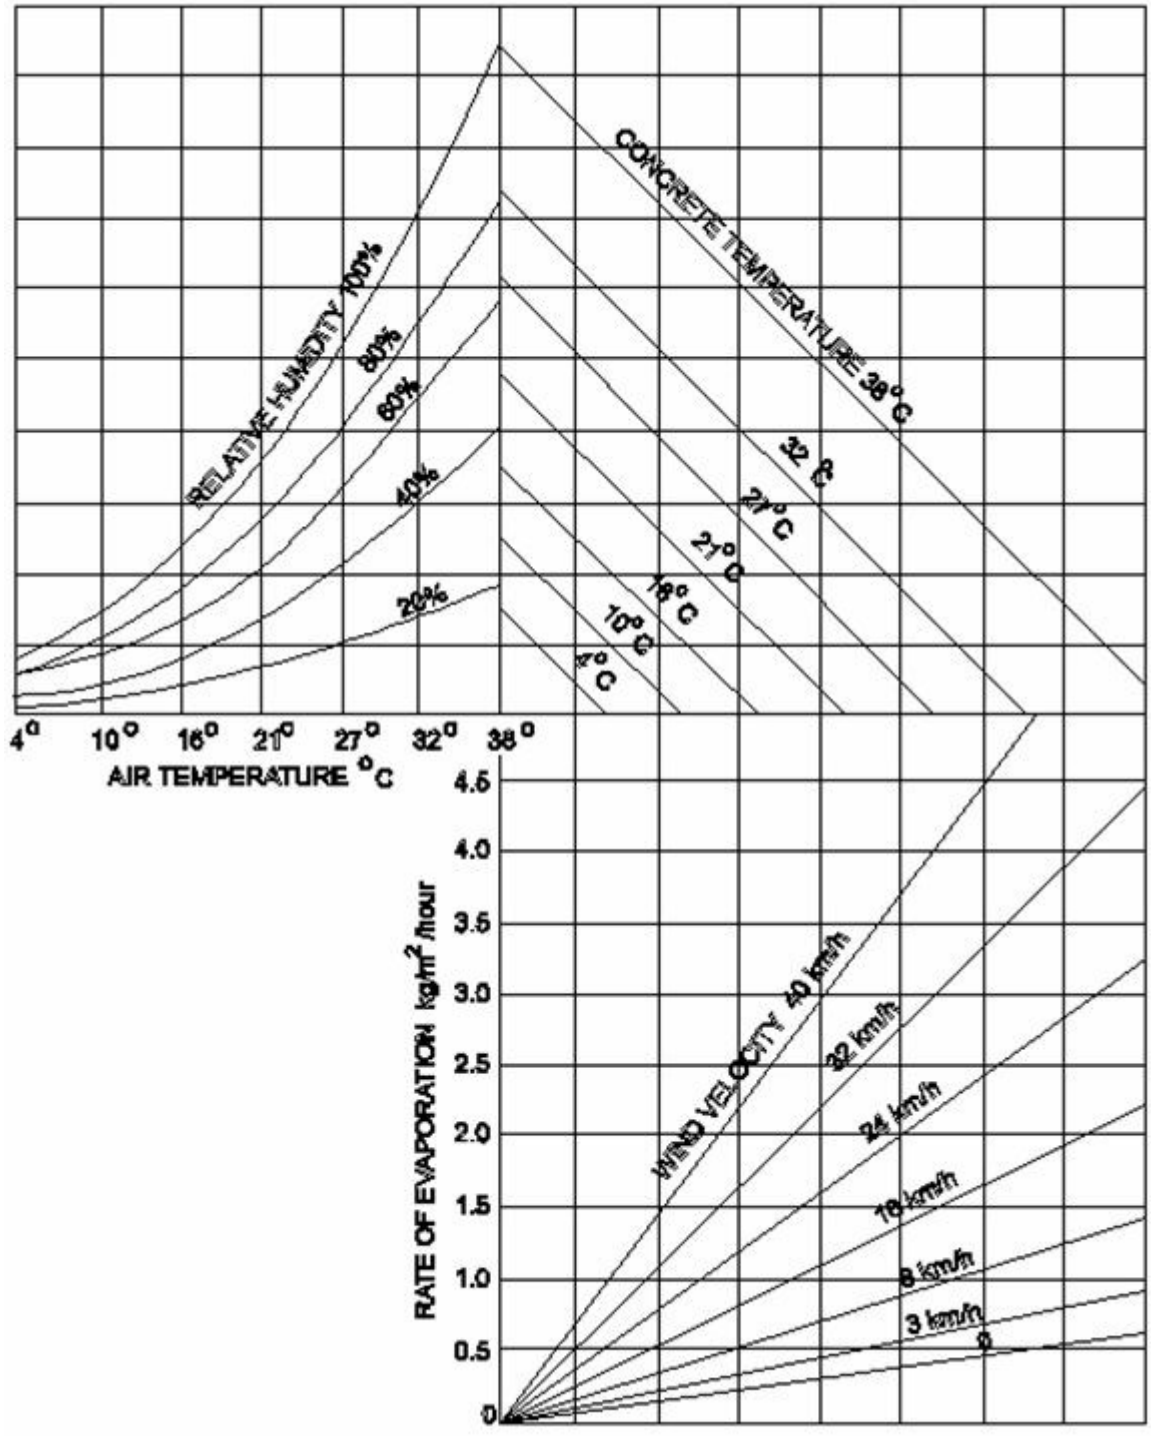

Figure SC6.4.6.14.1 Rate of evaporation

Note—the graph shows the effects of air temperature, humidity, concrete temperature and wind velocity together on the rate of evaporation of water from freshly placed and unprotected concrete.

Example:

- with air temperature at 27ºC
- with relative humidity at 40%
- with concrete temperature at 27ºC
- with a wind velocity of 26 km/h

the rate of evaporation would be 1.6 kg/m/hour.

To determine the evaporation rate from the graph, enter the graph at the air temperature (in this case 27ºC), and move vertically to intersect the curve for relative humidity encountered - here 40%. From this point move horizontally to the respective line for concrete temperature - here 27ºC. Move vertically down to the respective wind velocity curve - in this case interpolating for 26 km per hour - and then horizontally to the left to intersect the scale for the rate of evaporation.

(3) Mechanical paving

The mechanical paver shall be a self propelled machine with a gross operating mass of not less than 4 tonnes per lineal metre of paved width. It shall be capable of paving at a speed of one metre per minute or less as required to enable the continuous operation of the paver and obtain the required degree of compaction. It shall include the following features:

(a) an automatic control system with a sensing device to control line and level to the specified tolerances;

(b) means of spreading the mix uniformly and regulating the flow of mix to the vibrators without segregation of the components;

(c) internal vibrators capable of compacting the full depth of the concrete;

(d) adjustable extrusion screed and/or conforming plate to form the slab profile and produce the required finish on all surfaces; and

(e) capability of paving in the slab widths or combination of slab widths and slab depths shown on the drawings.

The mechanical paver shall spread, compact, screed and finish the freshly placed concrete in such a manner that a minimum of finishing by hand will be required. A dense and homogeneous concrete with a surface exhibiting low permeability shall be provided.

Surface texture shall be steel screed or float finish except that a hessian dragged finish shall be provided where the subbase is to be overlain by asphaltic concrete.

The supporting surface for the tracks of the paver, curing machine and any other equipment in the paving and curing train shall be in a smooth and firm condition.

Once spreading commences, the concrete paving operation shall be continuous. The mechanical paver shall be operated so that its forward progress shall not be stopped due to lack of concrete. If disruptions occur for any reason, the Superintendent may direct that a construction joint be formed before the recommencement of paving operations.

(4) Hand placing

Forms shall be so designed and constructed that they can be removed without damaging the concrete and shall be true to line and grade and braced in a substantial and unyielding manner. Forms shall be mortar tight and debonded to ensure non adhesion of concrete to the forms.

Concrete shall be delivered in agitator trucks and shall be deposited uniformly in the forms without segregation. The concrete shall be compacted by poker vibrators and by at least two passes of a hand guided vibratory screed traversing the full width of the slab on each pass. Any buildup of concrete between the forms and vibratory screed shall be prevented.

If disruptions occur for any reason, the Superintendent may direct that a construction joint be formed before the recommencement of paving operations.

A dense and homogeneous concrete with a surface exhibiting low permeability shall be provided.

Surface texture shall be steel screed or float finish except that a hessian dragged finish shall be provided where the subbase is to be overlain by asphaltic concrete.

(5) Alignment and surface tolerances

(a) Horizontal alignment tolerance

The outer edges of the subbase shall be square to the subgrade and shall be constructed 50mm wider than the plan position of the base formation with a tolerance of 25mm.

Where an edge of a slab is to form a longitudinal construction joint line, the allowable horizontal alignment tolerances shall comply with clause SC6.4.6.14.8(2) Longitudinal construction joints.

(b) Surface tolerances

The level at any point on the top of the subbase shall not vary by more than 0mm above or 20mm below

that shown on the drawings or as directed by the Superintendent. Where the concrete is found to be above the level tolerance, it shall be removed. Where the concrete is found to be below level tolerance, it shall be made up with base concrete.

The top surface of the subbase shall also not deviate from a 3m straightedge, laid in any direction, by more than 5mm.

(6) Curing

The subbase shall be cured by the use of one of the following:

(a) chlorinated rubber curing compound complying with AS3799 Class C Type 1D or resin-based curing compound complying with AS3799 Class B, Type 1D or Type 2, if an asphalt base is used; or

(b) white pigmented wax emulsion curing compound complying with AS3799 Class A Type 2, if a concrete base is used; or

(c) bitumen emulsion Grade CRS/170 complying with AS1160 for either asphalt or concrete base.

The Contractor shall submit, for the information of the Superintendent, a current Certificate of Compliance for the curing compound from an Australian Laboratory, approved by the Superintendent, showing an Efficiency Index of not less than 90% when tested in accordance with Appendix B of AS3799.

The curing compound shall be applied using a fine spray immediately following texturing at the rate stated on the Certificate of Compliance or at a minimum of 0.2 litres per square metre, whichever rate is the greater. Bitumen emulsion shall be applied at a minimum rate of 0.35 litres of residual bitumen per square metre. When applied with a hand lance the rates should be increased by 25%.

The average application rate shall be checked by the Contractor and certified to the Superintendent by calculating the amount of curing compound applied to a measured area representative of a lot and nominated by the Superintendent.

The curing membrane shall be maintained intact for seven days after placing the concrete. Any damage to the curing membrane shall be made good by handspraying of the affected areas.

Equipment and materials for curing operations shall be kept on site at all times during concrete pours.

(7) Protection of work

The Contractor shall ensure that the temperature of the concrete does not fall below 5ºC during the first twenty four hours after placing. The Contractor shall provide, for the information of the Superintendent, details of procedures and equipment proposed to be used for the protection of sections recently placed in the event of low air temperatures. If the Contractor fails to maintain the temperature of the concrete at or above 5ºC and if, in the opinion of the Superintendent, the concrete exhibits any deficiencies, due to failure to comply with this Specification, the concrete shall be rejected.

The Contractor shall protect the work from rain damage and shall provide, for the information of the Superintendent, detailed proposals for procedures and equipment to be used for such protection.

Neither traffic nor construction equipment, other than that associated with testing, shall be allowed on the subbase until the strength of the subbase has reached at least 4.0MPa. Thereafter, only construction equipment necessary for the following operations shall be permitted to traffic the subbase:

(a) bond-breaker and spall treatment;

(b) concrete or asphalt paving; and

(c) Notwithstanding the above, any damage caused to the subbase by the Contractor's operations shall be rectified to the Superintendent's satisfaction.

SC6.4.6.14.8 Joints

(1) Transverse construction joints

Transverse construction joints shall:

(a) be provided only at discontinuities in the placement of concrete determined by the Contractor's paving operations;

(b) be constructed normal to the edge line and to the dimensions shown on the drawings;

(c) not deviate from a 3m straightedge placed along the joint by more than 10mm; and

(d) cut back the edge of the previously placed concrete by sawing the concrete, to at least 1/3 the slab depth to expose an even, clean, sound, vertical surface, without disturbing the concrete that is to remain in place.

(2) Longitudinal construction joints
Longitudinal construction joints shall:

(a) be formed no closer than 300mm of the base longitudinal joints as shown in the drawings, unless directed otherwise by the Superintendent;

(b) not deviate from the plan or nominated position at any point by more than 20mm;

(c) not deviate from a 3m straightedge placed along the joint by more than 10mm, having made due allowances for any planned curvature; and

(d) be smooth across the joint.

SC6.4.6.14.9 Bond breaker and spall treatment

(1) General
Subbase to be covered by concrete base shall be provided with a wax emulsion bond breaker. The wax emulsion shall comply with AS3799 Class A Type 2.

Where the base consists of asphaltic concrete, no bond breaker shall be used. In this case bond is essential and wax emulsion curing compounds shall not be permitted.

Subbase with spalled areas shall be treated, where directed by the Superintendent, prior to application of the bond breaker or asphaltic concrete.

(2) Preparation of subbase
Immediately prior to any spalled area treatment and the application of bond breaker, the subbase surface shall be cleaned to the satisfaction of the Superintendent of all loose, foreign and deleterious material.

(3) Treatment of spalling
Where directed by the Superintendent, spalled areas shall be treated before the application of the bitumen bond breaker or asphaltic concrete by infilling with 6:1 sand/cement mortar to provide a surface flush with the surrounding concrete. The area shall be wetted and sprinkled with neat cement before screeding the mortar into the patches.

A spalled area, if directed to be treated, shall have such treatment completed no earlier than five working days before the application of the bond breaker. Treated spalled areas damaged by the Contractor or others shall be made good by the Contractor.

(4) Application of bond breaker
The wax emulsion used as bond breaker should be the same as used for curing compound. This second application shall be applied at a minimum rate of 0.2 litres per square metre and not earlier than 72 hours before the placement of the base concrete.

The method of application shall conform to the requirements of Clause SC6.4.6.14.10(6) Curing.

(5) Treatment of unplanned cracks
The Superintendent shall direct treatment of unplanned cracks whose width exceeds 0.3mm. This may take the form of applying an approved 300mm minimum width geotextile backed polymer modified bitumen strip

(reference Guide to Pavement Technology Part 4G: Geotextiles and Geogrids) over the crack prior to placement of the first asphalt base layer or concrete base, or an extra application of wax emulsion for a width of 300mm along the crack when a concrete base is required.

The Contractor shall install the Stress Alleviating Membrane strip in accordance with the manufacturer's instructions.

SC6.4.6.14.10 Subgrade beams

(1) General
Subgrade beams shall be provided below the subbase at expansion joints and isolation joints in the concrete base as shown in the drawings or as directed by the Superintendent. They shall extend the full length of joints unless otherwise indicated on the drawings.

(2) Excavation
Excavation for subgrade beams shall be to the dimensions shown on the drawings. All loose material shall be removed and the vertical faces trimmed to neat lines. The bottom of the trench shall be recompacted, where required, to the degree of consolidation of the adjacent undisturbed material. Excavated material shall be legally disposed of by the Contractor.

(3) Concrete
Concrete in subgrade beams shall comply with the requirements of sub-section SC6.4.6.28 Minor concrete works. The minimum compressive strength at 28 days shall be 32MPa.

(4) Steel reinforcement
Steel reinforcement shall be of the type and size shown on the drawings and shall be supplied and installed in accordance with sub-section SC6.4.6.15 Plain and reinforced concrete base.

(5) Construction and protection
Subgrade beams shall be constructed before construction of the subbase. The top surface of the subgrade beam shall be level with the top of the subgrade. Any loose subgrade material shall be recompacted to the correct level. If the contractor elects to remove any loose material, the voids shall be filled with mortar or concrete and screeded to provide a surface flush with the top of the subgrade beam and the surrounding subgrade.

A steel float shall be used to produce a smooth surface finish, free of any texture.

The subgrade beams shall be protected from damage by plant, motor vehicles and the paving operation. Any damage shall be made good by the Contractor.

(6) Curing
The top surface of the subgrade beam shall be cured in accordance with clause SC6.4.6.14.7 Curing before placing the subbase.

(7) Bond breaker
The top surface of the subgrade beam shall be treated with a bond breaker which shall consist of a further application of curing compound neither less than twenty four hours nor more than seventy two hours before placing of subbase concrete.

SC6.4.6.14.11 Trial concrete subbase

Before the commencement of paving, the Contractor shall construct a trial section of concrete subbase on the carriageway to demonstrate to the Superintendent the Contractor's capability of constructing subbase in accordance with the sub-section. This section shall be constructed so that it may be incorporated in the finished work.

The trial subbase shall be constructed using the same materials, concrete mix, equipment and methods the Contractor intends to use for the remaining subbase work. The Contractor shall demonstrate the methods proposed to be used for texturing, the application of curing compound and the construction of joints.

The trial shall also be used to demonstrate that the Contractor's allowances for concrete strength, compaction and slab thickness are adequate to achieve the minimum requirements specified.

A trial length of between 100m and 200m or lesser length in compliance with council requirements for mechanical paving equipment or between 20m and 50m for hand placement is required. The trial length shall be the maximum width proposed to be laid, and shall be constructed in one continuous operation.

Unless advised by the Superintendent of any deficiencies in the trial concrete subbase, due to failure to comply with this sub-section, the Contractor may proceed with placing concrete subbase from a time five working days after the completion of the trial concrete subbase or such earlier time as the Superintendent may allow. In the event of deficiencies in the trial concrete subbase, the Superintendent may order the Contractor to construct a further length of trial concrete subbase which shall be treated as the first. If, after three trials, the subbase still is deficient in some way, the Superintendent may require the Contractor to justify to the satisfaction of the Superintendent why the work should be allowed to continue using that method and/or equipment and/or materials and/or personnel.

The Superintendent shall have the right to call for a new trial section at any stage of work under the contract when changes by the Contractor in the equipment, materials, mix, plant or rate of paving are deemed by the Superintendent to warrant such procedure or when concrete as placed does not comply with this sub-section.

SC6.4.6.14.12 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.14.4 below:

Item	Activity	Limits/Tolerances	Clause
1.	**Materials for Concrete**		
	a. Misshapen Particles	2 : 1 ratio < 35%	SC6.4.6.14.3(5)(a)
	b. Aggregates Grading	Deviation from submitted sample not greater than Table C247.1	SC6.4.6.14.2(5)(b)
	c. Durability	Wet Strength > 50kN 10% Fines < 35%	SC6.4.6.14.2(5)(c)
2.	**Concrete**	Drying Shrinkage <450 microstrain	SC6.4.6.14.3(3)
	a. Shrinkage		
	b. Consistency	Mechanically placed: >25mm<40mm Hand Placed: >50mm <65mm	SC6.4.6.14.3(4)
	c. Air Content	≥3, ≤7%	SC6.4.6.14.3(5)
	d. Thickness	Concrete shall be removed if thickness >20mm below specified thickness.	SC6.4.6.14.5(5)
	e. Mixing and Transport	After addition of cement to the aggregate, concrete shall be incorporated into the work within: (i) One and a half hours where transported by truck mixer or agitator. (ii) One hour where transported by non agitating trucks.	SC6.4.6.14.6(4)

Item	Activity	Limits/Tolerances	Clause
	f. Placing	Concrete shall not be placed when the air temperature in the shade is less than 5ºC or >38ºC. Temperature of concrete shall be >10ºC but <32ºC.	SC6.4.6.14.7(1)
		Concrete shall not be placed when the Rate of Evaporation exceeds 0.5kg per square metre per hour.	SC6.4.6.14.7(2)
3.	**Alignment and Surface Tolerances** a. Horizontal Alignment	Outer edges not to deviate from plan position by more than ±25mm.	SC6.4.6.14.7(5)
	b. Surface	Level on top surface to be no more than +0mm or -20mm to that shown on the drawings.	SC6.4.6.14.7(5)
		The top surface shall not deviate from a 3m straightedge laid in any direction by more than 5mm.	SC6.4.6.14.7(5)
4.	**Joints** a. Transverse Construction	Shall not deviate from a 3m straight-edge placed along the joint by more than 10mm.	SC6.4.6.14.8(1)
	b. Longitudinal Joint	(i) Shall not deviate from the plan or nominated position at any point by more than 20mm. (ii) Shall not deviate from a 3m straightedge placed along the joint by more than 10mm after allowing for any curvature.	SC6.4.6.14.8(2)
5.	**Bond Breaker** a. Wax Emulsion	Minimum 0.2 litres per square metre, not earlier than 72 hours before placement of base.	SC6.4.6.14.9(4)

SC6.4.6.15 Plain and reinforced concrete base

SC6.4.6.15.1 Introduction

(1) Scope

(a) This policy sub-section provides standards, advice and guidelines for the construction, by mechanical or hand placement of plain or reinforced concrete, including trial sections, slab anchors and terminal slabs.

(b) The work also includes the construction of reinforced concrete approach slabs for bridge abutments and traffic signal approach slabs.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Thickness and levels of slab

The base thickness and levels shall be detailed on design and construction drawings.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.9 - Open drains - kerb and channel
SC6.4.6.20 - Subsoil, foundation and pavement drains
SC6.4.6.14 - Mass concrete sub-base

(b) Australian Standards:
AS 1012.1 - *Sampling of fresh concrete*
AS 1012.3.1 - *Determination of properties related to the consistence of concrete - Slump test*
AS 1012.4.2 - *Determination of air content of freshly mixed concrete - Measuring reduction in air pressure in chamber above concrete*
AS 1012.8 – *Method of making and curing concrete*
AS 1012.9 - *Determination of the compressive strength of concrete specimens*
AS 1012.12.2 - *Determination of mass per unit volume of hardened concrete - Water displacement method*
AS 1012.13 - *Determination of the drying shrinkage of concrete for samples prepared in the field or in the laboratory*
AS 1012.14 – *Method for securing and testing cores from hardened concrete for compressive strength*
AS 1141.11.1 - *Particle size distribution – Sieving method*
AS 1141.14 - *Particle shape, by proportional calliper*
AS 1141.18 - *Crushed particles in coarse aggregate derived from gravel*
AS 1141.22 - *Wet/dry strength variation*
AS 1141.24 – *Aggregate soundness – Evaluation by exposure to sodium sulphate solution*
AS 1160 - *Bituminous emulsions for the construction and maintenance of pavements*
AS 1379 - *Specification and supply of concrete*
AS 1478.1 - *Chemical admixtures for concrete, mortar and grout – Part 1: Admixtures for concrete*
AS/NZS 1554.3 - *Welding of reinforcing steel*
AS 2758.1 - *Concrete aggregates*
AS 3582.1 - *Supplementary cementitious materials for use with Portland and blended cenemt – Fly ash*
AS 3799 - *Liquid membrane-forming curing compounds for concrete*
AS 3972 – *General purpose and blended cements*
AS/NZS 4671 - Steel reinforcing materials.

(c) Queensland Department of Transport and Main Roads technical standard:
MRTS40 - *Concrete Base in Pavements: Jointed unreinforced, Jointed Reinforced, Continuously Reinforced and Steel Fibre Reinforced Pavements (10/10).*

(d) Queensland Department of Transport and Main Roads Materials Testing Manual:

Q461 - *Durability of Sealant*
Q462 - *Resistance of Vulcanised Rubber to the Absorption of Oil*
Q463A - *High Temperature Recovery of Preformed Polychloroprene Elastomeric Joint Seals*
Q463B - *Low Temperature Recovery of Preformed Polychloroprene Elastomeric Joint Seals*

(e) ASTM Standards:
D792 – *Standard test methods for density and specific gravity (relative density) of plastics by displacement*
C793 – *Standard test method for effects of laboratory accelerated weathering on elastomeric joint sealants*
C794 – *Standard test method for adhesion-in-peel of elastomeric joint sealants*
D2240 – *Standard test method for rubber property - durometer hardness*
D2628 – *Standard specification for preformed polychloroprene elastomeric joint seals for concrete pavements*
D2835 – *Standard specification for lubricant for installation of preformed compression seals in concrete pavements.*

(f) US Military Specification:
MIL-S-8802 - *Sealing compound, temperature resistant, integral fuel tanks and fuel cell cavities, high adhesion*

SC6.4.6.15.2 Design and control of concrete mixes

(1) General - design and control of concrete mixes

(a) Details of the concrete mix (or mixes) and the materials, including source, to be used for each of any mechanically placed and/or hand placed base, including nominated slump and moisture condition of the aggregates (oven dry, saturated surface dry, or other specified moisture content) on which the mix is based. Each such mix shall be known as a “nominated mix”.

(b) Also, a certificate from a laboratory with appropriate NATA registration stating that each nominated mix and its constituents meet the requirements of this specification. All relevant test results shall accompany the certificate. All phases of any particular test must be performed at one laboratory. The certificate shall confirm that the required testing has been carried out in the twelve month period before the date of submission to the superintendent.

(c) In the tests supporting the above certification, the compressive strength gain curve shall be submitted showing the compressive strengths at ages 3, 7, 10 and 28 days determined in accordance with AS 1012.9. Each of the results shall be based on three specimens of concrete produced from a batch of the nominated mix. The compressive strength shall be the average of individual results within 2.0 MPa of the median. The compressive strength for 28 days shall not be less than 36.0 MPa.

(d) These details shall be submitted at least 21 days before using the nominated mix in the work.

(2) Variations to approved mixes

(a) The contractor shall not make any changes to the approved mix, its method of production or source of supply of constituents without the prior written approval of the superintendent.

(b) Where changes to an approved mix are proposed, the contractor shall provide details of the nominated mix and materials, in accordance with clause SC6.4.6.15.2(1) General – design and control of concrete mixes. If the variations to the quantities, qualities or sources of the constituents in the approved mix are less than 10 kg for portland cement and flyash and 5 per cent by mass for each other constituent, except admixtures, per yielded cubic metre of concrete, the superintendent may approve the changes without new trials being carried out.

(c) Notwithstanding these tolerances the minimum portland cement content shall be 270 kilograms per yielded cubic metre of concrete and the maximum flyash content shall be 50 kilograms per yielded cubic metre of concrete.

SC6.4.6.15.3 Materials for concrete

(1) Cement

(a) Cement shall be Type GP Portland cement complying with AS 3972 and shall be from a source approved under the Queensland Government’s State Purchasing Policy.

(b) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1) General – design and control of concrete mixes the Contractor shall nominate the brand and source of the cement. On approval of a nominated mix by the superintendent, the contractor shall use only the nominated cement in the work.

(c) Documentary evidence of the quality and source of the cement shall be furnished by the contractor to the superintendent upon request at any stage of the work.

(d) If the contractor proposes to use cement which has been stored for a period in excess of three months from the time of manufacture, a re-test shall be required to ensure the cement still complies with AS 3972, before the cement is used in the work.

(e) Cement shall be transported in watertight containers and shall be protected from moisture until used. Caked or lumpy cement shall not be used.

(2) Flyash

(a) Flyash shall be from a source approved under the Queensland Government's State Purchasing Policy. The use and quality of flyash shall comply with AS 3582.1.

(b) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1), the Contractor shall nominate the powerhouse source of the flyash. The Contractor shall use only flyash from the nominated powerhouse.

(c) Documentary evidence of the quality and source of the flyash shall be furnished by the Contractor to the Superintendent.

(3) Water

Water used in the production of concrete shall be potable, free from materials that may be deterimental to the production of concrete or reinforcement, and be neither salty nor brackish.

(4) Admixtures

(a) Chemical admixtures and their use shall comply with AS 1478.1. Admixtures shall not contain calcium chloride, calcium formate, or triethanolamine or any other accelerator. Admixtures or combinations of admixtures other than specified below, shall not be used. An air entraining agent shall be included in the mix and the air content of the concrete shall comply with clause SC6.4.6.15.4(5) Air content. Fresh concrete with an air content not complying with clause SC6.4.6.15.4(5) will be rejected.

(b) The dosage of admixtures shall be varied to account for air temperature and haulage times in accordance with the manufacturer's recommendations. A copy of the NATA endorsed Certificate of Compliance with AS 1478.1 shall be submitted to the Superintendent, together with the proposed 'dosage chart' in accordance with clause SC6.4.6.15.2(1).

(c) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1), the contractor shall nominate the proprietary source, type and name for each admixture to be used. Documentary evidence of the quality shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

(5) Aggregates

(a) General

(i) At least 40 per cent by mass of the total aggregates in the concrete mix shall be quartz sand. Quartz sand is aggregate having a nominal size of less than 5 mm and shall contain at least 70 per cent quartz, by mass. Where present, chert fragments will be regarded as "quartz" for the purpose of this specification, but the ratio of chert to quartz shall not exceed unity.

(ii) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1), the contractor shall nominate the sources of aggregate to be used in the concrete and shall submit details of the geological type of each aggregate.

(b) Fine aggregate

(i) Fine aggregate shall consist of clean, hard, tough, durable, uncoated grains uniform in quality.

Fine aggregate shall comply with AS 2758.1 in respect of bulk density, water absorption (maximum 5 per cent), with material finer than 2 micrometres and impurities and reactive materials. The sodium sulphate soundness, determined by AS 1141.24, shall not exceed the limits in Table SC6.4.6.15.1 Sodium sulphate soundness limits

Table SC6.4.6.15.1 Sodium sulphate soundness limits

Australian Standard Sieve	Per Cent Loss by Mass
4.75mm to 2.36mm	4
2.36mm to 1.18mm	6
1.18mm to 600µm	8
600µm to 300µm	12

(ii) In the case of a blend of two or more fine aggregates, the above limits shall apply to each constituent material.

(iii) The grading of the fine aggregate, determined by AS 1141.11, shall be within the limits given in Table SC6.4.6.15.2 Fine aggregate grading.

(iv) When submitting details of the nominated mix the contractor shall submit to the superintendent a NATA certified laboratory test report on the quality and grading of the fine aggregate proposed to be used. The grading shall be known as the "proposed fine aggregate grading".

(v) If the contractor proposes to blend two or more fine aggregates to provide the proposed grading then test reports for each constituent material shall be submitted separately and the superintendent advised of the proportions in which the various sizes and constituents are to be combined. The fine aggregate from each source and the combined aggregate shall comply with the requirements of this clause.

(vi) The grading of the fine aggregate used in the work shall not deviate from that of the proposed grading by more than the amounts in Table SC6.4.6.15.2 Fine aggregate grading.

(vii) Notwithstanding these tolerances, the fine aggregate used in the work shall comply with the limits shown in Table SC6.4.6.15.2 Fine aggregate grading.

Table SC6.4.6.15.2 Fine aggregate grading

Australian Standard Sieve	Proportion Passing (% of Mass of Sample)	Deviation from Proposed Grading (% of Mass of Sample)
9.50mm	100	± 3
4.75mm	90 - 100	± 10
2.36mm	65 - 95	± 10
1.18mm	40 - 80	± 10
600µm	24 - 52	± 5
300µm	8 - 25	± 2
150µm	1 - 8	
75µm	0 - 3	

(c) Coarse aggregate

(i) Coarse aggregate shall consist of clean, crushed, hard durable rock, metallurgical furnace slag or gravel. Coarse aggregate shall comply with AS 2758.1 in respect of particle density, bulk density, water absorption (maximum 2.5 per cent), material finer than 75 micrometres, weak particles, light particles, impurities and reactive materials, iron unsoundness and falling or dusting unsoundness. In all other respects, the coarse aggregate shall comply with this sub-section. If required, coarse aggregate shall be washed to satisfy these requirements.

(ii) The grading of the coarse aggregate, determined by AS 1141.11, shall be within the limits given in Table SC6.4.6.15.3 Coarse aggregate grading.

(iii) When submitting details of the nominated mix the Contractor shall submit to the Superintendent a NATA Certified Laboratory Test Report on the quality and grading of the coarse aggregate proposed to be used. The grading shall be known as the "proposed coarse aggregate grading".

(iv) If the contractor proposes to blend two or more coarse aggregates to provide the proposed grading

then test reports for each constituent material shall be submitted separately and the superintendent advised of the proportions in which the various sizes and constituents are to be combined. The coarse aggregate from each source and the combined aggregate shall comply with the requirements of this clause.

(v) The grading of the coarse aggregate used in the work shall not deviate from that of the proposed grading by more than the amounts in Table SC6.4.6.15.3 Coarse aggregate grading.

Table SC6.4.6.15.3 Coarse aggregate grading

Australian Standard Sieve	Proportion Passing (% of Mass of Sample)	Deviation from Proposed Grading (% of Mass of Sample)
26.50 mm	100	± 2
19.00 mm	95 - 100	± 5
13.20 mm	(accepted design mix)	± 5
9.50 mm	25 - 55	± 3
4.75 mm	0 - 10	
2.36 mm	0 - 2	

(vi) Notwithstanding these tolerances, the coarse aggregate used in the work shall comply with the limits shown in Table SC6.4.6.15.3.

(vii) The coarse aggregate shall also conform to the following requirements:

(A) Wet Strength - AS 1141.22.
Shall not be less than 80 kN for any fraction and/or constituent;

(B) 10 per cent Fines Wet/Dry Variation - AS 1141.22.
Shall not exceed 35 per cent for any fraction and/or constituent;

(C) Soundness - AS 1141.24
The loss in mass when tested with sodium sulphate shall not exceed 9 per cent for any constituent;

(D) Particle Shape - AS 1141.14
The proportion of misshapen particles (2:1 ratio) shall not exceed 35 per cent;

(E) Fractured Faces - AS 1141.18.
At least 80 per cent by mass of the particles shall have two or more fractured faces; and

(F) Material finer than 75 micrometres – AS 1141.12
Shall not exceed 1 per cent for any fraction and/or constituent.

(d) Storage

(i) Storage and handling facilities shall be such as to prevent the aggregates becoming intermixed or mixed with foreign materials, and to prevent segregation occurring.

(ii) The area surrounding the storage facilities and mixing plant shall be so constructed that delivery vehicles, loaders and trucks shall not be capable of introducing foreign matter to the aggregates at any time. If foreign matter is introduced or the area reaches a condition where, in the opinion of the superintendent, foreign matter may be introduced to the aggregates, production of concrete and delivery of materials shall cease until the condition is corrected to the satisfaction of the superintendent.

SC6.4.6.15.4 Quality requirements of concrete

(1) Cement and flyash content
The minimum Portland cement content shall be 270 kilograms per yielded cubic metre of concrete. The maximum flyash content shall be 50 kilograms per yielded cubic metre of concrete.

(2) Compressive strength
The compressive strength of concrete shall be determined in accordance with AS 1012.9. The minimum compressive strength at 28 days shall be 36 MPa.

(3) Shrinkage

The drying shrinkage of the nominated mix, determined by AS 1012.13, shall not exceed 450 microstrain after 21 days air drying. The drying shrinkage at the nominated slump plus 10 mm shall be taken as the average of the reading or readings within 5 per cent of the median of the three readings obtained in accordance with AS 1012.13.

(4) Consistency

The Contractor's nominated slump, determined in accordance with AS 1012.3.1, shall be neither less than 30 mm nor more than 40 mm for mechanically placed concrete and shall be neither less than 55 mm nor more than 65 mm for hand placed concrete.

(5) Air content

The air content of the concrete, determined in accordance with AS 1012.4.2, shall be neither less than 4 per cent nor more than 7 per cent, when discharged from the transport vehicle ready for placement.

(6) Relative compaction

The minimum relative compaction, determined in accordance with AS 1012.12.2, shall be 98 per cent.

SC6.4.6.15.5 Steel reinforcement

(1) Material

(a) The type and size of bars shall be as shown on the drawings.

(b) Steel reinforcement shall be free from loose or thick rust, grease, tar, paint, oil, mud, millscale, mortar or any other coating, but is not to be brought to a smooth polished condition.

(c) The Contractor shall supply evidence satisfactory to the superintendent that steel reinforcement complies with AS 4671 *Steel reinforcing materials*. Test certificates shall show the results of mechanical tests and chemical analysis of the reinforcing steel to be used.

(d) Where the material cannot be identified with a test certificate, samples shall be taken and testing arranged by the contractor. The samples shall be selected randomly and consist of three specimens each at least 1.2 m in length.

(e) Plastic bar chairs or plastic tipped wire chairs shall be capable of withstanding a load of 200 kg mass on the chair for 1 hour at 23 ± 5ºC without malfunction. The Contractor shall demonstrate that the proposed chairs conform with these requirements.

(2) Bending

Reinforcement shall be formed to the dimensions and shapes shown on the drawings. Reinforcement shall not be bent or straightened in a manner that will damage the material. Bars with kinks or bends not shown on the drawings shall not be used. Heating of reinforcement for the purposes of bending will only be permitted if uniform heat is applied. Temperature shall not exceed 450 ºC and the heating shall extend beyond the portion to be bent. Heated bars shall not be cooled by quenching.

(3) Splicing

(a) All reinforcement shall be furnished in the lengths indicated on the drawings. splicing of bars shall only be permitted with the approval of the superintendent and as shown on the drawings. The information shown on the drawings is to detail the location and method of splicing.

(b) The length of lapped splices not shown on the drawings shall be as follows for unhooked bars:

Plain bars, Grade 250	40 bar diameters;
Deformed bars, Grade 400	35 bar diameters; and
Hard-drawn wire	50 bar diameters.

(c) Splices in reinforcing fabric shall be measured as the overlap between the outermost wire in each sheet of fabric transverse to the direction of splice. This overlap shall not be less than the pitch of the transverse wires plus 25 mm.

(d) In welded splices, bars shall only be welded by an approved electrical method. Grade 400 deformed bars

shall not be welded.

(e) Welding shall comply with AS 1554.3. The welded splice shall meet requirements of tensile and bend tests specified for the parent metal.

(4) Storage

Reinforcement, unless promptly incorporated into the concrete, shall be stored under a waterproof cover and supported clear of the ground, and shall be protected from damage and from deterioration due to exposure.

(5) Placing

(a) Reinforcing bars and wire reinforcing fabric shall be accurately placed to the dimensions and details shown on the drawings. They shall be securely held by blocking from the forms, by supporting on concrete or plastic chairs or metal hangers, as approved by the superintendent, and by wiring together where required using annealed iron wire not less than 1.25 mm diameter. These supports shall be in a regular grid not exceeding 1 m and steel shall not be supported on metal supports which extend to any surface of the concrete, on wooden supports, nor on pieces of aggregate.

(b) Tack welding instead of wire ties may be used on reinforcing steel. Cold worked reinforcing bars shall not be tack welded. Tack welding must conform to AS 1554.3.

(c) The minimum cover of any bar to the nearest concrete surface shall be 50 mm unless otherwise shown on the drawings.

(d) Tie bars shall be placed in the pavement such that after placement they remain in their specified location. Tie bars shall not be placed through the finished upper surface of the pavement. Tie bars shall be placed either ahead of paving or by a bar vibrator into the edge of the joint or by an automatic tie bar inserter on the mechanical paver. Irrespective of the method of placement, tie bars extending from any side face of base concrete or gutter shall be anchored in a manner which will develop 85 per cent of the yield strength of the bar in tension.

(e) Placing and fastening of all reinforcement in the work shall be approved by the superintendent before concrete is placed and adequate time shall be allowed for inspections and any corrective work which the superintendent may require. Notice for the superintendent's inspection shall not be less than four working hours before the intended time of commencement of concrete pour or such time as determined by the superintendent. Council is to be advised no later than (48) hours before hand.

(f) Dowelled joints shall be provided as directed by the superintendent, parallel to the pavement surface and normal to the line of the joint, or as shown on the drawings. The dowels are to be installed ahead of paving by an approved dowel support assembly. One end of the dowel is to be sleeved which is to be placed on the same side of the joint for a distance of (L/2 + 25 mm) to make sure free movement of the concrete base slab (including temperature variations). The contractor is to check each dowels before placement and make sure the dowels are straight and free of irregularities including burrs and protrusions.

SC6.4.6.15.6 Production, transport and consistency of concrete

(1) Production and handling of concrete

(a) At least 4 weeks before commencing work, the Contractor shall submit, for the information of the superintendent, details of the proposed methods of handling, storing and batching materials for concrete, details of proposed mixers and methods of agitation, mixing and transport.

(b) The methods of handling, storing and batching materials for concrete shall be in accordance with AS 1379, with the following additional requirements:

(i) certificates of calibration issued by a recognised authority shall be made available for inspection by the superintendent, as evidence of the accuracy of the scales;

(ii) cementitious material shall be weighed in an individual hopper, with the Portland cement weighed first; and

(iii) the moisture content of the aggregates shall be determined at least daily immediately prior to batching. Corresponding corrections shall be made to the quantities of aggregates and water.

(c) Details of the proposed mixers and agitation methods shall be in accordance with the plant and

equipment sections of AS 1379, with the additional requirement that in Appendix A of AS 1379 the maximum permissible difference in slump shall be 10 mm.

(2) Mixing and transport

Mixing and transport methods shall be in accordance with the production and delivery sections of AS 1379, with the following additional requirements:

(a) the mixer shall be charged in accordance with the manufacturer's instructions;

(b) for the purpose of conducting mixer uniformity tests in accordance with Appendix A of AS 1379 on a split drum mixer producing centrally mixed concrete, the whole of the batch shall be discharged into the tray of a moving vehicle. The concrete shall then be sampled from the tray of the vehicle at points approximately 15 per cent and 85 per cent along the length of the tray;

(c) for truck mixed concrete, addition of water in accordance with the batch production section of AS 1379 shall be permitted only within ten minutes of completion of batching and within 200 m of the batching facilities. The delivery docket must clearly indicate the amount of water added, but in no circumstance shall the water:cement ratio be exceeded. Mixing of the concrete shall be completed at that location;

(d) admixtures shall be separately pre-diluted with mixing water and shall be incorporated by a method which ensures that no adverse interaction occurs;

(e) After addition of the cement to the aggregate, concrete shall be incorporated into the work within:

(i) one and a half hours, where transported by truck mixer or agitator; and

(ii) one hour, where transported by non-agitating trucks.

(f) the size of the batch in an agitator vehicle shall not exceed the manufacturer's rated capacity for the vehicle nor shall it exceed 80 per cent of the gross volume of the drum of the mixer; and

(g) concrete delivery dockets must be provided for each batch of mix. The docket must record the following delivery information:

(i) supplier name and location;

(ii) volume of material supplied;

(iii) product constituents; and

(iv) dispatch time and date.

(3) Mixing time

(a) Minimum mixing time will be as determined for the approved mix and verified when trial concrete base is constructed.

(b) Where by reason of delay, it is necessary to hold a batch in the mixer, mixing may be continued for a maximum of ten minutes except for split drum mixers where the maximum time shall be five minutes.

(c) For longer periods, the batch may be held in the mixer and turned over at regular intervals, subject to the time limits specified for incorporation of the concrete into the work not being exceeded.

(4) Consistency

(a) At all times between mixing and discharge, the slump of the concrete is to be within 10 mm for mechanically placed concrete and is to be within 15 mm for hand placed concrete.

(b) The consistency of the concrete shall be checked by use of a slump cone in accordance with AS 1012.3.1. The test shall be made on concrete samples obtained in accordance with AS 1012.1.

(c) The consistency of the concrete shall be checked within 30 minutes of adding cement to the aggregate. If the actual haul time exceeds 45 minutes, the consistency shall also be checked immediately prior to discharge. Concrete which is non-conforming in relation to consistency shall not be incorporated into the work. Check tests shall be done on each truck load of concrete.

SC6.4.6.15.7 Placing and finishing concrete base

(1) General

(a) At least 4 weeks before commencing work, the Contractor shall submit as part of the quality plan, to the superintendent, full details of the equipment and methods proposed for placing and finishing the concrete base together with a paving plan showing proposed paving widths, sequence, proposed jointing locations and estimated daily outputs.

(b) The Contractor shall give the superintendent seven days written notice of the intention to commence construction of the base on any section of work (including the placement of the trial concrete base in accordance with clause SC6.4.6.15.7(11) Trial concrete base. Submit work-as-executed survey details of the sub-base to the full extent of the works to the superintendent for confirmation of the constructed based. The survey should detail the locations where the constructed level is higher than the design levels. If the underlying layer is required to be spray sealed, the surveyor is to take levels on the top of the seal and after removal of foreign or loose material such as aggregate. The survey is to report as constructed levels to the nearest millimetre and survey on 5.0 m grid on a plan area that has been certified by a licensed surveyor. In the case of non-conforming locations and levels, the contractor is to locally reconstruct the pavement levels as directed by the superintendent and to the satisfaction of council.

(c) The sub-base surface shall be clean and free of loose or foreign or vegetative matter and is to be prepared in accordance with sub-section SC6.4.6.14 Mass concrete sub-base.

(d) Concrete shall not be placed either during rain or when the air temperature in the shade is below 5 ºC or above 38 ºC.

(e) The temperature of the concrete at the point of discharge from the transport vehicle shall be neither less than 10 ºC nor more than 32 ºC.

(f) Where required, slab anchors shall be constructed prior to construction of the base.

(2) Rate of evaporation

(a) When the value of rate of evaporation, determined from the graph in Figure SC6.4.6.15.1 Rate of evaporation, exceeds 0.50 kilograms per square metre per hour the contractor shall take precautionary measures to the superintendent's satisfaction, for the prevention of excessive moisture loss. If, in the opinion of the superintendent, such precautionary measures prove to be unsatisfactory, the contractor shall cease work while the evaporation rate is in excess of 0.50 kilograms per square metre per hour.

(b) Should the contractor elect to use an evaporation retarder to prevent excessive moisture loss, application shall be by fine spray after all finishing operations, except for minor manual bull floating.

(c) The contractor shall be responsible for measuring and recording concrete temperature and wind velocity at the point of concrete placement and for continuously measuring and recording air temperature and relative humidity at the site throughout the course of the work. The contractor shall provide and maintain all equipment and shall provide suitable personnel necessary for all such measuring and recording to accurately take place.

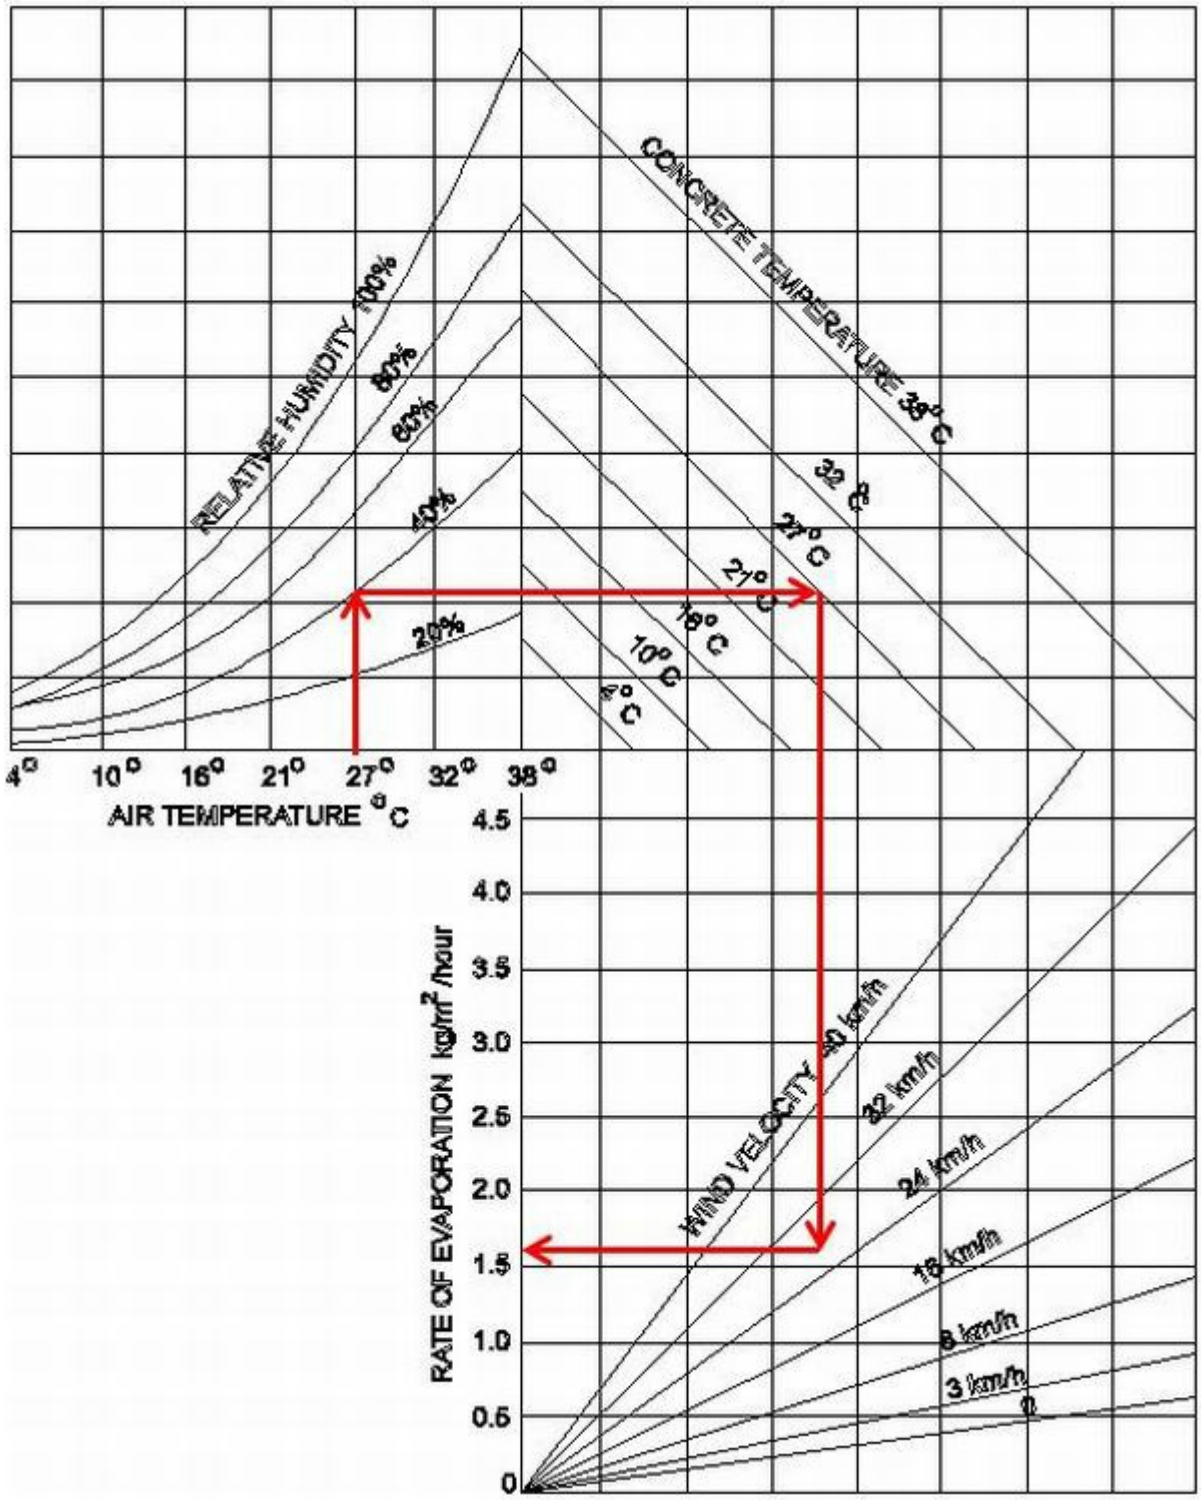

Figure SC6.4.6.15.1 Rate of evaporation

Note—the graph shows the effects of air temperature, humidity, concrete temperature and wind velocity together with the rate of evaporation of water from freshly placed and unprotected concrete.

Example:

- with air temperature at 27ºC
- with relative humidity at 40%
- with concrete temperature at 27ºC
- with a wind velocity of 26 km/h

the rate of evaporation would be 1.6 kg/m/hour.

To determine the evaporation rate from the graph, enter the graph at the air temperature (in this case 27ºC), and move vertically to intersect the curve for relative humidity encountered - here 40%. From this point move horizontally to the respective line for concrete temperature - here 27ºC. Move vertically down to the respective wind velocity curve - in this case interpolating for 26 km per hour - and then horizontally to the left to intersect the scale for the rate of evaporation.

(3) Mechanical paving

(a) The mechanical paver shall be a self-propelled machine with a gross operating mass of not less than 4 tonnes per lineal metre of paved width. It shall be capable of paving at a speed of one metre per minute or less as required to enable the continuous operation of the paver and obtain the required degree of compaction. It shall include the following features:

(i) an automatic control system with a sensing device to identify the control line and level – within the specified tolerances;

(ii) can spread the concrete mix uniformly and can regulate the flow of mix to the vibrators without segregation of the components;

(iii) has internal vibrators capable of compacting the full depth of the concrete;

(iv) has adjustable extrusion screeing and/or conforming plate to form the slab profile and produce the required finish on all surfaces; and

(v) has the capability of paving in the slab widths or combination of slab widths and slab depths shown on the drawings.

(b) The mechanical paver shall spread, compact, screed and finish the freshly placed concrete in such a manner that any finishing by hand is kept to a minimum. A dense and homogeneous concrete with a surface exhibiting low permeability is to be provided. It shall be textured in accordance with clause SC6.4.6.15.7(6) Texturing of surface.

(c) The supporting surface for the tracks of the paver, curing machine and any other equipment in the paving and curing train shall be in a smooth and firm condition.

(d) Once spreading commences, the concrete paving operation shall be continuous. The mechanical paver shall be operated so that its forward progress shall not be stopped due to lack of concrete. If disruptions occur for any reason, the superintendent may direct that a construction joint be formed before the recommencement of paving operations.

(e) Where an interruption to paving occurs, which is likely to result in a non-monolithic concrete mass, the contractor shall form a transverse construction joint in accordance with clause SC6.4.6.15.8(2) Transverse construction joints.

(f) Should subsequent testing at the location of an interruption indicate the presence of non-monolithic concrete, such concrete shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1) General – Removal and replacement of base, SC6.4.6.15.11(2) Removal and disposal of base and SC6.4.6.15.11(3) Replacement of base.

(4) Hand placing

(a) Hand placement shall only be used in areas where mechanical placement is impracticable or where it has been approved by the superintendent prior to commencement of work.

(b) Forms shall be so designed and constructed so that they can be removed without damaging the concrete and shall be true to line and grade and braced in a substantial and unyielding manner. Forms shall be mortar tight and de-bonded to ensure non adhesion of concrete to the forms.

(c) Concrete shall be delivered in agitator vehicles and shall be deposited uniformly in the forms without segregation. The concrete shall be compacted by poker vibrators and by at least two passes of a hand guided vibratory screed traversing the full width of the slab on each pass. Any build-up of concrete between the forms and vibratory screed shall be removed.

(d) If disruptions occur for any reason, the superintendent may direct that a construction joint to be formed before the recommencement of paving operations. The cost of forming such construction joints shall be borne by the Contractor.

(e) A dense and homogeneous concrete with a surface exhibiting low permeability, shall be provided. It shall be textured in accordance with clause SC6.4.6.15.7(6) Texturing of surface.

(f) Where an interruption to placing of concrete occurs, which is likely to result in a non-monolithic concrete mass, the contractor shall form a transverse construction joint in accordance with clause SC6.4.6.15.8(2) Transverse construction joints.

(g) Should subsequent testing at the location of an interruption indicate the presence of non-monolithic

concrete, such concrete shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1) General – Removal and replacement of base, SC6.4.6.15.11(2) Removal and disposal of base and SC6.4.6.15.11(3) Replacement of base.

(5) Alignment and surface tolerances

(a) Horizontal alignment tolerance

(i) The outer edges of the concrete base shall be square to the sub-base and shall not deviate from the plan position at any point by more than 10 mm.

(ii) Where an edge of a slab is to form a longitudinal joint line, the allowable horizontal alignment tolerances shall comply with clause SC6.4.6.15.8(7) longitudinal isolation joints.

(b) Tolerances and ride-ability

(i) The tolerance on thickness of the concrete base shall be zero below the specified thickness and in accordance with clause SC6.4.6.14.7(5)(b) for excess thickness.

(ii) The top surface of the base shall also not deviate at any measurement from a 3 m straightedge, laid in any direction, by more than 5 mm. Measurements for conformance shall be taken in accordance with the maximum lot size and minimum test frequencies in accordance with SC6.4.5 Construction management. Notwithstanding this requirement, the surface shall not pond water.

(6) Texturing of surface

Texturing of the concrete surface may be effected by use of a fine broom or hessian drag. The contractor shall submit to the superintendent details of the proposed texturing method and equipment.

(7) Curing

(a) The base shall be cured by the use of one of the following:

(i) Chlorinated rubber curing compound complying with AS 3799 Class C Type 1D or resin-based curing compound complying with AS 3799 Class B, Type 1D or Type 2, if an asphalt wearing surface is used, or

(ii) White pigmented wax emulsion curing compound complying with AS 3799 Class A Type 2, if no asphalt wearing surface is used, or

(iii) Bitumen emulsion Grade CRS/170 complying with AS 1160 for either asphalt wearing or no asphalt wearing surface.

(b) The contractor shall submit, for the information of the superintendent, a current certificate of compliance from an Australian laboratory, approved by the superintendent, showing an efficiency index of not less than 90 per cent when tested in accordance with Appendix B of AS 3799.

(c) The curing compound shall be applied using a fine spray immediately following texturing at the rate stated on the certificate of compliance or at a minimum of 0.2 litres per square metre, whichever rate is the greater. Bitumen emulsion shall be applied at a minimum rate of 0.5 litres per square metre. When applied with a hand lance the rates shall be increased by 25 per cent.

(d) The average application rate shall be checked by the contractor and certified to the superintendent by calculating the amount of curing compound applied to a measured area which is representative of a lot - and nominated by the Superintendent.

(e) The curing membrane shall be maintained intact for 7 days after placing the concrete. Any damage to the curing membrane shall be made good by handspraying of the affected areas.

(f) Equipment and materials for curing operations shall be kept on site at all times during concrete pours.

(8) Protection of work

(a) The Contractor shall protect the work from rain damage and shall provide, for the information of the superintendent, detailed proposals for procedures and equipment to be used for such protection.

(b) Neither traffic nor construction equipment, other than that associated with testing, sawcutting, groove cleaning or joint sealing, shall be allowed on the finished base until the joints have been permanently sealed and at least 10 days have elapsed since placing concrete, and the concrete has reached a

compressive strength of at least 20 MPa.

(9) Odd-shaped and mismatched slabs

(a) A slab is a portion of concrete base bounded by joints or free edges. A slab shall be considered to be odd shaped if the ratio of the longer dimension to the shorter dimension exceeds 1.6 or if the joint pattern produces an angle of less than 80 degrees between two adjacent sides. Slab dimensions shall be taken as the average dimension measured normal and parallel to the longitudinal joints. Slabs containing block-outs for drainage structures shall be considered as odd shaped.

(b) Where any joint meets a slab and is not continued across that slab, that slab shall be considered a mismatched slab.

(c) Unless otherwise shown on the drawings, odd shaped and mismatched slabs shall be reinforced with F82 reinforcing fabric placed with 50 mm to 60 mm cover to the surface of the base. Fabric shall be clear of all transverse and longitudinal joints by 50 mm to 100 mm.

(10) Terminal slabs

Terminal slabs shall be constructed adjoining bridge approach slabs and at changes from a rigid pavement to a flexible pavement. Terminal slabs shall be constructed to the dimensions and details shown on the drawings.

(11) Trial concrete base

(a) Before the commencement of paving, the contractor shall construct a trial section of concrete base on the carriageway to demonstrate to the superintendent the contractor's capability of constructing the concrete base in accordance with the specifications. This section shall be constructed so that it may be incorporated in the finished work.

(b) The trial base shall be constructed using the same materials, concrete mix, equipment and methods the contractor intends to use for the remaining base work. The contractor shall demonstrate the methods proposed to be used for texturing, the application of curing compound, the construction and sawing of joints and the placement of tie bars and dowels.

(c) The trial shall also be used to demonstrate that the contractor's allowances for concrete strength, compaction and slab thickness are adequate to achieve the minimum requirements specified.

(d) A trial length of between 20 m and 100 m for mechanical paving equipment or between 10 m and 30 m for hand placement is required. The maximum width proposed to be laid, shall be constructed in one continuous operation.

(e) Unless advised by the superintendent of any deficiencies in the trial concrete base, due to failure to comply with this sub-section, the contractor may proceed with placing the concrete base from a time ten working days after the completion of the trial concrete base or such earlier time as the superintendent may allow. In the event of deficiencies in the trial concrete base, the superintendent may order the contractor to construct a further length of trial concrete base which shall be treated as the first. If, after three trials, the base still is deficient in some way, the superintendent may require the contractor to justify to the satisfaction of the superintendent why the work should be allowed to continue using that method and/or equipment and/or materials and/or personnel.

(f) The superintendent shall have the right to call for a new trial section at any stage of work under the contract when changes by the contractor in the equipment, materials, mix, plant or rate of paving are deemed by the superintendent to warrant such a trial or when concrete as placed does not comply with this sub-section.

SC6.4.6.15.8 Joints

(1) General - joints

Joints shall be provided at locations indicated on the drawings or as approved by the superintendent.

(2) Transverse construction joints

(a) Transverse construction joints shall:

(i) be provided only at discontinuities in the placement of concrete determined by the contractor's paving operations;

(ii) not be placed closer than 1.5 m to a transverse contraction joint. Where necessary, the superintendent shall authorise a change in the spacing and/or skew of transverse contraction joints to ensure that sufficient clearance is obtained;

(iii) be constructed normal to the control line and to the dimensions and details shown on the drawings. The tie bars shall comply with clauses SC6.4.6.15.5(1) Material and SC6.4.6.15.5(5) Placing;

(iv) be smooth across the joint before texturing; and

(v) not deviate from a 3 m straightedge placed along the joint by more than 10 mm.

(b) Prior to the placement of adjacent concrete, the surface of the concrete shall be roughened to expose coarse aggregate. The roughened surface and the projecting reinforcement shall be washed clean and all excess water and loose material removed.

(3) Transverse contraction joints

(a) General

(i) Transverse contraction joints shall be continuous across the full width of the concrete base and shall be sawn unless otherwise approved by the superintendent.

(ii) Where the concrete base is to be overlaid with asphalt wearing course, the superintendent may approve the joint to be formed with a suitable plastic joint inducing system.

(iii) Transverse contraction joints shall be constructed normal to the control line and to the dimensions and details shown on the drawings. Where necessary, the joint may be skewed to a maximum 1 in 12 to accommodate construction joints and slab anchors.

(b) Saw-cutting

(i) The Contractor shall ensure that saw-cutting be conducted between 6 and 24 hours after initial paving so as not to cause excessive ravelling of aggregate adjacent to the cut and so as to prevent cracking of the concrete baseother than at the bottom of the 3 mm saw-cut. The contractor shall use the type of blade and equipment and the method of control best suited to the hardness of the concrete being sawn and shall have sufficient standby equipment available on site to maintain continuity of sawing.

(ii) The line of the transverse contraction joint shall be without any discontinuities. No edge shall deviate from a 3 m straight edge by more than 10 mm.

(iii) The surface of the transverse contraction joint shall not exhibit more than 5mm of vertical or horizontal edge ravelling. The length of edge ravelling shall not be more than 300 mm in any 1m length of joint on each edge. Saw debris shall be washed from the joint and pavement immediately after sawing.

(iv) Saw-cuts, which do not conform to the requirements of this clause, shall be rejected by the superintendent. Rejected saw-cuts may be repaired by a method approved by the superintendent.

(c) Cleaning

Immediately after any sawing, the saw-cut shall be cleaned of all debris. The cleaning method used shall not damage the saw-cut nor leave any substance deleterious to the concrete or to the adhesion of the joint sealants. The method shall incorporate a pressurised liquid or liquid/air jet. Cleaning liquid shall not be gravity fed from tanks.

(d) Temporary sealing

(i) Immediately after cleaning following the second saw-cut, if the transverse contraction joint is produced by a two cut operation, the joint shall be temporarily sealed by a continuous closed cell polyethylene backer rod of diameter shown on the drawings or as required by the superintendent.

(ii) The top of the sealant shall be neither higher than nor more than 10 mm below the concrete surface. The backer rod shall pass over any longitudinal joint seal already in place.

(iii) The temporary sealant shall be maintained by the contractor until the joint is sealed permanently.

Damaged or disturbed temporary sealants shall be removed, the transverse contraction joint is to be re-cleaned to the satisfaction of the superintendent and a new temporary sealant inserted.

(e) Permanent sealing

(i) General – permanent sealing

(A) Within 10 days of initial sawing and immediately on removal of the temporary sealant, the permanent sealant shall be placed in the joint.

(B) The permanent sealant shall be either a neoprene compression seal or an in situ cast silicone sealant. The contractor shall submit for the approval of the superintendent, a full technical description of the proposed sealant, including its operating parameters and the method of installation recommended by its manufacturer.

(ii) Neoprene compression sealants

(A) Neoprene compression sealants shall comply with all the requirements of ASTM 2628. Test methods used to determine compliance with these requirements shall include test methods Q462, Q463A and Q463B.

(B) At least four weeks before installation of the sealant, the contractor shall submit to the superintendent a certificate of compliance from a NATA registered laboratory showing that the sealant meets all the requirements of ASTM 2628.

(C) At the time of installation, the sides of the neoprene sealant shall be coated with a clear or concrete coloured lubricant compound approved by the superintendent and complying with ASTM D 2835. The sealant shall be inserted into the joint by using appropriate equipment and procedures which shall not damage the sealant during its insertion. The maximum increase in length of the sealant after installation shall be 5 per cent of original length. Any sealant exceeding 5 per cent extension shall be rejected. The sealant shall be located in the transverse contraction joint in the design orientation without twist or buckle.

(D) The sealant shall be continuous between formed longitudinal joints. Where such a discontinuity occurs, the sealant shall be angle butt jointed by a method approved by the superintendent. The top of the sealant shall be neither less than 5 mm nor more than 7 mm below the surface of the base and shall overlay any longitudinal sealants.

(iii) Silicone Sealants

(A) Silicone sealants shall be formed using a silicone joint sealant complying with the requirements listed in Table SC6.4.6.15.4 Silicone joint sealant requirements. At least 4 weeks before the installation of the sealant, the contractor shall submit to the superintendent a certificate of compliance, from a NATA registered laboratory, showing that the sealant meets all the requirements of Table SC6.4.6.15.4.

(B) The silicone joint sealant shall be grey in colour and shall be stored and installed in accordance with the manufacturer's written instructions. Installation of a silicone sealant shall take place only when the side walls of the groove have been grit blasted and are surface dry.

(C) Immediately before introducing the silicone sealant into the groove, any foreign or disturbed material shall be cleaned from the joint and from the top of the backer rod by dry air jet. The backer rod shall then be depressed to the depth such that the bottom of the silicone sealant shall be at the planned location and of the correct shape.

(D) If the backer rod is damaged in any way it shall be replaced for the full length of the joint.

(E) The method to be used for permanent sealing with silicone sealant shall be approved by the superintendent before permanent sealing commences. Notwithstanding any approval given by the Superintendent to a proposed method, the contractor shall be responsible for producing a permanent seal complying with all requirements of this specification.

Table SC6.4.6.15.4 Silicone joint sealant requirements

Test Method	Test	Requirements
ASTM-D-792	Specific Gravity	1.1 to 1.55
MIL-S-8802	Extrusion Rate	90 to 250 g per min
MIL-S-8802	Tack Free Time	30 to 70 min
ASTM D 2240	Durometer	10 to 25
Q461	Durability	Extension to 70% Compression to 50%
ASTM C794	Adhesion to Concrete	35N minimum average peel strength
ASTM C 793-7	Accelerated Weathering at 5,000 hours	No cracks, blisters or bond loss

(4) Transverse isolation joints

(a) Transverse isolation joints shall be provided at bridge approach slabs and at slab anchors where shown on the drawings and where directed by the superintendent.

(b) Transverse isolation joints shall be continuous across the full width of the concrete base normal to the control line and shall be constructed in accordance with the drawings.

(c) Transverse isolation joints shall not be placed closer than 2 m to other transverse joints. Where necessary, the superintendent shall authorise a change in the spacing and/or skew of adjacent transverse contraction joints to ensure that sufficient clearance is obtained.

(d) Joint filler shall consist of preformed jointing material of bituminous fibreboard and the joint sealant shall comply with the silicone sealant requirements of clause SC6.4.6.15.8(3) Transverse contraction joints. They shall be installed in accordance with the drawings and in a manner conforming to the manufacturers recommendations except that any reference to backer rods will not apply.

(e) The line of the isolation joint shall not deviate from a 3 m straightedge more than 10 mm.

(5) Longitudinal tied joints

(a) General – Longitudinal tied joints

(i) Longitudinal tied joints shall be provided at the locations shown on the drawings or where directed by the superintendent. The joints shall be parallel to the control line and/or to the dimensions and details shown on the drawings.

(ii) Longitudinal tied joints shall be formed or induced either by sawing or by machine insertion of a crack inducer ribbon.

(iii) The ties shall be 12 mm diameter deformed steel bars Grade 400Y, 1 m long and shall be inserted in accordance with clause SC6.4.6.15.5(5) Placing. Tie bars shall be located and spaced as shown on the drawings. All parts of any tie bar shall lie within 50 mm of its designed position. Tie bars shall be omitted within 500 mm of a transverse joint. The epoxy to be used when installing tie bars in existing concrete shall be hydrophilic epoxy resin. The setting system used shall develop an anchorage strength at least 85 per cent of the yield strength of the bar.

(iv) The line of longitudinal tied joints shall not deviate from the designed position at any point by more than 10 mm. The line shall also not deviate from a 3 m straight edge by more than 10 mm having made due allowance for any planned curvature.

(v) Where the longitudinal tied joint is formed or slip-formed, the joint face shall be corrugated in accordance with the details shown on the drawings.

(vi) Where the multi-lane width is greater than 18 m, a longitudinal isolation joint shall be constructed at each location shown on the drawings and in accordance with clause SC6.4.6.15.8(7) Longitudinal isolation joints.

(b) Sawn-induced joints

(i) Sawn longitudinal tied joints shall be provided to the dimensions shown on the drawings. Saw-cutting shall comply with clause SC6.4.6.15.9(3)(b) Saw-cutting.

(ii) Within 24 hours of sawing, the longitudinal tied joint shall be thoroughly cleaned of all debris and a neoprene backing rod, shall be inserted in accordance with the details shown on the drawings.

(iii) The sealant shall be coated with a lubricant adhesive compound approved by the superintendent. The compound shall have a colour compatible with the pavement colour. The sealant shall be inserted into the groove by means of suitable equipment which shall not damage the sealant during insertion. The maximum increase in length of the sealant after installation shall be 10 per cent of the original length, otherwise the sealant shall be rejected.

(iv) Joints in the sealant shall be kept to a minimum and shall be cemented together by an adhesive recommended by the manufacturer. The top of the sealant shall be neither less than 5 mm nor more than 7 mm below the surface of the concrete base, except where the sealant is depressed to lie under the transverse joint sealant.

(c) Ribbon-Induced Joints

(i) Ribbon induced longitudinal tied joints shall be provided to the dimensions and details shown on the drawings. The inducer ribbon shall be machine inserted so that the top of the ribbon does not protrude above the surface of the base, nor shall it lie below the surface of the base by more than 3 mm.

(ii) The inducer ribbon shall be a minimum of 0.5 mm thick. When placed, it shall be within 5º of the vertical plane. Any inducer ribbon that curls on placement when cut into the concrete base and is found to be curved in the transverse section by more than 3 mm its straight alignment, will be rejected.

(iii) At transverse construction joints, the inducer ribbon shall be carried through the joint sufficiently to allow a connection using strong stapling, or another method as approved by the superintendent. When a join, during paving, is necessary within the inducer ribbon - the inducer ribbon on the new spool shall be similarly joined to the tail of the inducer ribbon on the old spool.

(d) Treatment of sawn longitudinal tied joints prior to asphalt overlay

Where asphalt surfacing over sawn longitudinal tied joints is specified, the sealant shall be depressed to a depth below the concrete surface of not less than 10 mm and, following thorough cleaning, the joint shall be sealed flush with the concrete surface with a bituminous rubber compound, approved by the superintendent, which is to be compatible with the narrow groove.

(6) Longitudinal joint with kerb and/or channel

(a) Where kerbs and/or channel are to be constructed within the shoulder of a concrete base, they shall be formed directly onto the concrete sub-base and they may be cast either integrally with the concrete base or separately.

(b) Where constructed separately, they shall be tied to the concrete base by 12 mm diameter deformed steel tie bars grade 250S or 400Y, 1000 mm long at 1 m centres.

(c) The longitudinal joint shall be constructed parallel to the control line (parallel to the centre line for kerb ramps) and to the dimensions shown on the drawings. The tie bars shall be inserted in accordance with the drawings and clause SC6.4.6.15.5(5) Placing.

(d) The face of the longitudinal joint need not be scabbled however the joint does not need to be sealed.

(e) The line of the longitudinal joint shall be constructed to the tolerances specified for longitudinal tied joints in accordance with clause SC6.4.6.15.8 Longitudinal tied joints.

(f) The construction of kerb and/or channel shall be in accordance with kerb and channel sub-section SC6.4.6.9 Open drains regardless of method of construction except that the strength of the concrete used in the kerb and/or channel shall be 36 MPa.

(7) Longitudinal isolation joints

(a) Longitudinal isolation joints shall be provided where shown on the drawings and where directed by the superintendent.

(b) The line of the longitudinal isolation joint shall not deviate from the specified position by more than 10 mm. The line of the joint shall not deviate from a 3 m straight edge by more than 10mm.

(c) The joint filler shall consist of pre-formed jointing material of bituminous fibreboard and the joint sealant shall comply with the silicone sealant requirements of clause SC6.4.6.15.8(2) Transverse construction joints. They shall be installed in accordance with the drawings and in a manner conforming to the manufacturer's recommendations except any reference to backer rods will not apply.

SC6.4.6.15.9 Slab anchors

(1) General

(a) Slab anchors shall be constructed normal to the control line, to the dimensions and at the locations shown on the drawings.

(b) Slab anchors shall extend over the full width of the concrete base and the associated transverse expansion joint shall not be placed closer than 2 m to other transverse joints. Where necessary, the superintendent shall authorise a change in the spacing of transverse contraction joints to ensure that this minimum clearance is obtained.

(2) Excavation

(a) Excavation of trenches for slab anchors shall be to the dimensions and details shown on the drawings.

(b) All loose material shall be removed and the vertical faces trimmed to neat lines. The bottom of the trench shall be re-compacted, where required, to the degree of consolidation of the adjacent undisturbed material.

(c) The Contractor shall dispose of excavated material at locations approved by the superintendent.

(d) Where a slab anchor is required at the junction of an existing flexible pavement, a straight saw-cut to the full depth of the asphaltic concrete or bituminous seal shall be made in the flexible pavement along the joint line. Excavation of the trench shall then take place as described above without disturbance or damage to the existing flexible pavement. Any disturbance or damage to the flexible pavement shall be made good as directed by the superintendent.

(e) A subsoil drain shall be provided at the bottom of the trench, in accordance with subsection SC6.4.6.20 Subsoil, foundation and pavement drains and details shown on the drawings.

(3) Concrete

(a) Concrete for slab anchors shall be produced, transported and placed in accordance with the requirements for hand placed concrete base.

(b) Slab anchors shall be poured separately from the concrete base slabs and to the dimensions and details shown on the drawings - up to the top surface of the sub-base.

(c) A transverse isolation joint shall be provided on the downhill side of the slab anchor.

(d) Steel reinforcement in slab anchors shall be of the type and size shown on the drawings and shall be supplied and fixed in accordance with clauses SC6.4.6.15.5(1) Material and SC6.4.6.15.5(5) Placing.

(e) Bridge approach slabs, if not in the bridge contract, shall be constructed at bridge abutments to the dimensions and details shown on the drawings and in accordance with the requirements for the concrete base.

SC6.4.6.15.10 Conformance of concrete strength, compaction and thickness

(1) Concrete cylinders

(a) Test specimens

(i) Test specimens for determining the compressive strength of concrete shall be standard cylinders complying with AS 1012.8. The contractor shall supply a sufficient number of moulds to meet these requirements for the frequency of testing specified in this clause. The contractor will also arrange for a laboratory with appropriate NATA registration to conduct the sampling of fresh concrete and the making, curing, delivery and testing of specimens. Copies of test results shall be forwarded to the superintendent.

(ii) Samples of concrete for testing shall be taken in accordance with AS 1012.1. The selection of the

batches to be sampled shall be taken randomly. The specimens shall be moulded from each sample so that they are as identical as practicable.

(iii) The method of making and curing specimens shall be in accordance with AS 1012.8 with compaction by internal vibration.

(iv) The contractor shall mark the specimens for identification purposes.

(b) Frequency of moulding of test specimens

Test specimens shall be moulded at 7 days and 28 days or as directed by the superintendent - for the determination of the compressive strength. Each test specimen shall be moulded as follows:

(i) for each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens;

A lot is defined as a continuous pour of up to 50 cubic metres of concrete placed.

(c) Inspection, capping and crushing of specimens

(i) Specimens required by this sub-section shall be tested at the NATA registered laboratory nominated by the contractor.

(ii) Specimens shall be inspected, capped and crushed in accordance with AS 1012.9.

(iii) Before crushing, the mass per unit volume of the seven day specimens shall also be determined in accordance with AS 1012.12.2, so that the relative compaction of cores taken from the same lot of concrete base can be determined.

(2) Compressive strength of concrete

(a) General

The compressive strength of the concrete represented by a pair of specimens moulded from one sample shall be the average compressive strength of the two specimens unless the two results differ by more than 3 MPa, in which case the higher result shall be taken to represent the compressive strength of the lot of concrete.

(b) Adjustment of test compressive strength for age of specimen

Should any specimen be tested more than 28 days after moulding the equivalent 28 day compressive strength shall be the test compressive strength divided by the factor applying to the age of the specimen at the time of the test shown in Table SC6.4.6.15.5 Concrete age conversion factors. For intermediate ages the factor shall be determined by interpolation.

Age of Specimen at time of test (days)	Factor
28	1.00
35	1.02
42	1.04
49	1.06
56	1.08
70	1.10
84	1.12
112	1.14
140	1.16
168	1.18
196	1.20
224	1.22
308	1.24
365 or greater	1.25

(c) Conformance for Compressive Strength

(i) If the 28 day compressive strength of test cylinders for any lot is less than 33 MPa or greater than 45 MPa, the lot represented by the test cylinders shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1) General – Removal and replacement of base, SC6.4.6.15.11(2) Removal and disposal of base and SC6.4.6.15.11(3) Replacement of base.

(ii) In case of non-conformance the contractor may elect to core the in situ concrete base for testing

of the actual compressive strength to represent the particular lot. The locations for testing shall be nominated by the superintendent. Such locations may be determined by the use of a nuclear density meter, or any alternative method approved by the Superintendent. Testing shall be carried out at the request of the contractor. Base concrete failing to reach the required in situ compressive strength shall not be re-tested for at least 72 hours after the determination of the value of the in situ compressive strength.

(iii) After testing for compressive strength of the sample concrete cores, as required, the superintendent shall consider the test results and shall, at his absolute discretion determine the compressive strength of the concrete to be either:

(A) The average of the 28 day compressive strength of the pair of specimens moulded at the time of placing; or

(B) The equivalent 28 day compressive strength of the core.

(iv) A lot is defined as a continuous pour of up to 50 cubic metres of base represented by a set of test specimens cast from a sample of the concrete used in its construction.

(v) Thickness measurements of the concrete base shall be determined and certified by a licensed surveyor. Measurements are to be taken at the edges or by coring. Audit checks using a suitable probe may be carried out whilst the concrete is being placed. The readings shall be rounded off to the nearest 5 mm.

(vi) Concrete base which is below the specified thickness shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1), SC6.4.6.15.11(2) and SC6.4.6.15.11(3) .

(vii) Base which is thicker than the design thickness will be acceptable provided the finish satisfies the requirements of Clause SC6.4.6.15.7 Placing and Finishing Concrete Base and that the finished surface base level complies with clause SC6.4.6.14.7 (5) (b)

(3) Relative compaction of concrete

(a) Test specimens

(i) Test specimens for determining the relative compaction of the concrete placed in the work shall be cores cut from the work. Cores shall be cut from the full depth of the concrete base to the requirements of AS 1012.14, with the following exceptions:

(A) the requirement that the concrete shall be at least 28 days old before the core is removed shall not apply. However concrete must be not less than 3 days old in the warm season and 6 days old in the cool season, before removal; and

(B) the nominal diameter of the cores shall not be less than 75 mm.

(ii) The location of coring shall be chosen to exclude joints, steel reinforcement or tie bars from the core. The locations are not intended to be random, but are intended to ensure that the whole of the concrete base conforms to the minimum requirements of this sub section. Cores shall be marked for identification by the contractor.

(iii) Cores shall be placed immediately either in a tank of lime saturated water or in an individual plastic bag and sealed to prevent water loss. Cores stored in plastic bags shall be kept in the shade.

(iv) Cores shall not be subjected to temperatures in excess of either ambient temperature or 23 ºC whichever is the higher and they shall not be subjected to temperature less than 10 ºC, until delivered to the testing laboratory.

(b) Frequency of coring

(i) The Contractor shall take a minimum of one core specimen from each lot of concrete base represented by standard cylinders moulded in accordance with clause SC6.4.6.15.10(1) Concrete cylinders.

(ii) In the case of hand placed concrete base, two cores shall be taken to represent a section of work. A section of work shall be confined between construction joints. Hand worked or placed base that is cast with machine placed concrete and not separated from the machine placed concrete shall be deemed to be part of the machine placed concrete, and be cored and tested as part of the

machine placed concrete base.

(c) Repair of core holes

(i) The Contractor shall clean and restore all core holes taken in the base with non-shrink cementitious concrete having a compressive strength of not less than that in the base and a maximum nominal aggregate size of 10 mm.

(ii) The surface of the restored hole shall be similar to the surrounding surface in texture and colour.

(d) Testing of cores for compaction

(i) The core specimens shall be wet conditioned in accordance with AS 1012.14 for not less than 24 hours immediately prior to testing for compaction. Testing to determine mass per unit volume shall be carried out on specimens at age seven days.

(ii) The relative compaction of a core specimen shall be the ratio, expressed as a percentage, of the mass per unit volume of the core specimen to the average mass per unit volume of the standard cylinders used to determine the seven day compressive strength from the same lot of concrete base. The mass per unit volume of both standard cylinders and cores shall be determined in accordance with AS 1012.12.2.

(e) Conformance for Compaction

(i) If the relative compaction is less than 97 per cent, the lot represented by the core shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1), SC6.4.6.15.11(2) and SC6.4.6.15.11(3).

(ii) Core specimens for compressive strength testing shall be wet conditioned, prepared and tested in accordance with AS 1012.14. Cores obtained for compaction shall not be re used for compressive strength testing.

(iii) The test strength shall be adjusted for age in accordance with clause SC6.4.6.15.10(2) Compressive strength and for length/diameter ratio in accordance with Table SC6.4.6.15.6 Correction factors by multiplying by the correction factor in Table SC6.4.6.15.6 Correction factors.

(iv) If the 28 day compressive strength of the core is less than 33 MPa, the lot represented by the compaction core shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1), SC6.4.6.15.11(2) and SC6.4.6.15.11(3).

Table SC6.4.6.15.6 Correction factors

Length/Diameter Ratio	Correction Factor
2.00	1.00
1.75	0.98
1.50	0.96
1.25	0.93
1.00	0.89

SC6.4.6.15.11 Removal and replacement of base

(1) General – Removal and replacement of base

(a) Where directed by the superintendent, rejected base shall be removed and replaced in accordance with this clause. Rejected base, which extends more than 25 m longitudinally, shall be replaced by mechanical means unless the slabs are odd shaped or mismatched. Replacement shall be in full slab widths between longitudinal joints and/or external edges.

(b) At least 7 days before the commencement of concrete base removal, the contractor shall submit, for the approval of the superintendent, details of the proposed methods of carrying out the work which shall be such as to prevent damage to the adjoining concrete base and the underlying sub-base.

(2) Removal and disposal of base

(a) At each end of the section of concrete base to be removed, a transverse saw-cut shall be made for the full depth of the base layer. Such transverse saw-cut shall be normal to the control line and not closer

than 1.5 m to an existing contraction joint in the base. No over-sawing into the adjoining concrete base or underlying sub-base shall be permitted.

(b) Longitudinal saw-cuts shall be made along the existing longitudinal joints to define the edges of the base section to be removed. Such longitudinal saw-cuts shall not extend more than 250 mm past the transverse saw-cut at each end of the section to be removed and shall not extend into the underlying sub-base.

(c) No over-sawing shall be permitted on any internal saw-cuts made by the contractor to aid in the removal of the concrete base.

(d) The contractor shall dispose of the removed concrete base slabs at sites acceptable to the superintendent.

(e) Any slab, adjoining the removed slabs, damaged by the contractor's operations shall also be removed and replaced in accordance with this clause.

(3) Replacement of base

(a) Before construction of the replacement base, the sub-base shall be prepared and de-bonded in accordance with sub-section SC6.4.6.14 Mass concrete sub-base.

(b) All work involved in the replacement of the concrete base shall comply with this sub-section, including the following additional requirements:

(i) The joint faces on the adjoining slab at the transverse saw-cuts shall be deeply scabbled below the top 25 mm which shall be left smooth. Tie bars shall be provided to form a transverse construction joint in accordance with clause SC6.4.6.15.8(2) Transverse construction joints.

(ii) Transverse contraction joints shall be continuous across the full width of the base containing the replaced section. The length of the joint across the full width of the base shall be sealed with the same sealant as in adjacent work and in accordance with clause SC6.4.6.15.8(3) Transverse contraction joints.

(iii) The lower two thirds of the depth of the longitudinal joint faces shall be deeply scabbled and any concrete considered to be unsound by the superintendent shall be removed. A crack inducer ribbon shall be attached to the surface of any formed longitudinal joint in the replacement concrete base and tie bars provided to form a longitudinal tied joint in accordance with clause SC6.4.6.15.8(5) Longitudinal tied joints.

(iv) Tie bars placed into hardened concrete shall be set by the use of a hydrophilic epoxy resin. The setting system used shall develop an anchorage strength at least 85 per cent of the yield strength of the bar.

(v) Neither traffic nor construction equipment other than that associated with testing, saw-cutting, groove cleaning or joint sealing shall be allowed on the section of replaced concrete base until the joints have been permanently sealed and at least 10 days have elapsed since placing the replacement concrete base or it has reached a compressive strength of at least 20 MPa.

SC6.4.6.15.12 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.15.7 below:

Table SC6.4.6.15.7 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Aggregates** a. General	Mass of the total aggregates in concrete mix shall consist of at least 40% quartz sand	SC6.4.6.15.3(5)(a)
	b. Fine Aggregate (i) Grading	To be within the limits as per Table SC6.4.6.15.2 and shall not deviate from Proposed Grading by more than amounts in Table SC6.4.6.15.2	SC6.4.6.15.3(5)(b)

Item	Activity	Limits/Tolerances	Clause
	(ii) Wet Strength	Not less than 80kN for any fraction and/or constituent	SC6.4.6.15.3(5)(c)
	(iii) 10% Fines Wet/Dry Variation	Not to exceed 35% for any fraction and/or constituent	SC6.4.6.15.3(5)(c)
	(iv) Soundness	The loss in mass when tested with sodium sulphate to be less than 9% for any constituent	SC6.4.6.15.3(5)(c)
	(v) Particle Shape	The proportion of misshapen particles (2:1 ratio) to be less than 35%	SC6.4.6.15.3(5)(c)
	(vi) Fractured Faces	At least 80% by mass of the particles shall have two or more fractured faces	SC6.4.6.15.3(5)(c)
2.	**Concrete Quality** a. Cement Content	At least 270kg per yielded cubic metre of concrete	SC6.4.6.15.4(1)
	b. Flyash	Not greater than 50kg per yielded cubic metre of concrete	SC6.4.6.15.4(1)
	c.Compressive Strength	The minimum 28 day compressive strength shall be 36.0 Mpa	SC6.4.6.15.4(2)
	d. Shrinkage	Not to exceed 450 microstrain after 3 weeks of air drying	SC6.4.6.15.4(3)
	e. Consistency	Nominated slump shall be neither less than 30mm nor more than 40mm for mechanically placed concrete. It shall be neither less than 55mm nor more than 65mm for hand placed concrete.	SC6.4.6.15.4(4)
	f. Air content	Shall not be less than 4% nor more than 7% when discharged from the transport vehicle ready for placement	SC6.4.6.15.4(5)
3.	**Concrete Mixing and Transport**	After addition of cement to the aggregate, concrete shall be incorporated into the work within: (i) One and a half hours where transported by truck mixer or agitator. (ii) One hour where transported by non-agitating trucks.	SC6.4.6.15.6(2)
4.	**Concrete Placing**	Concrete shall not be placed when the air temperature in the shade is above 38ºC. The temperature of the concrete shall be neither less than 10ºC nor more than 32ºC.	SC6.4.6.15.7(1)
		Where the value of Rate of Evaporation exceeds 0.50kg per square metre per hour, the Contractor shall cease work.	SC6.4.6.15.7(2)
5.	**Alignment and Surface** a. Horizontal Alignment	The outer edges of the base shall not deviate from the plan position at any point by more than 10mm.	SC6.4.6.15.7(5)(a)

Item	Activity	Limits/Tolerances	Clause
	b. Surface Level	The level at any point on the top of the base shall not vary by more than +10mm or -0mm from that shown on the drawings or as directed by the superintendent. The top surface of the base shall not deviate from a 3m straight edge, laid in any direction, by more than 5mm.	SC6.4.6.15.7(5)(b)
6.	**Joints** a. Transverse Construction	The line of the transverse construction joints shall not deviate from a 3m straight edge placed along the joint by more than 10mm.	SC6.4.6.15.8(2)
	b. Transverse Contraction	(i) May be reduced locally to a skew of 1 in 12 to accommodate construction joints and slab anchors. (ii) No edge shall deviate from a 3m straight edge by more than 10mm. (iii) The surface of the transverse contraction joint shall not exhibit more than 5mm of vertical or horizontal edge ravelling. The length of edge ravelling shall not be more than 300mm in any 1m length of joint on each edge. (iv) Temporary sealing - the top of the sealant shall be neither higher than nor more than 10mm below the concrete surface. (v) Permanent Sealing The top of the sealant shall be neither less than 5mm nor more than 7mm below the surface of the base.	SC6.4.6.15.8(3)
	c. Transverse Isolation	The line of the transverse expansion joint shall not deviate from a 3m straight edge more than 10mm.	SC6.4.6.15.8(4)
	d. Longitudinal Tied Joints	(i) All parts of any tie bar shall be within 50mm of its designed position. (ii) The line of longitudinal tied joints shall not deviate from the designed position at any point by more than 10mm. The line shall also not deviate from a 3m straight edge by more than 10mm having made due allowance for any planned curvature. (iii) For sawn-induced joints, the maximum increase in length of the sealant after installation shall be 10% of the original length. The top of the sealant shall be neither less than 5mm nor more than 7mm below the surface of the base. (iv) For ribbon-induced joints, the inducer ribbon shall be a minimum of 0.5mm thick and when placed it shall be within 5 of the vertical plane.	SC6.4.6.15.8(5)

Item	Activity	Limits/Tolerances	Clause
	e. Longitudinal Isolation Joints	The line of the longitudinal isolation joint shall not deviate from the specified position by more than 10mm. The line of the joint shall not deviate from a 3m straight edge by more than 10mm.	SC6.4.6.15.8(7)
7.	**Slab Anchors**	Not placed closer than 2.0m to transverse joints (other than associated transverse expansion joints).	SC6.4.6.15.9(1)

SC6.4.6.16 Sprayed bituminous surfacing

SC6.4.6.16.1 Introduction

(1) Scope

This policy sub-section provides standards, advice and guidelines for the supply of all materials and the application of any or all of the following types of sprayed bituminous surfacing:

(a) prime
The application of a primer of field or refinery prepared cutback bitumen without aggregate to provide penetration of the surface (preferably from 5 to 10mm) and waterproofing;

(b) primerseal
The application of a primerbinder of field or refinery prepared cutback bitumen to provide surface penetration (preferably from 2mm to 5mm) and incorporation of a light cover of aggregate to provide a temporary wearing surface;

(c) seal or reseal
The application of a bituminous binder into which aggregate is incorporated to provide a durable wearing surface (including bitumen emulsion or polymer modified seals); and

(d) slurry surfacing
The application of a bituminous emulsion binder with or without polymer modifier and with or without continuous aggregate, mineral fillers, additives and water, properly proportioned to enrich the binder content and refresh the existing wearing course material. This is a preventive maintenance treatment and shall not be used in new construction.

The locations and required types of sprayed bituminous surfacings, including types of binders and aggregate sizes, shall be as shown on the construction drawings and/or as detailed in SC6.4.6.16 Attachment A Details of work.

For multiple application treatments, the binder and aggregate may be required to be laid in one or more separate applications indicated in SC6.4.6.16 Attachment B.

Requirements for adhesion agent in the bitumen and tolerances for binder application rates are set out in SC6.4.6.16 Attachment B Binder details.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note - A reference to drawings is a reference to construction drawings.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-section:
SC6.4.6.30 - Control of traffic

(b) Australian Standards:
AS 1160 - *Bituminous emulsions for the construction and maintenance of pavements*
AS 2008 - *Residual bitumen for pavements*
AS 2157 - *Cutback bitumen*
AS 2758.2 - *Aggregate for sprayed bituminous surfacing*
AS 3568 - *Oils for reducing the viscosity of residual bitumen for pavements*

(c) Queensland Department of Transport and Main Roads Technical Standards:
MRTS11 - *Sprayed Bituminous Surfacing (excluding Emulsion)*
MRTS12 - *Sprayed Bituminous Emulsion Surfacing*
MRTS13 - Bituminous Slurry Surfacing
MRTS17 - *Bitumen*

MRTS18 - *Polymer Modified Binder*
MRTS19 - *Cutter and Flux Oils*
MRTS20 - *Cutback Bitumen*
MRTS21 - *Bituminous Emulsion*
MRTS22 - *Supply of Cover Aggregate*

(d) Queensland state legislation:
Fire and Rescue Service Act 1990

(e) Other:
Austroads, *Guide to Pavement Technology Part 4K: Seals*
Austroads, *Bituminous Materials Sealing Safety Guide*

(3) Control of traffic
The Contractor shall provide for the control of traffic in accordance with the requirements of policy sub-section SC6.4.6.30 Control of traffic while undertaking the work and shall take all necessary precautions to protect the work from damage until such time as the new seal coat has developed sufficient strength to carry normal traffic without disturbance of the aggregate.

Where early use of the new seal is required to facilitate the movement of traffic, vehicles may be allowed to run on the work after initial rolling has taken place provided that vehicles are controlled to such slow speeds that no lateral displacement of aggregate occurs. Where necessary, the Contractor shall use patrol vehicles to ensure that traffic travels at an acceptable speed.

The Contractor shall take all necessary steps to avoid or minimise delays and inconvenience to road users during the course of the work. Where adequate detours or side tracks are included in the Contract or are otherwise available, traffic shall be temporarily diverted while the work is in progress.

If facilities for the diversion of traffic are not available, the Contractor may spray part width of the pavement in the one operation and make available to traffic the adjacent strip of roadway, except during the actual spraying operation when all traffic movement through the work shall cease. Traffic shall not be permitted to encroach upon the edge of the sprayed bituminous material until such time as it is covered with aggregate.

SC6.4.6.16.2 Materials

(1) Sampling and testing of materials
Sampling and testing of materials shall be arranged by the Contractor and carried out by a laboratory with appropriate NATA registration in accordance with the requirements of the relevant Queensland Department of Transport and Main Roads (DTMR) Specification.

(2) Bituminous materials and additives
Bituminous materials shall be in accordance with the relevant DTMR Specifications.

(3) Bitumen adhesion agent

(a) Bitumen adhesion agents.
Adhesion agents must conform to the following requirements:

(i) adhesion agent is to be added to bitumen at the rate of 5kg for every 1,000 Litres of bitumen CL170 and 10kg for every 1,000 litres of polymer modified bitumen; and

(ii) adhesion agents approved for use are Diamintol, or Bitumite EXP3995 if Diamintol is unavailable.

(4) Oils for reducing viscosity of bitumen
Cutter Oil shall conform to MRTS 19.

Delivery and storage procedures for cutter oil delivered in drums or in bulk shall ensure that all containers are free from any deleterious material prior to filling with cutter oil, and all drums are stored to ensure that entry of water through seals or welds in the drums is prevented.

(5) Aggregate

Aggregate shall conform to MRS22.

The Contractor shall obtain test results for each lot/stockpile of aggregate and certification of compliance from a laboratory with appropriate NATA accreditation, before aggregate from the lot is incorporated in the works.

SC6.4.6.16.3 Design of bituminous surfacing

(1) Before commencing sprayed bituminous surfacing work, the Superintendent will confirm the approved details of the proposed bituminous surfacing design for the work. Additional details are required to be submitted to the Superintendent prior to carrying out the work for check with the proposed bituminous surfacing design. These additional details include:

(a) test results for all nominated materials;

(b) aggregates source, geological type, nominated grading, average least dimension (ALD);

(c) pre-coating agent and bitumen adhesion agent types, proportions and manufacturer (if applicable);

(d) bitumen refinery source and certification of compliance;

(e) cutback bitumen refinery source of bitumen, type of cutter, source of cutter, cutter oil fraction, certification of compliance;

(f) polymer modified bitumen – refinery source of bitumen and manufacturer, class of polymer and fraction, certificate of compliance; and

(g) bitumen emulsion – refinery source of bitumen and manufacturer, grade of emulsion, certificate of compliance.

Design rates of application of binder and aggregate for bituminous surfacing shall be in accordance with *Guide to Pavement Technology Part 4K: Seals*. Design application rates shall be known as “nominated application rates” and materials as “nominated materials”.

SC6.4.6.16.4 Pre-coating of aggregate general

The aggregate pre-coating agent shall be applied to the aggregate in a manner and at a rate and time which will provide a complete, light, uniform, effective cover of all aggregate particles at the time of spreading.

Pre-coating of aggregate shall not be carried out when rain is imminent. If aggregate has been pre-coated and rain appears imminent, the aggregate shall be adequately covered to prevent the pre-coating material being washed from the aggregate particles.

The Contractor shall take precautions, such as covering stockpiles, to prevent settlement of dust, penetration of moisture or drying out of the pre-coating agent on the stockpiled aggregate.

Stockpiles pre-coated more than 14 days in advance of use shall be retreated unless otherwise approved by the Superintendent and shall not be used if less than 3 days old.

SC6.4.6.16.5 Application of sprayed bituminous surfacing

(1) General

The Contractor shall carry out sprayed bituminous surfacing to:

(a) provide a uniform application of binder with adequate adhesion to the underlying surface;

(b) provide a complete cover of interlocking aggregate particles; and

(c) achieve effective bond between binder and aggregate.

Details of equipment and methods to be used for sprayed bituminous surfacing shall be submitted to the Superintendent for approval prior to their use on the works.

(2) Plant

A mechanical sprayer shall be used to apply primer, primerbinder and binder. The sprayer shall have a current Sprayer Certificate issued by the Queensland Department of Transport and Main Roads.

The spray nozzles shall be of the make and type endorsed on the Sprayer Certificate. Any nozzles which may be damaged or become unduly worn or defective shall be replaced by satisfactory nozzles of similar type. A sufficient number of nozzles for this purpose shall be available at all times.

Mechanical spreading equipment shall be used to spread aggregate and shall be capable of achieving a uniform and accurate spreading rate.

Rollers shall be utilised in accordance with Clause SC6.4.6.16.4(9) Application and rolling of aggregate.

The Contractor shall remove from the site any plant or equipment considered by the Superintendent to be not fully operational or not in a satisfactory condition for carrying out work in accordance with this sub-section.

(3) Preparation of pavement surface

Before the application of primer, primerbinder or binder, the pavement surface shall be swept by the use of a mechanically operated rotary road broom or suction broom to provide a uniformly clean surface. If necessary, additional sweeping shall be done by hand, using stiff brooms. Sweeping shall, where possible, extend at least 300mm beyond each edge of the area to be sprayed.

Adherent patches of foreign material shall be removed from the surface of the pavement.

For the spraying of primer or primerbinder, the pavement surface shall be slightly damp to impede dust interfering with initial adhesion except where explicit instructions are provided with the seal design.

(4) Surface defects must be repaired prior to laying the wearing course. This may include crack filling, pothole repairs and repair of failed pavements.

Rut-filling and corrector must be applied where necessary to rectify any ruts and uneven surfaces prior to placing the wearing course.

Review of nominated application rates

The Contractor shall select the locations where each lot of aggregate is to be incorporated in the works.

The Superintendent shall review the bituminous surfacing design at each location based on the actual average least dimension (ALD) test result for the lot of aggregate instead of the nominated ALD value of the aggregate adopted at design. Due consideration must also be given to the surface texture of the prepared pavement surface and the likely degree of stone embedment, to establish if any additional minor adjustments to bitumen spray rates should be applied. The revised application rates shall be known as "target application rates".

The Contractor shall give the Superintendent notice of the Contractor's intention to commence sprayed bituminous surfacing. This notice shall confirm spray rates, aggregate size and ALD.

(5) Bitumen temperature requirements

Bitumen temperature requirements are as per MRTS 17, 18, 19, 20 and 21.

Table SC6.4.6.16.2 Cutback bitumen spraying temperatures

Grade	Temperature Range (ºC)
AMC 00	10 - 35
AMC 0	35 - 55
AMC 1	60 - 80
AMC 2	75 - 100
AMC 3	95 - 115
AMC 4	110 - 135
AMC 5	120 - 150
AMC 6	135 - 160
AMC 7	150 - 175

(6) Pavement temperature and weather conditions

The Contractor shall measure and record pavement temperatures at regular intervals during the course of the work. For this purpose, a spirit or mercury in glass thermometer or other suitable type of thermometer shall be placed in direct contact with the pavement and allowed to remain in position until the reading becomes steady. When a spirit or mercury in glass thermometer is used to measure pavement temperature, the bulb of the thermometer shall be covered from direct sunlight with a small heap of grit or similar material. Suitably calibrated infra-red thermometers may be used.

If the pavement is partly in sun and partly in shade, the temperatures for both conditions shall be taken and recorded.

Spraying primers, primerbinders and binders shall be undertaken only if the pavement temperature has been at or above 20ºC, 25ºC for PMB, 10ºC for emulsion for spraying for at least one hour before commencement of spraying and does not fall below 20ºC, 25ºC for PMB, 10ºC for emulsion for spraying during the period of spraying.

Spraying shall not be carried out on a wet pavement, while rain appears imminent or during high winds or dust storms.

(7) Incorporation of cutter oil, flux oil and adhesion agent

(a) Cutting back bitumen

The Contractor shall determine and record the proportion of cutter oil added to each sprayer load, using MRTS11 and based on the measured pavement temperatures.
The cutter oil, without being previously heated, shall be pumped into the sprayer, followed by the hot bitumen. The full sprayer load of cutback bitumen shall be circulated at a rate of at least 700 litres per minute for 20 minutes to ensure that the mixture is homogeneous.

If a part sprayer load of field cutback bitumen is unused on the date of mixing, and needs to be returned to the heater tanks, it shall be placed in an empty tank reserved for that purpose. No bitumen or cutter shall be added to the returned cutback bitumen unless the tank is fitted with an effective mechanical mixing system. When the returned cutback bitumen is subsequently used as part of a sprayer load, allowance shall be made for the cutter oil contained in the returned cutback bitumen.

(b) Fluxing bitumen

Where flux oil is to be included, it shall be added to the bitumen in the sprayer and the mixture circulated at a rate of at least 700 litres per minute for at least 20 minutes before spraying.

(c) Bitumen adhesion agent

Where bitumen adhesion agent is to be included, it shall be added to the bitumen in the sprayer and the mixture circulated twice at a rate of at least 1,000 litres per minute for at least twenty minutes before spraying. Spraying shall occur within 4 hours.

(8) Application of primer, primerbinder and binder

(a) General
The area to be sprayed with primerbinder or binder shall be limited to the area which can be covered with aggregate at the target application rate within ten minutes of spraying bitumen or cutback bitumen.

(b) Primer and primerbinder
Nominated and target application rates and quantities of primer and primerbinder shall apply to the whole material, including cutter oil, measured at 15ºC. Primer, Primerbinder and Binder application rates outside the tolerances indicated in SC6.4.6.16 Attachment B Binder details constitute a non-conformance.
After application of a primer, a period of at least forty eight hours, or such longer period as determined to be necessary for the primer to become completely dry, shall elapse before the binder for a seal is applied. All traffic shall be kept off the primed surface.

After application of a primerbinder, a period of at least fourteen days shall elapse before the binder for a seal is applied.

(c) Binder
The class of bitumen or grade of cutback bitumen shall be as specified in SC6.4.6.16 Attachment A Details of work.

Nominated and target application rates and quantities of binder shall be based on the volumes of bitumen measured at a temperature of 15ºC and shall not include any bitumen adhesion agent and/or cutter oil. If flux oil has been added to the bitumen, the quantity of flux oil shall be included as part of the binder. Binder application rates outside the tolerances provided in SC6.4.6.16 Attachment B Binder details shall constitute a non conformance.

Where bitumen adhesion agent and/or cutter oil have been added to the binder, the application rate of the total binder at 15ºC shall be adjusted to allow for the quantities of bitumen adhesion agent and/or cutter oil in the mixture.

The Contractor shall determine the hot application rate of total binder, including bitumen adhesion agent and/or cutter oil, using MRTS11.

Where refinery cutback bitumen is used as the binder, the target application rate of binder shall be increased by the Contractor to allow for the cutter oil in the mixture.

(d) Operation of the sprayer
Where the longitudinal edges of spray runs are not required to overlap, special type end nozzles must be used. Where an overlap is required, the overlap of spray between adjacent longitudinal runs shall be in the range 50-100mm for special type end nozzles. If intermediate nozzles are to be used to overlap adjacent longitudinal sprays the nozzles shall be set in the normal manner for intermediate nozzles and the overlap shall be in the range 250-350mm.

The spraying of primer, primerbinder or binder for each run of the sprayer shall commence on a protective strip of heavy paper weighing not less than 120g per square metre laid across and held securely to the pavement surface beforehand by addition of cover aggregate. The sprayer shall commence moving at a sufficient distance in advance of the protective strip to ensure that the road speed for correct application and correct alignment is attained at the commencement of spraying.

The sprayer shall maintain a uniform rate of application throughout the length of each sprayer run.

The spraying for each run shall terminate on a protective strip of paper laid across and held securely to the pavement surface beforehand. The width of paper at the commencement and/or termination of each run shall not be less than that endorsed on the Sprayer Certificate.
Spraying shall cease immediately if any defect develops in the spraying equipment and spraying shall not recommence until the fault has been rectified.

Where any blockage or partial blockage of nozzles occurs, spraying shall cease immediately. If the blockage is due to the condition of the binder being sprayed and is likely to re-occur, that load together with any binder from the same bulk tanker or supply unit shall not be used in the works.

Where a mechanical sprayer is not able to satisfactorily spray small areas or areas of irregular shape, such areas shall be sprayed by means of the hand spray equipment attached to the sprayer. The work shall be planned to minimise the area sprayed by hand spray equipment.

After each sprayer run, the quantity of binder sprayed shall be checked against the area covered and any necessary adjustments shall be made to ensure that the target application rate is achieved in subsequent runs. If the actual application rate of binder after three runs differs by more than 5% from the target application rate, the sprayer shall not be used until a new Sprayer Certificate has been obtained.

Areas not within 5% of the target application rate of primer, primerbinder or binder shall constitute a “non-conformance”.

(9) Application and rolling of aggregate

The application of aggregate shall proceed immediately after spraying is commenced and shall be completed within ten minutes of spraying bitumen or cutback bitumen. For polymer modified binder spreading and rolling shall start immediately after spraying and continue until adhesion is complete.
Wet aggregate shall not be used.

The Contractor shall apply the aggregate of the specified nominal size and at the target aggregate application rate. Sufficient loaded and measured trucks of dry aggregate shall be at the site to provide full cover for the area sprayed.
The aggregate shall be spread uniformly over the sprayed surface by means of suitable mechanical spreading equipment.

Any bare or insufficiently covered areas shall be re run by the mechanical spreader or covered by hand as necessary to give a uniform and complete coverage. Any aggregate spread in excess of the target aggregate application rate shall be removed before rolling is commenced if it is localised and can be efficiently removed by hand brooming.
After the aggregate has been applied to each section of the work, initial rolling shall be carried out with two or more dual axle smooth pneumatic tyred multi wheel rollers of minimum load of 1t per tyre and minimum tyre pressure of 550 kPa. A roller with a rubber surface drum providing equivalent compactive effort may be used in lieu of a multi-wheeled roller. Initial rolling shall continue until the aggregate is firmly embedded in the primerbinder or binder. Roller speed shall be 15-25 km/h subject to safe working conditions.

If the aggregate is not evenly distributed over the surface of the pavement, the surface shall be traversed with a light drag broom after the initial rolling. If the broom has any tendency to dislodge aggregate particles bedded in the primerbinder or binder, the Contractor shall defer or eliminate the drag brooming. Where drag brooming is eliminated, the Contractor shall substitute light hand brooming.

Backrolling shall then be carried out for a minimum period of 1 hour per 1,000 square metres sprayed for roads having a traffic volume of less than 500 vehicles per lane per day and 1 hour per 1,500 square metres sprayed for other roads, up to a maximum of 24 hours after the aggregate has been applied.

Where a bituminous surfacing is specified with separate applications of coarse and fine aggregate on a single application of binder, the coarse aggregate shall be applied first, rolled and any necessary brooming carried out as described above, before application of the fine aggregate and its subsequent rolling and brooming. In this case, the time limits for incorporation of aggregate shall apply only to the application of the coarse aggregate.

After final sweeping, and prior to removal of speed restriction and warning signs, the number of loose aggregate particles remaining on the surface of seals constructed with 10mm, or larger, aggregates not to exceed the values specified in Table SC6.4.6.16.3.

Table SC6.4.6.16.3 Maximum loose aggregate particles

Road type	Loose stones (particles/m²) max
Urban areas	20
Other medium to high traffic (> 250v/l/d)	30
Low traffic (< 250v/l/d)	40

Any remaining loose particles of aggregate shall be removed by light sweeping and/or vacuumed from the pavement and disposed of responsibly by the Contractor as per Table SC6.4.6.16.4 below or as directed to by the Superintendent.

Table SC6.4.6.16.4 Maximum time limits for sweeping or vacuuming

Traffic volume (vehicles/lane/day)	Maximum time limits
> 2,000	Within 8 hours of sealing
1,000 to 2,000	Within 24 hours of sealing
250 to 1,000	Within 48 hours of sealing
< 250	Within 5 days of sealing

Prior to leaving the work site, ensure that all services are uncovered and cleaned, if necessary. Remove from site all waste paper and rubbish arising from the sprayed sealing operations. Clean the stockpile site and store any excess material in a tidy heap or remove, depending on the requirements of the Superintendent.

(10) Work records

Particulars of the work performed shall be recorded by the Contractor on a spray record sheet. Details of primer, primerbinder, binder and aggregate applied shall be recorded immediately after every sprayer run. Each form shall be signed by the Contractor's representative as a true record of the work performed. The Contractor shall supply to the Superintendent a copy of each completed form.

(11) Protection

(a) New work

Protect the new work by providing warning signs as follows:

(i) provide signs to warn public of loose stones and absence of line marking including provision of temporary raised pavement markers;

(ii) maintain signs until loose aggregate has been removed and linemarking reinstated; and

(iii) if linemarking is to be undertaken by others, erect warning signs indicating the absence of linemarking to be maintained by the organisation responsible for linemarking.

(b) Services and road fixtures

The Contractor shall take all necessary precautions to prevent primer, primerbinder, binder, aggregate or other material used on the work from entering or adhering to gratings, hydrants or valve boxes, access chamber covers, bridge or culvert decks and other road fixtures.

Immediately after aggregate has been spread over the binder, the Contractor shall clean off or remove any sprayed surfacing material and leave the services and road fixtures in a condition equivalent to that existing when the Contractor commenced the sprayed surfacing work.

SC6.4.6.16.6 Nonconformance of materials and work

If any materials supplied or any section of sprayed bituminous surfacing work fail to conform to the requirements whether failure of the work is due to bad workmanship, defective materials supplied by the Contractor or materials made defective by the method of operation adopted, or any other cause then such failure or failures shall constitute a “non-conformance”.

The nonconforming section of sprayed bituminous surfacing work shall be either replaced or corrected as proposed by the Contractor, subject to the approval being obtained.

The rectified nonconformances, including any restoration work to any underlying or adjacent surface or structure,

which becomes necessary as a result of such replacement or correction, shall be the responsibility of the Contractor. Materials removed from the site by the Contractor shall be replaced with materials which conform to this sub-section.

SC6.4.6.16.7 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.16.5 below.

Table SC6.4.6.16.5 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Design of Bituminous Surfacing**	Contractor to provide details of design to Superintendent before proposed commencement of work.	SC6.4.6.16.3
2.	**Commencement of Work**	Contractor to give notice to the Superintendent of intention to commence work.	SC6.4.6.16.5(1)
3.	**Sweeping of Pavement Surface**	Sweeping shall extend at least 300mm beyond each edge of the area to be sprayed.	SC6.4.6.16.5(3)
4.	**Bitumen Heating** (a) Bitumen Temperature	When incorporated with cutter oil, bitumen shall be in temperature ranges as per MRTS.17 and 18 (06/09).	SC6.4.6.16.5(5)
	(b) Refinery Cutback Bitumen Temperature	At the time of spraying shall be in temperature range as per MRTS 20 (06/09).	SC6.4.6.16.5(5)
	(c) Retention of Temperature	Bituminous materials shall not be held at temperatures within the ranges of MRTS17,18 and 20 for periods in excess of 10 hours.	SC6.4.6.16.5(5)
5.	**Spraying Temperature** (a) Pavement Temperature	Bituminous surfacing shall not be undertaken if the pavement temperature has not been at or above 20°C, 25°C for PMB, 10°C for emulsion for at least one hour before commencement of spraying or if the pavement temperature falls below 20°C, 25°C for PMB, 10°C for emulsion during the period of spraying.	SC6.4.6.16.5(6)
6.	Cutting Back Bitumen	Circulation of hot bitumen and cutter oil mixture in the sprayer shall be at the rate of at least 700 litres per minute for 20 minutes.	SC6.4.6.16.5(7)
7.	Fluxing Bitumen or adding Bituminous Adhesion Agent	Circulation of fluxing oil or bituminous adhesion agent with hot bitumen shall be at the rate of at least 1,000 litres per minute for 20 minutes. Spraying to occur within 4 hours.	SC6.4.6.16.5(7)
8.	**Application of Bituminous Material** (a) Spray Area	Area to be sprayed shall be limited to area which can be covered by aggregate at target application rate within 10 minutes of spraying.	SC6.4.6.16.5(8)
	(b) Application Rates	Application rates and quantities shall apply to a temperature of 15ºC and have T1 tolerances of ±5% as set out in clause SC6.4.6.16.6 and T2 tolerances as set out in SC6.4.6.16 Attachment B.	SC6.4.6.16.5(8)
	(c) Primer	At least a 48 hour period shall elapse after spraying of primer before binder for a seal is applied.	SC6.4.6.16.5(8)
	(d) Primerbinder	At least a 14 day period shall elapse after spraying of primerbinder before application of binder.	SC6.4.6.16.5(8)

Item	Activity	Limits/Tolerances	Clause
9.	**Application of Aggregate** (a) Spreading Time	Application of aggregate shall be completed within 10 minutes of spraying bitumen or cutback bitumen on each section.	SC6.4.6.16.5(9)
10.	**Rolling** (a) Roller Numbers and Type	Initial rolling shall be carried out with two or more dual axle smooth pneumatic tyred multi-wheeled rollers. Minimum load of 1t per tyre and minimum tyre pressure 550KPa.	SC6.4.6.16.5(9)
	(b) Backrolling	(i) For traffic volume of <500 vehicles per lane per day, backrolling for minimum of one hour per 1,000 square metres sprayed.	SC6.4.6.16.5(9)
		(ii) For traffic volume >500 vehicles per lane per day, backrolling for minimum of one hour per 1,500 square metres sprayed.	SC6.4.6.16.5(9)

SC6.4.6.16 Attachment A: Details of work

Section Road Name From To	Prime Binder Type	Primer Seal		Seal or Reseal	
		Binder Type	Aggregate Nom. Size	Binder Type	Aggregate Nom. Size

Note —prime and primer seal binder type shall be indicated in this Attachment using the descriptive terms as follows:

Very Light Prime or Primer - equivalent cut back bitumen to grade AMCOO.
Light/Medium Prime or Primer - equivalent cutback bitumen to grade AMCO or AMC1.
Heavy Prime or Primer - equivalent cut back bitumen to grade AMC1 or AMC2.

SC6.4.6.17 Bituminous micro-surfacing

SC6.4.6.17.1 Introduction

(1) Scope

The work to be executed under this sub-section consists of the design, supply, mixing and placement of bituminous microsurfacing for surface correction and wearing surface applications on road pavements, carparks, cycleways and footpaths; or as a preventative maintenance treatment on roads with the objective of enriching the existing wearing course. The treatment must not be used in new road construction.

Bituminous microsurfacing must consist of a mixture of emulsified polymer modified bitumen binder, mineral aggregate, mineral filler, additives and water proportioned and mixed to form a slurry which is placed and spread evenly on the road surface. It must be capable of being spread in variably thick layers for surface correction and for wearing surface applications.

The size, nominal thickness, and extent of bituminous microsurfacing must be as shown on the drawings or as directed by the Superintendent.

For all new works on road and carpark pavements, this sub-section should be read in conjunction with sub-section SC6.4.6.16 Sprayed bitumen surfacing. For new works on road and carpark pavements, bituminous mircrosurfacing must be preceded by the application of a sprayed bituminous seal a minimum of 2 weeks prior to the application of the bituminous microsurfacing wearing course.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Terminology

Users of this specification should be aware that where terms are not specifically defined in the following section, AS1348 should be the default standard.

Bituminous microsurfacing	Is one of two types of bituminous slurry surfacing. It is distinguished from the other type, slurry seals, by the incorporation of polymer and other additives to the bituminous binder to improve the performance of the slurry surfacing. Bituminous microsurfacing is also commonly known under various proprietary names such as “cold overlay”, “microsealing”, “paveseal”, “microasphalt”, etc. The size of the bituminous microsurfacing is based on the nominal largest stone size in the mix. For the purpose of this sub-section, the size must be either Size 5 or Size 7.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy subsections to be read and applied in conjunction with this subsection are as follows:

SC6.4.6.16 Sprayed bitumen surfacing

SC6.4.5 Construction management

(b) Australian Standards:

AS1141.11.1	*Particle size distribution – Sieving method*
AS1141.12	*Material finer than 75 micrometre in aggregates (by washing)*
AS1141.22	*Wet/dry strength variation*
AS1141.23	*Los Angeles value*
AS1141.25.1	*Methods for sampling and testing aggregates - Degradation factor - Source rock*
AS1141.25.2	*Methods for sampling and testing aggregates - Degradation factor - Coarse aggregate*
AS1141.25.3	*Methods for sampling and testing aggregates - Degradation factor - Fine aggregate*

AS1141.42	*Pendulum friction test*
AS1160	*Bitumen emulsions for the construction and maintenance of pavements*
AS1289.3.7.1	*Determination of the sand equivalent of a soil using a power-operated shaker*
AS1348	*Glossary of terms - Roads and traffic engineering*
AS2008	*Residual bitumen for pavements*
AS2350	*Methods of testing Portland and blended cements*
AS2891.3.1	*Binder content and aggregate grading - Reflux method*

(c) International Slurry Surfacing Association Tests:
ISSA TB 100 - *Test method for wet track abrasion of slurry surfaces*
ISSA TB 109 - *Test Method for Measurement of Excess Asphalt in Bituminous Mixtures by Use of a Loaded Wheel Tester*
ISSA TB 114 - *Wet stripping test for cured slurry seal mixes*
ISSA TB 139 - *Method of classified emulsified asphalt/aggregate mixtures by modified cohesion test measurement of set and cure characteristics*
ISSA TB 144 - *Classification compatibility by Schulze-Breuer and ruck procedure*

SC6.4.6.17.2 Materials

(1) Sampling and testing of materials
Sampling and testing of materials must be arranged by the Contractor and carried out by a NATA registered laboratory for the nominated test methods.

(2) Binder
The binder supplied and used in the works must be an emulsified polymer modified bitumen, formulated to meet the performance requirements of the mix specified in clauses SC6.4.6.17.3(1) Mix properties and SC6.4.6.17.4(6) Surface texture.

Prior to emulsification, incorporation of polymer and additives, the bitumen must comply with AS2008.

The Contractor must provide the Superintendent with sufficient information to verify that the binder supplied is the same as that nominated in the mix design.

(3) Mineral aggregates
Mineral aggregates must consist of crushed rock or crushed gravel, or a mixture of crushed rock or crushed gravel and natural sand. It must consist of clean, hard, angular, durable particles, and free form clay, dirt, organic material or other deleterious matter.

The aggregate from each source must comply with the requirements given in Table SC6.4.6.17.1 Aggregate properties.

Table SC6.4.6.17.1 Aggregate properties

Property	Test Method	Requirement
Degradation Factor	AS1141. 25.1	50 minimum
Los Angeles Value	AS1141.23	30 maximum
Aggregate Wet Strength	AS1141.22	150kN minimum
Wet/Dry Strength Variation	AS1141.22	30% maximum
Polished Aggregate Friction Value	AS1141.42	45 minimum
Sand Equivalent	AS1289.3.7.1	60 minimum

When tested in accordance with AS1141.11 and AS1141.12, the aggregate (including mineral filler) must conform with the grading limits given in Table SC6.4.6.17.2 Grading limits for combined aggregate/filler.

Table SC6.4.6.17.2 Grading limits for combined aggregate/filler

Sieve Size	Percent Passing by Mass	
	Size 5	Size 7
13.2mm	100	100
9.5mm	100	100
6.7mm	100	85-100
4.75mm	90-100	70-90
2.36mm	50-70	45-70
1.18mm	30-50	28-50
600µm	20-35	19-34
300µm	12-25	12-25
150µm	7-18	7-18
75µm	4-10	5-15

The Contractor must nominate the source/s of aggregates to the Superintendent, and must submit NATA certified test reports on the quality and grading of the combined aggregate proposed to be used.

The Contractor must submit test results to the Superintendent for each lot/stockpile of aggregate a minimum of seven days prior to incorporation in the works.

(4) Mineral filler

Mineral filler must consist of hydrated lime, flyash, portland cement, or other material approved by the Superintendent.

The mineral filler must be dry, free from lumps and any deleterious material, with a minimum of 85% passing a 75µm sieve. In all other respects, the mineral filler must comply with the requirements of AS2350.

The quantity of filler added to the bituminous microsurfacing during placement must not vary by more than 1% of the total aggregate (by mass) from the filler content nominated in the mix design.

(5) Water

Water added to the bituminous microsurfacing must be potable and must be compatible with the component materials.

(6) Additives

Details of the type, source and nominal proportions of additives must be submitted to the Superintendent with the mix design.

SC6.4.6.17.3 Mix design

(1) Mix properties

The nominated mix design must satisfy the properties given in Table SC6.4.6.17.3 Mix properties.

Table SC6.4.6.17.3 Mix properties

Mix Property	Test Method	Requirement
Wear Loss	ISSA TB 100 6 day	800 g/m^2 maximum
Traffic Time	ISSA TB 139 30 minutes 60 minutes	12kg.cm minimum 20kg.cm minimum
Adhesion	ISSA TB 114 or ISSA TB 144	≥90% or 11 grade points minimum (AAA, BAA)

(2) Nominated mix

At least 7 days before commencing bituminous microsurfacing work, the Contractor must submit to the Superintendent for approval, details of the nominated bituminous mircrosurfacing mix design for the work including the target application rate (m^3 of mix/m^2 of road surface) and the corresponding nominal layer thickness, together with NATA certification and test results demonstrating that the nominated mix and its constituents meet the requirements of the specification.

The details of the nominated mix design must include the following:

(a) bitumen emulsion content of the mix, and the residual binder content of the emulsion;

(b) target combined aggregate/filler grading;

(c) proportions of constituent materials used;

(d) type and sources of aggregates, filler and binder; and

(e) all relevant compliance certificates.

(3) Approved mix

When a nominated mix has been approved by the Superintendent, it must be known as the “approved mix”. Work must not commence until a bituminous microsurfacing mix has been approved.

The combined aggregate/filler grading and the binder content of the approved mix will be termed the "approved grading" and the "approved binder content" respectively.

Any changes to the approved mix, its method of production or source of supply of constituents require written approval 21 days prior to proposed implementation.

SC6.4.6.17.4 Production and paving

(1) Requirements of production mix

Bituminous microsurfacing produced in the paving unit at the site must be known as the "production mix".

The production mix must comply with the requirements given in Table SC6.4.6.17.4 Maximum permitted variations from approved mix and must be confirmed by the Contractor as required in SC6.4.6.17.4(2) Sampling and testing of production mix.

The Contractor is responsible for taking samples for testing at a NATA registered laboratory to confirm compliance with Table SC6.4.6.17.4.

Table SC6.4.6.17.4 Maximum permitted variations from approved mix

Production Mix Properties	Maximum Permitted Variations from Approved Mix (by mass)	
	Size 5	Size 7
Grading*	Nil	Nil
Passing 9.50mm AS sieve and larger	Nil	± 7%
Passing 6.70mm	± 6%	± 6%
Passing 4.75mm	± 5%	± 5%
Passing 2.36mm and 1.18mm	± 4%	± 4%
Passing 0.600mm	± 3%	± 3%
Passing 0.300mm	± 2%	± 2%
Passing 0.150mm	± 1.5%	± 1.5%
Passing 0.075mm		
Residual Binder Content	- 0.5% + 1.0%	- 0.5% + 1.0%

Note—*these allowable variations must not fall outside the limits for design of nominated mix as given in Table SC6.4.6.17.2 Grading limits for combined aggregate/filler.

(2) Sampling and testing of production mix

(a) Lot definition

Compliance sampling and testing of bituminous microsurfacing must be undertaken on a lot by lot basis. For this purpose, 50m^3 or one day's production (whichever is the lesser), or such smaller quantity which is considered as representative of consistent production of the paving unit, will be considered as representative of consistent production of the paving unit.

(b) Responsibility of sampling

The Contractor is responsible for taking samples and must supply all facilities, equipment and labour for that purpose.

(c) Frequency of Sampling

For the testing of production mix, two 1.5kg representative samples of bituminous microsurfacing mustbe taken from each lot at random intervals. The samples must be taken from the discharge of the paving unit and the sample containers immediately sealed.

For the testing of the binder, two 2L samples of bitumen emulsion must be taken from each bulk delivery in accordance with AS1160.

(d) Testing

The samples of bituminous microsurfacing must be treated and tested at a NATA registered laboratory to confirm compliance with Table SC6.4.6.17.4 Maximum permitted variations from approved mix. Prior to testing for Residual Binder Content and Aggregate Gradation, as determined by AS2891.3.1, the samples must be dried to constant weight in an oven at 60ºC for a minimum of 15 hours.

Each delivery of emulsion must be tested for residual binder content in accordance with AS1160 Appendix D and accompanied by a certification of specification compliance traceable to the relevant batch at the supplier's storage tank.

The paving unit to be used must be calibrated for the component materials of the approved mix prior to the commencement of paving. Previous calibration documentation covering the same materials and approved mix must be acceptable provided that calibration has been carried out within the previous 12 months.

The documentation must include an individual calibration for each component material at various settings which can be related to the paving unit's metering devices.

No paving unit must be allowed on the work until the calibration has been verified and approved by the Superintendent.

(3) Preparation of pavement

The existing surface must be clean and free from any loose stones, dirt, dust and foreign matter. The surface must be swept beyond the edge of the area to be surfaced by at least 300mm. Any foreign matter adhering to the pavement and not swept off must be removed by other means. Any areas significantly affected by oil contamination must be cleaned to the satisfaction of the Superintendent.

The Contractor must take all necessary precautions to prevent the bituminous microsurfacing or other materials used on the work from entering or adhering to kerbs, gutters, driveways, gratings, hydrants, valve boxes, access chamber covers, bridge or culvert decks or other road fixtures. After the bituminous microsurfacing has been spread the Contractor must clean off any such material and leave such gratings, access chamber covers and other road fixtures, in a clean and satisfactory condition.

(4) Weather limitations

Bituminous microsurfacing must not commence if either the pavement or air temperature is below 10ºC and falling.

Bituminous slurry may be applied when both pavement and air temperatures are above 7ºC and rising, or above 10ºC.

Spreading must not proceed during rain or when rain appears imminent.

The Superintendent must require cease of works, if weather conditions are not appropriate.

(5) Spreading

The surface may be pre-dampened if necessary by fogging ahead of the spreader box. Water used for pre-wetting the surface must be applied so that the entire surface is damp with no apparent flowing water ahead of the spreader box. The application rate of the fog spray must be adjusted to suit temperature, surface texture, humidity and dryness of the surface being covered.

Bituminous microsurfacing must be mixed and applied using a purpose built paver. The mix must be of the desired consistency when deposited in the spreader box, and nothing more may be added other than minor amounts of water for the purpose of overcoming temporary build-up of microsurfacing in the corners of the spreader box.

The mixing time must be sufficient to produce a complete and uniform coating of the aggregate and the resulting mixture must be conveyed into the moving spreader box at a sufficient rate to always maintain an ample supply across the full width of the strike-off.

The strike-off must be adjusted to provide an application rate which will completely fill the surface voids and provide the nominal application rate of bituminous microsurfacing as scheduled.

After the bituminous microsurfacing has been spread, the Contractor must ensure that all kerbs, gutters, driveways, gratings, hydrants, valve boxes, access chamber covers, etc. are uncovered and left in a clean and satisfactory condition.

After the emulsion has broken and the mix is sufficiently stable, rolling must be carried out using pneumatic tyred rollers to produce a dense, even, homogeneous compacted surface where there is insufficient local traffic to achieve satisfactory compaction across the mat.

Bituminous microsurfacing must be capable of carrying slow moving traffic (<40 km/h) within 1 hour of application without permanent damage occurring, such as rutting or ravelling. When the time before the microsurfacing is capable of carrying traffic exceeds 1 hour, work must cease unless specifically approved by the Superintendent.

(6) Surface texture

The resulting surface after spreading must be uniform in appearance, and free of areas exhibiting segregation or

excessive or insufficient binder.

The surface texture must be demonstrated on a short test run for approval by the Superintendent. If the surface texture is acceptable to the Superintendent, then all subsequent work must be finished to an equivalent surface texture.

Where increased surface texture is required, a fabric skirt may be trailed behind the spreader box.

(7) Joints

Longitudinal joints in the wearing course must be straight and placed at either the edge or the centre of a traffic lane. If necessary, the edges and joints must be lightly screeded with a hand squeegee to achieve a smooth uniform appearance and to remove excess build-up of material.

(8) Shape and levels

Where a correction and wearing course have been placed, the finished surface level may not vary from the design level at any point by more than ±10mm. Additionally immediately adjacent to any kerb and/or gutter the finished surface level is not be below nor more than 10mm above the level of the lip of the adjacent gutter.

Notwithstanding the above, the deviation from a 3m long straight edge placed anywhere on the top of the finished surface may not exceed 10mm when assessed within 24 hours of work completion.

(9) Non-conformance of materials and finished surfacing

If any materials supplied fail to conform to the requirements in this sub-section or if any section of bituminous microsurfacing fails to conform to the requirements of this sub-section - whether failure of the work is due to bad workmanship, defective materials supplied by the Contractor or materials made defective by the method of operation adopted - then such failure or failures will constitute a “Notice of Non Conformance”. Such non-conforming sections of bituminous microsurfacing work must be either replaced or corrected.

The rectification of nonconformances, including any restoration work to any underlying or adjacent surface or structure, which becomes necessary as a result of such replacement or correction, is the Contractor’s responsibility. Materials removed from the site by the Contractor must be replaced with materials which conform to this sub-section.

(10) Control of traffic

The Contractor must provide for traffic in accordance with the requirements of sub-section SC6.4.6.30 Control of traffic while undertaking the work and must take all necessary precautions to protect the work from damage until such time as the new work has developed sufficient strength to carry normal traffic without damage.

The Contractor must take all necessary steps to avoid or minimise delays and inconvenience to road users during the course of the work. Where adequate detours or side tracks are included in the Contract or are otherwise available, traffic must be temporarily diverted while the work is in progress.

SC6.4.6.17.5 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.17.5 below.

Table SC6.4.6.17.5 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Spec Clause
1.	**Mineral Aggregate**	As per Table SC6.4.6.17.1	SC6.4.6.17.2(3)
2.	**Combined Aggregate/filler**	As per Table SC6.4.6.17.2	SC6.4.6.17.2(3)
3.	**Mineral Filler**	> 85% passing a 75 µm Sieve	SC6.4.6.17.2(4)
4.	**Mix Properties**		
	(a) Design properties	As per Table SC6.4.6.17.3	SC6.4.6.17.3(1)
	(b) Permitted variations	As per Table SC6.4.6.17.4	SC6.4.6.17.4(1)
5.	**Surface Preparation**	Sweeping must extend at least 300mm beyond edge of area to be surfaced	SC6.4.6.17.4(3)
6.	**Weather Limitations**	Microsurfacing must not commence if either air or pavement temperature is below 10°C and falling, and may only commence if both air and surface temperature is above 7°C and rising or above 10°C	SC6.4.6.17.4)4)
7.	**Shape and Levels**		
	(a) Finished Levels	Must not vary at any point by more than ± 10mm from design levels. Immediately adjacent to kerb and/or gutters, levels must not be below nor more than 10mm above design level	SC6.4.6.17.4(8)
	(b) Finished Shape	Deviation from the bottom of a 3m straight edge must not vary by more than 10mm	SC6.4.6.17.4(8)

SC6.4.6.18 Segmental paving

SC6.4.6.18.1 Introduction

(1) Scope

(a) This sub-section covers the construction of both clay and concrete segmental paving for road pavements, medians, traffic islands, driveways, cycleways, footpaths and other pedestrian areas.

(b) The work covered under this sub-section consists of the supply, placement and compaction of segmental pavers including the provision of a sand or crusher dust bedding course and joint filling sand, over bound or unbound base and/or subbase layer/s.

(c) This sub-section should be read in conjunction with the appropriate specifications for the construction of the base and subbase layers beneath the segmental paving, ie. SC6.4.6.12 Flexible pavements, SC6.4.6.14 Mass concrete subbase.

(d) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note - A reference to drawings is a reference to construction drawings.

(2) Choice of paver type, shape, class and laying pattern

(a) The choice of concrete or clay segmental pavers, the paver class (for clay pavers), shape type (for concrete pavers), shape name, colour, thickness and laying pattern must be as per decision requirement for each area of application.

(b) Unless otherwise specified, concrete pavers for road pavements must be placed in herringbone laying pattern and must be in accordance with the requirements for the appropriate road application shown in Table SC6.4.6.18.1.

(c) Unless otherwise specified, clay pavers for road pavements must be Class 4, minimum 65 mm nominal thickness, and placed in a herringbone laying pattern.

(d) Paving for cycleways and other pedestrian areas must be carried out in accordance with SC6.4.3.3 Footpath treatment and SC6.4.4.7 Pathways and cycleways.

(e) Paving for road pavements, medians and traffic islands must be carried out in accordance with SC6.4.4.1 Geometric road design and SC6.4.4.2 Pavement design.

(f) Paving for driveways must be carried out in accordance with SC6.4.3.5 Driveways and SC6.4.4.8 Standard drawings.

(3) Terminology

Concrete segmental pavers are units of not more than 0.1sqm in gross plan area, manufactured from concrete, with plain or dentated sides, with top and bottom faces parallel and with or without chamfered edges. Concrete pavers are identified by shape as being one of the following types:

(a) **Shape Type A** - Dentated chamfered units which key into each other on four sides, are capable of being laid in herringbone bond, and by their plan geometry, when interlocked, resist the spread of joints parallel to both the longitudinal and transverse axes of the units; or

(b) **Shape Type B** - Dentated units which key into each other on two sides, are not (usually) laid in herringbone bond, and by their plan geometry, when keyed together, resist the spread of joints parallel to the longitudinal axes of the units and rely on their dimensional accuracy and accuracy of laying to interlock on the other faces; or

(c) **Shape Type C** - Units which do not key together and which rely on their dimensional accuracy and accuracy of laying to develop interlock.

Clay pavers are manufactured from clay, shale or argillaceous materials which may be mixed with additives. Clay pavers may have square, bevelled (chamfered), rounded or rumbled edges. They are generally rectangular in shape, with the length twice the width, plus 2mm.

Laying patterns of pavers are identified as being either Herringbone, Basket-weave, or Stretcher as shown in SC6.4.6.18 Attachment A Laying patterns. Each of these may be laid at either 90º or 45º to the line of edge restraints. A variation of Stretcher is the Zig Zag Running Bond, also shown in SC6.4.6.18 Attachment A.

(4) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.9 - Open drains kerb and channel
SC6.4.6.10 - Earthworks (construction)
SC6.4.6.12 - Flexible pavements
SC6.4.6.14 - Mass concrete subbase
SC6.4.6.19 - Stabilisation
SC6.4.6.28 - Minor concrete works.

(b) Australian Standards:
AS1141.11.1 - *Particle size distribution - Sieving method*
AS/NZS4455 - *Masonry units, pavers, flags and segmental retaining wall units*
AS/NZS4456.0 - *Methods of test - General introduction and list of methods*
AS/NZS4456.3 – *Methods of test - Determining dimensions*
AS/NZS4456.5 – *Methods of test - Determining the breaking load of segmental pavers and flags*
AS/NZS4456.9 – *Methods of test - Determining abrasion resistance*
AS/NZS4586 - *Slip resistance classification of new pedestrian surface materials.*

(c) Concrete Masonry Association of Australia specifications:

CMAA T46-1997 - *Concrete segmental pavements - Detailing guide.*

(d) Clay Brick and Paver Institute specification:
CBPI Manual 1: 2003 - *Clay Paving Design and Construction.*

SC6.4.6.18.2 Materials

(1) General

(a) The Contractor must submit details of all proposed segmental paving materials, including bedding sand or crusher dust and joint filling sand. These details must be submitted to the Superintendent for approval supported with test results from a nominated NATA registered laboratory, confirming that the constituents comply with the requirements of this sub-section.

(b) No pavers may be delivered until the Superintendent has approved the type and quality of the pavers and noted the source of supply as compliant to the requirements of this sub-section.

(c) All pavers must have suitable “slip resistance” for pedestrian traffic and vehicular traffic with a classification “W” according to AS/NZS4586 for the Wet Pendulum Test. Where specific localities or levels of usage require a higher slip resistance classification, this classification must be indicated on the drawings. Such approval does not relieve the Contractor of any responsibility for supplying materials that comply with this sub-section.

(2) Concrete segmental pavers

(a) Concrete segmental pavers must comply with the requirements of relevant Concrete Masonry Association of Australia Specifications and AS/NZS4455 for each area of application.

(b) The material requirements for concrete pavers for each application, derived from CMAA MA57-2010 *Concrete segmental and flag pavements - guide to specifying*, are shown in Table SC6.4.6.18.1.

Table SC6.4.6.18.1 Material requirements for concrete segmental pavers

* At 28 days

† At 90 days

** where cleaning of pavers and flags is undertaken by mechanical means or where prevention of vehicle entry cannot be guaranteed, the minimum recommended pavers and flags are the 'Pedestrian and light vehicles only' for such pavement applications.

§ No abrasion criteria are specified for residential pavers. Abrasion resistance requirements for aesthetic or other purposes must be specified to the supplier/manufacturer.

NA Not applicable.

* Shape Type A pavers – dentated pavers that key into each other and by their plan generally interlock and resist relative movement of joints parallel to both the longitudinal and transverse axes of the pavers.
Examples of Type A shapes

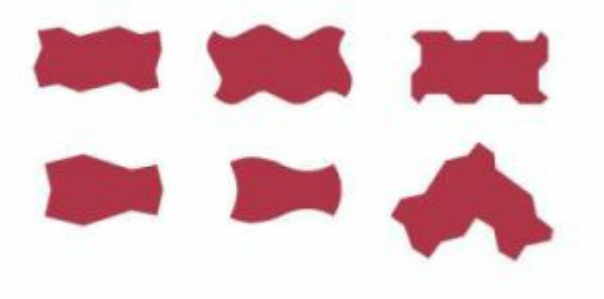

Table SC6.4.6.18.2 Maximum dimensional deviations determined by individual measurement

Category	Work Size dimensions, mm			
	Plan		Height	
	Standard deviation	Mean	Standard deviation	Mean
DP0	No requirement			
DPB1	2.0	± 3.0	3.0	± 2.5
DPB2	2.0	± 2.5	3.0	± 2.0
DPB3	Values declared by the supplier or by agreement between supplier and purchaser			
DPB4	1.5	± 2.0	2.0	± 2.0

Source: CMAA MA57-2010 Concrete segmental and flag pavements - guide to specifying - Table 2: Maximum Dimensional Deviations Determined for Pavers and Flags by Individual Measurement).

Note—all paving units will be categorised in accordance with AS/NZS4455.3 Method for Determining Dimensions.

(3) Clay segmental pavers
Clay segmental pavers must comply with the requirements of CBPI Manual 1:, *Clay paving design and construction* (chapter 3, Specifying clay pavers), and with the requirements of AS/NZS4455.

(4) Bedding sand or crusher dust

(a) The bedding material must be well-graded, consisting of clean, hard, uncoated grains uniform in quality, generally passing a 4.75 mm sieve. The bedding material must be from a single source or blended to achieve, when tested in accordance with AS1141.11, the following grading:

AS Sieve	**% Passing**
9.52mm	**100**
4.75	**95 - 100**
2.36	**80 - 100**
1.18	**50 - 85**

600µm	**25 - 60**
300	**10 - 30**
150	**5 - 15**
75	**0 - 10**

(b) The material must be of uniform moisture content when spread. It must be covered when stored on site to protect it from rain penetration.

(c) The bedding material must be free of deleterious soluble salts or other contaminants which may cause, or contribute to, efflorescence.

(5) Joint filling sand

(a) The joint filling sand must be well graded passing a 2.36mm sieve, and when tested in accordance with AS1141.11, having the following grading:

AS Sieve	**% Passing**
2.36mm	**100**
1.18	**90 - 100**
600µm	**60 - 90**
300	**30 - 60**
150	**15 - 30**
75	**5 - 10**

(b) The sand must be dry when spread. It must be covered when stored on site to protect it from rain penetration.

(c) The sand must be free of deleterious soluble salts or other contaminants.

(d) Material used for bedding is not suitable for joint filling.

(6) Concrete for edge restraints

(a) Concrete supplied and placed for the construction of edge strips must comply with sub-section SC6.4.6.28 Minor concrete works.

(b) Unless otherwise indicated on the drawings, or where the edge restraint is provided by kerb and/or gutter, the concrete used for edge restraints must have a minimum 28 day characteristic compressive strength of 32MPa for edge restraints to pavers on road pavements and 25MPa for edge restraints to pavers on footpaths, cycleways, medians and driveways.

SC6.4.6.18.3 Construction

(1) Subgrade preparation

(a) The subgrade must be formed to the required depth below finished surface level as shown on the drawings in accordance with SC6.4.6.10 Earthworks (construction).

(b) The finished subgrade foundation for the provision of subbase and/or base is subject to the approval of the Superintendent.

(2) Subbase

(a) As shown on the drawings, a subbase or working platform must be constructed in accordance with SC6.4.6.14.10 Subgrade Beams.

(b) The subbase must be constructed to the specified thickness, compaction and depth below finished surface level and to the design grade and crossfalls of the finished surface.

(c) The finished subbase is subject to the approval of the Superintendent.

(3) Base

(a) The base must be constructed to the specified thickness and depth below finished surface level, and to the design grade and crossfalls of the finished surface, as shown on the drawings in accordance with sub-section SC6.4.6.12 Flexible pavements.

(b) The base course must extend in width to at least the rear face of all new edge restraints.

(c) Notwithstanding the finished level tolerances contained within sub-section SC6.4.6.12 Flexible pavements for base of ±10mm of design levels, the level on the finished surface of the base course for road pavements to be overlain with segmental paving must be trimmed to within + 10mm or – 0mm of design levels. The deviation from a 3m long straight edge placed anywhere and laid in any direction on the top surface of the base course for all segmental paving must not exceed 10mm. Bedding material must not be used as a levelling material to compensate for base finishing outside the above tolerances.

(d) The finished surface of the base must drain freely without ponding.

(e) The finished base is subject to the approval of the Superintendent.

(4) Edge restraints

(a) Edge restraints in the form of kerb and/or gutter or edge strips must be constructed along the perimeter of all segmental paving as shown on the drawings. Concrete kerb and/or gutter and edge strips must be constructed in accordance with sub-section SC6.4.6.9 Open drains and SC6.4.6.28 Minor concrete works.

(b) Faces of edge restraints abutting pavers must be vertical.

(c) Edge restraints must be supported on compacted base and/or subbase of the thickness as shown on the drawings. Where not otherwise specified or indicated, the minimum thickness of compacted base beneath the edge restraints must be 100mm adjacent to road pavements and medians, and 50mm adjacent to footpaths, cycleways and driveways.

(d) Unless otherwise shown on the drawings, contraction joints, 20mm depth must be formed every 5m of edge restraint length.

(e) After the concrete has hardened and not earlier than 3 days after placing, unless otherwise directed by the Superintendent the spaces at the back of the edge restraint must be backfilled with earth, compacted in layers not greater than 150mm thick, then topsoiled to meet surrounding design levels.

(5) Bedding

(a) The bedding course must be spread in a single uniform layer and screeded in a loose condition to the nominated design profile and level. The bedding course must be laid such that a uniformly thick nominal 20-25mm layer is achieved following final compaction of the segmental paving.

(b) Any depressions in the screeding material exceeding 5mm must be loosened, raked and rescreeded before laying pavers.

(c) For the manual placing of paving units, the bedding material must be maintained at a uniform loose density. For mechanised laying, the bedding material must be uniformly and firmly, but not fully, compacted.

(d) Screeded material left overnight of subject to rain must be checked for level and rescreeded where necessary before pavers are placed. The material must not be screeded more than 2m in advance of the laying face at the completion of work on any day.

(6) Laying pavers

(a) Pavers must be uniformly placed on the screeded bedding to the nominated laying pattern. Pavers must be placed so that they are not in direct contact with each other and must have uniform 3mm nominal joint widths. The pavers must be mixed between various pallets to ensure that any colour variation from one pallet of pavers to the next is evenly distributed over the entire paved area.

(b) The first row must be located next to an edge restraint or an established straight line, and laid at a suitable angle to achieve the required orientation of pavers in the completed pavement.

(c) In each row, full units must be laid first. Edge or closer units must be neatly cut using a paver scour, or mechanical or hydraulic guillotine, and fitted subsequently. Cut pieces of pavers which are smaller in

size than one quarter of a full block must not be used.

(d) Access chambers, drainage gullies and similar penetrations through the pavement must be finished against the paving with a concrete surround or apron designed to suit and fit the laying pattern, otherwise complying with the requirements for edge restraints.

(e) Where pavers are placed over an isolation, contraction or expansion joint in an underlying concrete pavement, a joint must be provided in the pavers. The joint must consist of 10mm thick preformed jointing material of bituminous fibreboard.

(f) Any foot or barrow traffic must use boards overlaying paving to prevent disturbance of units prior to compaction. No other construction traffic is allowed on the pavement prior to compaction and provision of joint filling sand.

(g) On completion of subsequent bedding compaction and joint filling operations, all joints must have widths within the range 2-4mm.

(7) Bedding compaction

(a) After laying the pavers the bedding must be fully compacted and the surface brought to design levels and surface profiles by not less than two passes of a high frequency low amplitude plate compactor which covers at least 12 units. Compaction must continue until all pavers form a smooth surface with adjacent paver edges matching. The level difference between adjoining edges of any two pavers must be a maximum of 2mm, to avoid trip hazards, unless approved otherwise by the Superintendent for rough textured pavers.

(b) Any units which are structurally damaged during bedding compaction must be removed and replaced. The pavement must then be recompacted for at least 1m surrounding each replacement unit.

(c) The paving operations must be arranged so that the use of the plate compactor proceeds progressively behind the laying face without undue delay, and such that compaction is completed prior to cessation of construction activity on any day. Compaction must not be attempted within 1m of the laying face except on completion of the pavement against an edge restraint.

(d) The finished surface level must not vary from the design level at any point laid in any direction, by more than 6mm for all areas with Class 4 segmental pavements and 8mm for all other areas of segmental paving. Notwithstanding this, the finished surface of the segmental paving, including where the paving abuts an edge restraint other than a drainage inlet, must not deviate from the bottom of a 3m straight edge laid in any direction, except at grade changes, by more than 6mm for road pavements and 8mm for all other areas of segmental paving.

(e) The channels formed between abutting chamfered units must finish with their inverts not less than 5mm nor more than 10mm above adjacent drainage inlets.

(f) All compaction must be complete and the pavement must be brought to design profiles before spreading or placing sand filling in the joints.

(8) Filling joints

(a) As soon as practicable after bedding compaction, and in any case prior to termination of work on any day, dry sand for joint filling must be spread over the pavement and the joints filled by brooming.

(b) To ensure complete filling of the joints, both the filling sand and pavers must be as dry as practicable when sand is spread and broomed into the joints.

(c) The pavement must then receive one or more passes of a plate compactor and the joints then refilled with sand, with the process then repeated sufficiently to ensure that the joints are completely filled.

(9) Protection of work

Other than wheeled trolleys, forklifts and cluster-clamp vehicles, construction and other traffic may not use the pavement until bedding compaction and joint filling operations have been completed.

(10) Opening to traffic

(a) As soon as practicable after the filling of joints, construction vehicles may use the pavement, and should

be encouraged to traverse the greatest possible area of pavement to assist in the development of "lock-up".

(b) Excess joint filling sand must be removed prior to opening to traffic.

(c) The pavement must then be inspected by the Contractor at regular intervals up until the expiration of the defects liability period to ensure that all joints remain completely filled.

SC6.4.6.18.4 Limits and tolerances

The limits and tolerances applicable to the various clauses in this Specification are summarised in Table SC6.4.6.18.3 below:

Table SC6.4.6.18.3 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Base**		
	(a) Surface Level	Finished level of base for road pavements to be within +10mm or -0mm of design levels.	SC6.4.6.18.3(3)
		Finished level of base other than for road pavements, to be within ±10mm of design levels.	SC6.4.6.18.3(3)
		The top surface of the base for all segmental paving must not deviate from a 3m straight edge, laid in any direction, by more than 10mm.	SC6.4.6.18.3(3)
2.	**Laying Paving Units**		
	(a) Joint widths	Within the range 2 -4mm.	SC6.4.6.18.3(6)
3.	**Completed Segmental Paving** (a) Surface level	Finished surface level of pavers must not vary from design levels by more than ±6mm for road pavements and ±8mm for other than road pavements.	SC6.4.6.18.3(7)
		Finished surface of pavers must not deviate from a 3m straight edge, laid in any direction, by more than 6mm for road pavements and 8mm for other than road pavements.	SC6.4.6.18.3(7)
	(b) Level adjacent to drainage inlets	Invert level of channels between abutting chamfered units must be not less than 5mm and not more than 10mm above the level of adjacent drainage inlets.	SC6.4.6.18.3(7)
	(c) Difference in level of adjacent pavers	≤2mm	SC6.4.6.18.3(7)

SC6.4.6.19 Stabilisation

SC6.4.6.19.1 Introduction

(1) Scope

This sub-section identifies the materials requirements for stabilised materials provided by stationary plant production as well as materials and process requirements for in-situ stabilisation.

The work to be executed under this sub-section consists of the supply and incorporation of stabilising binders with material in a nominated pavement course or subgrade layer (including materials for the selected material zone, and selected backfill), at specified locations in the work and the spreading, compaction, trimming and curing of such materials.

This sub-section provides the requirements for stabilisation of the types of pavement courses and subgrade zones or layers as shown in Table SC6.4.6.19.1.

Table SC6.4.6.19.1 Types of pavement courses, subgrade zones or layers and stabilising binder

Pavement Course Or Subgrade Zone Or Layer	Stabilising Binder
PAVEMENT COURSE	
Base and Subbase	Cement Blended Stabilising Agent Hydrated Lime (pugmill) Quicklime (in-situ) Foam bitumen (MRTS07C)
SUBGRADE ZONE OR LAYER	
Selected Material Zone	Cement Blended Stabilising Agent Quicklime (in-situ) Hydrated Lime (pugmill)
Other Subgrade Layers	Cement Blended Stabilising Agent Quicklime (in-situ) Hydrated Lime (pugmill)
Selected Backfill Zone	Cement Hydrated Lime (pugmill)

The pavement course or subgrade zone or layer to be stabilised shall be as specified in sub section SC6.4.6.12 Flexible pavements, or as indicated on the drawings.
Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) The Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section one as follows:
SC6.4.6.4 Stormwater drainage
SC6.4.6.10 – Earthworks (construction)
SC6.4.6.12 - Flexible pavements
SC6.4.6.30 - Control of traffic

(b) Australian Standards:

NSW Roads and Maritime Services Test Methods

Test method T432: Rate of slaking of quicklime, 2012

SC6.4.6.19.2 Inspection, sampling and testing

(1) Pre-construction compliance

The Contractor shall provide a certificate from a laboratory with appropriate NATA registration stating that the stabilisation mix(es) submitted and the mix constituents comply with the mix nominated in approved stabilisation mix design approved as part of the pavement design and that the stabilised material meets the requirements of sub section SC6.4.6.12 Flexible pavements if incorporated into the works as a pavement layer or alternatively SC6.4.6.10 Earthworks (construction) or SC6.4.6.4 Stormwater drainage.

(2) Construction compliance

Regular inspection, sampling and testing of pavement and subgrade materials shall be undertaken by the Contractor while stabilisation is in progress in accordance with this sub section.

SC6.4.6.19.3 Materials

(1) Unsuitable materials and shape correction

These shall be with unbound gravel of Type 1, Type 2, Type 3 or Type 4 in accordance with SC6.4.6.10 and SC6.4.6.12 New material shall not have a water soluble sulphate content exceeding 1.9 grams of sulphate per litre.

(2) Cement and stablising agent

The type of cement used as the stabilising agent or a constituent in a blended stabilising agent shall comply with AS3972.

Documentary evidence of the quality and source of the cement shall be furnished by the Contractor to the Superintendent upon request at any time.

If the Contractor proposes to use cement which has been stored for a period in excess of 3 months from the time of manufacture, the Contractor shall arrange a re-test, to ensure the cement still complies with AS3972, before the cement is used in the work. Test results shall be forwarded to the Superintendent for approval at least 2 days in advance of usage of the material.

The Contractor shall order gravel material with the cement content required to achieve the designed unconfined compressive strength (UCS) of the pavement. It is the Contractor's responsibility to ensure the material being used achieves the required UCS.

(3) Quicklime stabilising agent
Quicklime, consisting essentially of calcium oxide in a highly reactive form, shall have the following properties at the point of spread:

(a) available lime - the content of calcium oxide, determined by AS4489.6.1, shall not be less than 85%. Unless otherwise specified, the spread rate for quick lime shall be 20kg/m^3; and

(b) slaking rate - the active slaking time shall not be greater than 20 minutes and the temperature rise on slaking, determined from the average of four samples tested in accordance with Test Method T432, shall not be less than 40°C in 6 minutes.

The particle size distribution of the quick lime determined by AS1141.11 shall comply with the following requirements in Table SC6.4.6.19.2.

Table SC6.4.6.19.2 Particle size distribution of quicklime

AS Sieve	Per Cent Passing
13.2mm	100
9.5mm	96 - 100
4.75mm	70 - 100
2.36mm	0 - 90

(4) Hydrated lime stabilising agent

(a) Hydrated lime, consisting essentially of calcium hydroxide, whether used as the sole stabilising agent or blended with other additives, shall have the following properties:

(i) available lime - the content of calcium hydroxide, determined by AS 3583.12, shall not be less than 80%;

(ii) form - the material shall be in a dry powder form; and

(iii) residue on sieving - the residue on a 300 micron sieve, determined by (Particle Size) AS3583.14, shall not exceed 2%.

(b) The properties which characterise the particular hydrated lime to be used in the stabilising agent submitted as part of the mix design are:

(i) percentage of calcium hydroxide;

(ii) fineness percentage by mass passing the 45 micron sieve (AS 2350.9); and

(iii) source.

(5) Ground granulated blast furnace slag stabilising agent
The ground granulated blast furnace slag shall conform to AS3582.2.
The properties which characterise the particular ground blast furnace slag to be used in the stabilising agent submitted as part of the mix design are:

(a) fineness percentage by mass passing the 45 micron sieve (AS2350.9);

(b) relative strength (28 days) (AS3583.6); and

(c) source.

(6) Flyash stabilising agent
Flyash shall conform to AS3582.1.

The properties which characterise the particular flyash to be used in the stabilising agent submitted as part of the mix design are:

(a) fineness - percentage by mass passing the 45 micron sieve (AS2350.9);

(b) loss on ignition (AS3583.3); and

(c) source.

(7) Blended stabilising agents

The Contractor may utilise a blended stabilising agent. The Contractor shall obtain mill and batch information which will make the blended stabilising agent traceable to the supplier's test results.

Handling and storage requirements of the Supplier shall be complied with by the Contractor who shall also arrange for sampling of the agent as required by the Superintendent.

The mass of components of the nominated blended stabilising agent shall not vary by more than ± 3% from the blend percentages nominated in the mix design described in approved stabilisation mix design.

When a blended stabilising agent is produced from a combined grinding of components the following properties will characterise the particular stabilising agent blend:

(a) source of each component;

(b) fineness percentage by mass passing the 45 micron sieve (AS2350.9); and

(c) setting time (AS2350.4).

(8) Water (for curing)

Water shall be free from harmful amounts of materials such as oils, salts, acids, alkalis and vegetable substances. The water shall not contain more than:

(a) 600 parts per million of chloride ion, determined by AS3583.13;

(b) 400 parts per million of sulphate ion, determined by AS1289.4.2.1; and

(c) 1% by mass of undissolved solids.

Water accepted as potable and fit for human consumption will not require testing to confirm suitability.

(9) Foam bitumen

In accordance with MRTS07C.

SC6.4.6.19.4 Stabilisation processes

(1) General

The Contractor shall submit details of the proposed equipment (including the mixing plant) and stabilisation procedures to be used in the work 14 days prior to commencement of the work. This submission, hereafter called the work plan, is to include the following:

(a) the sequence of operations;

(b) widths of stabilisation passes;

(c) provision for traffic if appropriate;

(d) comply with statutory requirements for WHS;

(e) testing methods and frequency;

(f) comply with this specification;

(g) survey control methods; and

(h) curing methods.

Notwithstanding submission to the Superintendent of the Contractor's equipment and stabilisation procedures, the work shall meet all the sub-section requirements, and statutory requirements for work health and safety, and the Contractor shall perform such tests as specified as the work proceeds, to ensure compliance.

Stabilisation of pavement materials shall not proceed during wet weather or if rain is imminent and likely to occur during any stage of the stabilisation process so as to significantly influence the resultant moisture content and uniformity of moisture content in the mix.

(2) Application of stabilising agent

(a) Stationary mixing plant

Application rate of stabilising agent shall be monitored at the pug mill or equivalent plant utilised as approved by the Superintendent.

Application rate measured in kg/t of product shall be monitored and recorded for every 100t of production.

The achieved accuracy of application rate shall be ±10% of the nominated rate nominated in approved pavement design's stabilisation mix design.

The application rate shall not be allowed to exceed the nominated rate by more than 10%.

(b) In-situ

For environmental reasons in urban areas the incorporation of stabilising agent is to be a closed system process where stabilising agent is added and mixed into the pavement within the bowl of the specialist mixing equipment.

Where approved in rural areas spreading shall be carried out using the mechanical spreader nominated in the work plan and subsequently approved by the Superintendent. The approved pavement design's stabilisation mix design nominates the spread rate.

The actual spread rate shall be within ±10% of the nominated rate. The Contractor shall verify this by testing the spread rate for each lot or 500m^2 of pavement treated (whichever is less) in each application of binder. Spread rate testing shall be performed by weighing the contents of a suitable four sided tray placed on the pavement and between the wheels of the closed system stabiliser. The rate of stabilising agent spread shall be calculated by dividing the mass collected (kg) by the area of the tray (m^2).

Where spreading/stabilising vehicles are fitted with load cells, the Contractor shall ascertain the average spreading rate of the stabilising agent by dividing the mass of the stabilising agent spread per run by the area of the run. The Contractor shall record this data for each run and make it available to the Superintendent promptly. Such action will not cancel the Contractor's obligation to undertake prescribed testing of spread rate if required by the Superintendent.

Spreading shall not proceed during windy conditions which may cause loss of stabilising agent or cause nuisance or danger to people or property. Where open spreading is approved.

Traffic or equipment not involved in spreading or mixing of the stabilising agent shall not pass over the spread material until it has been mixed into the layer to be stabilised. Where open spreading is approved.

Any spillage of the stabilising agent on site or at any loading location related to the site shall be removed as soon as possible and within the same work shift of such spillage.

(3) Mixing

(a) Stationary mixing plant

The stationary mixing plant shall be purpose built for the process of mixing road making materials. All equipment shall be maintained and calibrated so as to provide a uniformly mixed product without segregation of the aggregate material.

The plant shall provide for the controlled and metered inclusion of water into the mix.

The stationary mixing equipment shall incorporate a delivery system for mix materials capable of producing a uniform mixture to design requirements. This performance shall be confirmed by monitoring of unconfined compressive strength of production, in accordance with AS1289.6.1.1, with a pair of test specimens tested for each 100 tonnes of production.

(b) In-situ

Mixing equipment shall be purpose built for the process of in-situ mixing of road making materials. It shall be capable of mixing to the depth specified for the layer to be stabilised and of distributing the stabilising agent uniformly through the full depth and over the whole area of the layer to be stabilised. Where directed a minimum of two passes of the mixing equipment is required. As mixing blades or tynes wear they shall be replaced so as to maintain mixing efficiency consistent with that demonstrated during the trial section. The mixing equipment will be capable of supplying a calibrated amount of water to the mixing bowl in such a manner as to provide a uniformly moist mix to a target moisture content.

The resultant mix shall be uniform over the full depth so that there are no lenses, pockets, lumps or granules of stabilising agent present in the layer or adjacent to it.

The procedure nominated in the Work Plan shall minimise disturbance of the distribution of stabilising agent spread in advance of the mixing process.

The Contractor shall carry out visual inspections during mixing to ensure uniform mixing is being achieved in the layer. Inspection results shall be recorded as cited in SC6.4.5 Construction management.

The Superintendent may require that additional passes by the mixing equipment be carried out to improve the visual uniformity of the mix and/or the moisture content.

(c) Paving equipment

For plant-mixed stabilising pavements, the mixture shall be placed by self-propelled paving machine purpose built for this work and with the capacity to place and spread the mixture in one pass at the required uncompacted thickness, width and shape. Other methods of paving may be considered by council where the use of a self-propelled paving machine is impractical.

(4) Field working period (allowable working time)

The time period from addition of water during the mixing process until the completion of compaction is nominated as the field working period.

The nominated field working period shall be provided in Stabilisation Mix Design for the stabilising agent approved as part of the pavement design. The Nominated field working period shall be based on laboratory tests determining the time from mixing until such time as the calculated Wet Density for standard compaction procedures decreases by more than 2 percentage points. This testing shall be undertaken utilising AS 1289.5.1.1 and samples of the materials representative of those to be utilised in the works. If the field working period is not specified as part of the pavement design, the maximum period between the commencement of mixing and the completion of compaction and trimming shall be 3 hours.

The Contractor will complete the compaction process within the Nominated field working period unless specific approval is provided by the Superintendent to an adjustment for site and seasonal conditions.

(5) Trimming and compaction

After mixing the layer shall be trimmed and compacted in accordance with sub-section SC6.4.6.12 Flexible pavements to produce a tight dense surface parallel with the finished wearing surface so that the levels do not vary from the design levels beyond the tolerance for primary trimming specified in clause SC6.4.6.19.4(7)(a) Levels and surface trim.

Subsequent secondary trimming may be undertaken on one or more occasions in preparation for primer seal and with the objective of meeting shape and level requirements. Secondary trimming shall involve cutting to waste. Work methods that lead to the development of laminations in the pavement will not be allowed and surface slurrying will not be accepted. The Contractor's survey control methods as stated in the work plan will be adequate to ensure that the pavement layer thickness is not reduced during secondary trimming to an extent such that it fails to comply with the requirement for layer thickness in accordance with the tolerance specified in clause SC6.4.6.19.4(7)(b) Layer thickness. When required by the Superintendent survey results shall be provided to confirm that the pavement layer thickness remains within tolerance after secondary

trimming.

Measurements with a 3m straight edge shall be taken at a minimum of ten randomly selected stations so as to represent each 200m lane length or part thereof. Deviation of the surface from the bottom of a 3m straight edge placed in any direction will meet the tolerance shown in clause SC6.4.6.19.4(7)(a). This testing will be undertaken immediately prior to sealing or prior to agreed practical completion for any work component.

The stabilised layer shall be compacted over the entire area and depth so that the relative compaction determined by AS 1289.5.1.1 is not less than as detailed in sub-sections SC6.4.6.12 Flexible pavements, SC6.4.6.10 Earthworks (construction) or SC6.4.6.4 Stormwater drainage as appropriate.

To provide true relative compaction assessments the lots shall be sampled and tested within the nominated field working period in accordance with AS1289.5.1.1.

The maximum wet density (standard compaction) will be determined by sampling immediately after the determination of field density and testing will be undertaken within 2 hours of sampling. A determination of maximum wet density (standard compaction) representing the full layer depth is required for each sampling location when calculation of relative compaction is undertaken.

The field density may be determined by in situ sand replacement testing or by single probe Nuclear Density Meter in direct transmission mode in accordance with AS1289.5.8.1.

(6) Joints

Joints are defined in this sub-section to comprise interfaces between work episodes that are separated in time by more than the nominal field working period for the nominated stabilisation mix design. A longitudinal joint shall be considered to be a joint generally parallel to the road centreline. A transverse joint occurs when a length of work is terminated and extended at a later time after a period which exceeds the nominated field working period.

All longitudinal and transverse joints shall be formed by cutting back into the previously stabilised and fully compacted sections. A minimum longitudinal overlap of mixing runs shall be 75mm. Transverse joints shall be overlapped by a minimum of 2m. The material disturbed during cutting back shall be remixed at full depth and incorporated into the new work. No longitudinal joints shall be allowed within 500mm of the centreline of a typical wheelpath.

The level and shape of the joints shall be within the limits specified in clause SC6.4.6.19.4(7) Tolerances.

(7) Tolerances

(a) Levels and surface trim

The surface level after primary trimming shall be within a tolerance of +30mm and +10mm of the levels shown on the drawings.

The surface level after secondary trimming shall be within a tolerance of +15mm and -15mm of the levels shown on the drawings.

The pavement surface after secondary trimming and immediately prior to sealing shall be of a quality such that deviation under a 3m straight edge does not exceed 12mm.

Ensure the final surface level is within ± 15mm of the design levels in the event only a single trim is carried out.

(b) Layer thickness

The final thickness of the stabilised layer at any point shall be within a tolerance of +20mm and 10mm of the nominated layer thickness.

The average thickness of the layer in a lot shall be determined from measurements of six randomly selected locations over any 200m length of a lot. The average thickness shall not be less than that

required to meet the specified final thickness tolerances after trimming.

The layer thickness shall be measured at the edges of the stabilising run after compaction commences. The layer thickness shall be measured relative to the finished design level.

(c) Width
The width measured at any point of the stabilised layer shall be not less than the specified width as shown in the drawings by more than 50mm.

The average width of the layer shall be determined from measurements at three sites selected at random by the Superintendent over any 200m length of a lot and shall be not less than the specified width.

(8) Curing
The Contractor shall submit to the Superintendent details of the proposed method of curing as part of the Work Plan.

The stabilised work shall be protected against rapid drying out by keeping it continuously wet or damp during the period prior to the provision of a subsequent layer or the application of a prime or primer-seal.

Water curing shall consist of frequent light uniform spraying (using fine spray jets) that will not produce significant run off or flooding on sections of the area. Conventional spray bars and high pressure nozzles are not permitted. Slurrying of the surface or leaching of the stabilising agent shall be avoided.

Under this sub-section provision for curing up to the period indicated in the approved Stabilisation Mix Design shall be the responsibility of the Contractor.

(9) Trial section of stabilised earthworks
Prior to the commencement of works submit a trial section of stabilised earthworks to demonstrate the methods proposed to conform with this sub-section.

This trial section is constructed so that it may be incorporated in the finished work with a length of approximately 50m.

Construct the trial stabilisation using the materials, equipment and methods for placing and finishing the same as would be used for the entire stabilisation works. Demonstrate the methods proposed to be used for the construction of joints.

In the event of deficiencies in the stabilisation the trial section may not be approved. The method, equipment, materials and personnel will require to be reviewed and an explanation submitted. A further length of trial stabilisation may be requested. Non-conforming trial sections of stabilised earthworks must be removed to ensure preventing damage to the remaining stabilised earthworks and underlying materials. Dispose of the removed materials at an approved location.

(10) Insitu lime stabilisation of subgrade

Lime stabilisation of subgrade material shall be carried out as a two day operation to a minimum depth of 250mm, except for natural subgrades of CBR 0.5% where stabilisation depth shall be a minimum of 300mm. The stabilising agent shall be spread using a purpose built spreader and the stabilising agent and water shall be incorporated into the material using a reclaimer/stabiliser. Alternatively, a reclaimer/stabiliser with a calibrated integrated spreader/applicator may be used to incorporate the stabilising agent and water directly into the material to be stabilised. Where a reclaimer/stabiliser with calibrated integrated spreader/applicator is used, quicklime shall not be used as the stabilising agent.

Day 1: a single lime pass at a rate of up to half the required rate shall be applied. Where quicklime is spread over the subgrade, it shall be slaked in accordance with the requirements in this document. In situations where hydrated lime is used, slaking is not required mixing the stabilising agent into the soil. The hydrated lime or lime slurry formed from the slaking of quicklime shall then be mixed into the material in accordance with the

requirements in this document. The depth of mixing shall not exceed 90% of the specified stabilisation thickness. The material shall be lightly rolled to seal the surface prior to the completion of work on that particular day.

Day 2: after the overnight amelioration period, the balance of the required lime shall be spread in accordance with the requirements in this document. Where quicklime is spread over the subgrade, it shall be slaked in accordance with the requirements in this document. In situations where hydrated lime is used, slaking is not required before mixing the stabilising agent into the soil. The hydrated lime or lime slurry formed from the slaking of quicklime shall then be mixed into the material in accordance with the requirements in this document. Notwithstanding this, a minimum of two mixing passes shall be completed.

Lime shall be spread at a maximum spread rate of 12kg/m2. The number of passes shall be calculated to comply with this requirement. The stabilising agent shall be uniformly spread over the insitu material at a controlled rate (mass per unit area, kg/m2). The total rate of spread shall be such that the stabilising agent spread rate for the compacted material is within the specified tolerances. Once the stabilising agent has been spread, no traffic, other than the construction plant employed for the stabilisation work, shall travel over it. After each spreading run at least one mixing run, and trimming and/or compaction as required, shall be completed. Further mixing operations between spreading runs shall comply with requirements in this document.

Quicklime shall be slaked with sufficient water to allow complete hydration such that the material remains friable after slaking and no further exothermic reaction occurs when further water is added to the lime. All through traffic shall be stopped during any slaking operation.

The entire stabilisation process shall not proceed in any of the following situations:

- during rainfall;
- when rainfall appears to be imminent;
- during periods when the wind is strong enough to cause particles of the stabilising agent to become airborne;
- during conditions that may result in the work causing nuisance or danger to people, property, the environment, or livestock;
- when the pavement temperature, measured 50mm below the surface, drops below 10°C; and
- when the air temperature, measured in the shade exceeds 40°C.

SC6.4.6.19.5 Limits and tolerances

The limits and tolerances applicable to the various clauses of this sub-section are summarised in Table SC6.4.6.19.3 Summary of limits and tolerances below.

Table SC6.4.6.19.3 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	Quicklime		
	a) Available Lime	>85% Calcium Oxide content	SC6.4.6.19.3(3) Quicklime
	b) Slaking Rate	Active Slaking time < 20 minutes, and temperature rise on slaking not less than 40ºC in 6 minutes (for an average of four samples).	SC6.4.6.19.3(3) Quicklime
	c) Particle Distribution	Fraction passing AS Sieve: 100% for 13.2mm Sieve 96-100% for 9.5mm Sieve 70-100% for 4.75mm Sieve 0-90% for 2.36mm Sieve	SC6.4.6.19.3(3) Quicklime
2.	Hydrated Lime		
	a) Available Lime	>80% Calcium Hydroxide	SC6.4.6.19.3(4) Hydrated Lime
	b) Particle Size	<2% residue on a 300 micron Sieve	SC6.4.6.19.3(4) Hydrated Lime

Item	Activity	Limits/Tolerances	Clause
3.	Blended Stabilising Agents	Blend percentages shall not vary by more than ±3% from those nominated in SC6.4.6.19 Attachment A (Stabilisation mix design)	SC6.4.6.19.3(7) Blended Stabilising Agents
4.	Water		
	a) Chloride ion content	<600 PPM Chloride ion	SC6.4.6.19.3(8) Water
	b) Sulphate ion content	<400 PPM Sulphate ion	SC6.4.6.19.3(8) Water
	c) Undissolved solids	<1% by mass of undissolved solids	SC6.4.6.19.3(8) Water
5.	Application of Stabilising Agent		
	a) Spread Rate or Incorporation Rate for in-situ plant.	Actual spread rate shall be within ±10% of the nominated rate	SC6.4.6.19.4(2) Application of Stabilising Agent
6.	Trimming and Compaction		
	a) Surface Level	After primary trimming be within +30mm and +10mm of levels shown on drawings After secondary trimming be within ±15mm of levels shown on drawings	SC6.4.6.19.4(7)(a) Tolerances
	b) Layer Thickness	Final thickness of layers shall not vary more than +20mm and -10mm of required thickness	SC6.4.6.19.4(7)(b) Tolerances
	c) Shape	Shall not deviate more than 12mm under a 3m straight edge immediately prior to first sealing	SC6.4.6.19.4(7)(a) Tolerances
7.	Joints		
	a) Longitudinal Overlap	> 75mm overlap of mixing runs	SC6.4.6.19.4(6) Joints
	b) Transverse Overlap	> 2m overlap of transverse joints	SC6.4.6.19.4(6) Joints
	c) Longitudinal Joints	Shall not be allowed within 0.5m of the centreline of a typical wheelpath	SC6.4.6.19.4(6) Joints
8.	Width		
	a) Width of Stabilised Layer	At any point, the width shall be not less than 50mm short of the width shown on the drawings with an average width always greater than that shown on the drawings.	SC6.4.6.19.4(7)(c) Tolerances

SC6.4.6.19 Attachment A: Stabilisation mix design

SC6.4.6.20 Subsoil, foundation and pavement drains

SC6.4.6.20.1 Introduction

(1) Scope

(a) The work to be executed under this sub-section covers the excavation, bedding, installation and backfilling of subsoil, sub-pavement, intra pavement, edge and foundation drains.

(b) Subsoil and foundation drains shall be constructed where and as shown on the drawings or as directed by the Superintendent.

(c) This sub-section should be read in conjunction with SC6.4.6.21 Subsurface drainage.

(d) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Order of construction

(a) Subsoil and sub-pavement drains
Subsoil drains shall be constructed as soon as possible after necessary earthworks are completed in the area of the drain. Where stabilisation of the subgrade is required, subsoil drains shall be constructed after completion of stabilisation, except where excessive ground water is encountered, they may be constructed prior to stabilisation of the subgrade.

Where a selected material zone is specified and excessive ground water is encountered, subsoil drains may be installed in two stages as follows:

(i) Stage 1: standard subsoil drains installed below the base of the cutting prior to placement of select material in the selected material zone; and

(ii) Stage 2: extension of subsoil drain to top of the selected material zone after placement of selected material.

(b) Intra-pavement drains
Intra-pavement drains shall be constructed after the completion of the layer below the pervious pavement material or 40mm open graded asphaltic concrete subbase and preceding the construction of the subsequent layers.

(c) Edge drains
Edge drains shall be constructed after the construction of the rigid pavement and before the placement and compaction of verge material.

(d) Foundation drains
Foundation drains shall be constructed after completion of clearing and stripping operations, and preceding the commencement of embankment construction.

(3) Terminology

Subsoil drains	are intended for the drainage of ground water and/or the pavement in cuttings.
Sub-Pavement Drains	are intended for the drainage of the pavement layers unless the subbase is open graded or pervious in nature in which case intra-pavement drains shall be provided.
Intra-Pavement Drains	are intended for the drainage of the pavement layers of a flexible pavement where the subbase comprises an open graded or pervious pavement material or open graded asphaltic concrete.
Edge Drains	are intended for the drainage of rigid pavements.
Foundation drains	are required for the drainage of seepage, springs and wet areas within and adjacent to the foundations.

(4) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with

this sub-section are as follows:
SC6.4.6.10 Earthworks (construction)
SC6.4.6.12 Flexible pavements
SC6.4.6.13 Asphaltic concrete
SC6.4.6.21 Subsurface drainage

(b) Australian Standards:

AS 1289.3.3.1	*Calculation of the plasticity index of a soil*
AS 1289.5.4.1	*Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS 1477	*PVC pipes and fittings for pressure applications*
AS 1289.5.6.1	(R2016) Methods of testing soils for engineering purposes Soil compaction and density tests - Compaction control test - Density index method for a cohesionless material

SC6.4.6.20.2 Construction

(1) Subsoil and sub-pavement drains

(a) Excavation

(i) Excavation shall be undertaken in accordance with the requirement of SC6.4.6.21 Subsurface drainage.

(ii) Trenches shall be trimmed to the required line and depth in accordance with the approved drain design specific to site conditions and as directed by the Superintendent.

(iii) The bottom of the trench shall be excavated to the same grade as the design pavement surface in the direction of the trench except where the grade of the design pavement surface in the direction of the trench is less than 0.25 per cent. In this case, the trench depth shall be increased to provide a minimum grade of fall in the trench of 0.25 per cent.

(iv) The bottom of the trench shall be excavated so that no localised ponding of water occurs. The bottom of the trench must not be more than 50 mm below the specified level of the invert of the pipe and ensure that the bottom and sides of the excavation are smooth with no protrusion that will damage the geotextile where required.

(v) If at any location the trench is excavated below the specified floor level, the trench shall be backfilled with non-porous subgrade material so that when the subgrade material is compacted to a relative compaction, determined by AS 1289.5.4.1, of at least 95 per cent (standard compaction), the bottom of the trench shall be at the specified floor level.

(vi) Where the drain is constructed in two stages, the excavation for Stage 2 shall be carried out after placement and compaction of the selected material zone or the stabilised subgrade layer. The Stage 2 trench shall be excavated to the same line and width as the Stage 1 trench and to a depth to provide a clean, full contact with the filter material placed in Stage 1. All excavated material shall be disposed to waste or incorporated into fills.

(vii) After the completion of excavation, the Contractor must present to the Superintendent the trench for inspection to ensure conformance with shape, grade line, filling and compaction and removal of any protrusions.

(b) Laying of pipe

(i) The 100mm diameter corrugated slotted plastic piping, complying with SC6.4.6.21 Subsurface drainage, shall be laid on a bed of filter material 50mm in thickness and shall be laid to the specified line and grade. The pipe shall not deviate from the specified line by more than 100mm at any point

(ii) The type of filter material shall be shown on the drawings as per the requirements of SC6.4.6.21 Subsurface drainage and shall be confirmed by the Superintendent prior to placement of material.

(iii) Joints in the pipeline shall be kept to the minimum number and, where required, shall be made using a suitable external joint coupling. The inlet end of the pipe shall be fitted with a cap.

(c) Backfilling

(i) The trench shall be backfilled with filter material to the level specified. The type of filter material shall be shown on the drawings as per the requirements of SC6.4.6.21 Subsurface drainage and shall be confirmed by the Superintendent prior to placement. The filter material shall be placed and

compacted in layers with a maximum compacted thickness of 300 mm. Tamping around and over the pipe shall be done in such a manner as to avoid damage or disturbance to the pipe.

(ii) The filter material shall be compacted for its full depth to a Density Index of not less than 70 per cent as determined by AS 1289.5.6.1.

(iii) The upper section of the trench, above the level specified for filter material backfill, shall be backfilled with selected free draining backfill material, conforming to the requirements of SC6.4.6.10 Earthworks (construction), compacted for its full depth to a relative compaction of not less than 97 per cent (standard compaction) as determined by AS 1289.5.4.1.

(iv) Where shown on the drawings or as directed by the Superintendent, a geotextile conforming with the requirements of SC6.4.6.21 Subsurface drainage, shall be provided at the interface between the filter material and adjoining materials. Cover the bottom and sides of the trench with sufficient free fabric to wrap around the completed drain. Conform to the shape of the trench with minimal wrinkles, folds or air voids between fabric and trench, but not stretched on the soil. Laps of 500mm shall be provided at joints in the fabric. The Contractor must take all reasonable care to ensure that the geotextile is not damaged during installation and backfilling operations. Ensure the period between initial laying out and final cover of the geotextile with drainage backfill layer does not exceed 14 days. Where possible place geotextiles just ahead of construction works and cover with materials within 48 hours. Any geotextile fabric exposed for longer than 14 days must be removed and replaced by the Contractor as directed by the Superintendent.

(v) Where the outlet section of pipes discharging through the fill batters, the trench shall be backfilled with the nominated filter material to a depth of 50mm above the pipe. The balance of trench shall be backfilled with earth backfill material of maximum particle size of 50mm and shall be compacted for the full depth to a relative compaction of 95 per cent (standard compaction) as determined by AS 1289.5.4.1.

(d) Outlets

(i) Outlets are to be provided at maximum intervals of 150m. Where possible, subsoil drains shall discharge into gully pits and other stormwater drainage structures. Where not possible, an outlet shall be constructed of unslotted plastic pipe of the same diameter as the main run to discharge below the edge of the road shoulder. An outlet structure in accordance with the drawings shall be constructed at the discharge end with appropriate treatment to address erosion of adjacent areas.

(ii) The outlet shall be made rodent proof in accordance with the requirements of SC6.4.6.21 Subsurface drainage.

(iii) The outlet shall be located so that erosion of the adjacent area does not occur, or shall be protected by the placement of selected stone in the splash zone of the outlet.

(e) Cleanouts

(i) Cleanouts are to be provided at the commencement of each run of subsoil drain line and at intervals of approximately 60m or as shown on the drawings.

(ii) Details of the required cleanout construction are shown on the drawings. The standard Cl caps as shown on the drawings shall be supplied by the Contractor.

(iii) Upon completion of backfilling, pump clean water into the cleanout at the commencement of each run until only clean water discharges at the outlet. The minimum rate of flow of flushing water at the inlet must be 100L/min.

(2) Intra-pavement drains

(a) Excavation

(i) A "V" shaped trench approximately 75mm deep shall be cut to the required line in the pavement layer immediately below the permeable pavement layer. No excavation is required below a 40mm open graded asphaltic concrete subbase layer.

(ii) The bottom of the trench is to be to the same grade as the roadway. The bottom of the trench shall be constructed so that localised ponding of water does not occur.

(iii) Where the pipe is to discharge through the fill batter a trench shall be constructed on a grade

suitable for the pipe to discharge its contents without scour. After laying the pipe the trench shall be backfilled with fill material and compacted for the full depth to a relative compaction of not less than 95 per cent (standard compaction) as determined by AS 1289.5.4.1.

(b) Laying of pipe

(i) Thick walled unplasticised PVC pressure pipe, complying with AS 1477, and having a nominal diameter of 58mm, and a minimum pipe wall thickness of 6.5mm, shall be used with crushed rock subbases having not more than 10 per cent of material passing the 9.5mm AS sieve and having layer thicknesses neither less than 150mm nor more than 200mm or open graded asphalt subbases having layer thicknesses neither less than 80mm nor greater than 100mm.

(ii) Where crushed rock subbases require pavement drains and have a depth exceeding 200mm, the type of pavement drain will need to be certified to have adequate crushing strength and a written approval from the Superintendent to the proposed pavement drain type will be required. Similar proposals shall require Superintendent and council approval for pavement drain in asphalt subbases greater than 100mm in depth.

(iii) All pipe shall be slotted except where otherwise shown on the drawings. Details of slot sizes and spacings shall be in accordance with SC6.4.6.21 Attachment A for thick walled unplasticised PVC pressure pipe.

(iv) Thick walled unplasticised PVC pressure pipe shall have square ends and shall be butt jointed.

(v) Where spigot and socket type pipes are used, the pipes shall be joined with the socket ends facing upstream.

(vi) The pipe shall be laid to the specified line and level. The pipe shall not deviate from the specified line by more than 100mm at any point.

(vii) The inlet ends of all pipes shall be fitted with caps.

(viii) All pipes shall be securely held to the layer under the free-draining subbase to prevent movement of the pipes during placement and compaction of the free draining subbase. At least 7 days before commencement of pipe laying, the Contractor shall submit details of the proposed method of securing the pipes to the layer under the free-draining subbase for the approval of the Superintendent.

(ix) Notwithstanding the Superintendent's approval to the use of a method of securing the pipes to the layer under the free draining subbase, if such securing method allows movement of the pipes, the method shall be discontinued and the Contractor shall propose an alternative securing method for approval by the Superintendent.

(x) Any additional costs resulting from the use of the alternative method of securing the pipes shall be borne by the Contractor.

(xi) The outlet length of pipe from the outside edge of the free-draining subbase to an outlet structure in the embankment batter shall be unslotted and the pipe joints in this length of pipe shall be sealed with suitable couplings or mastic.

(c) Backfilling

(i) Subbase material shall be spread, compacted and trimmed, where appropriate, as follows:

(A) for crushed rock subbase, in accordance with sub-section SC6.4.6.12 Flexible pavements; and

(B) for open graded asphalt subbase, in accordance with sub-section SC6.4.6.13 Asphaltic concrete.

(ii) Tipping, spreading and compaction of the subbase shall be undertaken in such a manner as not to damage the intra-pavement drain pipes. If any pipes are damaged as a result of the tipping, spreading and compaction of the subbase, the Contractor shall remove and replace the damaged pipes.

(iii) The cost of the removal and replacement of such damaged pipes shall be borne by the Contractor.

(iv) The thickness of the layer of subbase material enclosing the pipe shall be within the limits specified in clause SC6.4.6.20.2(b) Laying of pipe for the type of pipe used in the intra-pavement drain.

(d) Outlets

(i) Outlets are to be provided as shown on the drawings or at maximum intervals of 150m. Where possible intra-pavement drains shall discharge into gully pits and other stormwater drainage structures. Where not possible, each pipe shall be extended using a 60 degree bend and unslotted pipe to discharge through the fill batter and an outlet structure constructed on the discharge end in accordance with the drawings.

(ii) The outlet shall be made rodent proof in accordance with the requirements of SC6.4.6.21 Subsurface drainage.

(iii) The outlet shall be located so that erosion of the adjacent area does not occur, or shall be protected by the placement of selected stone in the splash zone of the outlet.

(iv) Joints in the pipeline shall be kept to the minimum number and, where required, shall be made using a suitable external joint coupling. The inlet end of the pipe shall be fitted with a PVC cap.

(3) Edge drains

(a) Excavation

(i) The verge material shall be trimmed to subgrade level and to the minimum width shown on the drawings. The bottom of the trench is to be constructed at the same grade as the roadway and in such a manner that localised ponding of water does not occur.

(ii) Where the grade of the roadway is less than 0.25 per cent the trench shall be excavated to provide a minimum grade of 0.25 per cent.

(iii) When the pipe is to discharge through the fill batter a suitable trench shall be excavated to provide the required grade.

(b) Laying of pipe

(i) Generally, 65mm diameter slotted corrugated plastic pipe enclosed in seamless tubular filter fabric, complying with SC6.4.6.21 Subsurface drainage, shall be used for edge drains.

(ii) Where any part of a shoulder consists of material other than concrete, slotted thick walled unplasticised PVC pressure pipe, complying with AS 1477, shall be used. Spigot and socket type pipes shall be joined with the socket ends facing upstream and the ends of each pipe shall be securely held against the vertical face of the rigid pavement. At least seven days before commencement of pipe laying, the Contractor shall submit details of the proposed method of securing the pipes against the rigid pavement for the approval of the council.

(iii) The pipe shall be laid on a prepared bed to the specified line and level. The pipe shall not deviate from the specified line by more than 100mm at any point.

(iv) Joints in the pipe shall be kept to a minimum number and shall be made using an external joint coupling approved by the Superintendent.

(v) The inlet end of the pipe shall be fitted with a cap.

(vi) The outlet section of a pipe from the vertical face of the rigid pavement to an outlet in the embankment batter shall be unslotted and the pipe joints in this length of pipe shall be sealed with mastic.

(c) Backfilling

(i) The pipe shall be covered with Type B filter material to the dimensions shown on the drawings.

(ii) Mechanical compaction of this filter material is not required, however after placement of the filter material it shall be soaked with water. Where necessary additional filter material shall be added and soaked to provide the final dimensions shown on the drawings.

(iii) Backfilling over the edge drain shall be done in such a manner as to avoid damage or disturbance of the pipe. Backfill material shall be selected material as required for verges and in accordance with the requirements of sub-section SC6.4.6.10 Earthworks (construction). Backfilling shall be compacted to a relative compaction of not less than 100 per cent (standard compaction) as determined by AS 1289.5.4.1.

(iv) Upon completion of backfilling, pump clean water into the cleanout at the commencement of each

run until only clean water discharges at the outlet. The minimum rate of flow of flushing water at the inlet must be 100L/min.

(d) Cleanouts

(i) Cleanouts are to be provided at the commencement of each run of edge drain line and at intervals of approximately 60m or as shown on the drawings.

(ii) Details of the required cleanout construction are shown on the drawings. The standard CI caps as shown on the drawings shall be supplied by the Contractor.

(e) Outlets

(i) Unless otherwise shown on the drawings outlets are to be provided at maximum intervals of 150 m. Where possible edge drains shall discharge into gully pits and other stormwater drainage structures. Where not possible, an outlet shall be constructed of unslotted plastic pipe of the same diameter as the main run to discharge below the edge of the road shoulder. An outlet structure in accordance with the drawings shall be constructed at the discharge end.

(ii) The outlet shall be made rodent proof in accordance with the requirements of SC6.4.6.21 Subsurface drainage.

(iii) The outlet shall be located so that erosion of the adjacent area does not occur, or shall be protected by the placement of selected stone in the splash zone of the outlet.

(4) Foundation drains

(a) Excavation

Excavation shall be undertaken in accordance with the requirements of SC6.4.6.21 Subsurface drainage and clause SC6.4.6.20.2(1) Subsoil and sub-pavement drains of this sub-section.

(b) Laying of pipe

(i) The 100mm diameter corrugated slotted plastic piping, complying with SC6.4.6.21 Subsurface drainage, shall be laid on a bed of filter material 50mm in thickness and shall be laid to the required line and grade.

(ii) The type of filter material shall be shown on the drawings as per the requirements of sub-section SC6.4.6.21 Subsurface drainage or as directed by the Superintendent.

(iii) Joints in the pipeline shall be kept to the minimum number and, where required, shall be made using a suitable external joint coupling. The inlet end of the pipe shall be fitted with a PVC cap.

(c) Backfilling

(i) The trench shall be backfilled with filter material in accordance with the provisions of clause SC6.4.6.20.2(3)(c) Backfilling.

(ii) The upper section of the trench, above the level specified for filter material backfill, shall be backfilled with suitable earth backfill material, compacted for its full depth to a relative compaction of not less than 97 per cent (standard compaction) as determined by AS 1289.5.4.1.

(iii) Where shown on the drawings or as directed by the Superintendent, a geotextile, conforming with the requirements of SC6.4.6.21 Subsurface drainage, shall be provided at the interface between the filter material and adjoining materials. Laps of 500mm shall be provided at joints in the fabric.

(d) Outlets

An outlet structure in accordance with the detail shown on the drawings and SC6.4.6.21 Subsurface drainage shall be constructed at the discharge end.

The outlet shall be located so that erosion of the adjacent area does not occur or shall be protected by the placement of selected stone in the splash zone of the outlet.

SC6.4.6.20.3 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.20.1 Summary of limits and tolerances below.

Table SC6.4.6.20.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Excavation**		SC6.4.6.20.2(3)(a)

SC6.4.6.21 Sub-surface drainage

SC6.4.6.21.1 Introduction

(1) Introduction

This is the general specification common and applicable to all types of subsurface drainage and must be read in conjunction with subsurface drainage sub-sections:

(a) SC6.4.6.20 Subsoil, foundations and pavement drains; and

(b) SC6.4.6.8 Drainage mats.

(2) Scope

(a) The work to be executed under this sub-section consists of:

(i) preparation for subsurface drainage construction;

(ii) siting of subsurface drainage facilities;

(iii) the supply of all materials associated with the provision of the subsurface drainage system;

(iv) all activities and quality requirements associated with the supply, placement and compaction of filter material;

(v) the provision of a detailed record of all subsurface drain installations; and

(vi) the marking on the ground of the location of all subsurface drains.

(b) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

(3) Extent of work

Details of the work are to be shown on the approved drawings.

(4) Temporary drainage during construction

(a) All drainage works carried out by the Contractor must provide measures of erosion and sedimentation in accordance with the requirements of the accepted project erosion and sediment control plan and/or *Best Practice Erosion and Sediment Control* and make adequate provision for runoff flows at drainage works under construction or at surrounding areas/structure.

(b) The Contractor must make adequate provision for runoff flows at subsurface drainage works under construction, to avoid damage or nuisance due to scour, sedimentation, soil erosion, flooding, diversion of flow, damming, undermining, seepage, slumping or other adverse effects to the Works or surrounding areas and structures as a result of the Contractor's activities.

(c) The Contractor's material and equipment must be located clear of watercourses or secured so that they will not cause danger or damage in the event of large runoff flows.

(5) Siting of work

(a) Before commencing construction of any subsurface drainage activity, the Contractor must set out on site the position of the work to the location and levels shown on the drawings, and must present this set-out for inspection by the Superintendent.

(b) The Superintendent may amend the locations or designed levels or the lengths to suit actual site conditions. Should the Superintendent require a change to the conditions of installation an appropriate variation must be ordered.

(c) Should the Contractor propose changes to the location, length, designed levels, conditions of installation or cover to suit the Contractor’s construction procedures, the Contractor must present the proposed set-out in addition to the designed set-out for consideration by the Superintendent. No changes shall be made unless the prior written approval of the Superintendent is obtained.

(6) Excavation

(a) In undertaking trench excavation the Contractor must provide any shoring, sheet piling or other stabilisation of the sides necessary to comply with statutory requirements.

(b) Where public utilities exist in the vicinity of drainage works the Contractor must obtain the approval of the relevant authority/corporation to the method of excavation before commencing excavation.

(c) Excavation by blasting, if permitted, must be carried out to ensure that the peak particle velocity measured on the ground adjacent to any previously installed structure does not exceed 25 millimetres per second. The Contractor must comply with other requirements concerning blasting operations in SC6.4.6.10 Earthworks (construction).

(d) Trenches must be excavated to the line, grade, width and depth shown on the drawings or as directed by the Superintendent. The bottom of the trench must be constructed so that no localised ponding can occur. All loose material must be removed by the Contractor.

(e) Any material at the bottom of the trench or at foundation level which the Superintendent deems to be unsuitable must be removed and disposed in accordance with SC6.4.6.10 Earthworks (construction) by the Contractor and replaced with backfill material in accordance with the requirements of this sub-section. The bottom of the excavated trench or foundation, after any unsuitable material has been removed and replaced, must be parallel with the specified level or grade of the pipe.

(f) The excavated material shall be used in the construction of embankments backfilling or spoiled in accordance with SC6.4.6.10 Earthworks (construction).

(7) Backfilling

Backfilling must be carried out in accordance with the requirements of the relevant subsurface drainage structures sub-sections.

(8) Outlet structures for subsurface drainage

(a) Subsurface drainage pipes must be connected to discharge into gully pits or to outlet structures as shown on the drawings or as directed by the Superintendent.

(b) Outlets must be spaced at a maximum interval of 150m.

(c) Outlets, including those discharging into gully pits, must be made rodent proof using galvanised wire netting unless otherwise indicated on the approved drawings.

(d) The outlet must be located so that erosion of the adjacent areas does not occur or must be protected by the placement of selected stone or similar treatment together with a marker post to indicate location and assist maintenance.

(e) Outlet pipes from curtain drains must be unslotted. At no point shall an outlet pipe be higher than the pipe at the end of the curtain drain.

(f) All concrete used in the construction of outlet structures must conform to the requirements of sub-section SC6.4.6.28 Minor concrete works.

(9) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

AS 1141.22	*Wet/dry strength variation*
AS 1289.5.5.1	*Determination of the minimum and maximum dry density of a cohesionless material – Standard method*
AS 1477	*PVC pipes and fittings for pressure applications*
AS 2439.1	*Perforated drainage pipe and associated fittings*
AS 2758.1	*Aggregates and rock for engineering purposes – Part 1: Concrete aggregates*
AS 3705	*Geotextiles - Identification, marking and general data*

AS 3706	*Geotextiles - Methods of test*
AS 3706.9	*Determination of permittivity, permeability and flow rate*
AS 3706.11	*Determination of durability - Resistance to degradation by light, heat and moisture*

(c) Other:

Austroads, *Guide to Pavement Technology - Part 4G Geotextiles.*

ASTM International, ASTM-D2434-68 – *Standard test method for permeability of granular soils (Constant Head)*

International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

SC6.4.6.21.2 Materials

(1) Corrugated plastic pipe

(a) Corrugated plastic pipe must be Class 1000 complying with AS2439.1 of 65mm or 100mm diameter as indicated on the drawings. All pipe must be slotted except where shown on the approved drawings.

(b) Joints, couplings, elbows, tees and caps must also comply with AS2439.1 and only the manufacturer's recommended fittings shall be used.

(c) The Contractor must obtain from the Manufacturer Test Certificate demonstrating compliance with AS2439.1.

(2) Other types of subsurface drainage

Where a Contractor wishes to use a subsurface drainage pipe other than corrugated plastic pipe, the Contractor must submit full details of the type of pipe, certification from the manufacturer of its suitability and quality and written acceptance by the council for its use in each particular application. Certification of the suitability of any pipe must address the crushing strength, flexural strength, jointing system and slotting details.

(3) Filter material

(a) General

The types of filter material covered by this sub-section shall include:

(i) Type A filter material for use in trench drains and Type B drainage mats;

(ii) Type B filter material for use in trench drains and Type B drainage mats;

(iii) Type C filter material comprising crushed rock for use in Type A drainage mats; and

(iv) Type D filter material comprising uncrushed river gravel for use in Type A drainage mats.

All filter material must consist of clean, hard, tough, durable particles. A sample of the proposed filter material must be submitted to the Superintendent for approval.

(b) Type A filter material

Type A filter material must be crushed rock complying with the following requirements in Table SC6.4.6.21.1.

Table SC6.4.6.21.1 Type A filter material

Test Method	Property	Requirement
AS 1141.11	Material passing AS sieve	Per cent by mass
	6.7mm	100
	4.75mm	85 to 100
	2.36mm	0 to 40
	1.18mm	0 to 5
	425µm	0 to 2

(c) Type B Filter Material

Type B filter material must be granular material complying with the following grading requirements in Table SC6.4.6.21.2.

Table SC6.4.6.21.2 Type B filter material

Test Method	Property	Requirement
AS 1141.11	Material passing AS sieve	Per cent by mass
	4.75mm	100
	2.36mm	95 to 100
	425µm	20 to 80
	300µm	0 to 30
	150µm	0 to 2
	75µm	0 to 0.1

In addition to the above grading requirements, Type B filter material must have a coefficient of saturated permeability, when compacted to its maximum dry density as determined by AS1289.5.5.1 and then tested in accordance with Test Method ASTM D2434 68, of at least 8m per day after 3 hours of flow.

Type B filter material must not vary from its original grading as a result of compaction processes by more than the following amounts listed in Table SC6.4.6.21.3.

Table SC6.4.6.21.3 Type B filter material variation

AS Sieve	Variation From Grading Before Treatment (per cent of mass)
2.36mm	± 3
1.18mm	± 1
425µm	± 1
300µm	± 1
150µm	± 0.5
75µm	± 0.1

(d) Type C Filter Material

Type C filter material must be crushed rock complying with the following requirements in Table SC6.4.6.21.4.

Table SC6.4.6.21.4 Type C Filter Material

Test Method	Property	Requirement
AS 1141.11	Maximum particle size	37.5mm
	Maximum passing the 9.5mm AS Sieve	5% by mass
	Maximum (D90:D10)*	3
AS 1141.22	Minimum wet strength	100kN
	Maximum 10% fines wet/dry variation	30%

Note—the D90 value must be determined by sieving the material using 75mm, 53mm, 37.5mm, 26.5mm, 19mm, 13.2mm and 9.5mm AS sieves, as appropriate, and then plotting the results on a graph of AS sieve size v percentage passing. The plotted points must be joined by straight lines and the D90 must shall be determined as the theoretical sieve size corresponding to 90 per cent passing.

D10 denotes the theoretical size of a sieve through which 10 per cent of the material would pass and must be determined from the same graph used to determine the D90 value.

(e) Type D Filter Material

Type D filter material must be uncrushed river gravel complying with the description of rounded aggregate in Table B1, Appendix B of AS2758.1 and the following requirements in Table SC6.4.6.21.5.

Table SC6.4.6.21.5 Type D Filter Material

Test Method	Property	Requirement
AS 1141.11	Maximum particle size	75mm
	Maximum passing the 9.5mm AS sieve	5% by mass
	Maximum (D90 : D10)	3
AS 1141.22	Minimum wet strength	100kN
	Maximum 10% fines wet/dry variation	30%

(4) Geotextile

Prior to placing geotextiles, documentary evidence that the geotextile and installation process conform to the requirements of this sub-section must be produced and submitted to the Superintendent.

(a) General

The geotextile, other than seamless tubular filter fabric, must consist of either a woven or a non-woven type which must be manufactured from synthetic materials other than polyamide. Rolls of geotextile shall be marked with product identification and supplied with data sheets and information in accordance with the requirements of AS 3705.

The geotextile must be bio stable and resistant to attack by alkalis, acids, dry heat, steam, moisture, brine, mineral oil, petrol, diesel and detergents when tested in accordance with the appropriate parts of AS3706.

The geotextile must be resistant to ultra violet light. No geotextile shall be left exposed to sunlight during storage and construction for a period longer than a total of 21 days. If exposure in excess of 21 days does occur, the geotextile must be tested in accordance with AS 3706.11 and if its characteristics have deteriorated to or below 90 per cent of the characteristics claimed by the manufacturer or the characteristics determined on unexposed geotextile, whichever is the better, it must be removed and replaced with a geotextile complying with this specification.

The geotextile material type, strength rating “G”, and minimum mass requirements must be as shown on the drawings.

The type, properties, functions, design and construction requirements for a particular application of geotextile installation must be compatible with recommendations provided by the Guide to Pavement Technology – Part 4G, as well as requirements indicated on the drawings.

In addition to the above mentioned requirements, geotextiles for curtain drains must consist of either polyester, polypropylene or polyethylene. The required rates of water flow are shown on Table 4.1 of Guide to Pavement Technology – Part 4G, under 100mm constant head determined using the perpendicular flow test to conform with AS3706.9.

(b) Seamless tubular filter fabric

Seamless knitted tubular filter fabric must be used to enclose all slotted pipes and must be manufactured from either polypropylene or polyester. The fabric must be free of imperfections in weave or yarn and have abrasion resistant and weave stability qualities such that it shall not form holes, ladder, deweave, tear or unravel more than 5mm from a cut end.

Fitting of the seamless tubular filter fabric must be in accordance with the requirements of SC6.4.6.21 Attachment A. Filter fabric that is excessively stretched, torn or otherwise damaged during fitting of the fabric, storage, transportation or pipe laying will be removed and replaced so as to eliminate any damaged lengths.

SC6.4.6.21.3 Recording of subsurface drainage information

(1) The Contractor must keep a detailed record of all subsurface drainage pipes and the completed subsurface drainage systems must be shown on the work as executed plans to be returned to the Superintendent upon completion of work.

In addition, the Contractor must prepare a subsurface drainage information sheet or sheets; at the completion of construction of each drain or drainage system and must submit the subsurface drainage sheet or sheets to the Superintendent within 5 working days of the completion of the drain or drainage system.

SC6.4.6.21.4 Limits and tolerances

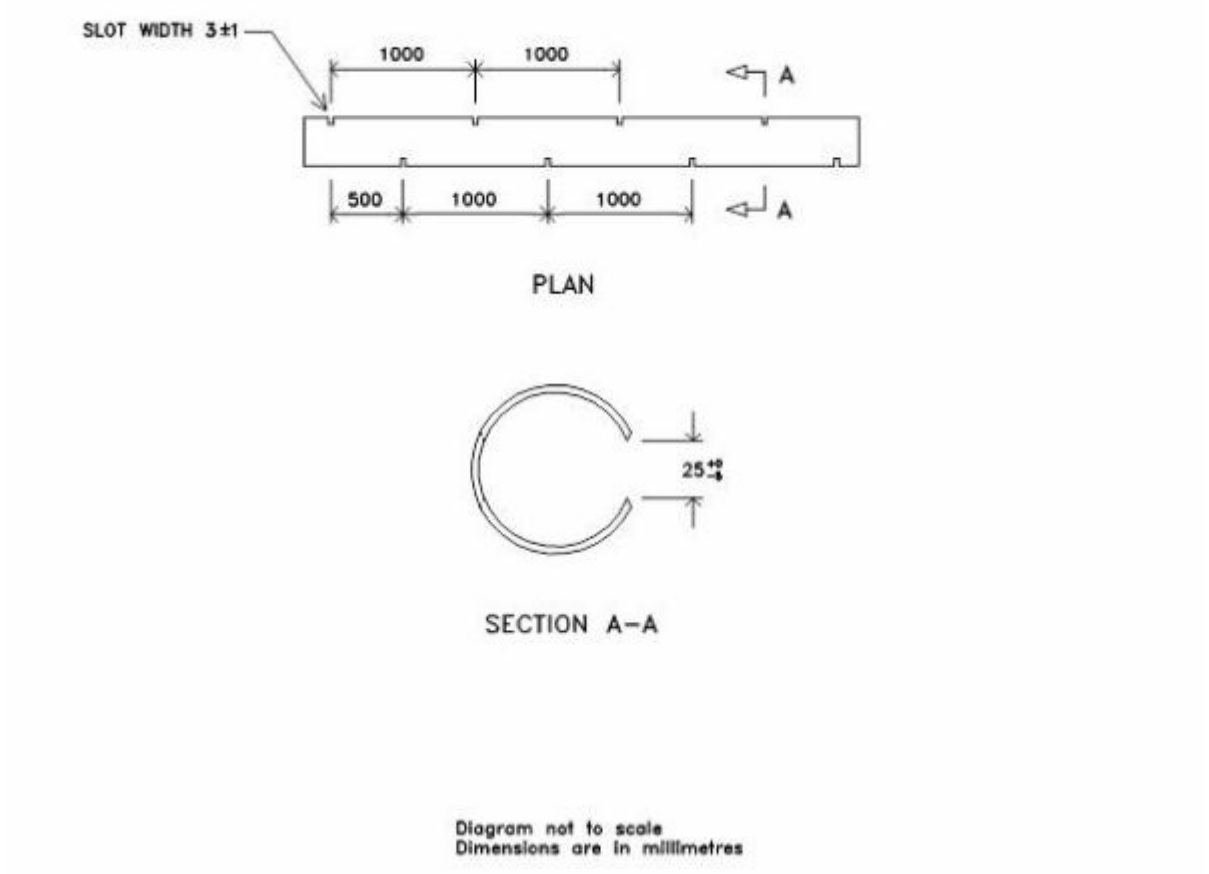
The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.21.6 Summary of limits and tolerances below.

Table SC6.4.6.4.21.6 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Excavation by Blasting** Peak particle velocity	25mm/s	SC6.4.6.21.1(6)
2.	**Outlets** Spacing	Max 150m	SC6.4.6.21.1(8)
3.	**Filter Material**		
	(a) Type A	Table SC6.4.6.21.1	SC6.4.6.21.2(3)
	(b) Type B	Tables SC6.4.6.21.2 and SC6.4.6.21.3	SC6.4.6.21.2(3)
	(c) Type C	Table SC6.4.6.21.4	SC6.4.6.21.2(3)
	(d) Type D	Table SC6.4.6.21.5	SC6.4.6.21.2(3)
4.	**Geotextile**		
	(a) Exposure to sunlight	<21 days If >21 days deterioration not to exceed 10% of claimed characteristics	SC6.4.6.21.2(4)

Attachment A

Figure SC6.4.6.21.1 Slotting details for thick walled PVC plastic pipe



1. Slotted pipes fitted with seamless tubular filter fabric

(a) Procedure for fitting seamless tubular filter fabric to slotted pipe

(i) Seamless tubular filter fabric must be fitted to slotted pipe immediately before the slotted pipe is to be laid in its final position in the work.

(ii) The filter fabric must be initially pulled over and onto a short length of smooth pipe of internal diameter between 20mm and 30mm greater than the external diameter of the slotted pipe to be enclosed by filter fabric. The short, larger diameter pipe must be referred to as the "mandrel".

(iii) The pipe to be enclosed by the filter fabric must be passed through the mandrel. The filter fabric must be slipped on to the pipe as the pipe emerges from the mandrel leaving enough overhang of the filter fabric to make a suitable joint with the filter fabric on the adjacent pipe. The filter fabric must be firmly held to the forward end of the pipe so that it cannot slip back along the pipe.

(iv) The pipe must be pulled right through the mandrel allowing the filter fabric to progressively slip over the pipe. The filter fabric shall be restrained from easily slipping off the mandrel thus ensuring the filter fabric is stretch fitted onto the pipe.

(v) When the end of the pipe emerges from the mandrel, the filter fabric must be clamped to that end of the pipe so that the filter fabric cannot slip down the pipe. The filter fabric must remain clamped to each end of the pipe to ensure the filter fabric remains stretch fitted onto the pipe when the pipe is placed in its final position in the drain. The filter fabric must be cut cleanly leaving enough overhang off the end of the pipe to make a fully covered join with the filter fabric on the adjacent pipe when the pipes are installed in the drain.

(b) Precautions to be taken when using slotted pipe fitted with seamless tubular filter fabric

(i) Slotted pipe fitted with seamless tubular filter fabric must not be dragged over the ground. If carried, the pipe must be lifted clear of the ground and the filter fabric must be protected from damage at all times.

(ii) Seamless tubular filter fabric which has been so damaged as to affect its filtering properties must be removed from the pipe and replaced with undamaged filter fabric.

(iii) If at any time during the installation of a slotted pipe it is found that the enclosed filter fabric has become loose on the pipe it must be restretched to its correct position. If restretching causes any damage to the filter fabric, the damaged filter fabric must be removed from the pipe and replaced with undamaged filter fabric.

SC6.4.6.22 Pavement markings

SC6.4.6.22.1 Introduction

(1) Scope

This sub-section provides standards, advice and guidelines for the removal, setting out, supply and application of pavement marking paint, thermoplastic pavement marking material, pavement marking tape and raised pavement markers. Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-section:

SC6.4.6.30 - Control of traffic

(b) Australian Standards:

AS1580.205.4	*- Paints and related materials – Methods of test – Application properties – Airless spraying*
AS1906.3	*- Raised pavement markers (retroreflective and non-retroreflective)*
AS2009	*- Glass beads for pavement-marking materials*
AS2700	*- Colour Standards for general purposes*
AS4049.1	*- Solvent-borne paint - For use with surface applied glass beads*
AS4049.2	*- Thermoplastic pavement marking materials - For use with surface applied glass beads*
AS4049.3	*- Waterborne paint - For use with surface applied glass beads*

(c) Queensland Department of Transport and Main Roads Publications:

Manual of Uniform Traffic Control Devices (MUTCD)

Guide to pavement markings (GTPM)

Q513 *Wet Film Thickness of Paint (Wheel Gauge), Materials Testing Manual*

MRS45 *Road Surface Delineation*

Traffic and Road Use Management Manual (TRUM):

- TRUM 1.34 - Coloured surface treatments for bicycle lanes, Volume 1: Signing and pavement marking
- TRUM 3.23 - School zones, Volume 3: Road Safety

(d) Other:

Australian Paint Approval Scheme – Specification 0041/4 - Roadmarking paint, thermoplastic

Australian Paint Approval Scheme – Specification 0041/5 - Roadmarking paint, water borne

(3) Type of markings

Details of the various types of pavement markings and devices are in accordance with the requirements of the MUTCD, TRUM and GTPM.

Colours

White paint must have a colour equivalent to or whiter than Off White, Colour Y35 in AS2700.

Where yellow is used, the colour shall be equivalent to Y12, Wattle or Y14, Golden Yellow as detailed in AS2700 or any other colour deemed to lie between these two colours.

Where Green is used as a coloured surfacing on bicycle lanes, guidance on the application of green coloured surface treatments is contained within TRUM 1.34. The colour must be equivalent to Emerald, Colour G13; Traffic Green, Colour G16 or Shamrock, Colour G23 in AS2700. Where only one shade of each colour is specified, Traffic Green, Colour G16 is used.

(4) Types of materials to be applied
The materials shall be applied as follows:

(a) Pavement marking paint
Permanent markings on all wearing surfaces. Temporary markings, other than on the final wearing surfaces. Traffic islands and kerbs where specified;

(b) Thermoplastic pavement marking material
Permanent markings where explicitly indicated on the drawings;

(c) Pavement marking tape
Temporary markings on final wearing surfaces;
Temporary raised pavement markers (TRPMs);
Temporary markers fixed on any surface as a temporary marking.

(d) Reflective glass beads
To be applied to all painted and thermoplastic markings; and

(e) Raised pavement markers
Studs which may be retroreflective (RRPM) or non-retroreflective (NRPM) set into the roadway or attached to the road surface with adhesives, lane dividers, or pavement bars are installed as permanent as shown on the drawings.

(5) Material quality
The Contractor shall submit to the Superintendent NATA Registered Laboratory Test Reports, at least 7 days before work is scheduled to commence, on the quality of the materials, including paint, glass beads, raised pavement markers and thermoplastic material proposed for use.
Only materials conforming to the requirements of the referenced Specifications/Standards shall be used.

(6) Setting out
The Contractor shall set out the work "spotting" to ensure that all markings are placed in accordance with the drawings.
The locations of pavement markings shall not vary by more than 20mm from the locations shown on the drawings. Spotting for longitudinal lines is generally at 10m intervals with 3m intervals on curves of less than 50m radius.
The contractor must obtain approval from the administrator of the spotting prior to any application of pavement marking.

(7) Surface preparation
Surfaces which are to receive pavement markings shall be cleaned of all dirt, loose material and other contaminants. Pavement surfaces shall be thoroughly dry immediately prior to the application of pavement markings. Pavement marking shall not be carried out during wet weather or, if rain is likely to fall during the process.
In all cases, the reinstatement of longitudinal markings, particularly barrier lines and dividing lines, should occur as soon as possible after the new seal has been laid.
Where raised pavement markers are specified for pavements having a concrete wearing surface, the full area under each raised pavement marker shall be lightly scabbled to remove fine mortar material (laitance).
All painted markings whether installed by machine or hand are retroreflectorised by the application of drop-on glass beads (ballotini).

(8) Provision for traffic and protection of work
In accordance with MUTCD, Part 3 Works on Roads, and SC6.4.6.30 Control of traffic while undertaking the work and shall protect the pavement markings until the material has hardened sufficiently (no pick-up) so that traffic will not cause damage.

(9) Maintenance of pavement markings
The Contractor shall be responsible for the maintenance, and replacement if necessary, of raised pavement markers and all pavement marking during the contract period and the contract defects liability period.
Council requires all linemarking to be refreshed prior to to the end of the Defects Liability Period.

SC6.4.6.22.2 Pavement marking paint

(1) Materials

Paint shall comply with the requirements of AS4049.1 or AS4049.3. In this sub-section, the term “paint” shall mean “pavement marking paint”.

Glass beads shall comply with the requirements of AS2009 for drop-on beads.

(2) Mixing of paint

All paint shall be thoroughly mixed in its original container before use in accordance with the manufacturer’s recommendations to produce a smooth uniform product consistent with the freshly manufactured product.

(3) Application of paint and beads

All longitudinal lines shall be sprayed by an approved self-propelled machine. Line must have uniform thickness and intensity. Two coats of paint and glass beads shall be applied on longitudinal lines to new surfaces. The first coat shall be cured to “no pick up time” prior to the application of the second coat. The two sets of lines forming a one way or two way barrier line pattern shall be sprayed concurrently.

Hand spraying with the use of templates to control the pattern and shape shall be permitted for transverse lines, symbols, legends, arrows and chevrons.

The paint shall be applied uniformly and the wet film thickness shall be neither less than 0.35mm nor more than 0.4mm.

Glass beads shall be applied by air propulsion to the surface of all longitudinal lines at a net application rate of 1.3kg/sqm immediately after application of the paint. The actual application rate shall be set to overcome any loss of beads between the bead dispenser and the sprayed line.

Glass beads shall be similarly applied to all other paint markings at a net application rate of 0.3kg/sqm immediately after application of the paint by an applied method.

Pavement markings shall be straight or with smooth, even curves where intended. All edges shall have a clean, sharp cut off. Any marking material applied beyond the defined edge of the marking shall be removed leaving a neat and smooth marking on the surface of the pavement.

The lengths and widths of longitudinal lines and transverse lines must be within the tolerance specified in MUTCD/GTPM and MRST45.

The dimensions of arrows, chevrons and speed markings must be within the tolerances specified in MUTCD/GTPM as appropriate.

Arrows and speed markings shall be placed square with the centreline of the traffic lane.

Glass beads shall be uniformly incorporated in all coats of paint concurrently with the application of the paint.

Longitudinal line marking, when applied, must have a minimum retroreflectivity of 350mcd/lux/m2 measured between 10 and 20 days of wear.

(4) Field testing

The thickness of the wet film applied to the road pavement shall be checked by the method described in AS1580, comb gauge or test Q513 – (07/10).

The application rate of glass beads applied to the surface of the markings shall be checked by the method described in SC6.4.6.22 Attachment A Procedure for measurement of rate of application of spherical glass beads.

(5) Application rates

The minimum application rates for the paint and glass beads shall be as specified in Table SC6.4.22.1.

Table SC6.4.6.22.1 Application rates for paint and glass beads

Work type	Coverage (minimum per coat)	Wet application rate
Longitudinal lines – first coat Type B (drop-on beads)	> 300g/m^2	0.375L/m^2 ± 0.25
Longitudinal lines – second coat Type B (drop-on beads)	> 300g/m^2	0.375L/m^2 ± 0.25
Longitudinal lines – repaint Type B (drop-on beads)	> 200g/m^2	0.300L/m^2 ± 0.20
Longitudinal lines – second coat or repaint applying Type D beads	> 400g/m^2	0.500L/m^2 ± 0.25
Transverse lines – Type B (drop-on beads)	> 300g/m^2	0.375L/m^2 ± 0.25
Transverse lines – Type D beads	> 400g/m^2	0.500L/m^2 ± 0.25

Source: MRTS 45

The combination application rates for anti skid and glass beads shall not exceed the values specified above and in SC6.4.6.22.2(6) unless specified by the manufacturer.

Table SC6.4.6.22.2 Volume of glass beads (ml) required in 10 seconds of operation

Road Speed km/h	Line Widths			
	75mm	**100mm**	**125mm**	**150mm**
8	371	495	619	742
13	603	804	1006	1207
16	742	990	1238	1484

Note—

1. Tolerance of +10% shall be permissible when measuring the above volume.
2. When two or more glass bead dispensers are to be used, each dispenser shall be checked separately to make up the totals shown.
3. Glass beads weigh approximately 1.53g/ml.

(6) Anti skid

Transverse markings shall incorporate an anti skid treatment with a skid resistance greater than 45 BPN. The application of anti-skid shall comply with the manufacturer's requirements.

SC6.4.6.22.3 Thermoplastic pavement marking material

(1) Primer

A primer, of the type recommended by the manufacturer of the thermoplastic material, shall be applied to the surface immediately in advance of, but concurrent with, the application of thermoplastic material.

The primer shall be applied at the application rate recommended by the manufacturer and shall not be thinned.

(2) Application of thermoplastic material

Thermoplastic material may be applied by screeding, extrusion or profiling or as preformed material.

Thermoplastic material shall be applied to the pavement at a temperature between 180ºC and 200ºC unless a different temperature is recommended by the manufacturer.

The pavement surface to which thermoplastic material is applied shall be completely coated by the material and any voids in the pavement surface shall be filled.

(3) Application rate

Thermoplastic material shall be applied at the minimum thickness specified in Table SC6.4.6.22.3.

Location	Minimum application thickness (mm)
Longitudinal lines	2
Transverse markings	2

Editor's note - the term “thermoplastic material” shall mean “thermoplastic pavement marking material”.

Where specified, glass beads shall be applied immediately to the surface of the molten thermoplastic material at a rate of not less than 0.12kg/m2.

(4) Materials

Thermoplastic pavement marking material shall comply with the requirements of AS4049.2.

Glass beads shall be incorporated in thermoplastic material, in the proportion of 10% of the total mass, as part of the aggregate constituent and shall comply with the requirements of AS2009, Intermix type.

Glass beads for surface application shall comply with the requirements of AS2009, Drop-on beads.

Tack coat material shall be to the manufacturer's specification.

(5) Preparation of thermoplastic material on site

Immediately before application, the thermoplastic material shall be uniformly heated in a suitable oil bath kettle to the temperature recommended by the manufacturer. The thermoplastic material shall not be heated above the temperature recommended by the manufacturer. The thermoplastic material shall not remain molten for more than 6 hours for hydrocarbon resins and 4 hours for wood and gum resins. Should over-heating occur and/or the time expires for molten materials, then the thermoplastic material shall be discarded.

(6) Application of thermoplastic material and beads

Where the wearing surface of the pavement is smooth or polished, a tack coat of material may be required by the Superintendent and shall be applied in accordance with the recommendations of the thermoplastic manufacturer. The tack coat shall be applied immediately before the application of the thermoplastic material in accordance with the directions of the manufacturer of the thermoplastic material and the manufacturer of the tack coat material.

All longitudinal lines shall be sprayed by a self-propelled machine. The two sets of lines forming a one way or two way barrier line shall be sprayed concurrently. The thermoplastic material shall be applied uniformly and the cold film thickness shall be 2mm with a tolerance of plus or minus 0.5mm.

Glass beads shall be applied by air propulsion to the surface of all longitudinal lines at a net application rate of 0.3kg/sqm immediately after application of the thermoplastic material. The actual application rate shall be set to overcome any loss of beads between the bead dispenser and the sprayed line.

All transverse lines, symbols, legends and arrows shall be screeded. The screeded thermoplastic material shall be applied using a mobile applicator, and templates to control the pattern.

Preformed thermoplastic sheeting applied in accordance with manufacturer’s specifications is an approved process.

The thermoplastic material for transverse lines, symbols, legends and arrows shall be applied uniformly and the cold film thickness shall be 3.5mm with a tolerance of plus or minus 1.5mm. The surface finish shall be smooth.

Glass beads for other than longitudinal lines shall be uniformly applied to screeded markings at a net application rate of 0.3kg/sqm immediately after application of the thermoplastic material.

Pavement marking must be straight or with smooth, even curves where intended. All edges shall have a clean, sharp cut off. Any marking material applied beyond the defined edge of the marking shall be removed leaving a

neat and smooth marking on the wearing surface of the pavement.

The lengths of longitudinal lines shall not vary by more than 20mm from the lengths shown in MUTCD/GTPM. The widths of longitudinal lines shall not vary by more than 10mm from the widths shown in MUTCD/GTPM. The lengths and widths of transverse lines shall not vary by more than 10mm from the lengths and widths shown in MUTCD/GTPM.

The dimensions of arrows, chevrons and speed markings shall not vary by more than 50mm from the dimensions shown on the drawings or in MUTCD/ GTPM as appropriate. Arrows and speed markings shall be placed square with the centreline of the traffic lane.

(7) Field testing
The thickness of the cold film of thermoplastic material applied to the road pavement shall be checked by measurement, using a micrometer, of the thickness of thermoplastic material applied to a metal test plate. The application rate of glass beads applied to the surface of the markings shall be checked by the method described in SC6.4.6.22 Attachment A Procedure for measurement of rate of application of spherical glass beads.

SC6.4.6.22.4 Pavement marking tape

(1) Materials
Pavement marking tape shall be a strippable type of tape, such as “Staymark Detour Grade”, or equivalent tape approved by the Superintendent. Pavement marking tape must only be used on temporary works.

(2) Application of pavement marking tape
The method of application of pavement marking tape, including surface preparation, shall be in accordance with the manufacturer's recommendations.

(3) Removal of pavement marking tape
When directed by the Superintendent, the Contractor shall remove pavement marking tape in accordance with the manufacturer's recommendations.

(4) Temporary raised pavement markers (TRPMs)
Temporary raised pavement markers must comply with the requirements of AS1906.

Temporary raised pavement markers may be used to mark the temporary travelled path at short-term work sites, or to indicate the permanent travelled path on new work prior to the application of permanent pavement markings.

The use of temporary raised pavement markers may preclude the need for spotting where existing markings are to be reinstated after a reseal, and for respotting if proposed line markings were set out before the final seal on new works is applied. In these cases, the distance between TRPMs should be the same as would apply for spotting.

Temporary raised pavement markers should not take the place of spotting, as TRPMs may be broken off by traffic before final marking can be carried out. Once the longitudinal lines have been marked, the Temporary raised pavement marker flaps can be removed by cutting them off flush with the pavement surface.

SC6.4.6.22.5 Raised pavement markers

(1) Materials
Raised pavement markers, both reflective and non reflective, shall comply with AS1906.3 and shall have the dimensions shown on the drawings.
The adhesive used for attaching the raised pavement markers to the wearing surface of the pavement shall be a hot-melt bitumen adhesive or an equivalent product approved.

(2) Installation of raised pavement markers

The use of raised retroreflective pavement markers must be in accordance with the MUTCD, GTPM and TRUM 1.25 Fire Hydrant Indication System.

Raised pavement markers shall be fixed to the wearing surface of the pavement using a hot melt bitumen adhesive or an equivalent product. The adhesive shall be freshly heated to the manufacturer's instructions and thoroughly mixed.

The adhesive shall be spread uniformly over the underside of the raised pavement marker to a depth of approximately 10mm. The raised pavement marker shall be pressed down onto the pavement surface in its correct position and shall be rotated slightly until the adhesive is squeezed out around all edges of the marker. The raised pavement marker shall not be disturbed until the adhesive has set.

On rough surfaces, such as newly laid coarse sprayed bituminous seals, an initial pad of adhesive of diameter 20mm larger than the diameter of the base of the raised pavement marker, shall be provided. The adhesive shall be applied to fill the irregularities in the pavement surface to produce a flat, smooth surface flush with the upper stone level. The adhesive pad shall be allowed to set. Additional adhesive shall be applied to the pavement, as described above, and then the raised pavement marker shall be pressed down onto the adhesive pad on the pavement surface to ensure good adhesion.

When installed, raised pavement markers shall conform to the tolerances specified in Table SC6.4.6.22.4.

Table SC6.4.6.22.4 Tolerances - raised pavement markers

	Tolerance (mm)	Distance
Lateral position –	+ 25, - 50	from edge of line
• barrier/edge line	± 10	from edge of line
• broken line	± 10	from centre of line
• flush medians		
Longitudinal position –	± 10	1m from start of line
• broken line	± 100	1m from start of line
• new construction	± 300	1m from start of line
• replacement		

(1) General

The Contractor shall remove pavement markings, no longer required, from the wearing surface of pavements without significant damage to the surface.

Where required, existing pavement markings must be removed by the appropriate method stated in Table SC6.4.6.22.5.

The method of removal shall be submitted to the Superintendent for approval before commencement of the work.

Table SC6.4.6.22.5 Method of removal of existing pavement marking

Method of removal	Duration of result
Black paint	< 1 week
Emulsion and sand	< 2 weeks
Black cold applied resin or plastic	< 6 months
Chip seal	Permanent
Line grinder (asphalt only)	Permanent
Profiler (asphalt only)	Permanent
Abrasive blasting	Permanent

SC6.4.6.22.7 Surface treatments for bicycle lanes and school zone threshold

(1) Coloured surface treatments for bicycle lanes

Refer to the Traffic and Road Use Management Manual - Coloured Surface Treatments For Bicycle Lanes.

(a) The preferred colour is G13 Emerald (AS2700 S 1996). To accommodate different materials and varying conditions, an approximate colour match to one of the following three AS2700 S greens is permitted - G13 Emerald, G16 Traffic green or G23 Shamrock. Approximate colour match is determined in accordance with AS/NZS1580.601.1.

(b) A consistent green colour should be provided along a route or within a given locality.

(c) Where green surface colouring is used, it should be continuous through the required area and be bounded by the bicycle lane lines. Pavement markings, such as bicycle symbols and any directional arrows, should be placed over the coloured surface.

(d) A coloured surface treatment needs to do more than just provide a colour contrast. It must be designed to function like any other road surfacing, providing a sound, durable surface layer, which maintains the required texture and skid resistance for its design life.

(e) The design and specification of a coloured surface treatment for bicycle lanes should:

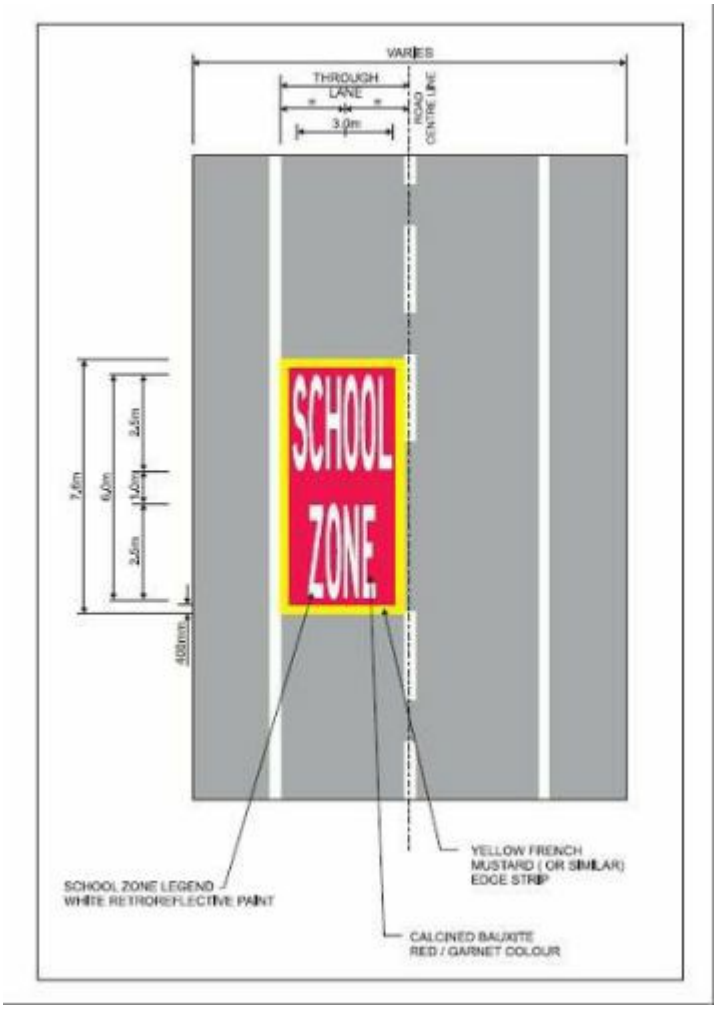
- ensure the suitability of the existing surface to support and bond with the colour treatment;
- provide a surface texture and skid resistance suitable for bicycle use, including in wet conditions; and
- limit differential skid resistance between the bicycle lane and adjacent traffic lanes.

(f) The Department of Transport and Main Roads is considering development of a formal specification for coloured surface treatments for Queensland. Until this is available it is recommended that advice on performance requirements, and the suitability of any product or service being considered for use, be sought from the Superintendent for approval before commencement of the work.

(2) Surface treatments for school zone thresholds

Refer to the Traffic and Road Use Management Manual - 3.23 Traffic and Road Use Management Manual - School Zones.

Threshold treatments may be provided at entrances to school zones to create a change in driver perception of the speed environment. A typical threshold treatment for a school zone is shown in Figure SC6.4.6.22.1.



Source:TRUM.

Figure SC6.4.6.22.1 Typical threshold treatment for a school zone

Advice on performance requirements, and the suitability of any product or service being considered for use, is to be sought from the Superintendent for approval before commencement of the work.

The pavement marking treatment (set out, type of material, preparation of surface, rate of application, method of application and maintenance) must be submitted to the Superintendent for approval before commencement of the work.

SC6.4.6.22.8 Limits and tolerances

The limits and tolerances applicable to the various clauses of this Specification are summarised in Table SC6.4.6.22.6 – Summary of limits and tolerances below:

Table SC6.4.6.22.6 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Location of Markings**	± 20mm from specified location	SC6.4.6.22.1(6)
2.	**Longitudinal Lines**		
	(a) Length	± 20mm from lengths shown in MUTCD/MRDGPM	SC6.4.6.22.2(3) SC6.4.6.22.3(3)
	(b) Width	± 10mm from widths shown in MUTCD/MRDGPM	SC6.4.6.22.2(3) SC6.4.6.22.3(3)
3.	**Transverse Lines**		

	(a) Length	± 10mm from lengths and widths shown in MUTCD/MRDGPM	SC6.4.6.22.2(3)
	(b) Width		SC6.4.6.22.2(3)
4.	**Arrows, Chevrons, Speed Markings etc.**	± 50mm from the dimensions shown in MUTCD/MRDGPM	SC6.4.6.22.2(3) SC6.4.6.22.3(3)
5.	**Application of Paint**		
	(a) Film Thickness	>0.35mm <0.40mm	SC6.4.6.22.2(3)
6.	**Application of Thermoplastic**		
	(a) Longitudinal Lines Cold Film Thickness	2.0mm ± 0.5mm	SC6.4.6.22.3(3)
	(b) Transverse Lines, Symbols, Arrows etc. Cold Film Thickness	3.5mm ± 1.5mm	SC6.4.6.22.3(3)
7.	**Glass Beads**		
	(a) Volume used in operation	0.3kg/sqm + 10%	SC6.4.6.22.2(3) SC6.4.6.22.3(3)

Attachment A: Procedure for measurement of rate of application of spherical glass beads

(1) **Scope**

The following procedure shall be adopted for field measurement of the rate of application of spherical glass beads on to wet paint or thermoplastic surfaces.

(2) **Spherical Glass Beads**

The glass beads shall comply with AS2009.

(3) **Measurement**

The method of field measurement shall be as follows:

(a) Turn off the paint or thermoplastic supply valves and operate the glass bead dispenser for exactly 10 seconds allowing glass beads to run into a plastic bag or tray.

(b) Pour the glass beads from the bag or tray into a suitable measuring cylinder calibrated in millilitres to measure the volume of glass beads collected. Level but do not compact the glass beads in the cylinder.

(c) Compare the volume of glass beads collected with the correct figure given in Table SC6.4.6.22.1 - Volume of Glass Beads (ml) required in 10 seconds of operation. Table SC6.4.6.22.1 - Volume of Glass Beads (ml) required in 10 seconds of operation shows the correct volumes of glass beads required to give a net application rate on the marked line of approximately 0.3kg/sqm for different line widths and road speeds. The glass bead volume figures given in Table SC6.4.6.22.1 - Volume of Glass Beads (ml) required in 10 seconds of operation are calculated for an actual application rate of 0.34kg/sqm.

(d) These figures are used for calibrating the machine because there is a loss of beads between the bead dispenser and the marked line; and

(e) The volume is measured with beads not compacted.

SC6.4.6.23 Guide posts

SC6.4.6.23.1 Introduction

(1) Scope

This policy subsection provides, minimum requirements for the setting out, supply of all materials and erection of guide posts in areas where street lighting is not provided to maintain safety of movement network.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-section:
SC6.4.6.30 - Control of traffic

(b) Australian Standards:
AS 1906.2 - *Retroreflective devices (non-pavement application)*
AS1580 -*Paints and related material*

(c) Queensland Department of Transport and Main Roads specification:
MRST14 *Road Furniture*

SC6.4.6.23.2 Materials

(1) General

Guide posts must be a proprietary metallic or flexible (driveable or non-driveable) post.

The surface of all posts must have a gloss or semi-gloss white finish. The surface shall be smooth and easily cleaned.

Proprietary posts must be minimum 1500 mm in length and must have one face of a minimum 80 mm width.

(2) Proprietary posts

Where a proprietary metallic or flexible guide post is proposed, the Contractor must supply details of the proposed guide post including the manufacturer's recommended installation procedure, technical specifications and test certificates for approval by the Superintendent.

(3) Delineators

Corner-cubed delineators, conforming to AS 1906.2 must be attached to each post. The delineators must conform to MRST14 *Road Furniture*.

SC6.4.6.23.3 Construction

(1) General

The Contractor must at all times conform to the requirements of sub-section SC6.4.6.30 Control of traffic.

Where the shoulder is in embankment or at natural surface level, the guide posts must be placed near the outer edge of the shoulder and at a uniform distance, minimum 1m, from the pavement edge line. Where the shoulder is located in a cutting, the guide posts must be placed on the road pavement side of the table drain, and minimum 1m from the pavement edge line, in such a manner that it does not impede the flow of water in the drain.

Guide posts must be erected at the locations shown on the Drawings. Underground services laid in proximity to the guide posts must be located prior to erection of posts all care must be taken not to damage such services.

(2) Erection of guide posts

Guide posts must be set vertically in the ground to a depth of approximately 500mm. In order to offset shoulder irregularities this depth must be varied so as to give uniform display of guide posts to a height of approximately 1000mm above ground level, with the tops evenly graded. Each guide post must be erected with the widest face at right angles to the centre line of the road.

Allowance must be made in the height of guide posts above the ground for the effects of superelevation and other road geometry in order to keep the guide posts within the range of the beam of vehicle headlights.

Backfilling must be compacted in layers of depth not more than 150mm for the full depth of the guide posts up to ground level. The density of the compacted backfilling must not be less than that of the adjacent undisturbed ground. Guide posts must be firm in the ground to the satisfaction of the Superintendent.

Proprietary guide posts, when installed in the ground in accordance with the recommendations of the manufacturer, must resist overturning, twisting and displacement from wind and impact forces. The Contractor must provide the manufacturer's instructions for anchorage.

If the guide posts are proposed to be installed on concrete pavements, the Contractor must provide the Superintendent details of fixing the guide posts to the concrete prior installation.

All necessary steps must be taken to prevent people and stock from stepping into the post holes during the erection of the guide posts.

(3) Delineators

"Corner Cubed" delineators, complying with AS1906.2, must be attached to each guide post using one way, anti-theft screws or rivets etc. In the case of proprietary posts, the delineators must be glued or otherwise fastened to the post in such a manner that they are not dislodged or rendered inactive under vehicular impact. The delineators must be mounted so that the top of the reflector is 100mm below the top of the guide post. The delineators must be so arranged that drivers approaching from either direction will see only red delineators on their left side and white delineators on their right side.

SC6.4.6.24 Signposting

SC6.4.6.24.1 Introduction

(1) Scope

This sub-section provides standards advice and guidelines for:

(a) the supply and erection of the regulatory, warning, guide, information and direction signs as described in Manual of Uniform Traffic Control Devices MUTCD.

(b) the supply and erection of sign support structures to support the signs, and

(c) the adjustment of existing signs and sign support structures.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:

SC6.4.6.28 - Minor concrete works

SC6.4.6.30 - Control of traffic

(b) Australian Standards:

AS 1163	*Cold-formed structural steel hollow sections*
AS 1214	*Hot-dip galvanised coatings on threaded fasteners (ISO metric coarse thread series)*
AS 1379	*Specification and supply of concrete*
AS/NZS 1554.1	*Welding of steel structures*
AS/NZS 1580.602.2	*Measurement of specular gloss of non-metallic paint films at 20 degrees, 60 degrees and 85 degrees*
AS 1580.108.2	*Dry film thickness - Paint inspection gauge*
AS/NZS 1734	*Aluminium and aluminium alloys - flat sheet, coiled sheet and plate*
AS/NZS 1866	*Aluminium and aluminium alloys - extruded rod, bar, solid and hollow shapes*
AS 2700	*Colour standards for general purposes*
AS/NZS 3678	*Structural steel - hot-rolled plates, floorplates and slabs*
AS/NZS 3679.1	*Structural steel - hot-rolled bars and sections*
AS 3990	*Mechanical equipment - Steelwork*
AS/NZS 4680	*Hot-dip galvanised (zinc) coatings on fabricated ferrous articles*

(c) Queensland Department of Transport and Main Roads Publications:

Manual of Uniform Traffic Control Devices (MUTCD)

Traffic and Road Use Management Manual (TRUM)

(3) Provision for traffic

The Contractor shall provide all necessary traffic safety measures in accordance with the requirements of sub-section SC6.4.6.30 Control of traffic while undertaking the work and shall organise the work to avoid or minimise delays and inconvenience to traffic.

Where a sign is erected before its intended use by traffic and is visible to traffic, the face of the sign shall be completely and securely wrapped in porous cloth sheeting or other opaque covering material approved by the Superintendent, until the Superintendent directs that the sign shall be uncovered.

SC6.4.6.24.2 Materials

(1) General

The Contractor shall advise the names of the proposed suppliers of signs and sign support structures for the Superintendent's concurrence. Only suppliers who have previously established or can now establish their competence to carry out the work in accordance with this sub-section shall be used.

The Contractor shall supply documentary evidence, satisfactory to the Superintendent that all materials and parts proposed for use comply with the requirements of the appropriate Australian Standard(s) as stated in this policy sub-section.

Details of the signs and sign support structures to be provided under the Contract shall be as shown on the drawings.

The dimensions, legend and background for each sign shall be in accordance with this sub section and the drawings.

(2) Sign blanks

Sign blanks shall be 1.6 mm thick aluminium sheet alloy. The aluminium alloy shall be Type 5251 or Type 5052 and Temper H38 or Temper H36 in accordance with AS 1734.

Sign blanks shall be free of cracks, tears and other surface blemishes and the edges shall be true and smooth. The dimensions of the sign blank shall be within plus or minus 1.5 mm of the dimensions specified and the finished sign shall be flat within a maximum allowable bow of 0.5 per cent of the maximum dimension of the sign blank in any direction.

Sign blanks shall be one piece except where the sign is of such a size as to require more than one full sheet of aluminium in which case a multipiece sign shall be allowed.

A multipiece sign shall be made up of the minimum number of pieces practical and sheets of the multipiece sign shall be butted together with a maximum gap of 1 mm at any point along the joint.

All joints shall be covered by a backing strip. The backing strip shall be riveted to each sheet with rivets, coloured to match the background material on the face of the sign, at a spacing not exceeding 200 mm. Backing strips shall be of the same material and colour as used for the sign blank and shall have a minimum width of 50 mm over the full length of the joint.

The aluminium extrusion used for mounting may be used as the backing strip for horizontal joints where it complies with the spacing requirements.

The face of each sign blank shall be chemically cleaned and etched or mechanically abraded. Where the sign blank is to receive a paint background, the face shall be spray painted with a compatible etch primer.

The back of each sign blank shall be uncoated and the surface finish shall be rendered dull and non reflective either by mechanical or chemical means and shall be free of scratches and blemishes.

Signs shall be supplied with square holes or aluminium extrusion backing for mounting purposes, at the centre spacings as shown on the drawings.

(3) Aluminium extrusion backing

The signs shall include special aluminium extruded sections for mounting purposes. The aluminium shall be Type 6063 T5 in accordance with AS 1866.

The aluminium extrusion shall be fixed at the centre spacings as shown on the drawings and shall be riveted to the sign blank with correctly coloured rivets at a spacing not exceeding 200 mm.

(4) Retro-reflective material for background and legend

Retro reflective material shall conform in colour and class to the requirements of AS 1743 and Table 1 in Section 1.2 of DTMR’s Traffic and Road Use Management manual for Class 1, Class 2 and Class 2A materials. Unless shown otherwise on the drawings, the material shall be Class 2.

(5) Non-reflective background material

(a) Background paint

Background paint shall be an approved long life industrial quality, two compound polyurethane paint. The paint shall exhibit high standards of adhesion, abrasion resistance, resistance to weathering and colour fastness under widely varying conditions of exposure. The paint shall be compatible with the etch primer used on the sign blank.

The paint shall be applied using conventional air spray application to give a uniform cover free of blemishes. A minimum dry film thickness of 38 microns is required when tested in accordance with AS 1580.108.2.

Background paint shall be as specified from one of the following colours:

(i) White Gloss

(ii) “Dark” Green Matt Colour No G61 as specified in AS 2700.

(iii) “Tourist” Brown Matt Colour No X65, Dark Brown, as specified in AS 2700.

(iv) “Dark Grey” Matt Colour No N64, Dark Grey as specified in AS 2700.

(b) Background sheet material
Adhesive cast vinyl sheet material or other equivalent material approved by the Superintendent may be used in place of background paint.

(c) The material shall be of uniform density and compatible with the material used for the legend both in application and durability.

The colours and gloss levels shall be uniform and conform to the requirements of clause SC6.4.6.24.2(5)(a) Background paint.

(6) Non-reflective material for legend

(a) Legend screening ink
Screening ink shall be a high quality, full gloss, non fade, non bleed and scratch resistant type of ink compatible with the material to which it is applied. Screening ink shall have durability at least equal to the material to which the screening ink is applied.

(b) Legend sheet material
Adhesive cast vinyl sheet material or other equivalent material approved by the Superintendent may be used in place of screening ink. The material shall be of uniform density and compatible with the material used for the background both in application and durability.

(c) Colours and finish
The requirements of clause SC6.4.6.24.2(5)(a) Background paint shall also apply to non reflective materials for legends but additional colours complying with AS 2700 may be specified.

(7) Rivets
Each rivet shall consist of a domed head and shank made of aluminium alloy and a steel mandrel which is discarded after securing the rivet.

A paint coating shall be applied to the domed head so that when the rivet is in position it will show the same colour as the material to which it is attached. Paint may cover the shank of the rivet, providing the coating thickness does not restrict the insertion of the shank into the standard drilled hole for that rivet.

The paint shall be an alkaloid enamel, which shall be applied after an appropriate treatment of the shank of the rivet to ensure long lasting adhesion.

(8) Reference markings
All signs shall be clearly and permanently stamped or engraved with an identification coding. The coding shall appear in ciphers of height neither less than 6 mm nor more than 10 mm on the rear of the sign and shall be carried out in such a manner that the front face of the sign is not damaged.

Manufacturers shall include coding information in the following format:

(a) sign reference number;

(b) manufacturer's name;

(c) month and year of manufacture; and

(d) manufacturer and class of retro reflective material.

(9) Sign support structures

(a) General
Sign support structures shall be fabricated from steel sections which shall comply with the requirements of AS 1163, AS 3678 and AS 3679.1.

Signs support structures shall be standard round galvanised posts of 50, 65 or 80 mm nominal bore or purpose designed steel structures as shown on the drawings and manufactured in accordance with the requirements of AS 1250.

Splices in members shall be restricted to a maximum of one splice per member. Splices shall be full penetration butt welds.

All welding shall be as shown on the drawings and in accordance with the requirements of AS 1554.1, Category GP.

(b) Protective treatment
Except for standard galvanised posts, all steel components including brackets shall be protected by hot dip galvanising after all fabrication processes are completed.

The steel components shall be finished by the hot dip galvanising process in accordance with AS/NZS 4680 to provide an average minimum coating thickness of 85 microns and a bright finished surface free from white rust and stains.

Bolts, nuts and washers and brackets shall be galvanised in accordance with AS 1214.

Splices in standard galvanised posts shall be painted by using an organic zinc rich primer, or inorganic zinc silicate paint, in accordance with the repair requirements in Appendix E of AS/NZS 4680.

Scratched and slightly damaged surfaces of galvanised coatings shall be renovated by using an organic zinc rich primer, or inorganic zinc silicate paint, in accordance with the repair requirements in Appendix E of AS/NZS 4680.

This method of renovation shall be restricted to areas not exceeding 2500 square millimetres on any one structure. Any structure with totally damaged coating areas exceeding 2500 square millimetres shall be regalvanised by the Contractor.

(c) Attachment of signs
Posts and other components shall be provided with the required sign attachment holes or fittings to suit the typical attachment systems as shown on the drawings. Sign panels shall be attached to each supporting member at each extrusion section or bolt hole in the sign panel.

The Contractor shall submit details of the proposed attachment systems for the Superintendent's approval.

SC6.4.6.24.3 Erection of new signs

(1) Setting out
The location of signs shall be as shown on the drawings or as directed by the Superintendent. The Contractor shall set out the work to ensure that all signs and support structures are placed in accordance with the drawings or as directed by the Superintendent.

Signs shall be aligned approximately at right angles to the direction of the traffic they are intended to serve. On curved alignments, the angle of placement should be determined by the course of approaching traffic rather than the orientation of the road at the point where the sign is located. Parking signs will generally be aligned at

45 degrees to the kerb line if not otherwise specified on drawings.

The Contractor shall submit details of and set out, for the Superintendent's inspection and approval, the proposed location and alignment of each sign support structure.

Work on the foundations of the sign support structure shall not commence until the Superintendent has approved the location and alignment of the sign support structure.

The Contractor is responsible in locating existing underground services in proximity of the signs prior to placement of footings and erection of signs to protect services from damage

(2) Clearing

The Contractor shall advise the superintendent of any trees and undergrowth within 3 m of the sign support structure and along a driver's line of sight to the front of the sign that are required to be cleared and removed. On receipt of this advice from the superintendent, council will inspect and advise what action is to be taken by the contractor.

(3) Sign structure footings

The footings for a simple pipe support or the footings for each post of a purpose-designed sign support structure shall be constructed in accordance with the drawings or as directed by the Superintendent.

The footings shall be neatly excavated to the depth and width shown on the drawings. The material from the excavation shall be disposed of in a responsible and legal manner.
When anchor bolt assemblies are specified they shall be accurately placed and firmly supported. Anchor bolt assemblies shall be provided with levelling nuts under the sign structure baseplates to allow adjustment of the structure after installation.

Steel reinforcement shall be placed as shown on the drawings.

Concrete in the footings of sign support structures shall comply with sub-section SC6.4.6.28 Minor concrete works and have a minimum compressive strength at 28 days of 20 MPa for pipe support footings and 32 MPa for purpose-designed support footings.

If ready mixed concrete is used, the concrete shall be mixed and delivered in accordance with AS 1379.

(4) Erection

All components shall be accurately positioned and supported during erection.

The top of each pipe support post shall extend sufficiently beyond the upper extrusion section or bolt holes on the sign panels to enable attachment of the signs. The top of each post shall be below the top edge of the sign panel.

For pipe support multi post installations, the tops of the posts shall be at the same level except where sign shape or the arrangement of sign panels dictates otherwise.

During erection, sign panels shall be suitably supported and braced and the sign face protected from damage. Signs damaged during erection shall be repaired to a standard equivalent to the original sign or replaced by the Contractor.

Galvanised coatings on purpose-designed support structures which are scratched or slightly damaged during erection shall be renovated by using an organic zinc rich primer, or inorganic zinc silicate paint, in accordance with the repair requirements in Appendix E of AS/NZS 4680. This method of renovation shall be restricted to areas not exceeding 2500 square millimetres on any one structure. Any structure with totally damaged coating areas exceeding 2500 square millimetres shall be regalvanised.

SC6.4.6.24.4 Adjustment of existing signs and support structures

Where shown on the drawings and where directed by the Superintendent, the Contractor shall adjust existing sign panels and sign support structures. The work shall include minor adjustments of existing sign panels and/or sign support structures or the work may extend to the dismantling of signs and sign support structures, relocation or replacement of sign support structures including footings and re erection of signs including all fittings.

SC6.4.6.24.5 Special requirements

(1) Street name, service and tourist signs

All street name, service and tourist signs shall comply with council's adopted signage system and with the details as shown on the drawings.

Proprietary signs shall be manufactured and installed in accordance with the requirements of Parts 1 and 6 of MUTCD to the following details:

(Sample only - to be completed by compiler)

(a) Colour:

(i) Legend - Blue, Non-reflective

(ii) Background - Yellow, Class 1 Retroreflective

(b) Lettering and Numerals:

(i) Font Type - Series D

(ii) Height – 100 mm

Details of council's logo shall be supplied to the Contractor by the council.

Details of the signs and legends are to be shown on the drawings.

The Contractor shall submit details of Manufacturer, all sign materials and sign attachment system to the Superintendent for approval by the council prior to commencement of sign manufacture.

SC6.4.6.24.6 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.24.1 Summary of limits and tolerances below:

Table SC6.4.6.24.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Sign Blanks**		
	(a) Dimensions	± 1.50mm	SC6.4.6.24.2(2)
	(b) Bow	< 0.5% of maximum dimension	SC6.4.6.24.2(2)
	(c) Butt gap in multipiece sign	< 1mm	SC6.4.6.24.2(2)
	(d) Rivet spacing in backing strip	< 200mm	SC6.4.6.24.2(2)
	(e) Backing strip width	> 50mm	SC6.4.6.24.2(2)
2.	**Extrusion Backing**		
	(a) Rivet Spacing	< 200mm	SC6.4.6.24.2(3)
3.	**Background Paint**		
	(a) For matt coatings, gloss level	> 12% and < 15%	SC6.4.6.24.2(5)
	(b) For gloss coatings, gloss level	> 85% and < 95%	SC6.4.6.24.2(5)

Item	Activity	Limits/Tolerances	Clause
4.	**Reference Marking**		
	(a) Height of Coding	> 6mm and < 10mm	SC6.4.6.24.2(8)
5.	**Sign Support Structures**		
	(a) Protective Treatment thickness	> 100 microns	SC6.4.6.24.2(9)(b)
	(b) Paint coating over Splices in standard galvanised posts	> 100 microns	SC6.4.6.24.2(9)(b)
	(c) Damaged Surface of galvanised surfaces		
	(i) Coating with zinc rich paint	Area < 2500 sq. mm	SC6.4.6.24.2(9)(b)
	(ii) Regalvanise	Area > 2500 sq. mm	SC6.4.6.24.2(9)(b)
6.	**Clearing**		
	(a) Trees and Undergrowth to be cleared	< 3 metres from sign support structure	SC6.4.6.24.3(2)
7.	**Concrete in Foundations of Sign Support Structures**		
	(a) Strength	> 25 MPa at 28 days	SC6.4.6.24.3(3)

SC6.4.6.25 Non-rigid road safety barrier system

SC6.4.6.25.1 Introduction

(1) Scope

The work to be executed under this sub-section consists of the setting out, supply of all materials and erection of road safety barriers and terminals, in accordance with the requirements for non-rigid road safety barrier systems in TMR Road Planning and Design Manual (Chapter 8), at the locations shown on the drawings or as directed by the Superintendent.

This sub-section details the requirements for public domain non-rigid road safety barrier systems. Where a patented non-rigid road safety barrier system is specified and shown on the drawings, all materials shall be in accordance with the manufacturer's specifications and, it shall be constructed strictly in accordance with the manufacturer's instructions.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied to this sub-section are as follows:
SC6.4.6.30 Control of traffic
SC6.4.6.28 Minor concrete works

(b) Department of Transport and Main Roads Standards:
Road Planning and Design Manual (RPDM) 1st edition – (Chapter 8), Safety Barriers and Road Side Furniture – as amended.

(c) Australian Standards:

AS/NZS 1906.2	*Retroreflective devices (non pavement application)*
AS/NZS 3845	*Road safety barrier systems*
AS/NZS 4680	*Hot-dip galvanised (zinc) coatings on fabricated ferrous articles*

SC6.4.6.25.2 Materials

(1) Components

All steel components for public domain non-rigid road safety barrier systems, W beam and Thriebeam, shall be designed and constructed strictly in accordance with the RPDM (Chapter 8 – as amended) using crushable energy-absorbing materials and shall be of the type as shown on the drawings.

(2) Certification

Road safety barrier components shall not be erected until the Contractor has produced documentary evidence to the Superintendent that such safety barrier components conform to the requirements of this sub-section.

For galvanized steel components provide a manufacturers certificate of compliance certifying that the zinc coating mass conforms to AS/NZS 4680 or, for components of proprietary safety barrier systems or devices, to the manufacturer's recommendations.

SC6.4.6.25.3 Construction

(1) General

The Contractor shall at all times conform to the requirements of sub-section SC6.4.6.30 Control of traffic.

Construction of non-rigid road safety barrier shall comply with RPDM, except where explicit departures are approved on the drawings.

Road safety barriers shall be erected after the construction of the base on concrete pavements and after the placing of the initial layer of asphaltic concrete or sprayed seal on a flexible pavement, unless otherwise approved by the Superintendent.

The Contractor shall set out the work to ensure that all road safety barriers and terminal sections are located,

in accordance with the drawings or as directed by the Superintendent.

Underground cables and ducts laid in the road safety barrier area shall be located prior to the erection of posts and all care must be taken not to damage such cables and ducts.

The posts should be set to the full depth as shown on the drawings. If this is not possible due to the presence of an underground obstruction, an alternative method of setting the posts, as approved by the Superintendent, shall be used.

Posts shall stand vertical and the spacing shall be such that when the safety barrier is erected no post movement is necessary in order to align holes or for any other reason.

(2) Erection of steel posts

The safety barrier posts are to be located as shown on the drawings. The top of the post shall be 750mm, 845mm or 905mm as appropriate for W beam, Thrie beam or modified blockout Thrie beam respectively, above the ground level, unless otherwise shown on the drawings. On terminal ends, the level of the posts shall be such as to conform to the extended crossfall of the main pavement unless otherwise shown on the drawings.

When erected in position the posts shall be on a smooth line both horizontally and vertically with the tops of posts within ±10 mm of the heights specified in paragraph 1 of this clause.

Steel posts shall be erected by driving, or by other means, as directed by the Superintendent, in accordance with the requirements for foundation posts in the TMR RPDM. The open section of the post shall point in the same direction as adjacent traffic. The posts are to be firm in the ground and any movement at ground level shall not exceed 3mm in any direction when force tested in accordance with TMR guidelines

The posts shall not have any obvious deformation as a result of driving. Any damage which does occur to the posts is to be repaired within 24 hours using an organic zinc-rich primer in accordance with the repair requirements of Appendix E in AS/NZS 4680.

Any post which has been excessively damaged will be rejected by the Superintendent and shall be replaced by the Contractor at their own expense.

(3) Erection of road safety barrier rails

Steel blockout pieces shall be erected with the open section pointing in the same direction as adjacent traffic.

All rail laps shall be in the same direction as adjacent traffic such that approach rail ends are not exposed to traffic.

Stiffening pieces, 300mm long, shall be used on intermediate posts.

Road safety barrier rails and blockout pieces shall be handled and erected in such a manner that no damage occurs to the galvanising. Any minor damage occasioned to the galvanising shall be repaired within 24 hours using an organic zinc-rich primer in accordance with the repair requirements of Appendix E in AS/NZS 4680.

Any road safety barrier rails or blockout pieces that have been excessively damaged will be rejected by the Superintendent and shall be replaced by the Contractor at their own expense.

Road safety barrier rail attachment bolts and splice bolts are to be tightened initially such that the barrier can be erected. Adjustments are then to be made to the rails using the slotted holes provided to produce a smooth regular line, free of any kinks or bumps. The overall line of the top of the safety barrier rails is to visually conform with the vertical alignment of the road pavement.

When the alignment both vertically and horizontally is obtained the splice bolts are to be fully tightened. The bolt head (not the shoulder) should be in full bearing with the rail.

(4) End treatment of road safety barriers

Both approach and departure ends of the road safety barrier shall be constructed with leading and trailing terminal sections at locations shown and as detailed on the drawings.

An appropriate terminal end treatment shall be constructed, as detailed on the drawings, at the approach and end locations of road safety barriers as shown on the drawings. Consideration of alternate terminal end treatments will include sufficient clearance behind the safety fence to accommodate pedestrians and cyclists, where applicable.

The approach and departure ends of double sided road safety barriers shall have terminal sections as detailed on the drawings.

Non-rigid road safety barrier connections to rigid road safety barriers or bridge parapets shall be as detailed on the drawings.

(5) Delineators

Delineators complying with AS 1906.2 shall be fixed with brackets to the road safety barrier, to the details and at the locations shown on the drawings beginning at the first post and then in accordance with Table SC6.4.6.25.1 below.

Table SC6.4.6.25.1 Spacing of reflectors on barriers

Radius of Curve	Spacing of Reflectors on Barrier
m	every
30 - 90	3rd post
90 - 180	5th post
180 - 275	8th post
275 - 365	11th post
over 365 (including straight road)	16th post

The delineators shall be so arranged that drivers approaching from either direction will see only red reflectors on their left side, and white reflectors on their right.

(6) Connection to existing safety fencing

The Contractor is to inspect and document the condition of all existing barrier fencing and its suitability to meet current specifications and standards, prior to connection or incorporation into the subject works. All documentation of existing fencing is to made available to the Superintendent for future inspection, if requested.

If any existing safety fencing is deemed not to comply with current design and safety standards, it is to be replaced.

SC6.4.6.25.4 Limits and tolerance

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.25.2 Summary of limits and tolerances below:

Table SC6.4.6.25.2 Summary of limits and tolerance

Item	Activity	Limits/Tolerances	Clause
	Vertical Alignment	± 10mm	SC6.4.6.25.3(2)
	(a) Tops of steel posts.		
	(i) Post Movement	£ 3mm	SC6.4.6.25.3(2)
	Concrete Footings	-0mm or +50mm	SC6.4.6.25.3(3)
	(a) Diameter		

SC6.4.6.26 Landscaping

SC6.4.6.26.1 Introduction

(1) Scope

This sub-section sets out the standards and provides advice and guidelines for the construction of landscape works that will become a council asset.

Landscape works includes but is not limited to, site co-ordination, turfing, gardens, grass seeding, tree plantings, pathways, paved areas, concrete works, stormwater drainage and infrastructure.
This sub-section consists of:

(a) the vegetation of cut and fill batters, median areas, pathway verges, open drains and other areas within the site. Vegetation includes the initial surface preparation, topsoiling, fertilising, sowing of seed and may include surface protection works, hydroseeding, hydromulching and straw mulching; and

(b) the supply of plants, planting at locations fertilising, mulching, staking, watering and maintenance of plants.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

All design and documentation, materials supplied and work carried out shall be in accordance with the following standards.

(a) Development manual planning scheme policy sub-sections to ne read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.10 - Earthworks (construction).

(b) Australian Standards:

AS 1160	*Bituminous emulsions for the construction and maintenance of pavements*
AS 1289	*Methods of testing soils for engineering purposes – General requirements and list of methods*
AS 1672.1	*Limes and limestones – Limes for building*
AS 2507	*The storage and handling of agricultural and veterinary chemicals*
AS 3000	*Electrical installations (known as the Australian/New Zealand Wiring Rules)*
AS 3700	*Masonry structures*
AS 3798	*Guidelines on earthworks for commercial and residential developments*
AS 3972	*General purpose and blended cements*
AS 4419	*Soils for landscaping and garden use*
AS 4454	*Composts, soil conditioners and mulches*
AS/NZS 4671	*Steel reinforcing materials*
AS 4843	*Synthetic weed blocking fabric*
AS 4970	*Protection of Trees on Development Sites*

(c) Other:

Electricity Act 1994
International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

(3) Terminology

For the purposes of this document the following definitions apply:

Defects liability period	refer to Section SC6.4.7 Acceptance of completed works.
Gardens, garden beds and garden areas	means a defined area of mulched “garden” containing various shrubs, trees, plants or hedges.

Litter	means bottles, paper, cigarette packets, cigarette butts, drink cans, ice cream sticks, plastic, rubber, glass, milk and fruit juice cartons, paper plates and the like. Litter also includes fallen branches, palm fronds, waste, household rubbish, condoms, sharps/syringes, leaves where leaves are unsightly or cause damage to lawn or garden areas, or other dumped material.
Maintenance period	equivalent to the defects liability period and includes the plant establishment period.
Plant establishment period	coincides with the defects liability period.
Planter box	means a transportable or in situ container designed specifically for containing a garden of trees and /or shrubs.
Sub grade	means the level at the underside of garden or turf top soil or the level at the underside of paving gravel base course.
Superintendent	means the nominated representative for council.

SC6.4.6.26.2 Works management

(1) Qualified personnel

Personnel shall be suitably qualified and competent in all aspects of landscape works and shall be familiar with all relevant Australian Standards. All maintenance work to new and existing trees shall be carried out under the supervision of an Arborist with formal qualifications (Level 5 Australian Qualification Framework) or at least 5 years recognised experience in Arboriculture.

(2) Design approval

The design of the landscape works will be prepared by a qualified Landscape Architect.

(3) Contractor inspections

Inspections must be certified and documented by a Registered landscape Architect (the supervising landscape architect). All approved works are required to be inspected by Townsville City Council.

(4) Council inspections

(a) Council may inspect the following:

(i) sub grade prior to placing fill;

(ii) sub grade prior to placing garden soil or turf soil;

(iii) sub grade prior to placing the gravel base course;

(iv) sub grade prior to placing paving or concrete works;

(v) installation of gypsum;

(vi) condition of plants after delivery to site and prior to planting, including planting holes prior to planting;

(vii) gardens prior to planting;

(viii) turf areas prior to laying turf;

(ix) areas to be hydro-mulched / seeded prior to treatment;

(x) concrete structures (formwork) prior to placing concrete;

(xi) block work and reinforcing prior to placing core fill concrete; and

(xii) other elements considered necessary by the Superintendent.

(b) Inspection of irrigation works shall be undertaken by the Superintendent and a council Irrigation Officer in association with the Landscape works and is detailed below:

(i) all mainline to be inspected prior to covering;

(ii) drip tube layout prior to covering;

(iii) 240v power conduit from Ergon POS to controller for correct depth prior to covering;

(iv) all envelopers (conduits) work under hard surfaces prior to covering;

(v) all envelopers (conduits) under hard surfaces must be continuous 100 mm PVC CL9, all conduit ends must be sealed with expanding foam prior to covering; and

(vi) water meter assembly installation prior to covering to ensure correct installation of thrust blocks and copper protection.

(5) Inspection results

(a) Work inspected that complies with the sub-section and/or the design plans will be accepted by council.

(b) Any work inspected that does not comply with the sub-section and/or the design plans, will not be accepted by council. Items not acceptable will be noted for rectification.

(c) The contractor is required to rectify these items prior to proceeding to the next construction phase and shall apply for a re-inspection by council on completion of the rectification work.

(6) A minimum of 24 hours notice by is required for notification of an Inspection. Failure by the Contractor to notify council of any inspections required, will result in the works being excavated at the Contractors cost to allow an inspection to be carried out.

(7) Inspection documentation.

Editor's note—this section relates to Inspection Test Plans and is currently under development.

SC6.4.6.26.3 Supply of materials

(1) Materials supply - general

(a) Substitutions

The Contractor shall notify the council immediately if an item is unavailable for inclusion in the works and shall provide alternative supply details if appropriate. Substitutions of any materials or products shall not be made unless approved by the Superintendent in writing.

(b) Material samples

In certain instances, council may request the Contractor to provide samples of materials to be installed or used for work under the development approval.

(c) Materials testing

In certain instances, council may request the Contractor to provide results of materials testing. Where applicable, testing requirements will be set out in the conditions of approval.

(d) Materials warranty

Where requested, the Contractor shall provide to council all relevant warranty details for the materials nominated in any conditions of approval.

(2) Supply of plants

(a) Plant specifications

(i) All plants supplied shall be in a healthy condition free from weeds, pests and diseases. Plants shall be well foliated, showing signs of active growth, true to type and of a form and shape considered typical for the species or variety.

(ii) Leaves shall be of normal size, shape, colour, and texture with no physical or insect damage or disease lesions.

(iii) The plant roots shall be fibrous, well developed and not root bound, with no kinking, knotting, girdling or spiralling and shall be free of any pests or diseases or any other root defects.

(iv) All plants supplied shall be hardened off and in a condition suitable for planting in the Townsville climate.

(v) Trees supplied (unless required to be multi-stemmed) shall have a single leading stem and shall

be self-supporting and unstaked.

(vi) Root bound plants, deformed plants and plants showing recent signs of root pruning will not be accepted.

(vii) At time of delivery to the site, each group of plant species shall be clearly and accurately labelled according to botanical nomenclature. Labels shall be water resistant and tied securely to one plant in every 20 for each species.

(viii) Plants which are above the minimum size requirements may be accepted for inclusion within the works.

(b) Container stock

Plants grown in containers shall have a root system firmly established with no large roots growing out of the container, shall be of such a size that the roots have penetrated to the bottom of the container and occupy 95-100% of the soil volume and/or have sufficient roots to hold the container soil together after removal of the plant from the container.

(c) Ex-ground stock plants

(i) Where plants are growing in ground prior to delivery to the site, the necessary root pruning and/or preparation procedures in accordance with accepted transplanting practice shall be commenced in sufficient time to ensure that, at the time of planting the plant is ready and will meet the specified requirements. Transplanting of ex-ground stock should be conducted under the supervision of a qualified (Level 3 Australian Qualification Framework) horticulturalist or arborist.

(ii) Refer to Table SC6.4.6.26.1 for minimum acceptable root ball sizes for ex-ground stock plants.

Table SC6.4.6.26.1 Acceptable root ball sizes

Small Trees		Large Trees	
Height of Tree (mm)	Root Ball Diameter (mm)	Approximate Tree Trunk Diameter (mm) (300 mm above ground)	Root Ball Diameter (mm)
600 - 900	300	40	500
900 - 1200	350	50	550
1200 - 1500	400	65	600
1500 - 1800	450	75	800
1800 - 2100	550	100	950
2400 - 2700	600	125	1200
2700 - 3000	650	150	1450
3000 - 3600	750	175	1600
3600 - 4200	800		
4200 - 5000	900		

(d) Substitutions

Substitutions of plants shall not be permitted unless approved in writing by council. In the event that a plant is unavailable the Contractor may request to provide a substitution. Substituted plants shall be of the same specified type, quality and size unless otherwise agreed to by council.

(3) Supply of imported soil mix

(a) Imported soil mix shall be organic soil, soil blend or top dressing in accordance with the Australian Standard AS 4419 Soils for landscaping and garden use.

(b) The Contractor shall note the requirements of AS 4419.

(4) Supply of turf

(a) Turf shall be the species nominated on the drawings and shall be supplied by a specialist grower of cultivated turf.

(b) The soil of the turf sod shall be an even thickness of 25 mm minimum.

(c) Turf shall be free from any matter toxic to plant growth and shall be free from roots, weed or weed

seeds.

(5) Supply of hydro seeding/mulching
The specific mix/blend of hydro seeding/mulching required shall be nominated on the drawings and supplied by specialist supplier of hydro seeding/mulch.

(6) Supply of mulch materials

(a) All mulch materials supplied shall be in accordance with the current relevant AS 4454 Composts, soil conditioners and mulches.

(b) Organic and inorganic mulch shall be of the type and quality as noted on the drawings.

(c) Organic mulch derived from vegetation cleared on site may only be used where it is free from deleterious materials such as rock, soil and weed material.

(7) Tree stakes and ties

(a) Unless otherwise noted on the drawings or approved by council, tree stakes shall be durable hardwood, straight, free from knots or twists and pointed at one end.

(b) Small plants may only require 1 stake where required.

(c) For trees up to 45 litre 2 stakes – 50 mm x 50 mm x 1800 mm long.

(d) For trees over 45 litre 3 stakes – 50 mm x 50 mm x 2400 mm long.

(e) Ties shall be 50 mm wide furniture grade hessian webbing or similar.

(f) Supply of proprietary items
Timber/concrete garden edging, soil conditioners, root barrier, furniture items, play equipment and other project specific items shall be supplied to the requirements and details noted on design and/or construction drawings.

(8) Supply of gypsum
Gypsum application rates shall be supply in accordance with AS 4454 and as required by soil types specific to the site.

(9) Supply of fertiliser
Fertilisers supplied shall be:

(a) delivered to the site in sealed bags clearly marked to show the manufacturer or vendor, weight, fertiliser type, N:P:K. ratio, recommended uses and application rates; and

(b) applied at the locations and frequencies in accordance with the manufacturer's recommendations.

SC6.4.6.26.4 Earthworks

(1) General
Earthworks relates to gardens, grass areas, pathways and paved areas and includes:

(a) site clearing;

(b) stripping of existing vegetation;

(c) stripping of existing top soil;

(d) excavation to sub grade level;

(e) filling to sub grade level; and

(f) cultivation of the sub grade surface.

(2) Quality management
All materials supplied and work carried out shall be in accordance with the current, relevant Australian Standards:

(a) AS 1289 - Methods of testing soils for engineering purposes; and

(b) AS 3798 - Guidelines on earthworks for commercial and residential developments.

(3) Existing services

Per sub-section SC6.4.6.11 Clearing and grubbing, the Contractor is required to locate all existing and newly installed services prior to commencement of any earthworks. Care shall be taken in areas to be excavated, filled or cultivated not to unearth or damage services. Any damage to services caused by the Contractor shall be reinstated by the Contractor at no cost to council.

(4) Site preparation

(a) Clearing/Demolition

(i) Clearing shall mean the removal of trees, shrubs, scrub and undergrowth and other vegetation above ground level and includes the removal of artificial obstructions such as fences, concrete slabs rubbish, timber, boulders, rubble and other man made products.

(ii) Clearing shall be carried out in accordance with sub-section SC6.4.6.11 Clearing and grubbing.

(b) Grubbing

Grubbing shall mean the removal from below ground level of trees, roots, stumps, rocks and artificial obstructions as defined and specified by sub-section SC6.4.6.11 Clearing and grubbing.

(c) Stripping of existing vegetation

Areas to be excavated or filled shall be stripped of all vegetation to a depth just sufficient to include the root zone (nominal 50 mm). All stripping of vegetation is to be in accordance with sub-section SC6.4.6.11 Clearing and grubbing and must not affect trees/vegetation to be retained, as per clauses SC6.4.5.2.1(18) and (19).

The striped material shall be removed from site or may be stockpiled on site for later reuse, if approved by council and in accordance with clause SC6.4.5.2.1(17) Stockpiling of materials.

(d) Existing topsoil

Existing topsoil excavated on site may be reused provided that the material conforms to the AS 4419 requirements and is approved for reuse by the Superintendent. The material may be stockpiled on site, in accordance with clauses SC6.4.5.2.1(16) and (17).

(5) Excavation (down to sub grade level)

(a) General

The existing surface of areas to be excavated shall be stripped of all vegetation prior to excavating. Care shall be taken not to unnecessarily expose subsoils through the area of construction by over excavation, to prevent any potential for the development of acid sulphate conditions.

(b) Excavation in gardens

(i) Garden beds shall be excavated down to subgrade level as required to suit the finished surface levels, the depth of garden mix soil and the depth of mulch.

(ii) The subgrade shall be shaped and graded evenly to fall towards subsoil drains (if present) and the topsoil shall be shaped to fall from the centre of the bed outwards in all directions.

(iii) Excavation in gardens shall be in accordance with council's approved standard drawings.

Editor's note— standard drawings for these works are under development.

(c) Excavation in grass areas

(i) Grass areas shall be excavated down to subgrade level as required to suit finished surface levels, the depth of turf top soil and the depth of turf.

(ii) The subgrade shall be shaped and graded evenly to fall towards subsoil drains (if any) and shall be graded evenly to follow the finished surface profile.

(iii) Excavation in grass areas shall be in accordance with council's approved standard drawings.

Editor's note—standard drawings for these works are under development.

(d) Excavation for pathways and paved areas (paving)

(i) Pathways and paved areas shall be excavated down to subgrade level as required to suit finished surface levels, the depth of the gravel base course, bedding sand, pavers or concrete. The subgrade shall be shaped and graded evenly to the falls shown on the drawings and/or to fall to stormwater pits or subsoil drains.

(ii) Excavation for pathways and paved areas shall be in accordance with council's approved standard drawings.

Editor's note—standard drawings for these works are under development.

(e) Excavation near existing trees
Excavation near existing trees shall be undertaken in accordance with clause SC6.4.5.2.1(19) Work adjacent to trees and protection of environmentally significant vegetation.

(f) Spoil

(i) Spoil material resulting from excavation shall be reused on site wherever practicable, provided that the material conforms to the specified requirements for its intended use (e.g. filling or top soil) as per AS 4419.

(ii) Spoil material to be reused may be stockpiled on site as per clause SC6.4.5.2.1(17) Stockpiling of materials.

(iii) After the excavation process has been completed, the sub grade surface shall be inspected for springs, soft soil areas and other structural weaknesses. Where such weaknesses are encountered the following remedial works may be required:

(A) excavation and replacement of unsuitable material;

(B) surface drainage blankets of sand; and

(C) subsoil drains.

(6) Filling (up to sub grade level)

(a) Existing surface treatment
The existing surface of areas to be filled shall be stripped of all vegetation prior to placing any fill. The existing surface shall then be scarified to a depth of 200 mm. If required, water shall be added to bring the existing surface up to optimum moisture content prior to placing any fill.

(b) Unsuitable existing surface
After the stripping process has been completed, the existing ground surface shall be inspected for springs, soft soil areas and other structural weaknesses in the naturally occurring soil. Where such weaknesses are encountered, the following remedial works may be required:

(i) excavation and replacement of unsuitable material;

(ii) surface drainage blankets of sand; and

(iii) subsoil drains.

(c) Acceptable types of fill material for gardens and grass areas
Fill material to garden and grass areas shall be either:

(i) "general purpose soil" to AS 4419 Clause 4.1; or

(ii) "natural soil" to AS 4419 Clause 4.3; or

(iii) spoil from on site excavations if approved by the Superintendent, with a maximum particle size 25 mm.

(d) Acceptable types of fill material for pathways and paved areas
Fill material to pathways and paved areas shall be:

(i) crusher dust, free from organic matter and lumps of clay; or

(ii) crushed rock gravel uniformly graded, nominal particle size 25 mm; or

(iii) other granular material approved by the Superintendent.

All material used shall have a linear shrinkage - 0 - 8%, Soaked California Bearing Ratio – 15 minimum.

(e) Fill in gardens
Gardens shall be filled up to sub grade level as required to suit the finished surface levels, the depth of garden mix soil and the depth of mulch. The sub grade shall be shaped and graded evenly to fall towards subsoil drains (if any).

(f) Fill in grass areas
Grass areas shall be filled up to sub grade level as required to suit finished surface levels, the depth of turf top soil and the depth of turf. The sub grade shall be shaped and graded evenly to fall towards subsoil drains (if any) or gully pits and to mirror the finished surface profile.

(g) Fill to pathways and paved areas
Path ways and paved areas shall be filled up to subgrade level as required to suit the finished surface levels, the depth of the gravel base course, bedding sand, pavers or concrete. The subgrade shall be shaped and graded evenly to the falls shown on the drawings and/or to fall to stormwater pits.

(h) Fill around existing trees
For informatin regarding placement of fill and compaction issues refer to AS 4970 Protection of trees on development sites and Clause SC6.4.5.2.1(18) Work adjacent to trees and protection of environmentally significant vegetation.

(7) Placing and compacting fill

(a) Fill material shall be placed and compacted in successive horizontal layers to the dimensions, levels, grades, and cross sections as shown on the drawings and so that the surface is always self-draining. Refer to Table SC6.4.6.26.2 for compaction standards. Care shall be taken to ensure that fill to garden areas is not excessively compacted.

(b) Each fill layer shall be scarified, and/or harrowed and processed to a finely divided condition, uniformly watered or aerated as the case may be, to obtain moisture content within the range of 80% - 90% of the optimum moisture content. The loose depth of the material in each layer shall be not more than 150 mm.

(c) Fill shall be placed in layers simultaneously on both sides of structures, culverts and pipe work to avoid differential loading. Fill shall not be placed against concrete or masonry structures, walls and the like until the concrete or masonry work has been in place for a minimum of 14 days.

(d) Existing works and structures shall be protected from damage due to compaction operations. Compaction by mechanical means shall not be carried out within 300 mm of paths, kerbs or structures. Compaction in these locations shall be carried out by hand or the size of compaction equipment shall be limited to ensure no damage is caused. Commence compaction of each fill layer at the structure and proceed away from it.

Table SC6.4.6.26.2 Fill compaction standards

Location	Compaction standard
Gardens and Grassed Areas.	85% Relative Dry Density Standard Compaction.
Pathways, Paved Areas and Structures.	95% Relative Dry Density Standard Compaction.

(8) Grading

(a) Runoff from impervious surfaces such as roofs, driveways and car parks, and overland flows from turf and garden beds is to be captured and allowed to infiltrate into subsoils by reshaping existing landforms through the use of swales, contour banks, soaks, percolation pits and basins, rain gardens and bioretention filters.

(b) To reduce runoff and erosion and encourage rainwater infiltration into soil, a landscape embankment is not to exceed grades of 1 in 5.

(c) The regrading of land is not to occur within the tree protection zone of existing trees to be retained.

(9) Cultivation

(a) Applies to gardens and grass areas (if directed or if noted on the drawings).

(b) Where shown on the drawings, the sub grade of Gardens and Grass Areas shall be cultivated prior to placing garden mix soil or turf top soil.

(c) The sub grade shall be thoroughly cultivated by ripping parallel to the final contours to loosen the compacted ground and to the depths nominated in Table SC6.4.6.26.3.

Table SC6.4.6.26.3 Cultivation depths

Location	Cultivation depth
Garden Areas	200 mm
Grass Areas	100 mm

(d) In areas of heavy clay natural soil, granulated gypsum shall be spread over the entire area of all gardens at a minimum rate of 2 kg per square metre and shall be thoroughly blended and incorporated into the subgrade during cultivation.

(e) In areas of heavy clay natural soil, granulated gypsum shall be spread over the entire area of all grass areas at a minimum rate of 2 kg per square metre and shall be:

(i) thoroughly blended and incorporated into the subgrade during cultivation if cultivation is to be carried out; or

(ii) spread prior to placing turf soil.

(f) Any soil additives and/or imported materials other than gypsum, that may be required to be applied to the natural soil shall be thoroughly blended with or spread over the subgrade.

(g) Cultivation shall not be carried out when the soil is wet or plastic.

(h) The Contractor shall ensure that no damage occurs to tree roots, underground services, kerbing and the like during the cultivation process. Cultivation by mechanical means shall not be carried out within the drip line of trees to be retained or within 300mm of pathways, paved areas and/or structures. Cultivation in these locations shall be carried out by hand. Refer to Clause SC6.4.5.2.1(19) Work adjacent to trees and protection of environmentally significant vegetation.

(i) After cultivation soil lumps shall have a maximum dimension of 50 mm. Stones exceeding 25 mm, clods of earth exceeding 50 mm, weeds, roots, sticks, rubbish and any other deleterious material brought to the surface during cultivation shall be removed. Any depressions caused by the removal of these materials shall be filled with top soil or on site spoil material approved by the Superintendent.

(j) After cultivation the surface shall be graded smoothly and evenly and trimmed to the required levels allowing for placing the specified depth of imported soil to achieve the finished surface levels as noted on the drawings. Care shall be taken to prevent areas of excessive compaction being caused by construction equipment.

(10) Backfilling trenches

(a) Backfill to trenches up to sub grade level under pathways and paved areas shall be clean sand or crusher dust compacted to 95% relative dry density standard compaction.

(b) Backfill to trenches up to sub grade level in gardens and grass areas shall be imported soil mix or material excavated from the trench or may be other on site material approved by the Superintendent.

(c) Trenches excavated in gardens within the imported garden mix soil shall be backfilled with imported garden mix soil mix as specified.

SC6.4.6.26.5 Vegetation of slopes and drains

(1) Execution and timing of work

(a) The work to be executed under this clause includes the vegetation of cut and fill batters, pathway verges, median areas, open drains and other areas within the site. Vegetation includes the initial surface preparation, topsoiling, fertilising and either sowing of seed or turfing as shown on the drawings.

(b) Exposed ground shall be vegetated before the area exceeds one hectare or lesser area in compliance

with council requirements.

(2) Materials

(a) Topsoil

The Contractor shall use topsoil stockpiled on site under the sub-section SC6.4.6.10 Earthworks (construction). Where imported topsoil is required it shall comply with AS 4419 and shall:

(i) be of a friable, porous nature;

(ii) be free of weeds and weed seeds, bulbs, corms and vegetable propagules;

(iii) contain no refuse or materials toxic to plant growth;

(iv) contain no stumps, roots, clay lumps or stones larger than 50 mm in size;

(v) have an organic content of at least 3 per cent by mass;

(vi) have a pH neither less than 5.5 nor more than 7.5; and

(vii) have a soluble salt content not exceeding 0.06 per cent by mass.

(b) Herbicide

Herbicide used shall be a glyphosate-based herbicide listed in SC6.4.6.26 Attachment A.

(c) Seed

(i) All seed used shall be of the species and varieties list in SC6.4.6.26 Attachment A and shall be sown at the application rates specified therein. The Contractor shall submit to the Superintendent the name/s of the proposed seed supplier/s within 2 weeks of the acceptance of the tender.

(ii) The Contractor's attention is drawn to the lead time that may be required to procure some native seed species. The native seed shall be delivered to the site in separate lots for each species and variety, clearly labelled to show species, variety and weight.

(iii) All seed must be accompanied by a "Certificate of Authenticity" which shall be furnished by the Contractor to the Superintendent upon request at any stage of the work. Grass and clover seed shall be pre-packed commercially with an accompanying certificate of germination.

(iv) The Contractor shall not take possession of the seed more than 7 days before sowing is to occur. The seed shall be stored in clean, air tight containers and kept away from direct sunlight. It shall not be exposed to the elements at any stage during storage.

(v) The Contractor shall replace at his own expense any exotic seed batch found not true to type.

(d) Turf

Turf shall consist of 25 mm depth of dense, well rooted, vigorous grass growth with 25 mm depth of topsoil. The type of grass turf to be used shall be selected from SC6.4.6.26 Attachment A and in accordance with the drawings. Unless specified, Kikuyu grass shall not be used. Turf shall be free of weeds, soil pests and diseases. The turf shall be supplied as rolls in long lengths of uniform width, not less than 300 mm, and shall be in sound unbroken condition.

(e) Fertiliser

Fertiliser shall be an organic type listed in SC6.4.6.26 Attachment A with Nitrogen: Phosphorus: Potassium (N:P:K) ratios of 8 : 3.6 : 2.

(f) Vegetable mulch

Vegetable mulch used in hydromulching shall consist of straw, chaff, wood fibre, paper pulp or similar material all finely shredded to a maximum dimension of 10 mm. Meadow hay or weeds shall not be used and paper pulp if used shall not exceed 50 per cent by mass of the total mulch.

(g) Water

Water used shall be potable.

(h) Binder

The binder used in hydromulching and strawmulching shall be Grade ASS, slow setting anionic bitumen emulsion, complying with AS 1160.

(i) Wetting agent

The soil wetting agent added in hydromulching or hydroseeding shall be listed in SC6.4.6.26 Attachment A and applied at the application rate specified therein.

(j) Pesticide
Pesticide used shall be a liquid or powder listed in SC6.4.6.26 Attachment A. The storage and handling of pesticides shall be in accordance with AS 2507.

(3) Vegetation of slopes 3 to 1 or flatter

(a) Preparation of surface

(i) Slopes shall be sprayed with herbicide applied at the rate specified in SC6.4.6.26 Attachment A to kill weed infestation. Sprayed areas shall remain undisturbed for two weeks.

(ii) The surface shall then be tyned to a depth of 200 mm to produce a loose surface and all large stones, rubbish and other materials that may hinder germination shall be removed before topsoiling.

(b) Topsoiling
Topsoil shall be uniformly applied to provide an average compacted thickness of 50 mm with a minimum compacted thickness of 30 mm at any location. The topsoiled area shall be cultivated to a depth of 50 mm to provide a roughened surface with soil lumps not exceeding 50 mm dimension.

(c) Mixing of seed
The Contractor shall give the Superintendent 2 days notice before each sowing operation. Seed shall be sown on the day of mixing with pesticide.

(d) Incorporation of pesticide
Immediately before sowing, all grass and native seed shall be treated with pesticide. The pesticide shall be thoroughly mixed as a dry powder with the seed at the rate specified in SC6.4.6.26 Attachment A to the equivalent mass of seed to be spread on 1 hectare of the surface in accordance with SC6.4.6.26 Attachment A.

(e) Sowing

(i) Sowing shall be carried out with an appropriate mechanical seeder. Where practicable, passes shall follow finished surface contours. Seed shall be sown at a depth of 5 mm or shall be raked or harrowed to provide 5 mm cover.

(ii) Seed and fertiliser shall be evenly distributed over the areas to be sown at the rates specified in SC6.4.6.26 Attachment A. Fertiliser shall be applied concurrently with the seeding operation.

(f) Turfing

(i) Turf shall be placed on the prepared topsoiled surface. Runs of turf shall butt hard against each other and be placed perpendicular to the direction of water flow. Turf seams shall then be topdressed with topsoil.

(ii) Four to six weeks after placement, the turf shall be lightly topdressed with topsoil to correct any undulations or unevenness in the established turf.

(g) Watering
The Contractor shall water areas to be sown to a moist condition and shall rewater areas to a moist condition without surface runoff on a daily basis for a minimum of 15 days after sowing, or as otherwise directed by the Superintendent, to promote and maintain growth.

(4) Vegetation of slopes steeper than 3 to 1

(a) General
Where required or directed by the Superintendent, slopes shall be vegetated by one of the following methods:

(i) topsoiling and hydromulching;

(ii) topsoiling, hydroseeding and straw mulching; or

(iii) hydroseeding.

(b) Preparation of surface

(i) Weeds shall be killed by spraying with herbicides as specified in SC6.4.6.26 Attachment A.

(ii) No more than 7 days before seeding all loose material shall be removed from fill batters and cut

batters, which are not stepped, by dragging a heavy steel chain of minimum weight of 30 kilograms per metre of length or by other methods approved by the Superintendent.

(c) Topsoiling

Where batters have been stepped, the steps shall be loosely filled with topsoil. Elsewhere, topsoil shall be uniformly applied to provide an average thickness of 50 mm with a minimum compacted thickness of 30 mm at any location.

(d) Hydromulching or hydroseeding

(i) The hydromulch or hydroseed shall comprise the materials shown in Table SC6.4.6.26.4. The materials shall be applied at the application rates shown in Table SC6.4.6.26.4.

(ii) Dry surfaces shall be watered by a fine spray before the application of the hydromulch.

(iii) During preparation of the hydromulch or hydroseed slurry, liquid form pesticide shall be added to the storage tank, to facilitate surface application, at a rate of 5 litres of pesticide to the equivalent volume of hydromulch or hydroseed slurry to be spread on 1 hectare of surface in accordance with Table SC6.4.6.26.4.

(iv) Storage tanks, containers and equipment to be used in hydromulching or hydroseeding of slopes shall be clean and free of contamination from previous operations.

(v) A slurry mixture shall be produced by addition of the specified materials in the tank and agitated to maintain a uniform consistency during application. It shall be applied uniformly over the whole surface.

(vi) Hydromulch or hydroseed shall not be applied under the following weather conditions at the site:

(A) when temperature is higher than 35 ºC;

(B) when winds exceed 15 km/hr;

(C) where, in the opinion of the Superintendent, the surface is too wet; or

(D) during rain periods or when rain appears imminent.

(vii) Application rates shall be in accordance with Table SC6.4.6.26.4.

Table SC6.4.6.26.4 Materials and application rates

Application Rate per Hectare		
Material	**Hydromulching**	**Hydroseeding**
i) Vegetable Mulch (kg)	2,500	Nil
ii) Water (L)	35,000	20,000
iii) Binder (L)	700	Nil
iv) Fertiliser	See SC6.4.6.26 Attachment A	
v) Seed	See SC6.4.6.26 Attachment A	
vi) Wetting Agent (L)	35	20
vii) Pesticide (L)	5	5

(e) Straw mulching

The mulch to be applied after hydroseeding shall comprise a matrix of straw and an anionic slow setting bitumen emulsion binder. Meadow hay shall not be used. The straw mulch shall be uniformly applied by a suitable blower unit at a rate of 250 bales (each of 20 kilograms) of straw per hectare of surface. The bitumen emulsion shall be incorporated as a spray into the air stream of the mulch blower at a rate of not less than 2,500 litres of bitumen emulsion per hectare of surface. The finished straw mat shall have a minimum thickness of 20 mm at any location.

(5) Vegetation of open drains

(a) Preparation of surface

The Contractor shall so execute the work that the excavation of open drains to the specified profiles is followed within 7 days by the vegetation of the surface as specified in this clause. Topsoil shall be spread to provide an average compacted thickness of 50 mm with a minimum compacted thickness of 30 mm at any location.

(b) Sowing
Before sowing, the surface shall be watered. Seed and fertiliser shall then be applied uniformly at the rates specified in SC6.4.6.26 Attachment A by one of the following procedures as directed by the Superintendent:

(i) mechanical sowing;

(ii) hydromulching or hydroseeding; and

(iii) by hand.

(c) Surface protection - general
Where shown on the drawings or directed by the Superintendent, one of the following protective treatments shall be applied immediately to all or part of the sown surface.

(d) Surface protection - spraying with bitumen emulsion
An anionic slow setting bitumen emulsion, conforming with Grade ASS of AS 1160, shall be sprayed over the surface at a rate of 1 litre of bitumen emulsion per square metre of surface.

(e) Surface protection - lining with organic fibre mat

(i) The channel surface shall be lined with an organic fibre mat listed in SC6.4.6.26 Attachment A. The runs of matting shall be laid along the direction of water flow. The matting shall be laid loosely on the soil surface and not stretched.

(ii) The upstream end of the matting shall be slotted into a trench 150 mm wide by 150 mm deep and pinned to the base of the trench at 200 mm centres. The trench shall be backfilled with soil and compacted by foot.

(iii) The pins shall be `U' shaped, 4 mm gauge wire, 50 mm wide and 150 mm long legs.

(iv) Adjacent runs of matting shall be overlapped 100 mm with the higher run lapped over the lower run. The matting shall be pinned along the sides of each run at 500 mm centres and along the middle of each run at 1 m centres. End overlaps shall be 150 mm wide with the higher run end lapped over the start of the lower run and pinned at 200 mm centres.

(f) Turfing

(i) Turf shall be as specified under clause SC6.4.6.26.5(2)(d).

(ii) Runs of turf shall butt hard against each other and be placed perpendicular to the direction of water flow in the drain, and pinned into position at 500 mm centres.

(iii) Seams of turf shall be topdressed with topsoil.

(g) Watering
The Contractor shall water treated areas in order to promote and maintain growth as specified under clause SC6.4.6.26.5(3)(g).

SC6.4.6.26.6 Garden construction

(1) Scope
The following work activities relate to the construction of garden beds, garden areas and mass planting areas:

(a) earthworks (excavation, filling and cultivation);

(b) supply and application of soil improvement additives;

(c) supply and placing garden mix soil;

(d) supply and placing mulch;

(e) supply and planting of trees, shrubs, ground cover plants and the like including stakes and other plant supports;

(f) supply and application of fertiliser;

(g) supply and installation of garden edging; and

(h) supply and installation of subsoil drains.

All garden construction shall be in accordance with the current relevant Australian Standards:

- AS 4419 - *Soils for landscaping and garden use*; and

- AS 4454 - *Composts, soil conditioners and mulches*.

(2) Co-ordination

The sequence for placing garden mix soil, installing irrigation, placing mulch and planting will vary according to the type of plants and irrigation system. The Contractor is required to liaise with other Contractors and the Superintendent to ensure the best possible method of construction is undertaken.

(3) Earthworks

Gardens may require Excavation or Filling to achieve the finished surface levels nominated on the drawings. After excavation or filling, all gardens may require cultivation.

(4) Garden bed dimensions

Planting bed dimensions are in accordance with the following:

(a) garden beds have an average minimum width of 1.2 m, provided that the bed is no less than 0.5 m wide; and

(b) root zone depths for plants are at least that of the root ball of the plant at planting.

(5) Soil condition

(a) Priority is to be given to using existing site soil as imported soil is a limited resource.

(b) Existing topsoil is conserved by either not disturbing the soil during construction or by stockpiling it prior to construction commencing, in accordance with SC6.4.5.2 Stockpiling of materials.

(c) Subsoil is to be cultivated to a minimum depth of 200 mm for garden beds and 100 mm for turfed areas unless this will adversely affect the roots of established trees.

(d) The minimum top soil depth is:

(i) 100 mm for non-irrigated turf areas;.

(ii) 200 mm for irrigated turf areas; and

(iii) 300 mm for garden beds.

(e) If additional soil is required to meet these minimum depths, soil is to meet AS4419 Soils for landscaping and garden use.

(f) The soil quality is sufficient to allow plants to grow effectively. Soil amelioration measures to improve the infiltration of existing soils, the soil's macropore and micropore balance and ensure a stable soil ecosystem, include the following:

(i) scarification of crusted topsoil layers;

(ii) aeration of topsoil layers;

(iii) deep ripping of subsoil layers;

(iv) using hand tools only within the tree protection zone of a tree identified for retention;

(v) the application of gypsum to sodic clay topsoils and subsoils;

(vi) installing a 50 mm layer of lucerne hay between the topsoil and mulch layer;

(vii) adding worms to the topsoil;

(viii) applying soil rhizobia in solution to the topsoil;

(ix) inoculating plants with Mycorrhizal fungi; and

(x) incorporating soil wetters, crystals and wettable foams.

(6) Soil improvement additives

Any soil additives to be applied shall be as required/recommended by soil test results.

(7) Placing imported soil in gardens

(a) Garden mix soil shall be an imported "Organic Soil".

(b) Garden mix soil shall be a minimum depth of 300 mm after consolidation.

(c) Garden mix soil shall be placed, spread and graded evenly in maximum 150 mm thick layers to finish at a level which allows the surface of the mulching material after consolidation to be flush with adjacent finished levels. Care shall be taken to prevent areas of excessive compaction being caused by construction equipment.

(d) Garden mix soil shall be graded evenly to form a gentle crowned appearance at the centre of the garden bed and/or shall conform to the finished levels detailed on the drawings.

(e) The surface of the garden mix soil shall be smooth and free from stones or lumps of soil prior to planting.

(8) Mulch material
Refer to clause SC6.4.6.26.3 Supply of materials.

(9) Placing mulch

(a) Mulch shall be placed as soon as practicable after planting and shall be placed progressively as planting proceeds along the length of the garden or planting area.

(b) Mulch shall be spread smoothly and evenly over the entire garden so that after initial consolidation the finished level of the mulch is flush with adjacent finished levels.

(c) Mulch shall be shaped around plants to slope into the plant and shall be kept a minimum of 50 mm clear of plant stems to avoid collar rot.

(d) Organic mulch
Organic mulch shall be placed to a depth not greater than 100 mm and as a minimum shall be maintained to a depth of 75 mm after consolidation.

(e) Inorganic mulch
Not less than 14 days prior to the placing of inorganic mulch, herbicide shall be applied to the entire area to be mulched and prior to placing the mulch.

(f) Inorganic mulch shall be placed to a minimum depth of 100 mm unless noted otherwise on the drawings for the type of mulch specified.

SC6.4.6.26.7 Planting

(1) General

(a) Planting shall be carried out in accordance with the best horticultural practices.

(b) Plants shall be installed at the spacings and locations detailed on the drawings to avoid existing services or to cover an area uniformly.

(c) In feature planting areas at least 25% of tree plantings are to be provided as larger advanced stock, with a minimum 25 litre pot size.

(d) The Contractor is required to locate all existing services prior to planting.

(e) Planting shall not be carried out if the soil is very wet or water logged or during periods of extreme weather conditions such as extreme heat, cold wind or rain.

(f) Plant supplies are to be healthy, attractive, and a general high standard of stock in order to ensure long-term viability of the specimen. The stock will be free from disease, pests and weeds and structural defects, as per clause SC6.4.6.26.3 Supply of materials.

(2) Planting procedure – container stock

(a) A planting hole with vertical sides shall be excavated to a width of twice the diameter of the root ball of the plant and to a minimum depth of 100 mm deeper than the height of the plant container.

(b) The depth of the planting hole shall allow for the clearance specified and shall be in relation to the finished surface level where applicable.

(c) The sub grade material at the bottom of the planting hole shall be loosened to a depth of at least 50% of the root ball depth and the compacted sides of the planting hole shall be loosened to prevent confinement of root growth to the hole. Additional excavation of the base of the planting hole may be

required to ensure that the plant has sufficient sub grade drainage.

(d) Plants shall be thoroughly watered in the pot prior to planting so that when removed from the pot the root ball is moist. Plants shall be removed from their pots without damage to the root system. Plants shall not be removed from pots until the planting hole is complete and ready for planting.

(e) The plant shall be placed in the centre of the hole with the stem vertical and shall be set at a height such that the top of the potting material is level with the surrounding soil. Plants placed on a slope shall be set in the centre of the hole with the top of the potting material level with the lowest side of the planting hole and the plant stem vertical.

(f) Fertiliser tablets or granules shall be placed in the planting hole at the time of planting in accordance with the manufacturers recommended rates of application. The fertiliser shall be placed around the plant at half the depth of the planting hole and shall be covered with backfill soil to ensure no direct contact with the plant roots.

(g) Plants other than container stock trees placed in gardens shall be backfilled with garden mix soil as specified for the entire planting hole. The garden mix soil shall be lightly tamped around the plant and thoroughly watered to eliminate air pockets.

(h) During planting care shall be taken to ensure that soil is not mixed with the mulch. Mulch that is contaminated with soil shall be replaced.

(i) Container stock trees shall be backfilled in 150 mm layers up to within 200 mm of the top of the planting hole. The backfill soil shall be tamped around the tree and thoroughly watered to eliminate air pockets. Backfill the top 200 mm with garden mix soil.

(j) In areas other than heavily planted borders, shrubs or tuft plants, each individual plant shall have a watering basin for the extent of the planting hole formed with garden mix soil around the base of the plant.

(k) Individual container stock trees located in irrigated grassed areas shall have a 150 mm high watering basin for the extent of the planting hole formed with garden mix soil around the base of the tree.

(l) Plants placed on a slope shall have a small horizontal terrace formed for the extent of the planting hole.

(m) Immediately after planting, the plants shall be watered to thoroughly water the root ball and the backfill. Watering shall be carried out progressively as planting proceeds to ensure that plants do not dry out and as a minimum, plants shall be watered within a maximum of 1 hour from planting.

(n) All identification labels, nursery ties and the like shall be removed from the plants immediately after planting

(3) Planting procedure - ex ground stock plants

Editor's note—content under development.

(4) Transplanting trees

(a) Trees to be transplanted will be noted on the construction drawings prior to the commencement of construction.

(b) Preparation of the tree prior to transplanting shall be carried out in accordance with accepted transplanting practice and any requirements provided by council to suit the particular species and project.

(c) Preparation of the tree for transplanting shall be commenced in sufficient time to ensure that at the time of planting the tree is adequately prepared and will meet the specified requirements.

(d) All transplanting work shall be carried out under the direction of a suitably qualified horticulturist or arborist.

(e) Planting of the transplanted tree shall be generally in accordance with the details shown on the drawings.

(f) The resulting excavation after the tree has been removed shall be backfilled with compacted fill material suitable for the location.

(5) Root barrier

(a) Locations and type of root barrier shall be noted on the drawings or shall be as directed by the Superintendent.

(b) Root barrier shall be installed as per the manufacturer's recommendations and with particular attention to the location of any underground services and service pits.

(c) Root barrier must be installed in all situations where it is likely that tree roots may interfere or adversely affect infrastructure - such as driveways, kerbs, pathways and other street furniture and buildings, e.g. where species such as Ficus are to be planted in reasonable proximity to pathways.

SC6.4.6.26.8 Staking, ties and guying

(1) Every container stock tree shall be staked and tied unless otherwise approved by the Superintendent. Tree stakes

(a) Stakes shall be:

(i) a minimum of 2 stakes per tree;

(ii) placed outside of the tree root ball;

(iii) driven into the ground a minimum one third of their length;

(iv) for smaller trees (trees up to 45 litre), at least 1.0 metre apart; and

(v) for columnar trees, spaced to avoid excessive root ball damage.

(b) Care shall be taken to avoid damage to the tree root system and any services when installing stakes.

(c) All stakes shall remain in place for the entire “maintenance period” unless otherwise instructed by the Superintendent.

(2) Ties

Ties shall be fixed securely with staples to the stakes in a figure eight pattern around the tree stem. As a minimum one tie at half the height of the main stem shall be provided with additional ties as necessary to stabilise the tree.

(3) Guying

(a) Trees requiring the installation of guying shall be noted on the construction drawings or shall be as directed by the Superintendent.

(b) Guying consists of a minimum of three heavy duty stakes of either steel or timber driven into solid ground, with heavy duty galvanised wire ties firmly fasten to the stakes and looped around the tree trunk with suitable wrapping to protect the trunk.

(c) Underground guying where required to be used, shall be positioned for stability purposes, placement of the guy wires shall away from the tree trunk to avoid girdling issues as the tree matures. Such tree guying practices shall be removed prior to Off Maintenance inspection and acceptance by council.

Editor’s note—underground guying is accepted where suitable for the tree in question.

SC6.4.6.26.9 Sub soil drains construction

(1) Sub soil drains in gardens may be required in areas of heavy clay soils and in roadway medians, roundabouts and the like. Sub soil drains shall be installed at the locations and to the details shown on the drawings.

(2) Pipes and fittings shall be perforated plastic Type 1 Class 200 to AS2439: Part 1. Sub soil drain filter fabrics shall be approved geo fabric material in accordance with the relevant Australian Standards.

(3) Pipe surround shall be a coarse washed river sand complying with the grading requirements given in Table SC6.4.6.26.5 and shall completely surround the perforated pipe.

(4) The subsoil drain pipe shall be laid to grade continuously to the outlets nominated on the drawings at a

minimum grade of 1:100.

(5) Sub soil drains may be inspected by the Superintendent prior to placing any garden mix soil or backfill.

Table SC6.4.6.26.5 Recommended grading for sub-soil drain sand

A.S. SIEVE	% PASSING
9.5 mm	100
4.75 mm	98-100
2.36 mm	70-100
1.18 mm	30-78
600 µm	2-15
300 µm	0-4
150 µm	0-1

SC6.4.6.26.10 Garden edging

(1) Supply and installation of timber, concrete or recycled plastic proprietary garden edging shall be in accordance with the details on the drawings and the manufacturer's recommendations where applicable. Timber or recycled plastic garden edging must have a minimum thickness of 30 mm.

(2) Supply and installation of concrete kerbing shall be as specified in clause SC6.4.6.26.15.

SC6.4.6.26.11 Planter boxes

(1) Planter boxes shall be constructed at the locations and to the details shown on the construction drawings.

(2) Planter box soil shall be an imported soil mix (Potting Mix). Refer to project specific specifications where applicable.

(3) Planter boxes must have appropriate drainage (see clause SC6.4.6.26.9 Sub soil drains construction) provided that it is connected to a lawful discharge point. The drainage discharge is not permitted to cause nuisance, such as staining or sediments, to adjacent areas.

SC6.4.6.26.12 Grass area construction

(1) General

The following work activities relate to grass areas construction:

(a) earthworks (excavation, filling and cultivation);

(b) supply and application of soil improvement additives;

(c) supply and placing turf soil;

(d) supply and lay grass turf;

(e) supply and lay grass seeding;

(f) supply and installation of hydro-seeding/mulching; and

(g) supply and application of fertiliser.

All grass area construction shall be in accordance with the current relevant Australian Standards:

- AS 4419 Soils for landscaping and garden use; and
- AS 4454 Composts, soil conditioners and mulches.

(2) Co-ordination

The sequence for placing turf soil, installing irrigation and placing turf will vary according to the type of plants and irrigation system.

(3) Earthworks

Grass areas may require excavation or filling to achieve the finished surface levels detailed on the construction drawings. Refer to clause SC6.4.6.26.4 Earthworks.

(4) Placing turf soil

(a) Turf soil shall be an imported soil mix Type 2 “Soil Blend”.

(b) Turf soil shall be a minimum depth of 100 mm after light compaction.

(c) Turf areas shall be graded to fall evenly between the finished surface levels detailed on the drawings and/or shall be graded to drain freely to stormwater inlets without causing ponding. As a minimum turf areas shall be graded to fall at 1:100.

(d) Turf soil shall be spread evenly and shall be lightly compacted to finish at a level which allows for the finished turf surface to be flush with adjacent surfaces such as paved areas, pathways mowing strips and the like. Care shall be taken to prevent areas of excessive compaction being caused by construction equipment.

(e) The surface of the turf soil shall be smooth and free from stones or lumps of soil prior to laying the turf.

(5) Turf material

(a) Turf shall be the species nominated on the drawings and shall be supplied by a specialist grower of cultivated turf approved by the Superintendent.

(b) Where turf areas are provided within centre medians, round-abouts and other identified areas of road reserve where edging/mowing may require traffic control, all turf is to be Empire Zoysia or approved similar turf and of a minimum width of 1.6 m to allow for clear mowing access.

(6) Laying turf

(a) Prior to laying turf, fertiliser shall be thoroughly mixed into the turf soil. Refer to Table SC6.4.6.26.5 for application rates.

(b) Areas to be turfed shall be divided into sections that can be prepared and completed (including adequate watering) in the same day.

(c) Turf shall be laid in straight lines in a stretcher bond pattern across the fall of the slope or parallel with the long side of level areas. Cross joints shall be staggered with a maximum gap of 5 mm between adjacent sections of turf.

(d) Immediately after laying the turf shall be rolled with a roller weighing not more than 90 kg/m of width.

(e) As soon as practicable after rolling turf shall be watered thoroughly with a fine spray to a depth of 150 mm. Watering shall continue as necessary to maintain moisture to this depth and to maintain the turf in a healthy condition.

(f) Where levels have deviated from the design levels after placing and watering the turf shall be lifted and the section regraded with turf soil to achieve design levels prior to replacing the turf.

(g) Turf shall be protected from pedestrian traffic until established and shall be protected from vehicle traffic at all times.

SC6.4.6.26.13 Hyrdo seeding/mulching

(1) General

(a) Excavation, filling, cultivation and placing imported soil mix for hydro seeding/mulching areas shall be as specified for turf areas.

(b) Details for hydro seeding/mulching supply and sowing shall be as noted on the drawings and/or as specified under separate cover.

(c) Organic mulches are to be applied to landscaped garden beds and trees which:

(i) meet AS 4454 Composts, soil conditioners and mulches;

(ii) are applied to a depth of 75 – 100 mm;

(iii) are of a coarse texture to allow water penetration to prevent nitrogen drawdown of the soil;

(iv) are aged prior to application;

(v) do not use plastic sheeting, typically used for weed suppression as it prevents rainwater from infiltrating soils and inhibits gaseous exchange between the soil and air; and

(vi) use a biodegradable mulch mat on any waterway embankment.

(d) Inorganic mulches, such as recycled concrete or brick cobbles, are limited to feature or themed landscapes, or in windy areas where organic mulches may be blown away.

(2) Supply of mulch materials

(a) Mulch materials supplied shall be free of deleterious and extraneous matter such as soil, weeds, seeds, rubbish, vermin, insects, pests, fungus, sticks, disease, declared plants or noxious weeds and shall be free of any matter toxic to plant growth or germination.

(b) All mulch materials supplied shall be in accordance with AS 4454 Composts, soil conditioners and mulches.

(c) Organic mulch
Organic mulch may be either:

(i) tea tree mulch from an approved supplier; or

(ii) wood chip produced by the chipping of native and other approved vegetation removed during the clearing and grubbing process on site (max 50 mm size); or

(iii) wood chip obtained from a council stockpile as directed by the Superintendent or his delegated site supervisor; or

(iv) other material as noted on the drawings.

(d) Inorganic mulch
Inorganic mulch shall be of the type and quality and noted on the construction drawings.

(3) Surface preparation

(a) Level sites
Prior to hydro seeding/mulching the area to be treated shall be graded to fall evenly between the finished surface levels detailed on the drawings and/or shall be graded to drain freely to stormwater inlets without causing ponding.

(b) Embankments and slopes (1 on 5 maximum slope)
Prior to hydro seeding/mulching the area shall be lightly cultivated across the slope to minimise surface run-off and erosion. After cultivation, soil crumb size shall not exceed 20 mm.

(c) The surface of the area to be treated shall be free from weeds, stones, roots, sticks or other deleterious material and have a general moisture content of around 10% just prior to applying the hydroseed/mulch.

(4) Irrigation
An approved temporary above ground irrigation system shall be installed to ensure establishment of the hydro seeding/mulching is achieved within the timer frame specified. Refer to SC6.4.6.27 Irrigation.

SC6.4.6.26.14 Paving construction
Refer to sub-section SC6.4.6.18 Segmental paving.

All areas of road reserve fronting a subject site must be assessed against, and treated in accordance with SC6.4.3.3 Footpath treatment policy where specified.

SC6.4.6.26.15 Concrete kerbs
This section contains specific details for construction of concrete kerb in landscape and open space situations. Concrete kerb is most commonly used for garden edge or as a restraint for softfall areas in playgrounds.

All concrete garden edge kerb or similar structure shall have minimum rectangular profile dimensions of 150 mm wide x 200 mm deep with edges rounded to a radius of 20 mm (minimum) and constructed in accordance with clause

SC6.4.6.28.2(2) Kerb and channel. Where the concrete garden edge kerb abuts grass areas, the surface of the kerb must finish level with the surface level of the grass area.

SC6.4.6.26.16 Concrete works

For all concrete works associated with Landscaping activities refer to sub-section 6.4.6.28 Minor concrete works.

SC6.4.6.26.17 Masonry work

This section covers the supply of all materials, placing and finishing of all masonry blockwork including concrete core-filling and clay brickwork. Masonry Work includes walls, retaining walls, free standing piers, structures and the like. All masonry work shall conform to the requirements of AS 3700.

(1) Materials

(a) Blocks - Hollow load bearing masonry blocks shall conform to the requirements of AS 3700 - Section 2, and shall have a characteristic unconfined compressive strength of 15 MPa unless nominated otherwise agreed.

(b) Masonry blocks shall be sound, dry, clean and crack free and shall have been cured for not less than 14 days before delivery. The correct type of block shall be used to make provision for all lintels, pilasters, bond beams, openings, etc.

(c) Clean out blocks shall be used in the first course of all reinforced cores and/or where cores are to be concrete filled.

(d) Cement - for mortar shall be Portland Cement Type A and shall conform in all respects with the requirements of AS 3972.

(e) Sand - for mortar shall be clean, sharp and free from organic impurities and excess fines and efflorescing salts.

(f) Water - used in mixing concrete shall be clean and free from injurious amounts of oil, acid, alkali, organic matter or other deleterious substances.

(g) Hydrated lime shall conform to the requirements of AS 1672.1.

(h) Admixtures - no air-entraining additives or other admixtures shall be incorporated in the mortar unless specifically approved by the Superintendent.

(i) Reinforcement - shall comply with AS/NZS 4671 as applicable.

(j) Clay bricks - and brickwork shall conform to AS 3700. Clay brick shall have a characteristic unconfined compressive strength of 40 MPa unless otherwise agreed.

(2) Mortar for blockwork

(a) All mortar for blockwork shall consist of a homogeneous mixture of the ingredients and shall be classified as M4 in AS 3700. The following proportions by volume shall be used unless the minimum compressive strength of mortar at 28 days has been nominated on the drawings. Cement 1: Lime 0 to 0.25: Sand 3.

(b) The mortar components shall be properly volume batched using calibrated volume boxes. Batching by shovel will not be permitted.

(c) Mortar shall be mixed in an approved mixing machine for not less than 3 minutes. Handmixing shall not be permitted unless specifically approved by the Superintendent. The dry ingredients shall be thoroughly mixed prior to the addition of water, which shall then be worked thoroughly through the mixture.

(d) Mortar shall be transported in a covered container such that excessive evaporation will be prevented. Retempering of mortar shall not be permitted.

(3) Core-fill concrete

(a) Core-fill concrete shall comply with the relevant requirements of AS 3600 Concrete Structures. Ready mixed concrete from an approved supplier shall be used. As a minimum and unless shown otherwise on the drawings, core-fill concrete supplied shall have the following properties in Table SC6.4.6.26.6.

Property	Design Value
Characteristic strenght F'c at 28 days	N 20
Norminal maximum size of aggregate	10 mm
Slump	230 mm +/-30 mm

(b) Testing of core-fill concrete supplied shall be carried out by the Concrete Supplier as part of the suppliers Quality Assurance System. The Contractor is required to provide the Superintendent with copies of the suppliers Test Certificates relating to the particular batch of core-fill concrete supplied.

Core-fill concrete supplied that does not meet the requirements of this specification shall be liable to rejection by the Superintendent. If directed by the Superintendent the Contractor will rectify any masonry wall which has been filled with rejected core-fill concrete.

(4) Laying blocks

(a) All work shall be carried out by experienced tradesmen to the general requirements of AS 3700 - Section 8. Blockwork shall be laid in lifts or not more than 2400 mm in height.

(b) All blocks shall be laid dry and wetting of the blocks shall not be permitted under any circumstances.

(c) Cutting of blocks shall be reduced to an absolute minimum by setting out to avoid irregular or broken bond.

(d) Blocks shall be stacked on planks or other supports free from contact with the ground and shall be covered at all times to ensure that the blocks remain dry.

(e) Blocks shall be laid in straight uniform courses of running bond unless noted otherwise on the drawings. Intersecting walls shall be bonded as shown on the drawings.

(f) The surface of the concrete footing, floor slab, beam, etc. on which the base course is to be laid shall be thoroughly cleaned prior to laying the base course to ensure all laitance is removed.

(g) The base course shall incorporate clean out blocks at every reinforced core, with the clean out opening on the inside face of the wall.

(h) Reinforcement starter bars shall be checked for alignment prior to laying the base course. Starter bars shall be vertical. Bending starter bars to allow the laying of the base course is not acceptable. Any starter bars out of position shall be rectified by the Contractor as directed by the Superintendent.

(i) For unreinforced and reinforced masonry walls, horizontal joints shall have full mortar coverage on the face shells and on the webs.

(j) For unreinforced masonry walls all vertical joints shall have full mortar coverage. For reinforced masonry walls all vertical joints shall be buttered only for the thickness of the face shells.

(k) All horizontal and vertical joints shall be 10 mm in width with a maximum mortar intrusion into the cores of 6 mm. Mortar droppings into cavities or cores shall be avoided.

(l) Tooling of the joints shall be done when the mortar is partially set but still sufficiently plastic to bond. All tooling shall be done with a V-shaped or round bar in a manner that will compact the mortar rather than drag it out. Raked joints shall not be permitted to encroach more than 5 mm in depth.

(m) If it is necessary to move a block after it has been set in place with mortar, then the block shall be removed from the wall, the mortar removed and the block shall be reset in fresh mortar.

(n) Capping blocks shall be fixed with a suitable flexible external grade adhesive as detailed on the drawings. Laying capping blocks in mortar only is not acceptable.

(o) Where new blockwork is to be laid on top of an existing masonry block wall, the existing core concrete shall be cleaned to expose all aggregate and treated using an adhesion enhancer such as bondcrete or approved equivalent before block laying is commenced.

(p) Extreme care shall be exercised to prevent mortar adhering to the face of blockwork. Acid shall not be used to clean down masonry walls.

(5) Reinforcement

(a) Steel reinforcement shall be supplied and bent in accordance with AS 3700. Rebending of reinforcement

with or without heating is not permitted unless approved by the Superintendent.

(b) Steel reinforcement shall be free from rust, oil, varnish, mud or any other coatings, cracks, scale blister and other defects and shall comply in all respects with AS/NZS 4671.

(c) All horizontal reinforcement shall be laid into the wall as the block laying progresses. Galvanised wire loops shall be cast into the horizontal joints prior to placing the reinforcement to ensure correct positioning of the reinforcement.

(d) Vertical reinforcement shall be placed after the wall has been laid and shall be placed in the core with the correct cover to the face of the blocks as detailed on the drawings. Unless noted otherwise on the drawings vertical reinforcement shall be placed in the centre of the core.

(e) Splice lengths for both horizontal and vertical reinforcement shall not be less than 45 bar diameters for plain round bars or 30 diameters for deformed bars or 450 mm, whichever is the greater.

(f) All reinforced block walls shall have vertical reinforcement in the core at the ends, corners, sides of openings, adjacent to control joints, at unbonded intersections and at the maximum centres between these points.

(6) Cast in elements

(a) The Contractor shall co-ordinate with all other trades as necessary to ensure that all conduits, fitments, penetrations and the like are incorporated in the masonry as detailed on the drawings and as specified.

(b) All bolts, anchors and other steel fittings shall be accurately set into the walls as the work progresses and positioned such that they shall be thoroughly embedded in mortar or core-filling concrete as required.

(c) Where items to be cast into the blockwork are found to be out of position and cannot be satisfactorily corrected, then the section of blockwork shall be completely demolished, and then reconstructed to allow correct positioning.

(7) Joints in blockwork

(a) Joints in blockwork shall be the type and at the locations detailed on the drawings. Joints with steel dowels shall have the dowels securely supported to ensure that the dowel remains in the correct position during the placing of core-fill concrete.

(b) Construction joints shall be located as detailed on the drawings or shall be located where agreed with the Superintendent to suit specific site requirements.

(c) Joint filling compounds shall be as detailed on the drawings and shall be installed in accordance with the manufacturers recommendations, with particular attention to the preparation of the blockwork surface to suit the application of the joint filling compound.

(8) Placing core-fill concrete

(a) Masonry walls shall cure for at least 3 days before core-fill concrete is placed.

(b) The cores to receive core-fill concrete shall be cleaned of all mortar protrusions by rodding from the top of the wall. All mortar droppings and foreign matter shall then be removed via the clean out openings at the base of the wall, the vertical reinforcement positioned and formwork fixed in place to seal the clean out block opening.

(c) Core filling shall not proceed until the reinforcement and cores have been inspected by the Superintendent. Clean out openings shall not be sealed until the inspection has been carried out.

(d) Core-fill concrete shall be thoroughly compacted into place as it is poured with the aid of small immersion vibrators or rodding. Block cores shall be topped up after settlement occurs.

(e) Core-fill concrete shall be placed for the full height of the blockwork in lifts of not more than 2400 mm in height. A minimum delay period of 1 hour and a maximum delay period of 3 hours shall be observed between lifts.

(f) Proprietary core plates shall be used to confine the core-fill concrete to the reinforced cores.

(g) Placing of core-fill concrete in bond beams shall be done in one continuous operation for the full length of the bond beam. Construction joints in bond beams other than control joints, are not acceptable.

(h) Extreme care shall be exercised to prevent slurry adhering to the face of blockwork. Acid shall not be used to clean down masonry walls.

(9) Mortar for clay bricks

(a) All mortar for clay bricks shall consist of a homogeneous mixture of the ingredients and shall be classified as M3. Refer to AS 3700.

(b) The following proportions by volume shall be used unless the minimum compressive strength of mortar at 28 days has been nominated on the drawings. Cement: 1, Lime: 1, Sand: 6.

(c) Mortar for clay bricks shall be generally in accordance with clause SC6.4.6.26.17(2) Mortar for block work.

(10) Laying clay bricks

(a) Clay bricks shall be fully bedded and fully faced. Bed joints shall be 10 mm nominal height.

(b) Clay brick masonry walls shall be laid with galvanised brick ties at 600 mm maximum centres each way and at 300 mm centres adjacent to openings in accordance with manufacturer's specifications.

(c) Laying of clay bricks shall be generally in accordance with clause SC6.4.6.26.17(4) Laying blocks.

(11) Protection of walls

(a) During construction and after the wall is laid and prior to placing core-fill concrete; under no circumstances shall masonry blocks be wetted or allowed to become wet.

(b) At the completion of a day's work and during wet weather the top and sides of all walls shall be covered to prevent rain penetrating the cores and wetting the blocks.

(c) During the construction of masonry walls and prior to the core-fill concrete having gained its full strength, the Contractor shall protect the wall by suitable means such as bracing to ensure that the wall is not damaged and to ensure the safety of workers on the site.

(12) Tolerances

(a) All masonry shall be built true and plumb such that the maximum "out-of-plumb" in a 3 m height does not exceed 10 mm.

(b) The bed joint at any level shall be within ± 3 mm.

(13) Surface finishes to masonry

(a) Surface finishes, such as painting, rendering or textured finishes shall be as detailed on the drawings or as nominated in the Finishes Schedule.

(b) Prior to applying any surface finish the substrate shall be free from dirt, dust, oil, grease, mould, fungi, efflorescence, release agents, bond breakers, scaling and laitance or any other contaminants or foreign material that may affect adhesion. Remove all traces of loosely adhering material by scraping, grinding, wire brushing or air blowing as necessary.

(c) Preparation of the surfaces to be treated, application of the surface finish and curing after application if required, shall be carried out in strict accordance with the manufacturer's recommendations. Particular attention shall be made to application during suitable weather conditions.

(d) Gap fill and/or sealant material used for joints or cracks in walls shall be checked for compatibility with the proposed surface finish.

(e) Anti-vandal coatings shall be used in circumstances where walls are exposed (i.e. not screened by soft landscaping) and prone to graffiti.

(f) Dissimilar materials adjacent to surfaces to be treated shall be masked to avoid contact, (e.g. capping and flashings).

(g) The Contractor shall provide the Superintendent with all warranty details of the surface finishes.

SC6.4.6.26.18 Stormwater drainage

All stormwater drainage shall be constructed in accordance with the relevant stormwater drainage guidelines contained in SC6.4.6.4 Stormwater drainage.

SC6.4.6.26.19 Infrastructure items

Supply and installation of infrastructure items such as timber decking, timber and steel fencing, seats, picnic sets, barbeques, play equipment and signage shall be as detailed on the drawings and constructed in strict accordance with the manufacturers' specifications. The Contractor shall provide the Superintendent with all warranty details. Concrete for footings, plinths and the like for infrastructure items shall be in accordance with clause SC6.4.6.26.16 Concrete works.

SC6.4.6.26.20 Electrical

The installation of electrical components shall comply with the requirements of AS 3000. Where required under the *Electricity Act 1994*, electrical installations shall be installed by a registered Electrical Contractor as defined by that Act. Refer to the electrical engineer's drawings and specifications for all requirements.

SC6.4.6.26.21 Summary of limited and tolerance

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.26.7 below.

Item	Activity	Limits/Tolerances	Clause
1.	**Topsoil**	>3% by mass	SC6.4.6.26.5(2)(a).
	a) Organic Content		
	b) pH	>5.5 <7.5	SC6.4.6.26.5(2)(a)
	c) Soluble Salt	<0.06% by mass	SC6.4.6.26.5(2)(a)
2.	**Turf**	Widths >300mm.	SC6.4.6.26.5(2)(d)
3.	**Vegetable mulch**	maximum size <10mm	SC6.4.6.26.5(2)(f)
	a) Material	<50% by mass of total mulch	SC6.4.6.26.5(2)(f)
	b) Paper Pulp		
4.	**Topsoiling**	Minimum compacted thickness	SC6.4.6.26.5(3)(b)
		at any location of 30mm	SC6.4.6.26.5(4)(c)
			SC6.4.6.26.5(5)(a)
5.	**Straw mulching**	Finished thickness >20mm.	SC6.4.6.26.5(4)(e)
	a) Straw Mat		
6.	**Mulch**	Shall not exceed 5% by volume.	SC6.4.6.26.3(6)
	a) Fines		
	b) Woodchip	Maximum size <50mm.	SC6.4.6.26.3(6)
7.	**Plant material**	Contain >20% <25% by volume	SC6.4.6.26.3(2)
	a) Container Soil Mix	of clay.	

Attachments

SC6.4.6.26 Attachment A: Landscaping materials

MATERIAL *(sample only - to be completed by compiler)*	**TYPE**	**MINIMUM APPLICATION RATE**
1. HERBICIDE *	"Roundup"	As per manufacturers recommendations
2. SEED		
a) Grass	Rye Corn (April-August) or	60 kg/ha
Japanese Millet (September-March		60 kg/ha
Hulled Couch		5 kg/ha
Red Clover (Inoculated)		5 kg/ha
White Clover (Inoculated)		5 kg/ha
"Elka" Perennial Rye		5 kg/ha
(b) Native	Acacia dealbata	4 kg/ha
Acacia buxifolia		1 kg/ha
Acacia decurrens		1 kg/ha
Acacia pravissima		1 kg/ha
Leptospermum lanigerum		1 kg/ha
Hardenbergia violacea		500 g/ha
Kennedia prostrata		500 g/ha
Acacia implexa		200 g/ha
Banksia marginata		200 g/ha
Bursaria spinosa		200 g/ha
Callistemon pallidus		200 g/ha
Dodonaea viscoca		200 g/ha
3. TURF GRASS (a) Medians (b) Verges/Footpaths (c) Other Areas	Couch Buffalo Couch	Refer to drawings " "
4. FERTILISER * (a) Vegetation of Slopes/Drains (b) Landscape Planting	Dynamic Lifter "Nitro" "Kokei" pellets	1000 kg/ha
5. WETTING AGENT *	"Aquasoil"	1 litre/1000 litres of mix water
6. PESTICIDE * (a) Liquid (b) Powder	"Lorsban 500 EC" "Lorsban 250 W"	5 litres 10 kg
7. ORGANIC FIBRE MAT *	"Sta-firma" (light grade)	-
8. MULCH	Composted/Pasteurized	100mm thick
* Material shall be as listed or equivalent as approved by council.		

SC6.4.6.27 Irrigation

SC6.4.6.27.1 Introduction

(1) Scope

(a) This sub-section sets out the standards for design, installation and construction of irrigation systems that will become a Townsville City Council asset.

(b) Irrigation systems that will be connected to an alternative water supply have additional requirements to this sub-section.

(2) Reference and source documents

All design and documentation, materials supplied and work carried out shall be in accordance with the following:-

(a) Australian Standards:

AS 1432	*Copper tubes for plumbing, gas fitting and drainage applications*
AS/NZS 1477	*PVC pipes and fittings for pressure applications*
AS 2032	*Installation of PVC pipe systems*
AS 2033	*Installation of polyethylene pipe systems*
AS 2053	*Conduits and fittings for electrical installations (all Parts)*
AS 2129	*Flanges for pipes and valves and fittings*
AS 2698.2	*Plastics pipes and fittings for irrigation and rural applications –Polyethylene rural pipe*
AS 2698.3	*Plastics pipes and fittings for irrigation and rural applications –Mechanical joint fittings for use with polyethylene micro-irrigation pipes*
AS 2845.1	*Water supply – Backflow prevention devices – Materials, design and performance requirements*
AS 2845.2	*Water supply – Backflow prevention devices – Registered air gaps and registered break tanks*
AS 2845.3	*Water supply – Backflow prevention devices - Field testing and maintenance of testable devices*
AS 3000	*Electrical installation (known as the Australian/New Zealand Wiring Rules)*
AS/NZS 3008.1.1	*Electrical Installations –Selection of cables - Cables for alternating voltages up to and including 0.6/1 kV - Typical Australian installation conditions*
AS/NZS 3500	*Plumbing and Drainage*
AS/NZS 3500.0	*Plumbing and drainage Part 0: Glossary of terms*
AS/NZS 3500.1	*Plumbing and drainage – Water services*
AS 3500.1.1	*National plumbing and drainage - Water supply – Performance requirements*
AS 3500.2.1	*National Plumbing and Drainage Sanitary plumbing and drainage - Performance requirements*
AS 3500.2.2	*National Plumbing and Drainage Sanitary plumbing and drainage - Acceptable Solutions*
AS/NZS 3808	*Insulating and sheathing materials for electrical cables*
AS/NZ 3879	*Solvent cements and priming fluids for PVC (PVC-U and PVC-M) and ASA pipes and fittings*
AS/NZS 4129	*Fittings for polyethylene (PE) pipes for pressure applications*
AS/NZS 4130	*Polyethylene (PE) pipes for pressure applications*
AS/NZ 4158	*Thermal-bonded polymeric coatings on valves and fittings for water industry purposes*

(b) Legislation:

Water Act 2000

Electricity Safety Act 2002

Work Health and Safety Act 2011

(c) Other:

Department of Energy and Water Supply, *Queensland Water Recycling Guidelines*, December 2005

(d) Authorities

The rules and regulations of the relevant local electricity supply authority.

The rules and regulations of the relevant local water supply authority.
The requirements of any other Authority having jurisdiction over the installation.

SC6.4.6.27.2 Irrigation pipework

(1) Standards
All pipes shall be supplied, installed and joined in accordance with the manufacturer's recommendations and all relevant, current Australian Standards.

(2) Class of pipe

(a) Main line pipes (pressurised) of nominal 80mm diameter and larger shall be minimum Class 12 uPVC rubber ring jointed (RRJ) or PN12.5 (Poly pipe).

(b) Main line pipes (pressurised) of nominal diameter less than 80mm shall be minimum Class 12 uPVC solvent welded joint (SWJ) or PN12.5 (Poly pipe).

(c) All lateral line pipes (non pressurised) shall be minimum Class 6 (uPVC) or PN6.3 (Poly pipe), except for lateral line pipe work under road pavements which shall be Class 12 (uPVC) or PN12.5 (Poly pipe).

(d) Supply line to a drinking fountain or a water tap shall be a minimum of 32 mm Class 12 uPVC or PN12.5 (Poly Pipe). Copper pipe is not acceptable.

(e) Copper pipe to a Water meter, drinking fountain and water tap assemblies shall be minimum Type B.

(f) All irrigation pipe work under pavements (road or otherwise) shall be encased in a conduit.

(3) Conduit crossings

(a) All conduits used to encase irrigation line pipes shall be 100mm Class 9 PVC SWJ Pipe as standard unless otherwise approved by the Superintendent. Storm water or waste water pipe used as conduit is not acceptable.

(b) Conduit crossing ends shall be sealed with duct tape to stop the ingress of soil and material from entering the conduit.

(c) Conduit crossings within road reserves and medians are to have the outer 50mm of conduit sealed with expanded foam, to stop the transportation of water through the conduit.

(d) Where underground bores or conduits crossings have been installed, a stainless steel tag shall be used to mark the start and finish of the conduit. The tag shall be a minimum of 38mm diameter and 1.6mm thick. It is to be nailed, glued or set into the surface of the crossing. The marker shall be engraved with the words "Irrigation Water", given a unique number and recorded on the as constructed drawings.

(4) Pipe fittings

(a) All fittings for uPVC pipe shall be minimum Class 18 PVC SWJ.

(b) All fittings for poly pipe shall be metric compression fittings, Plasson or Philmac.

(c) All fittings for low density pipe shall be barbed type, with all joints fitted with stainless steel cobra clamps – or approved equivalent.

(d) All threaded fittings, except sprinklers, shall be sealed using PTFE thread tape and Liquid Teflon.

(5) Pipe installation generally

(a) Interior of pipes shall be kept free of dirt and debris at all times.

(b) Where pipe work is left unfinished during installation, the open ends of pipes shall be sealed off with plastic secured to the end of the pipe or have end caps fitted.

(c) Pipes laid in a common trench shall be separated by a minimum of 100mm.

(d) Refer to SC6.4.4.8 Standard drawings SD-13.1, Figures 1 to 6 for pipe alignments for all irrigation works in road reserves.

(6) UPVC rubber ring jointed pipe – installation (i.e. Main line pipes of nominal 80mm diameter and larger).

(a) All uPVC rubber ring jointed pipe work shall be installed in accordance with the manufacturer's recommendations and AS 2032.

(b) All uPVC rubber ring jointed pipe work shall be laid in a minimum of 100mm sand bedding and surround.

(c) All connections and changes of direction horizontally and vertically in rubber ring joint (RRJ) pipe work shall be installed with concrete thrust blocks.

(d) Thrust block design and size shall follow pipe manufacturers recommendations ("Thrust Block Design – Pressure Pipeline Fittings" Iplex uPVC Design Manual). Thrust blocks shall be 15 MPA concrete in accordance with AS 2032. All thrust blocks are to be cast in situ against undisturbed ground and shall have neatly formed sides.

(e) The ends of pipes used for rubber ring joint (RRJ) connections shall have a smooth chamfer 15 degrees to the outer edge and shall be free of all burrs and rough edges. Rubber rings and lubricant used shall be in accordance with the pipe manufacturer's recommendations.

(f) Each pipe length shall be laid in the following direction; water flow runs from the socket end to the spigot end of the pipe, with the exception of ring mains.

(g) Trenches may be curved to avoid obstructions within the limits of the curvature of the pipe.

(7) UPVC Solvent welded joint pipe installation (i.e. main line pipes of nominal diameter less than 80mm or lateral line pipes).

(a) All uPVC Solvent welded joint pipe work shall be installed in accordance with the manufacturer's recommendations and AS 2032.

(b) All uPVC solvent welded joints shall be primed and cemented.

(c) Primer and solvent cement shall conform to AS/NZ 3879.

(d) Primer is to be "Priming Fluid (red)".

(e) Solvent is to be "Christy's PVC Red Hot Blue Glue" or approved Type "p" solvent cement.

(f) All pipes shall be primed before cementing the joint.

(g) Pipe ends shall be free of all burs and rough edges.

(h) All uPVC solvent welded joints shall not be subjected to water pressure for at least 24 hours after cementing the joint.

(i) All mainline uPVC solvent welded joint pipes shall be laid in a minimum of 100mm sand bedding and surround.

(8) Polyethylene pipe installation

(a) All polyethylene pipe work shall be installed in accordance with the manufacturer's recommendations and AS 2033.

(b) Poly pipe shall be laid with sufficient allowance for contraction and expansion of the pipe.

(c) Pipe ends shall be free of all burs and rough edges and shall be chamfered with the appropriate tool before jointing.

(d) Polyethylene tapping saddles are only to be used to connect sprinklers and dripper tube to polyethylene pipe work.

(9) Trenching

(a) All pipe work shall be laid in trenches, with the exception of:

(i) pipes which are installed in underground conduits; or

(ii) pipes which are installed above ground due to obstacles i.e. bridges, walls, etc.

(b) Trenches shall:

(i) be sufficiently wide to allow adequate working clearance;

(ii) be excavated in straight lines between bends or pits;

(iii) have vertical sides and be a constant depth for the full length of the trench; and

(iv) be of adequate depth to allow for pipe bedding and adequate cover to the pipe as specified.

(c) Trenches for multiple pipes shall be sufficiently wide to allow adequate working clearance and a minimum of 100mm separation between pipes.

(d) Pipes shall be firmly and evenly supported with bedding material or approved backfill material in the centre of the trench.

(e) Minor adjustment to the irrigation systems design layout will be permitted to clear underground obstructions.

(f) Trenching machinery shall be avoided within 1m of existing services. Hand trench to expose existing services, prior to connection or use of trenching machinery.

(g) Cover to pipes

The minimum and maximum depth of cover to pipes shall be as noted in Table SC6.4.6.27.1.

Table SC6.4.6.27.1 Depth of cover to pipes

Pipe	Minimum	Maximum
Main lines in road reserves (UPVC and Polyethylene)	600mm	750mm
Main lines all other locations (UPVC and Polyethylene)	400mm	600mm
Lateral lines - all locations	300mm	500mm
Drinking fountain and water tap supply lines. (except in land fill sites)	300mm	400mm
Drinking fountain and water tap supply lines in land fill sites	450mm	600mm
Dripper tube (turf)	75mm	100mm
Dripper tube (garden)	Surface	Surface

Note—depth of cover is defined as the distance from the top of the pipe to the finished surface level or from the top of the pipe to the underside of paving, concrete or road pavement. Refer to SC6.4.4.8 Standard drawings SD-18.1 for Typical Pipe Trench details.

(10) Pipe bedding

(a) A minimum of 100mm sand bedding and surround is required for:

(i) all main lines;

(ii) all uPVC Rubber Ring Jointed pipes;

(iii) all pipes under road pavements;

(iv) all pipes laid on solid rock;

(v) all pipes where rubble, rocks and/or debris is encountered in the trench;

(vi) all potable water lines; and

(vii) all electrical conduits.

(b) Bedding sand shall be clean sand with rounded grains free of any rocks, debris and organic matter and graded such that 100 per cent passes a 4.75mm sieve size.

(c) Pipe work, other than those listed in clause SC6.4.6.27.2(10)(a) may be laid without sand bedding, provided the trench is free of rubble, rocks and /or debris.

(d) Pipe work, other than those listed in clause SC6.4.6.27.2(10)(a), in locations where the natural earth contains rocks, debris and any materials that may damage pipes over time or where excessive ground movement is likely to occur shall be laid in a minimum of 75mm sand bedding and surround.

(11) Approved backfill to trenches

(a) Excavated material may be used as backfill, provided that the material is free of rubble, rocks, debris, organic material and any sharp or solid objects and/or materials that may damage the pipe over time.

(b) Where material excavated from the trench is unsuitable for backfill, clean sand, garden loam shall be used as backfill.

(c) Backfill to trenches shall be compacted with a wheel roll or plate compactor. Completed backfill is to be mounded 50mm higher than the surrounding surface for the full length of the trench, to allow for further consolidation.

(d) Backfill to trenches under road pavements and pathways shall be crusher dust material placed in 150mm compacted layers.

(e) On completion of backfilling operations, all excess material is to be either reused on site where possible or shall be removed from the site.

(12) Exposed pipes

(a) Any exposed pipe shall be constructed of stainless steel or lagged copper and shall comply with AS/NZS 3500 standards for exposed pipe.

(b) All above ground works are to conform to AS/NZS 3500.1, Section 5.7 "Support and fixing above ground".

(c) Bracing around the pipes is to be lined with an appropriate material to prevent damage to the pipe.

(d) Pipes are to be labelled “potable” or "non potable" in accordance with Australian Standards.

(13) Proximity to other services

Table SC6.4.6.27.2 lists the separation required between water pipes and electricity and gas services. Separation for all other services shall be as outlined in AS/NZS 3500.1 Section 5.3 entitled “Proximity to other services”.

Service	Separation
Electrical Cables with Warning Tape or Mechanical Protection (Water Pipes DN65mm and below)	100mm
Electrical Cables with Warning Tape or Mechanical Protection (Water Pipes larger than DN65mm)	300mm
Electrical Cables with no Warning Tape or Mechanical Protection	600mm
Consumer Gas Pipe with Marker Tape 150mm above complying with AS2648.1 (Water Pipes DN65mm)	100mm
Consumer Gas Pipe with Marker Tape 150mm above complying with AS2648.1 (Water Pipes larger than DN65mm)	300mm
Consumer Gas with no Marker Tape or Mechanical Protection	600mm

SC6.4.6.27.3 Control system

(1) Scope

This section covers the furnishing of all labour, materials and services in connection with the fabrication, factory testing, delivery and site installation of the irrigation controller and associated cabinets.

(2) Network requirements

(a) Townsville City Council operates an irrigation control system that consists of a Motorola Irrinet Supervisory Control and Data Acquisition (SCADA) System. This system is commonly known as the Irrigation Central Control (ICC). The ICC System communicates to irrigation controllers throughout the Townsville region over UHF wireless telemetry communication networks.

(b) All irrigation controllers shall be operated via the ICC System unless an alternative controller system is approved by the Superintendent

(c) Contractors are required to provide an approved irrigation controller to adequately service the proposed irrigation system. The Controller shall provide for the number of stations including master valve and fertigation control valve required for:

(i) the current irrigation system to be installed; and

(ii) defined future requirements of the controller.

(d) Irrinet M Slave, Irrinet M and Irrinet ACE controllers by Motorola are the approved irrigation controllers.

(e) All irrigation controllers must be capable of communicating with the ICC System across the telemetry communication network. Each controller must be fitted with an approved radio transceiver and antenna.

The transceiver must have the correct frequency configuration to communicate on the network.

(f) Each irrigation controller shall be allocated a logical address by Maintenance Services – Irrigation Design Unit for communications to the ICC System.

(g) All irrigation controller system components shall operate within the ranges specified by the manufacturer.

(3) Irrigation controller selection

(a) Irrigation controllers are to be selected from Table SC6.4.6.27.3.

Table SC6.4.6.27.3 Controller selection list

Controller Name	Power Type / Source	Valve Capacity
AC Irrinet M Slave 12 - 24	AC / 240 V Mains	12 to 24
AC Irrinet M Slave 36 - 48	AC / 240 V Mains	36 to 48
AC Irrinet M 12 - 24	AC / 240 V Mains	12 to 24
AC Irrinet M 36 - 48	AC / 240 V Mains	36 to 48
AC Irrinet ACE 24 - 48	AC / 240 V Mains	24 to 48
XR 1 - 4	DC / 6 V Solar	1 to 4

(b) AC powered irrigation controllers are the preferred option of the Superintendent. DC powered irrigation controllers are not acceptable unless approved by the Superintendent.

(4) Operating environment
Ambient conditions

(a) All equipment mounted inside cabinets and cubicles shall be suitable for operation in temperatures up to 60 °C. Measures shall be taken to ensure that high ambient temperatures and full load operation do not cause temperatures to exceed maximum allowed operating temperatures.

(b) Since all cabinets are to be mounted outdoors, particular consideration shall be given to minimise heating by direct solar radiation.

(5) Irrigation controller specification (general)

(a) General requirements

(i) The irrigation controller cabinet and component parts shall conform in all respects to the highest standards of design and workmanship and appropriate requirements of the latest applicable state or local codes.

(ii) When mounting accessories to the back panel, use fine threaded tapped screws.

(iii) The irrigation controller cabinet shall be completely wired, and assembled, with all devices and controls installed as shown in SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-29.1 so that the entire assembly is an operating unit ready for installation and the wiring of field devices.

(iv) Wiring shall meet the latest requirements of the AS 3000 and applicable workplace safety codes.

(b) Wiring

(i) All wire shall be 0.5mm²/PVC 105/ stranded, insulated for 600 V.

(ii) A "bootlace ferrule" shall be used on wires connected to terminals which have only a screw for securing the wire. Ferrules shall be properly crimped using a professional crimping tool.

(iii) All manufacturer terminal block wiring shall be restricted to the panel side of the blocks. The manufacturer shall connect no more than two wires to any terminal point. The field side of the terminal blocks shall be left completely free of wires and jumpers. Wiring on terminal blocks shall be so arranged that not more than one wire to the field side of any terminal point will be connected with the exception of the earth.

(iv) All multiple common connections shall be wired via bridging links on the terminal blocks.

(v) Horizontal and vertical wiring between the terminal blocks and the devices shall be enclosed in ducts except wiring between the ducts and the devices may run exposed for distances not exceeding 100mm. Duct loading shall not exceed 75 per cent rated fill at any point.

(vi) All exposed wiring shall be formed neatly with square corners and where possible, grouped in packs. Each pack shall be bound with plastic ties and be substantially supported throughout its full length. Cabled wire is not acceptable.

(vii) Splicing of wires on electrical circuits is not acceptable.

(c) Terminal blocks

Terminal blocks shall be provided for all wiring which exits the panel. All terminal blocks shall be mounted and of the colour as shown in SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-24.8.

(d) Consumer power

(i) The irrigation control cabinet shall be equipped with a (Clipsal 4CC6 or approved equivalent) enclosed consumer panel. Consumer power shall be wired direct into the consumer panel. The consumer panel shall enclose a neutral link and an earth bus with the panel structure connected to the bus so as to effectively earth the entire structure. A solder-less clamp type terminal lug shall be provided at the end of the earth bus for a 6mm² stranded earth cable to be attached from the external earth-stake.

(ii) Whenever the electrical diagrams indicate an earth for a circuit at the panel, a single wire for each circuit earthed shall be run independently to the earth bus and fastened thereto using a ring lug and a machine screw inserted in a tapped hole.

(iii) Earthing of the enclosure and back panel from the consumers panel shall be made using 4mm² stranded earth cable.

(iv) The consumer panel shall be wired with a main isolation switch an RCD/MCB and a suitably rated "Isatrol" mains filter unit, din-rail mounted within the consumer panel to provide power to the GPOs. One double GPO and one single GPO are to be mounted on the face cover of the consumer panel. Care shall be taken when positioning the GPOs not to cover the access screw holes to the consumer panel.

(v) Each device requiring 240 V AC power shall have an individual line plug and plug into an allocated GPO on the consumer panel.

(vi) Power will be supplied as a single phase voltage at 50 Hz and 240 V ± 10 per cent.

(vii) All 240 V connections are to be tool proof and either housed in the consumer panel or behind a protective cover.

(6) Irrigation controller specifications (specific)

(a) Irrinet M Slave, Irrinet M and Irrinet ACE.

(i) Each controller's maximum valve output is listed in Table SC6.4.6.27.3 including master and fertigation valves. The controller shall have as a minimum, two inputs from electronic pulse water meter and rain switch.

(ii) The general control voltage shall be 24 VAC for controller outputs used for water valve operation.

(iii) The 24 VAC power is via the PELV system with common tied to earth.

(iv) The irrigation controller cabinet layout, dimensions and wiring are shown in SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD 29.1.

(v) The irrigation controller cabinet shall be a B&R NI (NI06062/S) or (NI06063/S) with dual key lock (NI030) or approved equivalent as shown within SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-29.1. The controller pole, mast and cross arms shall be coated with 2PAK Epoxy Paint in Heritage Green colour.

(vi) Control equipment shall be selected from the Preferred Equipment list - Controller and Telemetry Components within SC6.4.4.8 Standard drawings SD-5.1 through SD 5.10 and SD-20.1 through SD-29.1, unless otherwise specified by the Superintendent.

(vii) All firmware incorporated in CPUs and other intelligent modules shall be the latest released

version.

(viii) The radio telemetry equipment involves the installation of the following equipment:

(A) TX-3600 GME Transceiver with blind front panel, programmed with Parks Services frequencies;

(B) YB6-61 Yagi Antenna, UNV2 mounting bracket and RG58 coax cable terminated with a N88 N type male connector;

(C) PS123 GME Power Supply or DC1224X Aeon UPS (for Irrinet M controllers);

(D) IS50NX Surge Arrestor flange mounted with N type female connectors;

(E) RG58 Coax Fly Lead terminated with N88 N type and BNC113 male connectors; and

(F) Data cable connecting controller to transceiver.

(ix) The transceiver shall be mounted on the door such that the indicator lights are visible when the door to the panel is opened. The antenna cable and data cable are to be feed from the controller via the cabinet ducting towards the door hinge and onto the door bracket. The transceiver shall be mounted in such a way to allow for its easy removal. The mounting bracket is to be securely fastened to the back of the door. All cabling on the door shall be neat and fastened in place by cable ties, SC6.4.4.8 Standard drawings SD-26.2, SD-26.4 and SD-5.10 refers.

(x) A Surge Arrestor shall be mounted on the cabinet earth lug and suitably earthed refer SC6.4.4.8 Standard drawings SD-27.1 and SD-5.10. The coax fly lead shall be connected from the transceiver BNC connector to the “Equipment” side of the surge arrestor. The coax cable from the antenna will enter the panel and be terminated on the “Antenna” side of the surge arrestor.

(xi) Before the transceiver is powered up a qualified radio technician shall fit the antenna coax plug and carry out a SWR / radio check and set the modulation level.

(xii) The “data cable” shall connect the controller to the transceiver and shall be secured and neatly run through the ducting.

(xiii) PS123 GME Power Supply 240 VAC to 12 VDC is to be mounted on the door bracket to supply power to the Transceiver and Interposing Relays refer SC6.4.4.8 Standard drawings SD-5.5.

(xiv) DC1224X Aeon UPS (uninterrupted power supply) 240 VAC to 12 VDC is to be mounted on the door bracket to supply power to the Irrinet CPU memory and Transceiver, refer SC6.4.4.8 Standard drawings SD-20.1 through SD-29.1.

(xv) A separate 24 V AC power supply shall be provided as shown within SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-29.1:

(A) Irrinet M, Irrinet M Slave and Irrinet ACE controllers require 1 Powertech 240 V/24 V 150 VA Transformer part No. MP3045 to be direct mounted to supply power to the controller and field solenoids.

(xvi) The controller shall have two conduits connecting the cabinet to the ground. The following conduit types and sizes shall be used:

(A) M.D. 50 mm electrical conduit (24 V Control Cable); and

(B) H.D. 25 mm electrical conduit (240 V Power Supply).

(xvii) A Mini-Clik II Rain Switch or approved equivalent is to be installed on the controller pole. Construction details are given in SC6.4.4.8 Standard drawings SD-29.1. The device is to be set on a 13mm setting.

(b) Piccilo XR

(i) The output control voltage used is a DC Pulse through a 2 wire circuit suitable for activating DC latching coils used for water valve operation - Hunter ICV with DC Coil option or approved equivalent. With the Piccilo XR output voltage adjusted to 18 V (from the factory default of 12 V).

(ii) The controller assembly is powered by a 6 volt sealed lead acid battery which is charged via a solar panel and regulating semiconductors. SC6.4.4.8 Standard drawings SD-4.2.

(iii) The irrigation controller cabinet layout, dimensions and wiring are shown in SC6.4.4.8 Standard drawings SD-4.1 through SD-4.4.

(iv) The Irrigation controller cabinet shall be a B&R NI (NI03021/S) with single key lock (NI030) or

approved equivalent as shown within SC6.4.4.8 Standard drawings SD 4.1 through SD-4.4. The controller pole, mast and cross arms shall be coated with 2PAK Epoxy Paint in Heritage Green Colour.

(v) Control equipment shall be selected from the Preferred Equipment list - Controller and Telemetry Components within SC6.4.4.8 Standard drawings 4.5, unless otherwise specified by the Superintendent.

(vi) All firmware incorporated in CPUs and other intelligent modules shall be the latest released version.

(vii) The radio telemetry equipment involves the installation of the following equipment:

(A) Qty 1, CD51 Whip Antenna (cut to wave length) with .5M of RG58 coax cable terminated by a SMA type male connector;

(B) Qty 1, Antenna Mounting Bracket; and

(C) the radio telemetry component is integrated within the XR Controller unit. So no external transceiver is required.

(viii) The antenna coax SMA male plug shall be connected into the XR Controller SMA socket mounted on the top of the unit.

(ix) Before the XR Controller is powered up a qualified radio technician shall fit the antenna coax plug and carry out a SWR / radio check on site.

(x) A Kyocera Mini Module Solar Panel as detailed in SC6.4.4.8 Standard drawings SD 4.5 shall be fastened to the top of the enclosure refer SC6.4.4.8 Standard drawings SD-4.3. An external grade silicon base sealant shall be applied to the solar panel perimeter to maintain the enclosure IP rating.

(xi) The regulator components shall be installed as detailed in SC6.4.4.8 Standard drawings SD-4.2 and tested by an electronics technician prior to final connection of the battery and XR units.

(xii) A 6 V 12 AH SLA Battery is placed inside on the bottom of the enclosure and connected to the terminal blocks. Refer SC6.4.4.8 Standard drawings SD-4.1 and SD 4.2.

(xiii) The controller shall have one 25mm conduit connecting the cabinet to the first electrical pit.

(7) Controller location

The final location of the controller shall be determined by taking into consideration all of the following factors:

(a) radio path tests (to be carried out by a qualified radio technician) to ensure reliable communications from the controller to the ICC System Base Station;

(b) the location shall be clear of large trees or structures that may interfere with the performance of radio communications, or solar panel. In newly planted areas the location shall make allowance for future tree growth;

(c) safe 24 hour access for maintenance by maintenance services personnel and equipment;

(d) the location shall allow access by motor vehicle and elevated platform (antenna servicing); and

(e) the Controller shall not be installed less than 3 m from a roadway unless approved by the Superintendent.

(8) Cabinet installation

The pre-assembled Controllers shall be installed in the ground as follows:-

(a) The pre-assembled Controller cabinet support post shall be embedded in a 200mm diameter x 600mm deep hole with a 400mm deep concrete footing (N25 concrete minimum). The concrete shall be poured up to the underside of the conduits entering the support post. Covering the conduits in concrete is not acceptable. The Cabinet shall be installed at a height of 1200mm from the finished ground level to the underside of the cabinet (1090 mm for XR controllers Refer SC6.4.4.8 Standard drawings SD-4.4).

(b) XR Controller Cabinet is to be orientated with the door side facing north to maximise the absorption of solar radiation into the solar panel, unless approved by the Superintendent.

(9) Controller cabinet and controller wiring

(a) All conduits shall be terminated at the controller cabinet with a suitable conduit adaptor. All conduits shall be sealed with an external grade Butyl Mastic sealant, such as “Selleys Butyl Mastic” or similar approved to a depth of 25mm into the conduit to prevent vermin entering the controller cabinet.

(b) Earth stakes shall be located in the electrical pit adjacent the controller. The location of the earth stake is to be indicated on the as constructed drawing.

(c) Earth stake connections are to be sealed with cold gal paint.

(d) All field wired cables entering the controller cabinet shall be made secured – in this instance only by the application of sealant to the conduit end inside the enclosure (see clause (9)(a) above). From this point on, the double insulation shall be removed from the cable for ease of wiring to the terminal blocks.

(e) All single insulated cables inside control cabinets shall be loomed together and cable tied in a neat orderly manner to the panel so that the connections into the terminal strip are not stressed.

(f) All cables inside the controller cabinet shall be of sufficient length to ensure that all cores will reach their termination point without any stress or joining of cables.

(g) All field cables inside the controller cabinet shall be of sufficient length to ensure that all cores will reach the upper and lower most termination points without any stress or joining of cables.

(h) All cables to be connected within the controller cabinet shall be terminated with a bootlace ferrule, CABOC BLP 150 or similar approved. Pin lugs are not acceptable.

(10) Field electrical wiring

(a) Cable types

(i) All electrical cabling shall conform to current Australian Standards.

(ii) All cables shall be Tyflo multi-core irrigation cables or similar approved with a minimum core size of 1.5 mm. Table SC6.4.6.27.4 details cable specifications.

Table SC6.4.6.27.4 Multicore cable specifications

Nominal core dia.	Conductor no. and size	Amp rating	Resistance Ohms/Klm	Number of cores
1.5 mm	7/0.50	16	13.6	3,5,7,9,13
2.5 mm	7/0.67	23	7.4	2,7
4 mm	7/0.85	30	4.6	2

(iii) All cables shall have an outer sheath of flexible 75□C PVC to AS/NZS 3808, over an Inner core of a sheath of HDPE, over a multi-strand plain copper wire.

(iv) Inner cores are to be readily available in 13 colours namely- Black, Blue, Green, Dark Brown, Brown, Grey, Light Blue, Orange, Pink, Red, Violet, White and Yellow.

(b) Cable installation

(i) A 7 core cable shall be run continuously from the controller to the water meter assembly solely for the operation of Master Valve, Pulse Meter and Fertigation. The black core shall be common, red core shall be Master Valve control, brown core shall be Fertigation control and run to the Fertigation Venturi Point and the blue and white shall be Pulse Meter and Pulse Meter common respectively.

(ii) An additional 20% of the total number of cables or 2 extra cores (whichever is the greater) shall be provided as spares. Designated spares shall run from the controller to the furthest most point from the controller in the cable run. The spares are to be marked at the controller. At the furthest point all spares shall be connected together and sealed with heat shrink so that a continuity test can be performed at the controller to confirm the total number of spares.

(iii) All extra low voltage cables shall be installed inside a conduit. The conduit size used shall be a minimum size of 50mm or 2.5 times the combined size of all the cables being installed, whichever is the greater.

(iv) The single insulation on the cable core shall not be cut or damaged when the outer sheath (double

insulation) is removed. All cables shall have the insulation removed from the cores using appropriate cable strippers. Use of a knife or other sharp blade is not acceptable practice.

(v) Cables shall be continuous between electrical inspection pits. Cable joints located between electrical inspection pits are not acceptable. Cable joints shall be kept to a minimum and shall only occur at valve take off points.

(vi) Where required each individual cable shall be joined using the appropriately sized insulated crimp links, to maintain a double layer of insulation at the joint after the heat shrink is installed, and shall be installed with a professional ratchet type crimping tool.

(vii) Bare conductors shall not be exposed.

(viii) Each individual cable joint shall be waterproofed by using ES-2 resign filled heat shrink three times the length of the insulated crimp link.

(ix) Multiple cables shall not be joined or heat “shrinked” together.

(x) All cut unused cables (spares) shall be sealed using ES-2 resign filled heat shrink.

(xi) Cable markers shall be attached to each cable at every electrical inspection pit indicating the individual cable number as shown on the design plan; refer SC6.4.4.8 Standard drawings SD-7.2. Cable markers shall be round 38mm diameter aluminium identification tags commercially available. Numbering shall be clearly stamped onto one side of the tag using a punch set with 13mm high numerals. Tags shall be fastened to the appropriate cable using a quality grade plastic cable tie attached at the mid-point of the cable loop.

(xii) The Black cable shall be used as the designated common.

(xiii) All spare cable in electrical inspection pits shall be left full length, individually sealed with heat shrink and grouped together.

(xiv) All continuous cable that passes through an electrical inspection pit shall have a loop of at least 1.5m in length and be neatly coiled and tied.

(xv) A draw wire is to be left in the conduit from the controller cabinet to the first electrical inspection pit.

(xvi) All electrical cable locations shall be recorded on the as constructed drawings.

(c) Electrical inspection pits

(i) Electrical inspection pits shall be heavy duty rectangular with rounded ends and fitted with a precast concrete lid, type P1 or P2.

(ii) The first electrical inspection pit shall be located a maximum of 1m from the Controller cabinet support base. A draw wire together with the electrical cables is to be installed in the conduits from the controller to the first electrical pit to allow for future works.

(iii) Electrical inspection pits shall be located adjacent to valve boxes and offset from the main irrigation line a maximum of 200mm as shown in SC6.4.6.27 Attachment A 17.2 (Plan View).

(iv) Electrical inspection pits shall be located at changes in direction and no more than 50m spacing.

(v) Electrical inspection pits shall be installed so that the top of the pit is flush with the finished surface level and matches the slope of the finished surface level.

(vi) All electrical inspection pit locations shall be recorded on the as constructed drawings.

(vii) All conduits shall enter at the end of an electrical pit. Side entry of conduits into electrical pits in not permitted.

(viii) All conduits shall enter an electrical pit at no greater than 45 degrees of the horizontal centre.

(ix) Electrical pits shall not be installed in drainage swales or places where water is collected during rainfall and irrigation.

(x) Electrical pits shall not be installed less than 3m from the road kerb, unless approved by the Superintendent.

(d) Electrical conduits

(i) All electrical conduit shall conform to current Australian Standards.

(ii) All conduit (extra low voltage electrical) buried in ground shall be Grey M.D.

(iii) All electrical conduits that are exposed above ground shall have a protective outer sheath of polyethylene pipe rating PN12.5. The sheath is to encase the conduit for the entire length of conduit above ground and for a depth of 150mm minimum below ground.

(iv) All electrical conduits that are exposed above ground shall be fixed in place so that they are vertical and shall be secured firmly to the accessory.

(v) Electrical conduit above ground shall be adequately secured to avoid damage by grass cutting operations.

(vi) All electrical conduit ends shall be neatly cut and free of burrs or rough edges.

(vii) The final 500mm of conduit entering an electrical inspection pit shall be M.D. corrugated flexible conduit which is to be connected to the M.D. PVC Conduit by a Socket. SC6.4.4.8 Standard drawings SD-17.2 (Electrical Pit), gives a typical construction drawing of the assembly.

(e) Electrical conduit trenching

(i) All electrical conduits shall be laid in trenches and bedded in sand.

(ii) Low voltage conduits (240 V) shall be installed with continuous electrical warning tape laid over the conduit for the entire length of the trench.

(iii) Low voltage conduit (240 V) shall not be installed in the same trench as irrigation lines.

(iv) Extra low voltage conduits (24 V) installed in the same trench as irrigation lines shall be bedded in sand and separated from the irrigation lines by a minimum distance of 100mm.

(v) Depth of cover to electrical conduits from finished surface level or from the underside of finished pavement level (e.g. pavers or concrete) shall be:

(A) 300mm minimum - for extra low voltage cables (24 V); and

(B) 600mm minimum - for low voltage cables (240 V). Refer SC6.4.4.8 Standard drawings SD-18.1.

(vi) Electrical conduits under roadways shall be a minimum 50mm M.D. Electrical conduit encased in a 100mm Class 9 PVC Pipe.

SC6.4.6.27.4 Water meter assembly

(1) Design and installation

(a) Water meter assembly components vary, as follows:

(i) For drinking fountains and water taps (potable water) the water meter assembly includes:

(A) isolation valve; and

(B) mechanical water meter (supplied by Townsville Water, a business unit of Townsville City Council).

(ii) For irrigation the water meter assembly includes:

(A) isolation valve;

(B) mechanical water meter (supplied by Townsville Water);

(C) master valve and electronic flow meter unit;

(D) RPZ back flow prevention device with two isolation valves;

(E) screen filter;

(F) lockable cover;

(G) cable and conduit; and

(H) protective bollards (depending on location).

Table SC6.4.6.27.5 Allowable water meter assembly component size combinations

Water Service	Townsville Water Water Meter	Irrigation Water Meter	Backflow	Master Valve
25mm	25mm	32mm Arad Multijet (1 pulse/10L)	25mm	25mm Hunter ICV*
32mm	32mm	32mm Arad Multijet (1 pulse/10L)	32mm	25mm or 40mm Hunter ICV*
50mm	50mm	Include in Master Valve (1 pulse/10L)	50mm	50mm Arad Hydrometer
80mm	80mm	Include in Master Valve (1 pulse/10L)	80mm	80mm Arad Hydrometer
100mm	100mm	Include in Master Valve (1 pulse/100L)	100mm	100mm Arad Hydrometer

*external master valve

(iii) All water meter assemblies with a 25mm and 32mm Water Service are to have a master valve external to the main assembly. Refer to SC6.4.4.8 Standard drawings SD-10.3 and SD-10.4.

(iv) Water meter assemblies with a water service sized, 50mm, 80mm and 100mm are to have a master valve as part of the main assembly. Refer to SC6.4.4.8 Standard drawings SD-10.1 and SD-10.2.

(b) Water meters

(i) All water meters and pipe work from the town mains to the water meter shall be supplied and fitted by Townsville Water.

(ii) The water meter type is selected by the following criteria:

(A) for drinking fountains and water taps a standard mechanical water meters shall be used.

(B) for irrigation refer to Table SC6.4.6.27.5 for water meter selection relative to the water service size.

(c) Master valves

(i) All irrigation systems shall be fitted with a master valve.

(ii) The master valve is to be selected by the following criteria:

(A) all water service assemblies sized 25mm and 32mm shall have an external master valve installed in a valve box and shall be fitted to the copper tail pipe of the backflow device. Refer to SC6.4.4.8 Standard drawings SD-10.3 and SD-10.4 for installation details; and

(B) all water service assemblies sized, 50mm, 80mm and 100mm shall be fitted with an assembly mounted master valve. The master valve is to consist of a flange mounted Arad Hydrometer including water (flow) meter module as detailed in Table 5 and 24VAC Solenoid actuator; or approved equivalent. Refer to SC6.4.4.8 Standard drawings SD-10.1 and SD-10.2 for installation details.

(d) Backflow devices design and installation

(i) Backflow prevention is to conform to AS 2845.1, AS 2845.2 and AS 2845.3.

(ii) The Backflow device shall be selected on the required size:

(A) 25mm, 32mm, and 50mm - Tyco Backflow System RP03 or similar to the following specification. The assembly shall be connected with the “ring and tail” to allow easy removal or replacement of the device in accordance with AS/NZS 3500.1. Main valve and internals shall be of stainless steel construction and to have pressure rating of 1600 kPa and a temperature rating of 90ºC. All internal parts and elastomers are to be accessible through a top entry point of the main valve to allow inline maintenance. Valve shall also be fitted with test points with BSPT threads to allow testing to AS 2845.3; and

(B) 80mm and 100mm - Tyco Backflow System RP03 or similar to the following specification. The main valve shall be constructed from ductile iron and coated with Rilsan Nylon 11 to AS/NZ 4158. All internals shall be constructed from stainless steel and to have pressure

rating of 1600 kPa and a temperature rating of 60ºC. Main valve body shall not form part of the wetted check valve sealing area or mechanism. All internal parts and elastomers are to be accessible through a top entry point of the main valve to allow inline maintenance. Valve connection shall be flanged to AS/NZS 4087. Valve shall also be fitted with test points with BSPT threads to allow testing to AS2845.3.

(iii) The velocity through the backflow device shall not exceed 2.2 m/s.

(iv) All backflow devices shall be reduced pressure zone (RPZ) rating.

(v) All backflow devices sized 25mm, 32mm, and 50mm shall be fitted with a locking mechanism, which prevents the two isolation valves and the three test cocks from unauthorised opening. The backflow device is to be lockable at a single point. A council standard series A padlock is to be fitted to the locking mechanism.

(e) Isolation valves

(i) All isolation valves fitted to the water service assembly shall be tested and approved to Australian Standards.

(ii) All isolation valves fitted to the water service assembly shall be selected on the following criteria:

(A) all water meter assemblies sized 25mm, 32mm and 50mm shall be fitted with brass ball valves; and

(B) all water meter assemblies sized 80mm and 100mm shall be fitted with resilient seated gate valves.

(f) Strainer

All water meter assemblies shall be fitted with a brass strainer immediately downstream of the isolation valve and upstream of the back flow device. Refer SC6.4.4.8 Standard drawings SD-10.1 to SD-10.4 for details.

(g) Water meter assembly installation

(i) The water meter assembly shall be supported by the appropriate size Support Stands as detailed in SC6.4.4.8 Standard drawings 10.5 and set into a concrete footing as detailed SC6.4.4.8 Standard drawings SD-10.1 to SD-10.4. A minimum distance of 300 mm from the underside of the assembly to the finished ground level is required.

(ii) A lockable stainless steel sheet metal cover shall be fitted over the water meter and master valve to prevent vandalism and weather damage. Water meter assembly covers shall be built from 316 Stainless Steel as detailed in SC6.4.4.8 Standard drawings SD-31.1 and SD-31.2 and for water meter assemblies sized:

(A) 25mm, 32mm, the cover shall be held in place using U-bolts; and

(B) 50mm, 80mm and 100mm the cover shall be fastened between each set of tightened flanges, using flange bolts.

(iii) Each cover shall be locked using a 40mm KA1 series lock.

(iv) A minimum of two recycled plastic bollards shall be provided at each water meter assembly as directed by the Superintendent, to protect the assembly from vehicle damage, except in garden beds.

Bollards shall be nominal 100mm diameter blue recycled plastic, embedded 450mm minimum into a 350 mm diameter concrete footing. The top of the bollards shall be 900mm above finished ground level.

(v) All cables running from the water meter to the ground shall be encased in a protective outer sheath of polyethylene pipe rating PN12.5. The conduit shall be firmly installed vertical to the ground so as not to be easily damaged by grass cutting operations.

(vi) Copper pipes shall be Type B.

(vii) All fittings to the backflow device shall be either copper of brass. PVC or Poly fittings are not acceptable.

(2) Valve assembly

(a) Design and installation

(i) The valve assembly includes:

(A) solenoid valve;

(B) ball valve;

(C) brass barrel union; and

(D) valve box.

(ii) Refer SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD-14.4 for standard details. Valves shall be connected to the main line via a tee.

(b) Solenoid valves

(i) Refer SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD-14.4 for solenoid valve assembly details.

(ii) Solenoid valves used shall be sized in accordance with Table SC6.4.6.27.6.

Table SC6.4.6.27.6 Approved solenoid valves

Manufacturer	Model	Size	Maximum flow rate (litres per minute).
Hunter	ICV	25mm	100
Hunter	ICV	40mm	250
Hunter	ICV	50mm	360
Hunter	ICV	80mm	700

(iii) Electronic solenoids for AC systems shall be 24 volt coils.

(iv) Electronic solenoids for DC systems shall be 12 volt 2 wire latching coils.

(v) Solenoid valves shall be wired in the following order:

(A) the first controller output shall be assigned to the master valve control;

(B) stations are to be wired to the controller outputs from output 2 on. Station 1 (Controller output 2) is to be located on one side of the site. The last station is to be located on the opposite side of the site. The controller outputs are to follow a logical geographical pattern from one side to another; and

(C) the same wire colour shall be maintained along the entire length of the cable run between the controller and each individual solenoid valve.

(vi) Only one valve shall be allocated per controller output.

(vii) Doubling up of stations on the same output is not allowed.

(viii) Valve boxes shall not be installed within 3m of the road kerb unless approved by the Superintendent.

(ix) The distance from a valve to the first sprinkler or first drip emitter shall not exceed 50m.

(c) Gate and Ball valves

(i) A Ball valve shall be installed on the upstream side of the Solenoid valve. A brass barrel union shall separate the Ball valve from the Solenoid valve to allow for ease of maintenance. Refer to SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD 14.4.

(ii) Ball valves shall be tested and approved to AS 3500.1.

(d) Valve boxes

(i) The valve assembly is to be located in a heavy-duty lockable valve box fitted with a stainless steel lock-down bolt in the lid.

(ii) Valve boxes shall be Heavy Duty Carson or similar approved.

(iii) Valve boxes used are to be of adequate size to ensure that there is sufficient space around the valve assembly to allow for ease of maintenance.

(iv) Valve boxes shall not require removal to facilitate maintenance of the valve assembly.

(v) All valve boxes shall be:

(A) supported on bricks so that the box does not rest on any pipes;

(B) installed so that the top of the box is flush with the finished turf surface level for turf areas, or 50mm to 100mm above the finished mulch surface level for garden areas;

(C) installed so that the clearance from the underside of the valve box lid to the top of the stem of the valve is; 150mm maximum – 50mm minimum for non drip valves and 75mm maximum – 50mm minimum for drip valves, refer SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD-14.4;

(D) installed so that the clearance from the underside of the valve housed within the valve box to the bottom of the box is at least equal to or greater than 50mm;

(E) the pipe holes shall be sealed with Geofabric around the openings to prevent the ingress of foreign material in the valve box;

(F) cutting of valve boxes for entry/exit of pipe work shall be keep to a minimum, boxes cannot be cut higher than 1/3 its height. Over cut boxes are not acceptable; and

(G) installed in association with its housed components so as not to require excessive cutting of the valve box to the satisfaction of the Superintendent.

(vi) All valve box lids shall be clearly marked with the identification of the contents using the follow key:

(A) IV = Isolation Valve;

(B) MV = Master Valve;

(C) A1 = Controller A Station 1 (Refer SC6.4.4.8 Standard drawings SD-8.1) for valve key; or

(D) 3 digit DTMF number as supplied by the Superintendent, for example “045” identifying the Irrinet System number.

(vii) Valve box lids shall be engraved by using a 50mm to 75mm high Signet 14474 / 14494 zinc Stencil Set or approved equivalent as a template. The engraving finish shall be evenly 1.5mm deep at its deepest point and between 4mm to 8mm wide by using an engraving power tool fitted with a spherical engraving bit. The finished engraving shall then be painted with a Signet 12205 White Marker or approved equivalent. Note excessively deep engraving will weaken valve box lids and is not acceptable.

(viii) No valve boxes shall be installed in drainage swales or places where water is collected during rainfall.

(ix) Stainless steel re-enforcing plates may be fitted to valve box lids to repair damaged threads only.

(x) Conduit connecting valve boxes with electrical inspection pits and other Valve Boxes is to be M.D. corrugated flexible conduit of a minimum 500mm and maximum 1500mm in length. SC6.4.4.8 Standard drawings SD-17.2 gives a typical construction drawing of the assembly.

(e) Valve nest enclosures

(i) Refer to SC6.4.4.8 Standard drawings SD-33.1 through SD-33.4 for valve nest enclosure details.

(ii) Valve nest enclosures may be installed where groups of more than three valves can be located together.

(iii) Allowance must be made for larger lateral pipe sizes to offset increased friction losses where longer lateral pipe lengths are required.

(iv) Allowance must be made for increase lateral sizes and quantity leaving the one location.

(v) Where three or more laterals leaving a valve nest cover share a common trench, bedding sand must be used to back fill trenches.

(vi) Lateral pipes leaving a valve nest cover must be run parallel in trenches (not twisted).

(vii) Valves inside a valve nest cover must be clearly identifiable via round 38mm diameter aluminium identification tags commercially available. DTMF numbering shall be clearly stamped onto one side of the tag using a punch set with 13mm high numerals. Tags shall be fastened to the appropriate solenoid valve using a quality grade plastic cable tie.

(viii) Electrical cables shall be cable tied to each solenoid valve control valve.

(ix) Enclosures shall be fitted with a pad lock and keyed to fit council “F” series.

(x) Solenoid valves shall be connected to a common copper manifold via individual brass barrel union and ball valve.

(xi) Copper manifolds (from 40mm to 80mm) must be of sufficient size to allow multiple stations to run simultaneously in program where required.

(xii) Copper manifolds connecting to PVC mainline shall be done via Cop-A-Mate flange or approved similar, installed 25mm above ground level.

(xiii) Copper manifolds connecting to Poly mainline shall be done via metric female compression fitting installed 25mm above ground level.

(xiv) Install Valve Nest Cover using 10mm 316 S.S dyna bolts fastened to 200mm diameter by 300mm deep concrete footings poured on site.

(xv) Top of concrete footings shall be installed level and 25mm above finished ground level.

SC6.4.6.27.5 Sprinklers, turf valves and drip irrigation

(1) Sprinkler design

(a) Sprinklers used shall be in accordance with Table SC6.4.6.27.7.

Table SC6.4.6.27.7 Approved sprinklers

Manufacturer	Model	Type
Hunter	PGP	Gear
Hunter	MPR	Rotating Nozzle**
Toro	570	Static
Rainbird	3500	Gear
Rainbird	5000 Plus	Gear
Rainbird	5505	Gear
Rainbird	6504	Gear

** Use on Toro 570 Body.

(b) Sprinkler uniformity shall not exceed a scheduling coefficient of 1.3 (5 per cent Window) SC6.4.4.8 Standard drawings SD-19.1, provides a definition of the scheduling coefficient and the process for calculation.

(c) Where possible, individual sprinkler stations shall be fitted with either all full circle sprinkler arcs or all part circle sprinkler arcs.

(d) All sprinklers on the same valve shall provide “matched precipitation”. The ratio of water supplied shall be even across all arcs of coverage. Sprinklers of different pressure and / or precipitation rate on the same station are not acceptable.

(e) The variation in flow between any sprinklers on a single station is not to exceed 10 per cent.

(f) All sprinklers are to be run at the manufacturer’s recommended pressure.

(g) All sprinkler heads on each individual station shall be the same type.

(h) Locations which are susceptible to low head drainage shall be fitted with either internal check valves, or Hunter or similar approved external check valves.

(i) No water shall be applied by design to locations where over spray is undesirable, (i.e. adjacent non-irrigated areas, roads, footpaths, private property etc.). The manufacturer’s published throw distance shall govern for design purposes.

(j) On roadway corners no water shall be applied by design to the road pavement whilst no unirrigated areas shall exceed 1m from the road edge. The manufacturers published throw distance shall govern. Examples of acceptable sprinkler layouts are given in SC6.4.4.8 Standard drawings SD-16.1.

(k) All static sprinklers are to be fitted with “fixed pattern” nozzles.

(l) Sprinklers are to be designed and installed in such a way that no electrical boxes, control cabinets, transformers, meter assemblies and the like are hit by direct water streams.

(2) Sprinkler installation

(a) No sprinklers shall be fitted until all main lines, lateral lines and risers have been flushed clean.

(b) Sprinklers shall be placed 150mm clear from walls, garden edges, pathways and the back face of concrete kerbs or concrete garden edges.

(c) Sprinklers shall be installed as detailed in SC6.4.4.8 Standard drawings SD-12.1 Figure 2, slightly above the finished surface level.

(d) Sprinklers shall be installed plumb unless placed on a slope in which case they shall match the slope of the surface.

(e) Where directed by the Superintendent sprinklers in grassed areas shall be installed with a sod of turf (300mm square) placed around them at the finished surface level to help stabilise the sprinkler.

(f) Sprinklers shall be connected to pipes (lateral lines) via either a tapping saddle or a BSP/F Tee and a flexible swing hose riser. All swing hose risers shall face downstream of the solenoid valve. Refer to SC6.4.4.8 Standard drawings SD-12.1 Figure 1.

(g) In locations where soils may be of a corrosive nature, 316 stainless steel bolt and nuts shall be used on all tapping saddles.

(h) The flexible swing hose riser used shall be either:

(i) 25mm safety yellow industrial hose, with nylon type elbows secured with stainless steel hose clamps; or

(ii) HR Products E-Z riser tube and E-Z riser elbows. (for sprinklers with 15mm and 20mm inlets).

The length of the flexible swing hose riser shall be no less than 500mm and no greater than 750 mm.

(i) Nozzle diffuser screws shall not reduce the wetted throw of a sprinkler by more than 20 per cent of the undiffused radius of a sprinkler.

(3) Bollard sprinkler installation

(a) Bollard sprinklers shall be installed where approved by the Superintendent in locations where sprinklers may be obstructed by plants or plant growth.

(b) Bollard sprinklers shall be assembled and installed as detailed in SC6.4.4.8 Standard drawings SD-12.2.

(4) Turf valves

(a) All turf valves shall be plasson.

(b) Turf valves shall be installed with an articulated riser connected to the main line via a tee coupling. Connecting turf valves to main line with tapping saddles is not allowed.

(c) Turf valves that are to be used as a hose watering point for garden establishment shall be installed in a valve box.

(d) Turf Valves Systems where sprinklers are directly inserted into the turf valves may be installed without a valve box flush with the soil surface.

(e) Turf valves located under valve box lids shall have the lid of the valve box clearly marked with an engraving tool and paint with the letters “TV”.

(5) Drip irrigation design and installation

(a) All drip irrigation systems shall be installed with an RPZ backflow device.

(b) The length of the drip tube shall be determined, based on all drippers along the line having sufficient pressure to operate 100 Kpa above the pressure compensation point as nominated by the dripper manufacturer. The maximum allowable inlet pressure shall be 300 Kpa.

(c) All drip tube used shall be Netafim Uni Ram 16 - 0.4m spacing @1.6lph or approved equivalent.

(d) The maximum spacing for drip tube is as shown in Table SC6.4.6.27.8.

Table SC6.4.6.27.8 Dripper spacing

SOIL TYPE	LOCATION	
	Grassed areas	Gardens
Loam and Clay Soil	400mm maximum	500mm maximum
Sandy Soil	300mm maximum	400mm maximum

(e) Refer SC6.4.4.8 Standard drawings SD-14.1 and SD-14.2 for typical drip irrigation details.

(f) Pressure compensation shall be fitted to each individual drip irrigation station. The devices used shall be retro fitted to the solenoid valve. The following two options are acceptable:

(i) Hunter Accu-Set pressure regulator, refer SC6.4.4.8 Standard drawings SD-14.3; and

(ii) inline pressure regulation device as specified by the Superintendent, refer to SC6.4.4.8 Standard drawings SD-14.4.

(g) A 120 mesh Disc Filtration system shall be installed immediately up stream of the solenoid valve in accordance with the manufacturer's specifications to ensure that the correctly sized filtration system is used. The following two filtration systems are acceptable:

(i) Netafim Tech Filter, (rated at 120 mesh by Netafim); and

(ii) Arkal 120 mesh Disc Filter fitted into a Netafim Tech filter housing, may be used during construction and for a period no greater than 1 month after installation of the drip tube.

(h) The filter, pressure regulator valve and solenoid valve assembly shall be installed in a valve box. Barrel Union/s shall be fitted to allow for easily removal of the filter, refer SC6.4.4.8 Standard drawings SD-14.3 and SD-14.4. The order of component installation from upstream to downstream is to be: Barrel Union, Filter, Barrel Union, Solenoid valve and Pressure Regulator. The fitting of these devices and the size of the valve box shall allow for:

(i) the filter cartridge to be easily serviced and changed; and

(ii) the pressure regulator to be easily adjusted and serviced.

(i) Drip tube shall be installed:

(i) in turf with 75mm cover to the finished surface level.

(ii) drip Tube laid on the surface shall be fitted with holding pins placed every 1.5m along the tube. Holding pins are to be constructed from 2.3mm minimum diameter Stainless Steel wire of 304 grade. Refer to SC6.4.4.8 Standard drawings SD-15.1 for details.

(j) Drip tube shall not be installed:

(i) directly into heavy clay or rocky soils where conditions may cause damage to the drip tube. In these soil types the drip tube must be installed between a 50mm surround of imported loan soil; and

(ii) in areas subject to significant vehicle traffic, where these condition would cause damage to the drip tube.

(k) All dripper lines shall terminate to a flushing manifold on the downstream side of the line. The head loss in the manifold shall be sized to lose no more than 1m based on twice the flow rate of the flow during normal operation. Each flushing line shall be fitted with a ball valve and 1 m of industrial vacuum and delivery hose. The ball valve shall be installed to provide easy operation. The ball valve shall be positioned in the valve box to prevent the industrial vacuum and delivery hose from kinking. The hose is to be held in place with a stainless steel hose clip. See SC6.4.4.8 Standard drawings SD-14.1 and SD-14.2 for component layouts. The valve box shall be sized as follows:

(i) 25mm ball valve – Carson or equivalent round valve box; and

(ii) 40mm and 50mm ball valves – Carson or equivalent rectangular valve box.

(l) All high point(s) in the dripper layout shall be fitted with a Bermad vacuum relief valve (Model ARV). The vacuum valve is to be installed in a valve box. A section of drip tube shall cross connect all drip tubes to the vacuum relief valve. The vacuum relief valve shall not be fitted to the supply manifold. See SC6.4.4.8 Standard drawings SD-14.1 and SD 14.2 for a typical installation.

(m) Netafim HCNL drip tube and/or Hunter adjustable check valves (or approved equivalent) shall be fitted if

the fall in the drip irrigation system exceeds 3m. Each side of the check valve shall be fitted with independent Flushing Valves and Vacuum Relief Valves. The check valves shall be set to 3m. The two methods for installation of the check valves are:

(i) check valves fitted to each drip tube; and

(ii) check valves fitted to both the supply manifold and the flushing manifold.

(n) Each drip irrigation station shall be fitted with operation indicators. The operation indicators consist of a Toro 570 100mm pop-up sprinkler fitted with an SST nozzle set to zero flow, sealed with silicon and installed level with the ground. The operation indicators are to be installed in a garden bed or next to a tree (not be a tripping hazard) and be visible from the drip valve assembly. Additional operation indicators shall be installed at the ends of each station and connected using a HR Products E-Z riser tube and 15mm E-Z riser elbows.

(o) Prior to the installation of the drip irrigation system the area to be drip irrigated shall be soaked with water and allowed to dry. Any resulting subsidence or soil shrinkage shall be filled with soil up to the finished surface level. The process of soaking with water and filling to a finished surface shall be repeated until the required surface level is achieved. Drip tubes may then be laid with the correct cover.

(p) On slopes the drip irrigation tubes shall following the contour lines of the area.

(q) “Snaking” of dripper lines shall be avoided.

(r) The minimum size of the header manifold is to be 25mm low density poly pipe.

(s) Drip tube shall be laid in straight runs inside roundabouts.

(t) No drip tube shall be installed within 150mm from walls, garden edges, pathways and the back face of concrete kerbs or concrete garden edges.

(u) Drip tube shall only be connected to low density poly pipe 25mm and 32mm using FI Tees and Netafim elbow adapters (3/4 inch to 17mm) with all low density pipe fittings clamped using Cobra stainless steel clamps or similar approved type. The use of quick start connectors is not approved by the Superintendent.

(v) Drip tube shall only be connected to PN 6.3 Poly Pipe using poly tapping saddles and Netafim elbow adapters (3/4 inch to 17mm). The use of grommet connectors is not approved by the Superintendent.

(w) In locations where soils may be of a corrosive nature, 316 stainless steel bolt and nuts shall be used on all tapping saddles.

SC6.4.6.27.6 Drinking fountain and water tap

(1) Drinking fountain

(a) A drinking fountain assembly includes:

(i) bowl - cast alloy, powder coated white;

(ii) turret - Ex 219 OD stainless steel tube powder coated "Heritage Green";

(iii) tap - BUB228C cam action Enware;

(iv) bubbler - Enware Type 61 push button bubbler with 3/8th - 1/2"x 3" male BSP tail;

(v) copper tube connection – 13mm Annealed Copper;

(vi) isolation valve;

(vii) precast concrete plinth base;

(viii) precast concrete pipe and aggregate backfill;

(ix) potable water supply line and water meter; and

(x) SC6.4.4.8 Standard drawings SD-32.1 contains the construction drawings for the fountain assembly.

(b) All pipe work to a drinking fountain shall comply with AS 3500. All pipe work installation to a drinking fountain, shall be carried out by a licensed plumber.

(c) The supply line to a drinking fountain shall be a “standalone” potable water line with its own water meter. Pipe work shall be a minimum 32mm PN12.5 Poly Pipe (from meter to isolation valve) laid in a trench with sand bedding and surround to the pipe and with 300 mm minimum cover over the pipe. Drinking

fountains and water taps may be installed on the same potable water line.

(d) The drinking fountain turret shall be installed on a precast concrete plinth base set on top of a 600 dia x 1.2m long reinforced concrete pipe embedded into the ground and backfilled with 20mm aggregate for drainage. Details of the base are given in SC6.4.4.8 Standard drawings SD-32.2. Alternately, the drinking fountain may be connected into an existing sewer drainage line.

(e) The Drinking fountain shall be isolated by a 15mm Ball Valve. The isolation valve shall be located a nominal 600mm from the drinking fountain adjacent the concrete plinth base and shall be installed in a circular valve box.

(f) The drinking fountain tap and bubbler shall be connected to the isolation valve with a flexible stainless steel hose.

(g) All bolts, screws and masonry anchor bolts fitted to the drinking fountain assembly shall be stainless steel.

(h) On completion and at commissioning of the drinking fountain the pressure shall be adjusted so the stream of water exiting the bubbler does not spill over the bowl.

(2) Water tap

(a) A water tap assembly includes:

(i) tap with vacuum breaker;

(ii) stainless steel support post;

(iii) concrete splash pad; and

(iv) potable water supply line and water meter.

(b) All pipe work to a water tap shall comply with AS 3500. All pipe work installation to a water tap shall be carried out by a licensed plumber.

(c) The supply pipe line to a water tap shall be a “standalone” potable water line with its own water meter. Pipe work shall be a minimum 32mm PN12.5 Poly Pipe (from the meter to copper tail pipe) laid in a trench with sand bedding and surround to the pipe and with 300mm minimum cover over the pipe. Water taps and drinking fountains may be installed on the same potable water line.

(d) Tap shall be a 15mm brass hose cock or similar approved connected to a 20mm copper tail pipe installed inside the support post.

(e) Support posts shall be 40mm x 40mm x 1.6mm stainless steel SHS fitted with a plastic cap and cast 350mm minimum into a 350mm dia x 450mm deep concrete footing.

(f) Splash pads shall be either:

(i) 600mm square x 100mm thick N25 concrete cast insitu; or

(ii) 600mm square x 50mm thick precast concrete.

(3) Fertigation

A fertigation point consisting of 25mm tested ball valve connected to the irrigation main line close down stream from the back flow assembly must be installed unless advised by the Superintendent. The fertigation point is to be housed in a round enclosure with the lid marked “FRT” for identification.

SC6.4.6.27.7 Effluent reuse systems

(1) Design and installation

(a) All works must comply with the *Queensland Water Recycling Guidelines*, current health and safety, environmental and related acts.

(b) Effluent reuse irrigation systems shall have:

(i) sprinklers fitted with lilac ID caps;

(ii) lilac coloured drip tubing;

(iii) lilac coloured valve box lids;

(iv) mainline and lateral pipe material (plastic) shall be lilac in colour or contain a lilac strip;

(v) all above ground pipe work shall be lilac coloured and/or clearly labelled “Recycled Water”, “Non Potable Water”; and

(vi) minimum separation of Pipe work for Potable and Recycles water systems shall be maintained at 300mm for below ground pipe work and 100mm for above ground pipe work.

SC6.4.6.27.8 Installations located in landfill sites

(1) Trenching in landfill sites

(a) When excavating in landfill sites or areas containing rock the trench shall be excavated to a minimum depth of 600mm.

(b) All trenching material removed from the trench shall be removed to the local refuse dump.

(c) All trenching spoil shall be totally removed from the surrounding surfaces and site and inspected by the Superintendent.

(d) Bedding sand shall be used to backfill to 200mm below finished soil level. The final 200mm shall be filled with an approved loam.

SC6.4.6.28 Minor concrete works

SC6.4.6.28.1 Introduction

(1) Scope

(a) This sub-section provide details for the supply and placement of concrete, including sprayed concrete, and ancillary requirements including excavation, preparation of foundations, forming up, placement of reinforcement and backfilling for work shown on the drawings but not having individual policy sub-sections. These works include kerb and channel, New Jersey type barriers, drainage pits and other supplementary structures, headwalls, box culverts, box culvert base slabs, driveways, footpaths, median toppings, retaining walls, footings, paving edge strips and works of a similar nature.

(b) The work also includes supply and placement of miscellaneous minor concrete work for water and sewerage construction such as valve chambers, thrust and anchor blocks, bulkheads, pumping stations, bedding, encasement and cast-in-situ access chambers.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.6 - Pipe drainage
SC6.4.6.10 - Earthworks (construction)
SC6.4.6.12 - Flexible pavements
SC6.4.5 Construction management.

(b) Australian Standards:

AS1012.1	*Sampling of fresh concrete*
AS1012.3.1	*Determination of properties related to the consistency of concrete - Slump test.*
AS1012.8.1	*Method of making and curing concrete - Compression and indirect tensile test specimens*
AS1012.8.2	*Method of making and curing concrete - Flexure test specimens*
AS1012.9	*Determination of the compressive strength of concrete specimens*
AS1012.14	*Method for securing and testing cores from hardened concrete for compressive strength*
AS1141.14	*Particle shape, by proportional caliper*
AS1141.21	*Aggregate crushing value*
AS1141.23	*Los Angeles value*
AS1141.24	*Aggregate soundness – Evaluation by exposure to sodium sulphate solution*
AS1289.3.3.1	*Calculation of the plasticity index of a soil*
AS1289.5.1.1	*Determination of the dry density/moisture content relation of a soil using standard compactive effort*
AS1289.5.4.1	*Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS1379	*Specification and supply of concrete*
AS1478.1	*Chemical admixtures for concrete, mortar and grout – Part 1: Admixtures for concrete*
AS/NZS1554.3	*Welding of reinforcing steel*
AS/NZS1859	*Reconstituted wood-based panels*
AS2082	*Visually stress-graded hardwood for structural purposes*
AS/NZS2271	*Plywood and blockboard for exterior use*
AS2758.1	*Concrete aggregates*
AS3600	*Concrete structures*
AS3610	*Formwork for concrete*
AS3799	*Liquid membrane-forming curing compounds for concrete*
AS3972	*General Purpose and blended cements*
AS/NZS4671	*Steel reinforcing materials*
AS/NZS4680	*Hot-dip galvanized (zinc) coatings on fabricated ferrous articles*

(c) Other:
NSW RTA, *Shotcrete design guidelines*

SC6.4.6.28.2 Excavation and foundations

(1) General

The foundation where specified, shall be formed at the required depth below the finished surface levels shown on the drawings. Rock foundations shall be neatly excavated to form a bed for the concrete, and shall be thoroughly scraped and cleaned. Soil foundation shall, as far as possible, be excavated neatly from the solid material to coincide with the under-surface of the concrete. Compaction requirements must meet the appropriate compliance standards as specified in sub-section SC6.4.6.10 Earthworks (construction).

All soft, yielding or other unsuitable material shall be replaced with sound material approved by the Superintendent, and the subgrade shall be compacted to provide a minimum relative compaction as specified in SC6.4.6.10 Earthworks (construction). If the subgrade is dry it shall be sprinkled with as much water as it will readily absorb, before the concrete is placed.

Preparation of the foundation is required in accordance with foundation type, as follows:

(a) concrete working base - remove projections above the plane surface, and loose material; and

(b) graded prepared subgrade - blind with sufficient sand to create a smooth surface free from hard projections. Wet the sand just before laying the underlay.

Editor's note—Provision of a vapour barrier for external slabs on ground prevents water loss to the subgrade and has the potential to reduce slab curling at edges and corners.

AS2870 Section 5.5 provides additional requirements and detailing of damp proof membranes for concrete slabs and footings exposed to either saline or acid sulphate soils. AS2870 Section C5.5 and CCAA T56 provide information on concrete exposed to saline soils.

Polymeric Film Underlay must be installed over the prepared foundation. Lap joints at least 200mm and seal the laps and penetrations with waterproof adhesive tape. Face the laps away from the direction of concrete pour. Take the underlay up vertical faces past the damp proof course where applicable, and tape fix at the top. Patch or seal punctures or tears before pouring concrete. Cut back as required after concrete has gained strength and forms have been removed.

The Contractor shall supply all necessary sheeting and bracing to safely support the excavation in accordance with statutory requirements. The excavation shall be kept free of water.

Prior to the construction of footings for cast-in-situ concrete walls on earth foundations, cover the latter with a mass concrete blinding slab. Unless otherwise specified, place precast concrete wall sections on a fresh mass concrete bedding layer while it is still in a plastic state. Ensure the following is adhered to:

(a) for earth foundation, place concrete not less than 50mm thick; and

(b) for rock foundation, place the concrete at least 50mm above the highest points of rock.

Place neither forms nor other materials on the bedding layer within 48 hours of the concrete being placed.

(2) Kerb and channel

Kerb and channel may be constructed in fixed forms, by extrusion or by slip forming, in accordance with AS2876.

The foundation, concrete quality, curing and testing details shall be in accordance with AS2876 except where placed on pavement courses, where the requirements of the respective pavement course must prevail. Kerb and channel will be constructed to the profile nominated on the drawings.

The top and face of the finished kerb and channel shall be true to line and the top surface shall be of uniform width, free from humps, sags or other irregularities. Kerb and channel shall have a steel float finish.

The level at any point on the surface of the kerb invert shall be within ±6mm of the design level. When a straight edge 3m long is laid on top of or along the face or invert of the kerb, the surface shall not vary more than 5mm from the edge of the straight edge, except at kerb laybacks, grade changes or curves or at gully pits requiring gutter depression. The drainage invert shall be free draining and shall not pond water.

Unless shown otherwise on the drawings, contraction joints, shall be formed every 5m of kerb invert length for a minimum of 50% of cross sectional area. The joint shall be tooled 20mm in depth to form a neat groove of 5mm minimum width.

Unless shown otherwise on the drawings, expansion joints, 15mm in width for the full depth of the kerb and channel, shall be constructed where the kerb invert abuts against kerb gully pits, both sides of kerb laybacks/ramps for vehicular or pedestrian access, retaining walls and overbridges. Expansion joints shall consist of a preformed jointing material of bituminous fibreboard.

Where kerb and channel is cast adjacent with a concrete pavement the same type of contraction, construction and expansion joints specified in the concrete base shall be continued across the kerb and channel.

All house stormwater outlets shall be provided and/or extended, to match the existing type and size of pipe, through the kerb as shown on the drawings providing correctly graded drainage outlet into channel. Pipework shall be in accordance with the requirements for UPVC pipes in sub-section SC6.4.6.6 Pipe drainage, or as directed by the Superintendent for other types of pipe.

At all driveway crossings, where shown on the drawings or where directed by the Superintendent, barrier kerb shall be discontinued to provide for vehicular or pedestrian access. At such locations, kerb laybacks/ramps must be constructed in accordance with the drawings and Standards. Footpath crossovers shall be constructed to meet the laybacks as shown on the drawings, or reinstated to match existing materials where not otherwise shown.

After the new kerb and channel has been constructed and not earlier than 3 days after placing, the spaces on both sides of the kerb and/or gutters shall be backfilled and reinstated in accordance with the drawings, or as instructed by the Superintendent.

Backfill material behind the kerb shall consist of granular material, free of organic material, clay and rock in excess of 50mm diameter, or material as approved by the Superintendent.

Backfill material behind the kerb shall be compacted in layers not greater than 150mm thick, to a relative compaction of 95% when tested in accordance with AS1289.5.4.1, for standard compactive effort. The whole of the work shall be finished in a neat and workmanlike manner, free draining and free from surface undulations and trip hazards.

Pavement material adjacent to new gutter shall be backfilled in accordance with the drawings or as directed by the Superintendent.

Where specified in drawings, kerb only work shall be pinned as detailed in Standard drawings.

(3) New jersey type barriers, driveways and footpaths

For New Jersey type barriers, driveways and footpaths a subbase of approved quality and of minimum 150mm compacted thickness, unless otherwise shown on the drawings, shall be placed over the subgrade. The surface shall then be checked for uniformity, line and level, and all irregularities shall be made good.

The subbase material shall be compacted to provide a minimum relative compaction as determined by AS1289.5.4.1 of 100% for standard compactive effort as specified in SC6.4.6.10 Earthworks (construction).

The finished subbase shall not deviate more than 15mm under a straight edge 3m long, subject to any necessary allowance on vertical curves.

(4) Drainage pits and other supplementary structures
Where the excavation is in sound rock, and the Superintendent so directs, part of the concrete lining of gully pits and other structures may be omitted, provided that a neatly formed pit of the required dimensions is constructed, and provided that the wall of the pit adjacent to and parallel with the road is constructed of formed concrete in all cases.

(5) Retaining walls, headwalls and wingwalls
In the case of rock foundations for retaining walls, headwalls and wingwalls, the excavation shall be carried into the rock for a minimum depth of 150mm. Where cut-off walls are to be provided, the depth of cut-off in rock foundations may be reduced to 100mm.

Prior to the construction of cast-in-situ concrete walls on earth foundations, the latter shall be covered by a mass concrete bedding layer at least 50mm thick and finished to a uniform surface. No forms or other materials shall be placed upon the bedding layer within a period of 48 hours after the concrete has been placed.

Unless otherwise specified, precast concrete wall sections shall be placed on a fresh mass concrete bedding layer while it is still in plastic state. In the case of soil foundations, the concrete shall be not less than 50mm thick, and where the foundation is in rock, the concrete shall be of such thickness as is required to provide a uniform surface at least 50mm above the highest points of rock.

SC6.4.6.28.3 Formwork

(1) General
Formwork shall be provided in accordance with AS3610 to produce hardened concrete to the lines, levels and shapes shown on the drawings or specified elsewhere. It shall have adequate strength to carry all applied loads, including the pressure of fresh concrete, vibration loads, weight of workers and equipment, without loss of shape. Forms shall be mortar tight and designed to allow removal without risk of damage to the completed structure. Joints in the formwork shall be perpendicular to the main axis of the shape of the concrete.

Where concrete is placed in earth excavations, side forms shall be provided to prevent contact between concrete and the insitu earth.

Design of formwork for high sections shall be such that it shall not be necessary to drop concrete freely from a greater height than 1.2m or to move concrete along the formwork after deposition.

Formwork material used shall be sound and suitable for the purpose intended and surface finish specified.

Provision shall be made for the accurate location and firm support of fittings, bolts, anchorages and formers of holes as shown on the drawings. Temporary fittings used for the support of the formwork shall be arranged to permit removal without damage to the concrete. The use of wires and or bolts extending to the surface of the concrete shall not be permitted except where shown on the drawings.

Forms for edges of concrete shall be filleted and for re-entrant angles chamfered as shown on the drawings.

Temporary openings shall be provided where necessary for cleaning out of formwork and inspection before concreting.

(2) Approval of formwork design
For box culverts and reinforced concrete retaining walls, detailed drawings, design calculations, description and/or samples of materials proposed for use shall be submitted for the Superintendent's concurrence before manufacture of the formwork is commenced.

(3) Provision for drainage
Where shown on the drawings, or where directed by the Superintendent, weepholes of 50mm diameter shall be provided in retaining walls and wingwalls.

(4) Construction

The type and quality of material selected for formwork and the workmanship used in construction shall be such that the surface finish specified shall be obtained. Construction shall be such that the erection tolerances shall be obtainable.

Timber for formwork shall be well seasoned, free from defects and, where in contact with fresh concrete, free from loose knots.

Timber forms for exposed surfaces shall be constructed from plywood or particle board with hardwood or approved softwood studs and wales. The plywood used for forms shall comply with AS2271, the hardwood shall comply with AS2082 and the particle board with AS/NZS1859.

Formwork for exposed surfaces shall be made from panels having uniform widths of not less than 1m and uniform lengths of not less than 2m, except where the dimensions of the member formed are less than the specified panel dimensions. Plywood panels shall be placed with the grain of the outer plies perpendicular to the studding or joists. Where form panels are attached directly to the studding or joists the panel shall be not less than 15mm thick. Form panels less than 15mm thick, otherwise conforming to these requirements may be used with a continuous backing of dressed material of 20mm minimum thickness. All form panels shall be placed in a neat, symmetrical pattern.

Forms for all surfaces which will be completely enclosed or permanently hidden below the ground may be constructed from dressed or undressed timber, steel, plywood or particle board.

Mild steel form surfaces in contact with concrete shall have all bolt and rivet heads counter-sunk and all welds ground back to even and smooth surfaces.

(5) Erection

(a) General

(i) Dimensions and position of forms shall be carefully checked after the forms are erected. Forms shall be aligned accurately and the location of all fittings, hold formers, etc. checked prior to placing concrete. Departure of the forms from the surfaces shown on the drawings shall not exceed 1/300 of the space between supports for any surface visible in the completed work and 1/150 for hidden work. For tolerances in plan position and levels, refer to clauses SC6.4.6.28.5(7) Finishing of unformed surfaces and SC6.4.6.28.5(10) Treatment of formed surfaces.

(ii) Joints as erected shall be mortar tight.

(iii) The interior surface of the forms shall be treated to ensure non-adhesion of the mortar. Commercial quality form oil or grease will be acceptable, but the oil or grease used on forms against surfaces to be exposed shall not stain or discolour the concrete surface. The coating shall be uniformly spread in a thin film and any surplus shall be removed prior to placing concrete. In the case of unlined timber forms, the timber shall be thoroughly wetted before oiling. Forms shall be treated before placing reinforcement to ensure that the form release agent will not contaminate the surface of the reinforcing steel or construction joints.

(iv) Formwork hardware shall be treated with a form release agent and so arranged that it may be removed from the concrete without excessive jarring or hammering.

(b) Approval by the Superintendent

(i) The formwork shall be inspected by the Superintendent, and the placing of reinforcement in the spaces formed, where specified, shall not commence until the formwork is approved by the Superintendent.

(ii) Placing of concrete shall not commence until the reinforcement, where specified, has been accepted by the Superintendent, and all dirt, chips, hardened concrete, mortar and all foreign matter removed from the forms.

(iii) When an inspection is requested by the Contractor, a notice of not less than 24 hours, excluding Saturdays, Sundays and public holidays, shall be given to the Superintendent.

SC6.4.6.28.4 Materials for concrete

(1) Cement

Cement shall be Type GP Portland Cement complying with AS3972.

When submitting details of the nominated mix in accordance with clause SC6.4.6.28.4(6) Testing of materials, the Contractor shall nominate the brand and source of the cement. On approval of the nominated mix by the Superintendent, the Contractor shall only use the nominated cement for the work.

Documentary or other acceptable evidence of the quality of the cement shall be furnished by the Contractor if required by the Superintendent.

If the Contractor proposes to use cement which has been stored for a period in excess of 3 months from the date of testing, a re-test shall be required at the Contractor's expense before the cement is used.

All cement shall be transported in watertight containers, and shall be protected from moisture until used. Caked or lumpy cement shall not be used.

(2) Water

Water shall be free from injurious amounts of materials harmful to concrete and to its reinforcement and neither salty nor brackish.

Water which is not potable for human beings shall not be used in reinforced concrete.

(3) Fine aggregate

Fine aggregates shall consist of clean, hard, tough, durable uncoated grains, uniform in quality, and shall conform to the requirements of AS2758.1 in respect of bulk density, water absorption (maximum 5%) material finer than 2 micrometres, impurities and reactive materials.

Fine aggregates shall be evenly graded within the absolute limits shown in Table SC6.4.6.28.1 Fine aggregate grading, and shall not deviate from the proposed grading by more than the amounts in Table SC6.4.6.28.1.

Table SC6.4.6.28.1 Fine aggregate grading

Australian Standard Sieve	Proportion Passing (% of Mass)	Deviation from Proposed Grading (% of Mass of Sample)
9.50mm	100	
4.75mm	90 - 100	±5
1.18mm	40 - 85	±10
300µm	8 - 30	±10
150µm	2 - 10	±5
75µm	0 - 4	±3

(4) Coarse aggregate

Coarse aggregate shall consist of clean, hard, durable, crushed stone, crushed river gravel, screened river gravel or metallurgical furnace slag and shall conform to the requirements of AS2758.1 in respect of particle density, bulk density, water absorption (maximum 2.5%), material finer than 75 micrometres, weak particles, light particles, impurities and reactive materials, iron unsoundness and falling or dusting unsoundness. In all other respects, the coarse aggregate shall comply with this sub-section. If required, coarse aggregate shall be washed to satisfy these requirements.

The percentage of wear shall be determined by AS1141.23, and the loss of weight shall not exceed 30%.

When required by the Superintendent, coarse aggregate shall be tested for conformance for any or all of the properties set out below:

(a) crushing value - AS1141.21
The aggregate crushing value shall not exceed 25%;

(b) soundness - AS1141.24
The loss of mass when tested with sodium sulphate shall not exceed 12%; and

(c) particle shape - AS1141.14
The proportion of misshapen particles (2:1 ratio) shall not exceed 35%.

Coarse aggregate shall be evenly graded within the absolute limits shown in Table SC6.4.6.28.2 Course aggregate grading and shall not deviate from the grading of the samples submitted under clause SC6.4.6.28.4(6) Testing of materials by more than shown.

Table SC6.4.6.28.2 Coarse aggregate grading

Australian Standard Sieve (mm)	Proportion Passing (% of Mass)			Deviation Proposed Grading (% of Mass of Sample)
	40mm Nominal	20mm Nominal	Extrusion Concrete	
	For Walls exceeding 150mm thickness	For all other structures		
53.0	100			±10
37.5	95 - 100			±10
26.5		100		±5
19.0	30 - 70	95 - 100		±5
13.2			100	
9.50	10 - 35	25 - 35		
4.75	0 - 10	0 - 10		
2.36	0 - 2	0 - 2		

(5) Admixtures
Chemical admixtures and their use shall comply with AS1478.1. Admixtures shall not contain calcium chloride, calcium formate, or triethanolamine or any other accelerator. Admixtures or combinations of admixtures other than specified below, shall not be used.

During the warm season, (October to March inclusive), a set retarding admixture approved by the Superintendent shall be used to control slump within the limits stated in clause SC6.4.6.28.5(4) Consistency. The dosage shall be varied to account for air temperature and haul time in accordance with the manufacturer's recommendations. A copy of the NATA endorsed Certificate of Compliance with AS1478.1 shall be submitted to the Superintendent, together with the proposed “dosage chart” in accordance with SC6.4.6.28.4(6) Testing of materials. If the Contractor proposes to vary the admixture between the warm and cool seasons such variation shall require approval by the Superintendent by providing the necessary certificate of compliance.

(6) Testing of materials
The Contractor shall submit to the Superintendent a copy of a NATA Certified Laboratory Test Report on the quality and gradings of the aggregates proposed to be used in the work.

The materials shall only be used after receipt of the Superintendent's notification of acceptance, and then only as long as the materials accord with the Specification.

SC6.4.6.28.5 Handling and treatment of concrete

(1) Measuring
All materials shall be measured by weight, except that:

(a) water may be measured by volume with an approved adjustable water-measuring and discharging device;

(b) cement may be measured by bags as packed by the manufacturer in which case batches shall be proportioned on the basis of one or more unbroken bags of cement, and for this purpose one bag of

cement shall be assumed to weigh 40kg. Bulk cement shall be weighed in an individual hopper and shall be kept separate from the aggregates until the components of the batch are discharged from the batching hopper; and

(c) measurement by volume for smaller works may be undertaken with the prior approval of the Superintendent.

(2) Measuring by weight, on-site mixing

Where concrete is to be mixed on site, and where mix control is likely to be less efficient than at a central batching plant, the weights of cement, fine and coarse aggregate shown in Table SC6.4.6.28.3 Materials in batch containing 1 bag (40kg) cement may be used as a guide to produce the classes of concrete specified. Small changes in the proportions of fine and coarse aggregate may be required to improve density or workability of the concrete. The use of proportions shown in Table SC6.4.6.28.3 shall not relieve the Contractor of his obligation to provide concrete of the specified compressive strength.

Table SC6.4.6.28.3 Materials in batch containing 1 bag (40kg) cement

MPa	Cement kg	Fine Aggregates kg	Coarse Aggregates kg	Total Aggregates kg
10	40	130	250	380
15	40	100	190	290
20	40	88	126	214

The proportions set out in Table SC6.4.6.28.3 make allowance for moisture contents of aggregates of 6% for fine aggregates and 1% for coarse aggregates. Where the moisture content of aggregates exceeds 8% or 3% respectively, the proportions of the mix shall be changed to compensate for the excess water in the aggregate.

(3) Measuring by volume, on-site mixing

Where measurement by volume is approved, the proportions of the materials shall be such as are required to produce a mix free of voids and having the specified strength at 28 days.

The nominal proportions given in Table SC6.4.6.28.4 Volume batching may be used as a guide for volume batching.

Table SC6.4.6.28.4 Volume batching

MPa	Parts by Volume		
	Cement	Fine Aggregate	Coarse Aggregate
10	1	3	6
15	1	2.25	4.5
20	1	2	3

The volumes of fine and coarse aggregates for each batch shall be measured in boxes or bins. The aggregates shall be measured loose (i.e. without compaction) in the boxes and shall be struck off level. Measurements by shovels or like methods will not be permitted. Batch proportions shall be so arranged that each batch contains 1 bag of cement. One 40kg bag of cement shall be assumed to have a volume of 27.5 litres.

(4) Consistency

A sufficient quantity of water shall be added to the mix so that the consistency of the concrete is such that it can be placed in the forms, compacted and worked into all corners without permitting the ingredients to segregate, or excess free water to collect on the surface. If required by the Superintendent, the Contractor shall determine the consistence of the concrete in accordance with AS1012.3.1. Except for extruded concrete, the nominated slump shall not exceed 80mm, plus the field tolerance of ±15mm.

In the case of concrete placed by an extrusion machine, the water in the mix shall be only sufficient to produce a slump of 10mm to 15mm.

(5) Mixing and delivery

(a) General

(i) Concrete may be mixed either at the site or at a central mixing plant. All concrete shall be mixed

with mechanically operated mixers. In an emergency, hand mixing may be permitted. Submit proposal for concrete mixing other than pre mixed concrete for approval by superintendent.

(ii) Any concrete which exhibits signs of segregation shall not be used.

(b) Machine mixing at site

(i) The mixing of concrete shall be done in a batch mixer which will ensure a uniform distribution of the materials throughout the batch.

(ii) The mixer shall be of such capacity that one or more whole bags of cement may be used per batch of concrete. The volume of the mixed material shall not exceed the manufacturer's rated capacity of the mixer.

(iii) The mixing time for each batch shall not be less than 1.5 minutes after all ingredients are assembled in the mixer, and prior to any portion of the batch being removed.

(iv) The entire contents of a batch shall be discharged from the mixer before any materials are placed therein for the succeeding batch.

(c) Mixing in an emergency

(i) In the case of breakdown of the mechanical mixing equipment, hand mixing in small quantities so as to complete a section of the work or reach a suitable construction joint is permitted.

(ii) Hand mixing shall be done on a water-tight platform of sufficient size to allow the mixing of at least two batches simultaneously. The amount of cement used shall be 10% more than the amount specified for machine mixed concrete.

(iii) The fine aggregate and cement shall first be mixed until a uniform colour is obtained, and then spread on the mixing platform in a thin layer. The coarse aggregate, which shall have been previously drenched with water, shall then be spread over the fine aggregate and cement in a uniform layer, and the whole mass turned over as further water is added with a rose sprinkler. After the water is added, the mass shall be turned at least three times, not including shovelling into barrows or forms, until the mixture is uniform in colour and appearance. Hand-mixed batches shall not exceed 25m^3 each.

(d) Ready-mixed concrete

(i) The concrete shall be mixed and delivered in accordance with the requirements of AS1379 relating to:

(A) mixing and delivery; and

(B) use of non-agitating equipment,

(ii) The water used for flushing the chutes and for cleaning shall be discharged in an area acceptable to the Superintendent. The chutes shall be long enough to permit delivery to the whole of the area enclosed by the forms.

(6) Placing and compacting concrete

No concrete shall be mixed or placed, without the approval of the Superintendent, while the air temperature is, or is likely to be within 24 hours, below 5°C or while the shade temperature exceeds 38°C. All concrete shall be placed in the dry. Prior to placing concrete the area shall be clean and moist but free from any ponding of water.

The concrete shall be mixed in the quantities required for immediate use and shall be placed in position as rapidly as possible. Any concrete which has developed initial set, or which does not reach the forms within 30 minutes after the water has been added (except when transported in agitator trucks) shall not be used.

The concrete shall be deposited in the forms, without separation of the aggregates. Concrete shall not be dropped freely from a height greater than 1.2m, or be deposited in large quantities at any point and moved or worked along the forms. Conveying equipment, including open troughs and chutes, where used, shall be made of metal, or have metal linings. Where used on steep slopes, troughs and chutes shall be equipped with baffles, or be placed in short lengths in such a way that the direction of flow of the concrete is changed. The concrete

shall be placed in horizontal layers in one continuous operation between the ends of the work and/or construction joints. Care shall be taken to fill every part of the forms and to work the coarser aggregate back from the face. The freshly placed concrete shall be compacted by continuous spading, slicing or by vibrator units. Vibrators shall not be left in one position for more than 30 seconds, and shall not be permitted to rest on reinforcement.

Exposed surfaces of the concrete shall be struck off and finished with a wooden float. Where shown on the drawings corners and edges shall be left neatly rounded or chamfered. Re-entrant angles shall be neatly filleted.

Concrete shall not be moved after it has been in the forms for more than 10 minutes.

In the case of concrete placed by an extrusion machine, small quantities of cement-sand slurry, comprised of two parts of plasterer's sand and one part of cement (by volume), together with sufficient water to bring it to a semi-fluid condition, shall be placed in the special receptacle in the machine, if the machine is so equipped and shall be fed onto the surface of the concrete at a rate sufficient to produce a smooth and uniform finish.

(7) Finishing of unformed surfaces

(a) Surfaces other than wearing surfaces

Unformed surfaces shall be compacted and tamped so as to flush mortar to the surface, screeded off and finally dressed with a wooden float to an even surface. Care shall be taken to drain or otherwise remove promptly any water which comes to the surface. A capping of mortar will not be permitted.

All future contact surfaces shall be left rough, with the coarse aggregate at the surface firmly embedded but not forced below the surface.

(b) Wearing surfaces

Where a concrete wearing surface is shown on the drawings the concrete shall be thoroughly compacted and the surface screeded off by a vibrating screed, or hand screeded where the distance between forms perpendicular to the direction of screed is no greater than 2m. Immediately following compaction and screeding the concrete shall be tested for high or low spots and any necessary corrections made. The surface shall be finished true and uniform and free from any glazed or trowelled finish and shall be finally dressed with a wooden template or float, or by the use of belting in an approved manner. The departure from grade shall not exceed 5mm in any 3m length.

Where an asphaltic concrete wearing surface is specified, the surface of the concrete, after being compacted, screeded and corrected, shall be dressed with a wooden float and finally broomed to produce a rough surface.

(c) Finished levels and location

The unformed surface of concrete structures not adjacent to road pavements shall not vary more than 25mm in plan position and not more than 25mm from the specified levels. In the case of barriers, drainage pits, culvert slabs and other structures adjacent to road pavements, the finished concrete shall not vary more than 10mm from the specified levels and alignment. Barriers, footpaths and similar shall not deviate from level or alignment by more than 5mm from a straight-edge 3m long, subject to any necessary allowances on vertical and horizontal curves.

(8) Curing and protection

All exposed surfaces of the freshly placed concrete shall be kept moist either by the use of plastic sheeting, damp sand or commercial curing compounds, in accordance with AS3799, for a minimum period of 3 days. During this time the work must be adequately protected from the effects of excessive surface evaporation, rain, running water, vandalism and other causes likely to damage the concrete. All costs involved in making good or replacing any work that has been damaged due to the above mentioned factors shall be borne by the Contractor.

Curing for concrete shall generally be in accordance with the appropriate surface exposure classification in AS3600.
If it is proposed to use a liquid membrane-forming curing compound submit the following information:

(a) certified test results for water retention to AS3799 Appendix B;

Editor's note—It is likely that polyvinyl alcohol (PVA-based) products will not comply with water retention requirements.

(b) evidence of compatibility with concrete, and with applied finishes including toppings and render, if any, including methods of obtaining the required adhesion.

For visually important surfaces, evidence that an acceptable final surface colour will be obtained.

(9) Removal of forms

All forms shall remain in place, after placement of concrete, for minimum periods specified hereinafter. These periods may be extended by the Superintendent if the air shade temperature falls below 10 °C during the periods specified.

Mass retaining walls, headwalls, wingwalls, gully pits, sumps, and similar drainage structures	48 hours
Footpaths, driveways and similar	17 hours
Sides of reinforced concrete walls when height of each day pour is:	
• under 0.6m	1 day
• 0.6m to 3m	2 days
• 3m to 6m	3 days
• 6m to 9m	5 days
Supporting forms under deck slabs of culverts	10 days

To permit the satisfactory finishing of barriers, forms shall be removed in not less than 12 hours nor more than 48 hours after placing concrete, depending upon weather conditions.

Care shall be taken in removing forms so that the concrete will not be cracked, chipped or otherwise damaged. The use of crowbars or other levering devices exerting pressure on the fresh concrete to loosen the forms will not be permitted.

No superimposed load shall be allowed on any part of a structure until the concrete has reached at least 70% of the design strength.

Hole formers such as pipes and bars shall be removed as soon as the concrete has hardened sufficiently for this to be done without damage to the concrete.

(10) Treatment of formed surfaces

All concrete surfaces shall be true and even, free from stone pockets, depressions or projections beyond the surface. All arrises shall be sharp and true, and mouldings shall be evenly mitred or rounded. Care shall be exercised in removing forms to ensure this result. Formed concrete surfaces shall be presented for inspection by the Superintendent within 1 day of stripping of formwork and finishes in accordance with the classes of surface finish in AS3610 as follows:

(a) Non-visible surfaces - Class 4.

(b) Visible surfaces - Class 2.

As soon as the forms are removed from mass or reinforced concrete work, all rough places, holes and porous spots shall be repaired by removing defective work and filling with stiff cement mortar having the same proportions of cement and fine aggregate as used in the concrete, and shall be brought to an even surface with a wooden float.

Any tie wires or other fitments extending to outside surfaces, shall be cut back after removal of forms, to a depth of at least 40mm with sharp chisels or cutters. All cavities caused by removal of fitments or tie wires shall be wetted and carefully packed with cement mortar, as above.

The surfaces of bolt cavities, tie wire holes, and all defects in concrete shall be coated prior to the placing of mortar, grout, or fresh concrete, with an approved bonding agent, in lieu of wetting with water. The method of

application of such agent and the conditions in which it is to be used shall generally be as laid down by the manufacturer.

The formed surfaces of concrete structures not adjacent to road pavements shall not vary more than 25mm in plan position and not more than 25mm from the specified levels. In the case of drainage pits and other structures adjacent to road pavements, the finished concrete shall not vary more than 10 mm from the specified levels and alignment.

(11) Joints

Submit proposed methods, timing and sequence of sawing joints for approval by superintendent a minimum of 7 days prior to works commencing.

Where horizontal construction joints are found to be necessary in walls, or cast-in-situ drainage structures the joints may be made at the base of walls and at other locations in the walls where approved by the Superintendent. In order to provide for bond between the new concrete and the concrete which has already set, the surface on which the new concrete is to be placed shall be thoroughly cleaned of loose material, foreign matter and laitance. The surface shall be roughened or keyed and saturated with water. After any excess water has been removed, the surface shall be thinly coated with a neat cement grout.

Retaining walls shall be provided with vertical expansion joints as shown on the drawings. The expansion joints shall consist of jointing material of approved quality, and of thickness shown on the drawings, and a depth sufficient to fill the joint. The jointing material shall be neatly cut to fit the surface of the concrete.

Where barriers are extruded or cast in place, narrow transverse vertical grooves, 20mm deep, shall be formed neatly in the surface of the freshly placed concrete to produce contraction joints for the control of cracking. The contraction joints, shall be at intervals of 3m.

In barriers, unless shown otherwise on the drawings, expansion joints, 15mm in width for the full depth of the barrier, shall be constructed at intervals not exceeding 15 m and where the barrier abuts against gully pits. Expansion joints shall consist of a preformed jointing material of bituminous fibreboard.

In footpaths, median toppings and driveways, unless otherwise shown on the drawings, expansion joints, 15mm in width for the full depth of paving, shall be constructed at intervals not exceeding 15m and where the pavement abuts against gutters, pits and structures. Expansion joints shall consist of a preformed jointing material of bituminous fibreboard.

All unreinforced paving shall be provided with narrow vertical grooves, 20mm deep to induce contraction joints for the control of cracking. The joints shall be formed in the freshly placed concrete in a neat regular pattern to form “slabs” no bigger than $2m^2$. The ratio of the longest side to the shortest side shall not exceed 1.6.

(12) Strength of concrete

When tested in accordance with AS 1012.9, the concrete shall have a characteristic compressive strength not less than that shown on the drawings or if not shown shall have a compressive strength not less than that specified in Table SC6.4.6.28.5 Concrete strength requirements for the particular class of work. The cement content restrictions shown in Table SC6.4.6.28.5 refer to Portland cement. Where General Purpose Blended cements are utilised the acceptable minima are indicated in brackets.

The characteristic strength shall be determined from the average of not less than two specimens, moulded from each class of concrete being used in the work, and selected to represent the whole of the concrete placed at the time of moulding.

In general, two pairs of test specimens shall be moulded for each $15m^3$ of concrete, or part thereof, one pair being intended for the 7 day test if required and the other pair for a 28 day test.

Table SC6.4.6.28.5 Concrete strength requirements

Use	Charac-teristic Strength MPa	Minimum Portland Cement per 3 metre (Minimum GB Blended Cement)	Coarse Aggregate Nominal Size	Characteristic Cylinder Strength Required	
				7 days	28 days
		kg	mm	MPa	MPa
Foundations, mass retaining walls	20	270 (330)	40	15	20
Mass concrete footings, pitching, linings etc.	20	270 (330)	20	15	20
Miscellaneous minor concrete work	20	270 (330)	20	15	20
Reinforced concrete culverts, drainage structures, driveways footpaths, headwalls, base slabs, sign structures. Large footings, retaining walls	32 50	320 (380) 350 (455)	20 20	24 36	32 50
Extruded concrete Safety Barriers	25 40	270 (330) 330 (380)	14 20	15 24	20 40

Note—the total cement and Portland cement quantities indicated as minima are aimed at providing suitably durable concrete for exterior public works under normal circumstances.

The strengths specified at 28 days shall be increased by multiplying by factors as shown in Table SC6.4.6.28.6 Concrete age conversion factors for tests at ages in excess of 28 days.

Table SC6.4.6.28.6 Concrete age conversion factors

*Age of test specimen in days of date of testing	Factor
28	1.00
35	1.02
42	1.04
49	1.06
56	1.08
70	1.10
84	1.12
112	1.14
140	1.16
168	1.18
196	1.20
224	1.22
308	1.24
365 and greater	1.25
*For intermediate ages the factor shall be determined on a pro-rata basis	

If the test specimens fail to achieve the specified characteristic strength, the Contractor may, with the approval of the Superintendent, arrange for cores to be taken from the work. If the average strength of such cores complies with the specified requirements nominated in Table SC6.4.6.28.5 Concrete strength requirements, the concrete will be accepted.

If cores taken fail to satisfy the strength requirements, the concrete shall be removed.

(13) Sampling concrete

Equipment and facilities shall be provided by the Contractor for the taking and storage of samples of any materials or concrete being used, or intended to be used in the work.

Concrete test specimens shall be cylinders 300mm long and 150mm diameter, moulded concurrently in the presence of the Superintendent or Superintendent's representative, in accordance with AS1012.8, from samples taken in accordance with AS1012.1.

SC6.4.6.28.6 Reinforcement for concrete

(1) Fibre reinforced concrete

Footpath/Bikeways/Driveways.
The concrete shall be reinforced with a mixed dose of High Performance Polymer and Discreet Graded Fibrillated filament fibres. These fibres shall be provided as a coarse filament in an engineered contoured sinusoidal profile of not less than 600 denier and discreet graded fibrillated filament fibres of not greater than 6 denier. These fibres are to be manufactured from virgin polypropylene and added to the concrete by the concrete company, at the rate of 4.6kg/m^3. The 4.6kg consists of 3.8kgs of HPP and 0.8kgs of discrete Graded Fibrillated filament fibres.

Two bags of "Novomesh" HPP as supplied by Tapex Concrete Fibres Qld or approved equivalent added per m^3, will be deemed suitable for council's use. Where footpaths/bikeways are not subject to wheel loads one bag of fibres per m^3 will suffice.
Any alternate product must have prior written approval obtained from council.

(2) Steel reinforcement

Steel reinforcement shall comply with AS/NZS4671 *Steel reinforcing materials*.
The type and size of bars shall be as shown on the drawings.

If changes are proposed to reinforcement shown on the drawings, submit details to superintendent for approval 2 days prior to commencing works.
Steel reinforcement shall be free from loose or thick rust, grease, tar, paint, oil, mud, millscale, mortar or any other coating, but shall not be brought to a smooth polished condition.

Damaged galvanising must be repaired in accordance with AS/NZS4680 Section 8 and notification of repairs made to the superintendent for approval.

The Contractor shall supply evidence satisfactory to the Superintendent that steel reinforcement complies with AS/NZS4671. Test certificates shall show the results of mechanical tests and chemical analysis.

Where the material cannot be identified with a test certificate, samples shall be taken and testing arranged by the Contractor. The samples shall be selected randomly and consist of three specimens each at least 1.2m in length. The cost of all samples and tests shall be borne by the Contractor.

Plastic bar chairs or plastic tipped wire chairs shall be capable of withstanding a load of 200kg mass on the chair for one hour at 23 ± 5°C without malfunction. The Contractor shall demonstrate that the proposed chairs conform with these requirements.

(3) Bending

Reinforcement shall be formed to the dimensions and shapes shown on the drawings. It shall not be bent or straightened in a manner that will injure the material, and bars with kinks or bends not shown on the drawings will not be accepted. Heating of reinforcement for purposes of bending will only be permitted if uniform heat is applied. Temperature shall not exceed 450°C and the heating shall extend beyond the portion to be bent. Heated bars shall not be cooled by quenching.

(4) Splicing

(a) General

All reinforcement shall be furnished in the lengths indicated on the drawings. If splicing is required, it shall be in accordance with the provisions of AS/NZS4671.

The cost of any test ordered in connection with splices not shown on the drawing shall be borne by the Contractor.

(b) Lapped splices

Laps in reinforcing bars, wire or fabric shall be as shown on the drawings. Laps not shown on the drawings shall be as follows for unhooked bars:

(i) Plain bars, Grade 250 40 bar diameters.

(ii) Deformed bars, Grade 400 35 bar diameters.

(iii) Hard-drawn wire 50 bar diameters.

Splices in reinforcing fabric shall be so made that the overlap, measured between outermost transverse wires of each sheet of fabric is not less than the spacing of those wires plus 25mm.

(5) Marking

Bars of identical shape shall be made up in bundles of three and securely tied together by soft iron wire. Each bundle shall have a stout metal label of not less than 40mm diameter attached to it. Each metal label shall be punched with the appropriate marking in accordance with the steel list shown on the drawings. If called for on the drawings the marking shall incorporate a prefix, and bars with different prefixes shall be stored separately.

(6) Storage

Reinforcement shall be stored above the surface of the ground and shall be protected from damage and from deterioration by exposure.

(7) Delivery and receipt of reinforcement

Unless the Contractor elects to have the reinforcement inspected at the site, no reinforcement shall be delivered to the site until all tests and inspections have been satisfactorily completed and permission to deliver has been granted by the Superintendent.

The Contractor shall give 10 working days' notice to the Superintendent for carrying out inspection and testing. The Superintendent will carry out the inspection and testing with reasonable expediency, but the Contractor shall not be entitled to an extra as a result of any delays in this connection.

(8) Placing

Reinforcement shall be accurately placed as shown on the drawings and shall be securely held by blocking from the forms, by supporting on concrete or plastic chairs, or metal hangers, and by wiring together at all intersections or at 0.5m centres, whichever is the greater distance, using annealed iron wire of diameter not less than 1.25mm. Steel shall not be supported on metal supports which extend to the surface of concrete, on wooden supports, or on pieces of coarse aggregate. Reinforcement shall have the minimum cover shown on the drawings or otherwise approved by the Superintendent.

The Superintendent may approve the use of tack welding instead of wire ties on reinforcing wire. All welding of reinforcing steel shall be in accordance with AS1554.3. Tack welding of cold-worked and hard grade bars shall not be permitted.

The reinforcement in each section of the work shall be approved by the Superintendent before any concrete is deposited in the section and adequate time shall be allowed for inspections and any corrective work which may be required. Notice for inspection shall not be less than four normal working hours.

Splices shall be staggered where practicable and when not shown on the drawings they shall be arranged as directed by the Superintendent.

Bars forming a lapped splice shall be securely wired together in at least two places, unless welded.

The clear cover of any bar, including stirrups, to the nearest concrete surface shall be as shown on the drawings. Where not so indicated it shall be as stated below:

(a) concrete normally in contact only with air:

(i) slabs: 40mm;

(ii) other than slabs: 45mm; and

(b) concrete in contact with earth or fresh water:

(i) slabs of box culverts: 50mm; and

(ii) other than culverts: 50mm.

(9) Cores, fixings and embedded items general

Cores, fixings and embedded items identified on shop drawings showing the proposed locations, clearances and cover, and indicating proposed repositioning of reinforcement must be presented for inspection by the superintendent.

If cutting or coring of hardened concrete is proposed, provide details to the superintendent for approval.

For adjoining elements to be fixed to or supported on the concrete, provide for the required fixings. If required, provide for temporary support of adjoining elements during construction of the concrete.

If in external or exposed locations, galvanize anchor bolts and embedded fixings, or propose alternative materials such as stainless steel.

Fix cores and embedded items to prevent movement during concrete placing. In locating cores, fixings and embedded items, reposition but do not cut reinforcement, and maintain cover to reinforcement.

Isolate embedded items so that water cannot track to concrete providing minimum cover to reinforcement.

SC6.4.6.28.7 Backfilling

(1) General

Backfilling at barriers, paving, etc., and minor concrete works shall not commence until after the concrete has hardened and not earlier than three days after placing.

No superimposed load on any part of what will become a load bearing structure within 21 days after placing concrete shall occur unless the structure is effectively and independently supported to the satisfaction of the Superintendent (approval must be sought at a minimum of 3 working days prior to loading upon evidence of early strength) or until the Contractor can demonstrate that 85% of the design strength of the concrete has been achieved.

Selected backfill shall be placed against retaining walls and cast-in-place box culverts for a horizontal distance equal to one-third of the height of the wall. It shall consist of granular material, free from clay and stone larger than 50mm gauge. The Plasticity Index of this selected backfill material shall not be less than 2 or more than 12 when tested in accordance with AS1289.3.3.1. The material must be placed in layers not exceeding 150 mm and must be compacted to provide a relative compaction as specified in sub-section SC6.4.6.10 - Earthworks (construction).

(2) Treatment at weepholes

Drainage adjacent to weepholes shall be provided by either a layer of broken stone or river gravel consisting of clean, hard, durable particles graded from 50mm to 10mm such that:

(a) the maximum particle dimension shall not exceed 50mm; and

(b) no more than 5% by mass shall pass the 9.5mm A.S. sieve.

The broken stone or river gravel, enclosed in a filter fabric suitable for drainage without scour, shall be continuous in the line of the weepholes, extend at least 300mm horizontally into the fill and extend at least

450mm vertically above the level of the weepholes.

Alternatively the Contractor may provide a synthetic membrane of equivalent drainage characteristics at no extra cost to the Principal. It shall be stored and installed in accordance with Manufacturer's instructions. The use of a synthetic membrane shall be subject to the Superintendent's approval.

SC6.4.6.28.8 Sprayed concrete

(1) References

NSW RTA – *Shotcrete Design Guidelines*.

(2) General

Sprayed concrete is concrete pneumatically applied at high velocity on to a surface. Application may be either a wet or dry process. A sound homogeneous product shall be provided with surface finish reasonably uniform in texture and free from blemishes.

The minimum depth of sprayed concrete to be applied shall be 75mm.

Sprayed concrete lining in open drains shall be coloured to match the adjoining rock colour.

Sprayed concrete shall have a minimum cement content of 380kg/m3 as discharged from the nozzle and shall have a minimum compressive strength of 25MPa at 28 days when tested by means of 75mm diameter cores taken from in-place sprayed concrete.

Cores shall be secured, accepted, cured, capped and tested in accordance with AS1012.14. Equipment and facilities shall be provided by the Contractor for the taking of cores from the work. The Contractor shall arrange for a laboratory with appropriate NATA registration for the curing and testing of the cores. Copies of test results shall be forwarded to the Superintendent.

The cost of all work and material required in the taking, handling, delivery and testing of cores shall be borne by the Contractor.

At least 14 days prior to applying any sprayed concrete the Contractor shall submit to the Superintendent details of his proposed procedure, plant, materials and mix proportions. Materials shall comply with AS3600.

(3) Test panels

Not less than 7 days before applying concrete, the Contractor shall prepare at least three test panels for each mix proposed, in conditions similar to those in the works and in the presence of the Superintendent. The test panels shall be made by applying a 75mm thickness of sprayed concrete to a hardboard panel approximately 750mm square. The sprayed concrete shall be applied to the panels in the same manner, using materials including steel reinforcing fabric, equipment, pressures and curing that will be used in the Works. The panels shall be submitted to the Superintendent for examination.

The Contractor shall cut four 75mm diameter cores from one test panel for each proposed mix approximately 48 hours after the panel has been sprayed. The cores shall be tested as for cores from in-place sprayed concrete. One core shall be compression tested at 3 days, one core at 7 days and the remaining two cores at 28 days.

Should any of the cores reveal defects such as lack of compaction, dry patches, voids or sand pockets or should the test panel exhibit an unacceptable surface finish, the Contractor shall modify the mix design and/or method of placement and prepare fresh test panels for testing and inspection.

Sprayed concrete shall not be applied to the Works until the Contractor produces test panels for the approval of the council.

(4) Surface preparation

Earth surfaces shall be graded, trimmed and compacted and shall be dampened prior to applying the sprayed concrete. The Contractor shall take any precautions necessary to prevent erosion when the sprayed concrete is applied.

Rock surfaces shall be cleaned of loose material, mud and other foreign matter that might prevent bonding of the sprayed concrete onto the rock surface. The rock surface shall be dampened prior to applying the sprayed concrete.

Corrugated steel pipes shall be cleaned of loose material, mud and any other foreign matter.

The Contractor shall remove free water and prevent the flow of water which could adversely affect the quality of the sprayed concrete.

(5) Application of sprayed concrete

Application shall begin at the bottom of the area being sprayed and shall be built up making several passes of the nozzle over the working area. The nozzle shall be held so that the stream of material shall impinge as nearly as possible perpendicular to the surface being coated. The velocity of discharge from the nozzle, the distance of the nozzle from the surface and the amount of water in the mix shall be regulated so as to produce a dense coating with minimum rebound of the material and no sagging. Rebound material shall be removed after the initial set by air jet or other suitable means from the surface as work proceeds and disposed of.

Spraying shall be discontinued if wind causes separation of the nozzle stream.

Concrete shall not be sprayed in air temperatures less than 5 °C.

Construction joints shall be kept to a minimum. A joint shall be formed by placing or trimming the sprayed concrete to an angle between 30° and 45° to the sprayed concrete surface. The joint edge shall be cleaned and wetted by air-water jet before recommencing concrete spraying.

When spraying around reinforcement, concrete is to be sprayed behind the reinforcement before concrete is allowed to accumulate on the face of the reinforcement.

Adjoining surfaces not requiring sprayed concrete shall be protected from splash and spray rebound. Splash or rebound material on these adjoining surfaces shall be removed by air-water jet or other suitable means as work proceeds.

(6) Curing

Curing shall commence within one hour of the application of sprayed concrete and may be by water or by colourless wax emulsion curing compound complying with AS3799 and applied in accordance with manufacturer’s specifications.

In water curing, the surface of the sprayed concrete shall be kept continuously wet for at least 7 days.

SC6.4.6.28.9 Summary of limits and tolerances

The limits and tolerances applicable to the various clauses in this Specification are summarised in Table SC6.4.6.28.7 – Summary of limits and tolerances below:

Item	Activity	Limits/Tolerances	Clause
1.	**Foundation**		
	(a) Relative Compaction	³95% RDD(standard compactive effort) within 0.3m below subgrade	SC.6.4.6.28.2(1)
2.	**Barriers, Footpaths etc.**		
	(a) Finished Subbase	To be trimmed and compacted so that the levels do not vary more than 15mm under a straight-edge 3m long.	SC6.4.6.28.2(2)

Item	Activity	Limits/Tolerances	Clause
	(b) Relative Compaction of Subbase	³100% (standard compactive effort)	SC6.4.6.28.2(2)
3.	**Formwork**		
	(a) Position of Forms	Forms shall be aligned accurately so that departure of the forms from the surfaces specified on the drawings shall not exceed 1/300 of the space between supports for any surface visible in the completed work and 1/150 for hidden work.	SC6.4.6.28.3(5)
4.	**Fine Aggregate**		
	(a) Grading	To be evenly graded within the absolute limits and shall not deviate from the grading of sample aggregate as per Table SC6.4.6.28.1.	SC6.4.6.28.4(3)
5.	**Coarse Aggregate**		
	(a) Percentage of wear	Loss of weight shall not exceed 30%	SC6.4.6.28.4(4)
	(b) Crushing Value	Crushing value shall not exceed 25%	SC6.4.6.28.4(4)
	(c) Soundness	The loss of mass when tested with sodium sulphate shall not exceed 12%	SC6.4.6.28.4(4)
	(d) Particle Shape	The proportion of misshapen particles (2:1 ratio) shall not exceed 35%	SC6.4.6.28.4(4)
	(e) Grading	To be evenly graded within the absolute limits and shall not deviate from the grading of sample aggregate as per Table SC6.4.6.28.2.	SC6.4.6.28.4(4)
6.	**Aggregate Moisture Content**	Where moisture content of fine aggregate exceeds 8%, or moisture content of coarse aggregate exceeds 3%, the proportion of mix shall be changed.	SC6.4.6.28.5(2)
7.	**Consistency**	In accordance with AS1012.3, Method 1 the slump shall not exceed the nominated slump ±15 mm.	SC6.4.6.28.5(4)
		In the case of concrete placed by extrusion machine, the slump will be between 10mm and 15mm.	SC6.4.6.28.5(4)
8.	**Ready-Mixed Concrete**		
	(a) Mixing & Delivery	The time taken from the introduction of water until the concrete is completely discharged shall be not more than 1.5 hours. Where non-agitating equipment is used the concrete shall be completely discharged not more than 30 minutes after the addition of water.	SC6.4.6.28.5(5)
9.	**Placing & Compacting of Concrete**	Concrete shall not be placed without the approval of the Superintendent if the air temperature within 24 hours is likely to be below 5°C or the shade temperature is likely to exceed 38°C.	SC6.4.6.28.5(6)
10.	**Finishing of Unformed/Formed Concrete Surfaces**		
	(a) Wearing Surface	to be finished true and uniform so that departure from designed grade shall not exceed 5mm in any 3m length.	SC6.4.6.28.5(7)(b)
	(b) Finished Surfaces		

Item	Activity	Limits/Tolerances	Clause
	(i) Not Adjacent to Roads	≤25mm Plan position	SC6.4.6.28.5(7)(c)
		≤25mm Level	SC6.4.6.28.5(10
	(ii) Adjacent to Roads	≤10mm Alignment	SC6.4.6.28.5(7)(c)
		≤10mm Level	SC6.4.6.28.5(10)
	(iii) Culvert Inverts	≤25mm Alignment	SC6.4.6.28.5(7)(c)
		≤10mm Level	SC6.4.6.28.5(10)

SC6.4.6.29 Boundary fencing

SC6.4.6.29.1 Introduction

(1) Scope

The work to be executed under this sub-section includes setting out, clearing of fence line, supply of material and erection of fencing and gates, in accordance with the drawings or as directed by the Superintendent.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections:

SC6.4.6.11 - Clearing and grubbing

SC6.4.6.28 - Minor concrete works

(b) Australian Standards:

AS 1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio.*

AS 1725.1 – *Chain link fabric fencing - Security fences and gates.*

AS 2423 - *Coated steel wire fencing products for terrestrial, aquatic and general use.*

(c) Queensland Department of Transport and Main Roads publication:

Manual of Uniform Traffic Control Devices (Queensland) (MUTCD)

SC6.4.6.29.2 Materials

(1) General

All materials shall be supplied by the Contractor and shall be of dimensions, manufacture and quality in accordance with the requirements of this policy and all galvanised wire fencing products shall conform to AS 2423.

For each type of material to be supplied, the Contractor shall submit to the Superintendent for approval the source, manufacturer, and also the type if applicable.No materials shall be used until approved by the Superintendent.

(2) Galvanised posts, braces and rails

All posts, bracing and rails shall be galvanised iron pipe in accordance with AS 1725.1. The pipes shall be to the dimensions shown on the drawings.

All pipe joints shall be welded. All welds shall be satisfactorily cleaned and painted with a cold galvanising compound to the satisfaction of the Superintendent.

(3) Chain wire

Galvanised chain wire mesh, 1200 mm high, 1450 mm high or 1830 mm high for Manproof Fencing shall be of 3.15 mm diameter wire woven to a 50 x 50 mm square mesh. Chain wire shall be supplied in lengths of not less than 30 m. The zinc coating shall be uniform, continuous, free from imperfections and thoroughly adherent. The coating shall be applied to the wire before the mesh is woven. The weight of the zinc coating shall not be less than 290 g/sq m of wire surface.

Where specified, the chain wire shall be coated in black PVC after galvanising.

(4) Wire netting

Wire netting shall be standard quality galvanised 1.40mm diameter wire, 40mm mesh, 1.05m wide for normal use and 1.60mm diameter wire, 50mm mesh, 0.90m wide where used in creek crossings.

(5) Gates

Gates shall be of galvanised tubular steel construction, 3.6m in width by 1.5m or 1.2m (as specified) in height,

and shall be fitted with substantial hinges, catch, drop bolts and locking chains unless otherwise shown on the drawings or directed by the Superintendent.

Where required, gates shall have stout and well supported rabbit-proof mesh to a height of at least 900mm above ground level.

(6) Reinforced concrete posts

(a) Strainer posts
Concrete strainer posts shall be approximately 150 x 150 square in section and lengths as shown on the drawings. Each post shall be provided with 12mm dia holes to suit the spacing of the wires shown on the drawings for the particular type(s) of fencing to be erected.

The posts shall be reinforced longitudinally with not less than four reinforcing bars each 12mm diameter. All posts shall have suitable stirrup reinforcement to control diagonal cracking. Longitudinal reinforcement shall have 25mm minimum cover. End cover on reinforcement shall be 25mm.

(b) Intermediate posts
Intermediate Posts shall generally conform to the requirements for Strainer Posts, except that the longitudinal reinforcing bars may be 9mm dia.

(7) Prestressed concrete posts

(a) Strainer posts
At least four longitudinal high carbon deformed high tensile strands (or equivalent) of 5mm diameter, shall be provided. The strands shall be tensioned to a stress of 800 MPa minimum prior to placing concrete. Cross sectional dimensions of the posts shall be as shown on the drawings.

Concrete shall have a minimum compressive strength of 32 MPa at 24 hours. In lieu of holes for wires, grooves may be provided to suit the spacing of the wires shown on the appropriate drawings for the particular types of fencing to be erected. The grooves shall be at least 5mm deep and 5mm wide at the surface of the post.

(b) Intermediate posts
Intermediate posts and strainer stays shall generally conform to the requirements for Strainer Posts except that two only high tensile, high carbon deformed strands shall be required.

Cross sectional dimensions shall be as shown on the drawings.

(8) Steel posts (rural fencing)
Steel posts shall be "STAR" pattern. Posts shall be drilled to suit the spacing of the wires shown on the Drawing(s), and shall be black varnished or galvanised. The total weight of 300 posts each 1.65m long shall be at least 1 tonne.

(9) Galvanised pipe posts (rural fencing)
Galvanised pipe posts shall be used where shown on the drawings. The pipes shall be of the dimensions shown on the drawings and shall be of first grade quality in accordance with AS 1725.

(10) Wires

(a) Plain wire
Plain wire shall be standard galvanised drawn annealed steel wire of diameters shown on the drawings.

(b) High tensile plain wire
High tensile wire shall be galvanised and of diameters shown on the drawings.

(c) Barbed wire
Barbed wire including barbs shall be 2.5mm diameter galvanised drawn annealed steel wire, with clusters of four barbs spaced at 90mm maximum. Alternatively barbed wire may be of 1.6mm diameter high tensile steel wire, with clusters of barbs spaced at 90mm maximum.

(d) Cable wire
Cable wire shall consist of three pairs of 2 x 3.15mm galvanised iron wire tightly twisted around posts and located as shown in the drawings.

(e) Tie wire
The wire shall be 2mm diameter galvanised wire.

(11) Concrete backfilling
All concrete backfilling of post holes specified on the drawings shall be of minimum 20 MPa 28 day compressive strength and shall conform to the requirements of sub-section SC6.4.6.28 Minor concrete works.

SC6.4.6.29.3 Construction

(1) General
Fencing shall be erected prior to the commencement of other work on a particular section of the work, unless directed otherwise by the Superintendent.

All fencing shall be erected in a workmanlike manner, and when completed shall be sound, strong and of neat appearance.

For a clear width of one metre on either side of the fence line, and for the full length of the line, all logs, boulders, stumps, roots, undergrowth and rubbish shall be removed and disposed of by the contractor in accordance with SC6.4.6.11 Clearing and grubbing. Trees within this area shall be removed only as directed by the Superintendent and approved by council's authorised officer.

If trees on or adjacent to the fence line are to be retained the arrangement of the fencing at the trees shall be as directed by the Superintendent.

Wire shall not be strained around or against any trees to be left in the fence line, and strainer posts are to be provided on both sides of each tree.

Where minor irregularities occur in the ground the vertical alignment of the fence shall not follow these irregularities, but shall be aligned to a uniform grade between definite changes in the natural slope of the ground.

All boundary fencing is to be erected on the common boundary line (where practicable) which has been surveyed and marked with pegs by a registered cadastral surveyor. The placement of the proposed fence (including footings), relative to the marked boundary line, is to be such that no (or minimal) loss of accessible land results for either property owner once the fence is erected. Any deviation of the proposed fence line away from the marked property boundary is to be mutually agreed to by all parties prior to erection of the fence.

The Contractor shall maintain the fencing at all times in a condition secure against the ingress or egress of stock, and shall take such precautions as are necessary to prevent people or stock from stepping into holes excavated for the construction of fencing.

Where old fencing is to be replaced by new fencing, all holes left after removal of the old fencing shall be backfilled and rammed firmly in layers of maximum depth 150mm.

The Contractor shall be held responsible for any loss, damage, or injury to buildings, goods, crops, livestock, property of any kind or persons due to negligence on the Contractor's part.

(2) Chain link fencing

(a) Erection of posts
All posts shall be erected vertically and set in concrete blocks approximately 250mm diameter and 600mm deep except for end, corner, strainer and gate posts which shall be set in concrete blocks approximately 250mm diameter and 900mm deep unless otherwise shown on the drawings. Concrete shall have a minimum compressive strength of 20 MPa at 28 days and shall conform to the requirements

of sub-section SC6.4.6.28 Minor concrete works.

Galvanised weather caps shall be fitted to all galvanised posts.

Strainer posts shall be used at ends of fencing, angles, intersections with other fencing, gates and at intermediate points. Distances between strainer posts shall not exceed 120m.

(b) Erection of wire

All wire shall be spaced as shown in the drawings. Wire shall be securely fastened and strained to an even tension between strainer posts.

Where specified, or shown on the drawings, chain wire mesh shall be erected on the outside of the posts and fastened with two turns of tie wire to each cable wire on both sides of each post and at intervals of not more than 900mm between posts and to each post midway between cable wires.

(3) Stock-proof fencing

(a) Erection of posts

All posts shall be erected vertically. Reinforced concrete posts shall be erected in neatly cut holes sunk in earth, or in rock where this is encountered. Steel posts, except where placed in rock, shall be driven with suitable driving equipment, care being taken not to damage the tops of the posts during driving.

Where prestressed posts are proposed to be used, they shall be either erected as for reinforced concrete posts or shall be driven. Where driven, the Contractor shall use a suitable post driver which shall be equipped with two sets of guiding rollers, to hold the post vertical and in position during driving.

A steel cap with a plywood cushion shall be used to protect the top of the post during driving.

If the post cannot be driven for the full depth specified, or if it becomes significantly damaged, or cannot be driven vertically, it shall be removed. The same post if undamaged, or a new post, shall be erected as described for reinforced concrete posts.

Posts shall be sunk to the depths shown in Table SC6.4.6.28.1 Post depth in ground.

Table SC6.4.6.29.1 Post depth in ground

Type of Post	Depth	
	Earth	Rock
Concrete Corner Posts and Strain Posts	900	*600
Concrete Intermediate Posts	600	*450
Steel Posts	450	450

Note —*permitted only in cases where posts of the correct length are provided (see below), otherwise the depth of sinking shall be the same as for earth.

Cutting of concrete posts will not be permitted, and in order to take advantage of the lesser depth of sinking permitted in rock, it will be necessary to use posts manufactured in lengths to suit the depth of sinking. Where rock is encountered, steel posts shall be sunk in drill holes of sufficient diameter to permit them to be refilled with cement mortar consisting of one part of cement to two parts of clean sand.

Earth shall be backfilled around intermediate posts in layers of maximum depth 150mm for the full depth of the hole and up to ground level. The relative compaction of the rammed material shall be not less than that of the original undisturbed ground.

Where concrete posts are placed in rock, the space around the posts shall be tightly filled with cement mortar consisting of one part of cement to two parts of sand, or concrete where this is available.

Strainer posts shall be used at ends of fencing, angles, intersections with other fencing, gates and at intermediate points. These posts shall be backfilled with approved concrete to their full depth.

Distances between strainer posts shall not exceed 120m in the case of fencing using steel intermediate posts, and 90m in the case of fencing for the retention of cattle (for which only concrete posts are permitted). Junctions with existing fencing shall be made in an approved manner.

(b) Erection of wires

All wire shall be placed as shown on the drawings. Wires shall be securely fastened and strained to an even tension between strainer posts with an approved wire strainer. Where barbed wire is to be used, it shall be tied in position at the top of intermediate posts, and where additional barbed wires are called for they shall be secured to the sides of the posts as shown on the drawings.

Where concrete posts are used and the barbed wires are secured either to the tops or sides of the posts by tie wire, the tie wire shall be stretched tight and shall fit snugly against the sides of the posts to prevent movement of the barbed wire.

Where prestressed posts are used, wires shall be securely tied so that they seat firmly in the grooves.

All joints in wires shall be as shown on the drawings.

(4) Crossing of watercourses and depressions

The crossing of all watercourses and depressions, shall be made secure by longer posts, suitably strutted as directed by the Superintendent. Additional cable wire and chain wire/wire netting shall be provided as necessary to make the fence stock proof.

The fence shall allow the passage of floodwater without the accumulation of debris. If directed by the Superintendent, flood gates shall be provided in accordance with clause SC6.4.6.29.3(6) Flood gates.

(5) Connections to existing fences

Existing cross fences shall be connected to the new fence using a strainer post with braces in each direction of strain (including cross fence) and the wires in both fences properly fastened to the post.

(6) Flood gates

(a) General

Suitable provision for the passage of flood waters past the fence shall be made at all watercourses. In all cases flood gates shall be of the type indicated on the drawings, or as directed by the Superintendent, and shall be erected so as to prevent the accumulation of flood debris, while remaining stock-proof or rabbit-proof.

(b) Small watercourses

Flood gates, in accordance with the drawings, shall be provided in small gullies at the locations indicated on the drawings or as directed by the Superintendent. The opening of each flood gate shall provide a waterway area at least twice that of the culvert opposite to which it is placed, or as otherwise directed by the Superintendent.

(c) Large gullies and creeks

Flood gates, in accordance with the drawings, shall be provided in gullies and creeks at the locations indicated on the drawings, or as directed by the Superintendent.

A 9mm galvanised wire rope shall be carried over the gully in one span, threaded through a strainer post and tied back to an anchor at an adjacent concrete intermediate post. Turnbuckles are to be provided at each end to tension the wire rope. Netting shall be suspended from the wire rope and shall be overlapped and securely tied. The netting shall be of sufficient length to lie on the ground for a distance of not less than 1.0m on the downstream side.

Ballast, of sound timber securely tied to the netting, shall be provided at the downstream end of the netting.

The sides of the gully shall be trimmed, as necessary, to ensure that the flood gate shall be stock-proof

or rabbit-proof. The flood gate shall have sufficient movement of the suspended portion under the flow of flood waters to prevent damage to the fence and the accumulation of debris against it. Each strainer post shall be stayed in three directions, as shown on the drawings.

(7) Erection of gates

Where gates are specified or shown on the drawings, they shall be erected so that they swing away from the road. Double gates shall be supplied if directed by the Superintendent, otherwise a single gate only shall be supplied.

At the location of gates the surface shall be levelled and shall be nearly horizontal. The area where the gates swing shall be similarly levelled.

The gates shall be hung as indicated in the drawings.

(8) Where required, existing fencing is to be removed as shown on the drawings.

No fencing is to be removed if there is a risk of egress or ingress of stock. If the existing fence is a rabbit-proof fence, then the contractor shall ensure that at night and weekends and other such times when work is not in hand that the whole of the fence is maintained in a rabbit-proof condition, even if temporary fencing is required.

All material removed in demolishing existing fencing shall be disposed by the Contractor as provided by clause SC6.4.6.29.3(9) Removal and disposal of surplus material and rubbish.

(9) Removal and disposal of surplus material and rubbish

All surplus material, offcuts, timber, roots and other debris resulting from the fencing contract shall be removed or otherwise disposed of to the satisfaction of the Superintendent.

The contractor shall not burn any timber, vegetation or refuse on site unless specifically approved by council's authorised officer.

(10) Cattle grids

Cattle grids shall be erected in accordance with the drawings.

The cattle grid shall be evenly bedded on a continuous layer of compacted sand or other granular material approved by the Superintendent. The bedding material shall be compacted so that the relative compaction as determined by AS 1289.5.4.1 is not less than 95 per cent.

Cattle grids shall be installed on raised abutments with approach ramps where possible. Alternatively, a cattle grid may be placed over an excavated pit, in which case adequate drainage shall be provided.

Crossfall for single lane cattle grids shall be level and for two lane cattle grids each section shall have a crossfall conforming to the crossfall of the approach road.

The cattle grid construction shall include all activities associated with the cattle grid including any adjustments to the fencing as shown on the drawings.

Advance signposting, in accordance with MUTCD, shall be provided on each approach to the cattle grid in accordance with sub-section SC6.4.6.24 Signposting.

SC6.4.6.30 Control of traffic

SC6.4.6.30.1 Introduction

(1) Scope

This sub-section provides standards, advice and guidelines for work necessary to provide for the safe movement of traffic and the protection of persons and property through and/or around the work site.

The extent of work includes the design, construction, maintenance and removal of temporary roadways and detours, the provision of traffic controllers, signposting, roadmarkings, raised pavement markers, lights, barriers and any other items required. All temporary traffic arrangements required by works are included under this sub-section except where specified otherwise.

Control of traffic shall be in accordance with Manual of Uniform Traffic Control Devices (MUTCD), this sub-section, and the drawings.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section one as follows:

SC6.4.6.4 - Stormwater drainage
SC6.4.6.5 - Drainage structures
SC6.4.6.6 - Pipe drainage
SC6.4.6.9 - Open drains
SC6.4.6.10 - Earthworks (construction)
SC6.4.6.11 Clearing and grubbing
SC6.4.6.12 - Flexible Pavements
SC6.4.6.13 - Asphaltic concrete
SC6.4.6.16 - Sprayed bitumen surfacing

(b) Australian Standards:

AS 1742 – *Manual of uniform traffic control devices*
AS 1742.3 - *Manual of uniform traffic control devices – Traffic control for works on roads*
AS 1743 - *Road Signs - Specifications*
AS 1744 - *Standard alphabets for road signs*
AS/NZS 1906 - *Retroreflective materials and devices for road traffic control purposes*
AS/NZS 4602 - *High visibility safety garments*

(c) Austroads publications:

Guide to Road Design - Part 3 Geometric Design
Guide to Traffic Management – Part 6 Intersections, Interchanges and Crossings
Guide to Road Safety – Part 9 Roadside Hazard Management

(d) Queensland Department of Transport and Main Roads publication:

Manual of Uniform Traffic Control Devices (Queensland) (MUTCD).

(e) Other:

International Erosion Control Association (IECA), *Best Practice Erosion and Sediment control council*

(3) Traffic guidance scheme

The Contractor shall construct the work with the least possible obstruction to traffic.

Two weeks before undertaking work which would involve any obstruction whatsoever to traffic the Contractor shall submit, for the Superintendent's approval, a Traffic guidance scheme in accordance with Part 3 of the MUTCD.

The Traffic guidance scheme shall include:

(a) design drawings for any temporary roadways and detours in accordance with clause SC6.4.6.30.2(3) Design drawings, showing pavement, wearing surface and drainage details;

(b) details of arrangements for construction under traffic in accordance with Part 3 of MUTCD;

(c) a signpost layout plan showing:

  (i) location, size and legend of all temporary signs;

  (ii) temporary regulatory signs and temporary speed zones, and

  (iii) all traffic control devices such as temporary traffic signals, linemarking, pavement reflectors, guideposts, guard fence and barrier boards; and

(d) working times when traffic control measures are in place to minimise disruption to traffic during periods of peak flows.

The Contractor shall obtain all necessary approvals for temporary traffic arrangements except where specified otherwise.

Where the Traffic guidance scheme involves Regulatory traffic control signs or devices and/or where a disruption to traffic (including pedestrian) to the existing road is likely to be significant, the contractor must undertake consultation with all stakeholders and where identified, must include changes to bus routes and the establishment of temporary bus stops, relocation of any taxi ranks and parking bays for people with disabilities, establishment of any work zones on the roadway amd arrangements for the safe movement of pedestrians past the work site as part of the application to council for approval.

In the case of an intersection with a State controlled road approval from the Department of Transport and Main Roads (DTMR) must also be obtained.

The Traffic guidance scheme shall be in accordance with the requirements of this sub-section and the drawings.

Special consideration to the safety of pedestrians and workers shall be given in the preparation of the Traffic guidance scheme. Particular care shall be taken when requiring reversal of traffic flows or the separation of unidirectional flow by medians or other physical separation.

An approved copy of the Traffic guidance scheme must be kept on site at all times. This must be used to check the arrangement and maintenance of traffic control devices.

For staged works and complex traffic guidance schemes, the Contractor shall conduct a regular safety audit during the construction phase including risk assessments for the workers safety as recommended in *Guide to Road Safety – Part 9 Roadside Hazard Management.*

For non-complex traffic guidance schemes such as short term and mobile works not involving full or part road closure or works involving relatively simple part-roadway closures, the Contractor is required to carry out risk assessments considering factors such as traffic volume and speed, road geometry and width and general behaviours of road users. A fully protected work site will be required if identified risks cannot be tolerated.

(4) Side roads and property accesses

The Contractor shall provide safe and convenient passage for vehicles, pedestrians and stock to and from side roads and property accesses connecting to the roadway. Work that affects the use of side roads and existing accesses shall not be undertaken without providing adequate alternative provisions to the prior satisfaction of the Superintendent.

Where interuptions to access is required, they are to be kept to a minimum and the contractor must advise the property owners of any interruption to access by way of a letter drop at least 24 hours before the intended interruption. The contractor shall repeat this advice verbally to the property owner where possible before proceeding with the access closure. All interuptions to access must have the the approval of the superintendent.

(5) Traffic controllers

The Contractor shall advise the Superintendent of the names of proposed traffic controllers with a signed declaration that they are appropriately trained in the duties of traffic controllers in accordance with the MUTCD.

In situation where restricted sight distance is identified by the Superintendent, an additional traffic controller shall be placed at the tail end of the queue.

(6) Approved clothing for work personnel

All personnel shall wear high visibility clothing to the requirements of the MUTCD.

(7) Temporary speed zoning

Where a temporary speed limit has been approved by the council, or in the case of a gazetted or State controlled road the District Manager of DTMR, the Contractor shall arrange for the supply of appropriate temporary speed zoning signs, including posts and fittings, for erection. Where and when directed by the Superintendent, the Contractor shall erect these signs, cover the signs when the speed zone is not in use and remove the signs when the speed zone is no longer required as part of the provision for traffic. A diary recording operation times of the speed zone shall be kept by the Contractor.

(8) Plant and equipment

During the day plant and equipment working in a position adjacent to traffic and having a projection beyond the normal width of the item, for example, a grader blade, shall have a fluorescent red flag attached to the outer end of the projection. During poor light conditions or at night, an additional traffic controller with an illuminated red wand shall direct traffic around such plant and equipment.

At night, where traffic is permitted to use the whole or portion of the existing road, all plant items and similar obstructions shall be removed from the normal path of vehicles to provide a lateral clearance of at least 6 m where practicable, with a minimum clearance of 1.2 m.

Plant and equipment, within 6 m of the normal path of vehicles, shall be lit by not less than two yellow steady lamps suspended vertically from the point of the obstruction nearest to a traffic lane and one yellow steady lamp at each end of the obstruction on the side furthest away from the traffic lane.

SC6.4.6.30.2 Temporary roadways and detours

(1) Approval

The design of all proposed temporary roadways and detours; to be undertaken in accordance with this policy sub-section

(2) Design standards

The standard of alignment and grading adopted shall be in accordance with specific provisions of this policy and shall otherwise be in accordance with the *Guide to Road Design – Part 3 Geometric Design*

Intersections shall be designed in accordance with the Guide to Traffic Management – Part 6 Intersections, Interchanges and Crossings.

Design drawings, geometric standards, design speed, wearing surface type and pavement design of the proposed temporary roadways and detours shall be submitted by the Contractor with the Traffic Guidance Scheme.

(3) Design drawings

Design drawings submitted for approval should show:

(a) alignment and grading at a horizontal scale of 1:2000 for rural roads and 1:500 for urban roads. Where the temporary road rejoins the existing road, levels showing the full cross section shall be extended along the existing road for a minimum length of 200 m;

(b) a sight distance diagram if opposing traffic is to use a single carriageway;

(c) intersections, and any other locations where traffic may be required to make turning, merging or diverging movements, at a scale of 1:500;

(d) pavement marking details;

(e) sufficient cross sections to indicate the feasibility of making connections between various parts of the work;

(f) sufficient dimensions, especially lane widths, to make clear the geometry and clearances of the proposed works;

(g) a north point or some other location method to orientate the plan;

(h) roadside furniture;

(i) drainage structures (existing/temporary and proposed); and

(j) pavement and surfacing type.

(4) Drainage

Drainage structures and drains shall be constructed in accordance with the following sub-sections:

(a) SC6.4.6.4 - Stormwater drainage;

(b) SC6.4.6.6 - Pipe drainage;

(c) SC6.4.6.5 - Drainage structures; and

(d) SC6.4.6.9 - Open drains.

Drainage proposed in accordance with clause SC6.4.6.30.1(2) Traffic guidance scheme shall be able to cope with upstream rainfall run off resulting from all rainfall intensities up to that expected for a once in five year frequency, without overflow over the road.

Pavements shall be designed and constructed to not pond water on the wearing surface or shoulders. Temporary formations to be constructed shall not dam water.

(5) Construction of earthworks and pavement

Temporary roadways shall be constructed in accordance with the following specifications:

(a) *Best Practice Erosion and Sediment Control*;

(b) SC6.4.6.11 Clearing and grubbing;

(c) SC6.4.6.10 Earthworks (construction); and

(d) SC6.4.6.12 Flexible Pavements.

(6) Surfacing

The wearing surface width shall extend across the full width of the traffic lanes plus the width for each shoulder, or as otherwise demonstarted.

The wearing surface shall be carried onto any existing connecting roadway so as to finish square to the existing roadway centreline.
Surfacing shall be constructed in accordance with:
SC6.4.6.16 - Sprayed bitumen surfacing; and
SC6.4.6.13 - Asphaltic concrete

(7) Road safety barrier

Corrugated steel road safety barrier shall be erected on all temporary embankments where the vertical height between the edge of the shoulder and the intersection of the embankment slope and natural surface exceeds 2m.

Road safety barrier shall be erected in accordance with:
SC6.4.6.25 - Non-Rigid Road Safety Barrier Systems.

(8) Opening to traffic

Temporary roadways and detours (including portable or temporary traffic signals sites) shall not be open to traffic until they have been inspected, approved and authorised in writing.

All signposting, pavement marking, guardfence and portable or temporary traffic signals shall be completed before the opening of temporary roadways to traffic.

The opening of temporary roadways shall be arranged so that sections of existing roadway being replaced are not disturbed for a minimum of 48 hours in the event of temporary roadway failure and there is a warrant to redirect traffic back onto the existing roadway. The determination to redirect traffic shall be by the Superintendent.

The redirection of traffic back onto the existing roadway shall be the responsibility of the Contractor.

Unless otherwise approved by the Superintendent, traffic shall be switched to a temporary roadway or detour only where the Contractor's usual workforce will be on site for a minimum of 2 days thereafter.

(9) Maintenance

The Contractor shall be responsible for the maintenance of temporary roadways and detours and shall ensure the road surface is kept safe for traffic. Any potholes or other failures shall be repaired without delay.

(10) Removal

Upon completion of the work the temporary roadways and/or detour arrangements shall be removed and the area restored to a condition equivalent to that which existed prior to the commencement of the work.

SC6.4.6.30.3 Arrangements for traffic

(1) Construction under traffic

Where a temporary roadway or a detour is not provided or available then, subject to the approval of the Superintendent, construction under traffic may be permitted provided a minimum of 3.5 m lane width is available for through traffic on a two lane roadway and where 3.5 m lanes are available in both directions for through traffic when working on multilane roads.

The carriageway/s shall be restored to a safe and trafficable state for through traffic prior to cessation of work each day in accordance with the approved Traffic guidance scheme.

Full details of temporary signposting, traffic control devices and traffic control methods, in accordance with the appropriate arrangement diagrams in MUTCD, are to be submitted for the Superintendent's approval at least 5 working days before undertaking any work which would involve construction under traffic.

(2) Opening completed work

The Contractor shall give the Superintendent at least 5 working days written notice confirming the date of opening completed work to traffic. The procedure for opening shall be determined through consultation between the Superintendent, the Contractor and the council.

The Contractor shall be responsible for the removal of all temporary traffic control devices no longer required for the safety of traffic, when the works or part thereof are opened to traffic.

SC6.4.6.30.4 Traffic control devices

(1) Arrangement of traffic control devices

The arrangement and placement of traffic control devices shall be carried out in accordance with the approved Traffic guidance scheme, and MUTCD. The arrangement diagrams illustrate the more common examples of the arrangement of traffic control devices and set out the minimum requirements.

All temporary traffic control devices, when no longer required, shall be covered and/or removed without delay in order to maintain unambiguous safe guidance to traffic.

(2) Maintenance of traffic control devices

All traffic control devices shall be maintained in accordance with MUTCD so that they are in good order and in the correct positions day and night. They shall be neat and clean, and signs shall be clear and legible at all times.

To ensure the preceding clause is complied with, the Contractor shall inspect the site at least once every 24 hours for the maintenance of all traffic control devices.

The Contractor may need to be contacted outside normal working hours to arrange for adjustments or maintenance of traffic control devices. The Contractor shall notify the Superintendent and the council in writing, the names, addresses, and means of communicating with personnel nominated for this purpose.

(3) Adequate traffic control devices

Where the Contractor fails to provide and maintain adequate traffic control devices specified in this sub-section, the Superintendent shall arrange to have such items provided and maintained.

(4) Regulatory traffic control signs and devices

A regulatory traffic control sign or device shall be in accordance with the MUTCD, and shall require approval by the council, or in the case of a gazetted or State controlled road, the District Manager of DTMR, before its erection. This approval should be obtained through the Superintendent, refer to clause SC6.4.6.30.1(6) Temporary speed zoning.

(5) Signs

Signs shall be designed and manufactured in accordance with AS 1743. Details of each letter shall be as shown in AS 1744.

The reflective material used on signs shall be Class 2 material complying with AS 1906.1 except where otherwise specified.

(6) Supplementary signs

Signs supplementary to the MUTCD are shown in SC6.4.6.30 Attachment A Supplementary temporary warning signs to MUTCD. Approval must be obtained from DTMR prior to their use.

(a) Heavy Machinery Crossing
This temporary sign, shown as Sign SW5-22, if approved, may be used in lieu of W5-22, trucks entering.

(b) Cycle Hazard Grooved Road
This temporary sign, shown as Sign ST1-10, if approved, may be used in addition to T1-10 of AS 1742.3 where the road is grooved and is a hazard to cyclists.

(c) Tar Spraying Possible Short Delay
This temporary sign, shown as Sign ST3-1, if approved, may be used in addition to T3-1 for bituminous surfacing works.

(7) Flashing arrow signs

Flashing arrow signs shall comply with MUTCD.

(8) Barrier boards

Barrier boards shall comply with MUTCD.

Trestles supporting the barrier boards may be manufactured of timber, metal or other suitable material and shall be yellow. The trestles shall provide firm supports for the barrier board and be kept in place by sandbags suitable devices. The bases of the trestles shall not protrude beyond the ends of the boards.

(9) High visibility mesh fencing

High visibility mesh fencing shall be constructed where shown on the drawings, Traffic Guidance Scheme or as directed by the Superintendent.

High visibility mesh fencing shall be constructed in accordance with MUTCD, containment fences.

The mesh fencing shall be approximately 1 m in height and of a red-orange colured flexible material as approved by the Superindendent.

(10) Temporary post-mounted delineators
In addition to the requirements of MUTCD, temporary post mounted delineators shall be provided in conjunction with high visibility mesh fencing which is erected parallel to and in close proximity to traffic.

(11) Cones and bollards
Traffic cones and bollards shall comply with MUTCD and be placed in accordance with the arrangement diagrams in MUTCD.

Unless cones are firmly fixed in position they shall be used only while work is in progress, or in locations where there is an employee in attendance who shall reinstate any of the cones which have been dislodged by traffic. Otherwise they shall be removed and bollards or barriers substituted.

Cones and bollards used under night conditions shall be reflectorised in accordance with MUTCD.

(12) Traffic warning lamps
Traffic warning lamps shall comply with MUTCD and shall be installed in accordance with MUTCD. The Contractor shall ensure that warning lamps are in good working order, correctly aligned and positioned with respect to the direction of traffic flow each night, before the site is left unattended.

(13) Temporary pavement markings
All pavement markings shall be reflectorised and consist of painted lines, roadmarking tape and/or raised pavement markers in accordance with the relevant Australian Standards or as otherwise approved by the Superintendent and shall be provided in accordance with MUTCD.

Where the adjoining roadway is edgelined, temporary roadways shall be similarly edgelined.

(14) Temporary linemarking
Where temporary linemarking is required on the final wearing surface, only pavement marking tape shall be used.

Where the pavement linemarking has become ineffective in the opinion of the Superintendent, remarking shall be undertaken within 48 hours of direction by the Superintendent.

Where a single carriageway is opened adjacent to or used in lieu of an existing dual carriageway length, pavement arrows indicating the direction of flow of traffic shall be placed at not more than 500 m or at a spacing nominated by the Superintendent. The arrows shall be removed if the section is then reincorporated as dual carriageway.

Immediately before or after placement of new markings all superseded pavement markings shall be obliterated or removed to the satisfaction of the Superintendent.

On a final surface, obliteration by painting shall not be permitted.

(15) Raised pavement markers
Where raised pavement markers have become ineffective in the opinion of the Superintendent, they shall be replaced within 24 hours of direction by the Superintendent.

All superseded raised pavement markers shall be immediately removed from the pavement by the Contractor.

Attachment

SC6.4.6.30 Attachment A Supplementary temporary warning signs to MUTCD

(1) Black letters and border on yellow reflectorised ground.

ST3-1

SC6.4.7 Acceptance of completed works

SC6.4.7.1 Release of the plan of survey

SC6.4.7.1.1 Introduction

The Release of the plan of survey sub-section details the requirements that must be met prior to the release of the Plan of Survey.

(1) Principles

Prior to the release of the Plan of Survey the developer must:

(a) comply with all conditions of the development permit; and

(b) ensure that all required fees, bonds, contributions, infrastructure charges and outstanding rates are paid.

Works will not be accepted on maintenance until the formal Plan of Survey has been released.
Where exceptional circumstances exist and an early release of the Plan of Survey is agreed to by the Director Planning and Development, the developer is required to bond any outstanding work.

(2) Terminology

Terms in this policy have the same definition as in the *Planning Act 2017*, unless otherwise defined.

DEHP	*Department of Environmental and Heritage Protection*
Plan of Survey	Includes all surveys undertaken by a cadastral surveyor as defined by the *Surveyors Act* 2003 and for the purpose of: • subdividing one or more lots; or • dedicating land to public use; or • redefining a lot by resurvey; or • amalgamating two or more lots to create a smaller number of lots; or • defining an area for an easement, lease, profit a prendre or covenant; or • any other purpose that the Registrar may require the registered proprietor to undertake.
On maintenance date	The date the works have been inspected and are complete, relevant conditions of the Development Permit have been satisfied, council has accepted maintenance responsibility for agreed public infrastructure and the developer commences the defects liability period.
Off maintenance date	The date the works are fully accepted by council following an inspection by council, which considers that all works are satisfactory, and the defects liability period concludes.
Maintenance period	The period of time between when council accepts the works on-maintenance until council accepts the works off-maintenance. This includes any establishment periods and the defect liability period, the period of time during which the developer is required to repair defects that occur. A defect is an imperfection, fault of deficiency in the works and does not include general wear and tear of items or damage due to misuse.

SC6.4.7.1.2 Release of plan of survey requirements

The following must be received or completed prior to the release of the Plan of Survey.

(1) Certification

(a) The developer must submit one print of each drawing, excluding council Standard Drawings:

(i) as originally approved by council;

(ii) including amendments incorporated in the construction of the development; and

(iii) overprinted with a certificate from a Licensed Surveyor or Registered Professional Engineer of

Queensland (RPEQ) as detailed below.

(b) An RPEQ and/or a Registered Landscape Architect must certify that the completed works comply with the development approval, the specific outcomes of the applicable regulations and good engineering practice.

The RPEQ and/or Registered Landscape Architect must also certify the 'as constructed drawings by including the following statement on each drawing:

"I/We (Name) of (Firm) hereby certify that the works as shown on the 'as constructed' drawings reflect any changes that were made during the course of construction (signed with RPEQ No and dated)".

(c) A Registered Surveyor must certify that the locations, surface and invert levels of all works and infrastructure presented on the as constructed drawings and digital submissions have been surveyed and are true and accurate representations of the works by including the following statement on each as constructed drawing:

"I/We (Name) of (Firm) herby certify that this drawing accurately describes and records the nature and the location of the works depicted hereon as they have been constructed for the purposes of the development (signed and dated)".

(2) As constructed drawings

One signed hard copy and digital copies of the as constructed drawings (AutoCAD DWG and a copy converted to PDF A1 format correctly scaled to A3 size) must be submitted and approved by council. As constructed information must be provided for all completed works, and must include the following information.

(a) Lot

(i) The lot layout as approved and as shown on the Plan of Survey.

(ii) Approved street names.

(b) Earthworks

(i) As constructed contours or where allotments are under 2000m^2 spot levels will be adequate to verify a minimum as constructed surface gradient of 1 in 250.

(ii) Denote location, extent and depth of fill.

(iii) The maximum depth of fill on each lot must be indicated.

(iv) Flood lines as adopted by council.

(v) Street names as approved by council and noted on the Plan of Survey.

(c) Infrastructure

(i) Pavement and kerb and channel information (e.g. edge of pavement and kerb and channel alignment and depths of pavement, kerb type, road surface type and depth, road pavement details, type and depth, road cross sections).

(ii) Stormwater drainage information, including:

(A) pipe alignments denoting sizes and invert levels at each end;

(B) manhole location; and

(C) inlet pit types to be denoted.

(iii) Major overflow paths and trunk drainage channels located and clearly shown.

(iv) Invert levels and offsets of the junction points and manhole connections where roof water drainage systems have been used.

(v) Sewerage 'as constructed plans', including all required details, lodged and approved.

(A) Location of maintenance structure (MH, MC, JU and end of PCS or house drain connection point); and

(B) Material type and sizes.

(vi) Details of all water mains, fittings of consequence and markers, including relevant dimensions,

included on as constructed plans, which are to be lodged and approved.

(vii) Location and dimensioning of subsoil cleanout points.

(viii) BOS data to detail location of house drain connection point - building envelop upgraded.

Editor's note: -

a) The accuracy of as constructed plans locating house connections is essential.

b) Council's Inspector, while on site, may take measurements that will permit some cross checking of as constructed plans. Should these checks indicate discrepancies, then reopening of the work will be required for checking measurement of the work.

(3) Ongoing operational requirements

Where requested, applicants are required to identify the ongoing operational requirements in a relevant Maintenance Plan, as detailed in Section SC6.4.2 Development application guidelines.

(4) The on maintenance inspection

The on maintenance inspection must be satisfactorily completed prior to the release of the Plan of Survey. The Consulting Engineer must undertake and report on the following prior to requesting the on maintenance inspection.

(a) Lodgement

(i) Demonstrated full compliance with all conditions of relevant Development Approvals.

(ii) Building approval for all buildings/structures, where required by the *Building Code of Australia* (BCA).

(iii) Plan of Survey submitted in accordance with approved proposal plan and any approved amendments, or where the Plans of Survey differ from the approved proposal plan, details of any changes must be provided with the application.

(iv) A Supervision Certificate from the Consulting Engineer and request to have the works accepted on maintenance.

(v) Infrastructure Agreements, if required, must be in place for the provision of and/or connection to trunk infrastructure.

(vi) Approval by other authorities, e.g. evidence of NBN Agreement, Certificate of Acceptance or Letter of Supply from Ergon.

(b) Sewer

Sewerage works

(i) Pressure test all sewers and manholes to ensure the requirements of the specification are met.

(ii) Check by internal examination (closed circuit television) that all sewers are straight, clean and to grade.

(iii) Check that all manholes are sound, smooth and clean and benched as per the required standard.

(iv) Check that house connection jump up construction complies with council's standards.

(v) Performance testing of pumping equipment. This testing will require the connection of the electricity supply and water to the pump station.

(vi) Obtain licences for overflows to the sewerage system from DEHP.

All sewerage works including pump stations, rising mains, trunk mains and the proposed sewers must have been inspected and certified by the supervising engineer as being 100 per cent complete and in full working order. Sewer systems must be installed, tested and operational. (Bonding of pump stations may be accepted; refer to SC6.4.7.3 Sewer pump-out agreements.

(c) Water

(i) Water reticulation

(A) Pressure test and supervise the swabbing (if necessary) and sterilisation of the water mains.

(B) Check location of hydrants and valves to ensure they are in their correct location.

(C) Check that all valves and hydrants are working satisfactorily (include lid arrangement as per SD-350).

(D) When water mains have been constructed, mains must be commissioned in accordance with council requirements.

(ii) All works associated with water supply on site must be 100 per cent complete, and all water mains must be tested and live. Reservoirs and associated pump stations must be commissioned prior to the lodgement of survey plans unless otherwise approved by council.

(d) Earthworks

(i) All allotment preparation work and earthworks on allotments must be 100 per cent complete in accordance with the requirements of SC6.4.6.10 Earthwork construction, with finished surface levels, the degree of compaction achieved and geotechnical assessments required on any of the allotments submitted and approved by council. All works within allotments must be fully completed and no further disturbance required on the allotments. Appropriate erosion and sediment control measures must also be in place for all disturbed areas.

(ii) Where specific revegetation works have been bonded for future completion, the earthworks and top soiling must be complete prior to the release of the Plan of Survey.

(iii) All survey pegs placed.

(e) Roads

(i) Roads must be completed and fully sealed.

(ii) Pavement line markings completed at major intersections.

(iii) All traffic control devices, including traffic islands to be completed.

(iv) All traffic signage to be in place and completed compliant with Manual of Uniform traffic control devices (MUTCD) requirements.

(v) Traffic signals, if present, to be installed, completed and fully functional, compliant with the relevant requirements and legislation.

(vi) Retaining walls within road reserve to be completed and maintenance requirements documented.

(vii) Fences and noise abatement/screening walls to be completed and maintenance requirements documented.

(f) Stormwater

(i) Stormwater drainage works must be installed with all erosion controls in place and able to function without detriment to the system. Allotments must be provided with the nominated flood immunity. All stormwater systems must be constructed, including kerb and channel. Downstream drainage easements must have been executed in favour of council, necessary drainage and other easement documentation must have been submitted, and required reserves for drainage, parkland, etc. must have been provided.

(ii) This excludes large water sensitive urban design (WSUD) measures such as bio-retention basins and wetlands, where the acceptance of the asset and ongoing maintenance requirements is to be in accordance with SC6.4.3.9 Water sensitive urban design guidelines.

(iii) Performance testing of pumping equipment must be passed satisfactorily. This testing will require the connection of the electricity supply and water to the pump station.

(g) Services

Evidence must be provided of street lighting, telecommunications and electrical supply works commitments. Satisfactory evidence must be provided to council of a negotiated agreement with service providers for telecommunications and NBN Co infrastructure, reticulation of electricity and the provision of street lighting, and gas service providers for provision of gas (if gas is provided).

(h) Payments and Bonds

(i) The full payment of fees and bonds, including the maintenance bond and any bonds for incomplete works. The maintenance bond will be a minimum 5 per cent of the value of the works as certified by the RPEQ and accepted by council, and must be lodged with council until the development is accepted as off maintenance.

(ii) All outstanding rates paid.

(iii) All infrastructure charges required by the conditions of the development permit must be paid.

(iv) Accompanied by the prescribed form and fee of an amount in accordance with council's fees and charges current at the time of payment.

(i) Land

The developer must covenant that all transfers of land and interests in land to council are free of encumbrances and registered in the Title's Office at the same time as the Plan of Survey is registered at no cost to council.

SC6.4.7.1.3 Bonds

To enable early release of the Plan of Survey it will be necessary to bond all outstanding works and requirements. Security bonds for incomplete works will be subject to a minimum value of $15,000.

(1) Standard bond conditions

(a) Estimates

(i) To verify the maintenance bond estimates, council must be supplied with a schedule of the works together with the appropriate estimated rates and amounts for all the items.

(ii) To verify the incomplete works bond estimates, council must be supplied with a schedule of the incomplete works together with the appropriate estimated rates and amounts for the incomplete works.

(iii) Such estimated prices must be fair and reasonable.

(b) Conditions

(i) The amount of the security for incomplete works must be for an amount of not less than one hundred and fifty per cent (150 per cent) of the certified cost of the works remaining to be completed as at the date of the release of the subject Plan of Survey.

(ii) Incomplete works must be itemised, valued and certified by an RPEQ.

(iii) All bonds submitted must be clearly identified as to the particulars of the site and the purpose of the bond.

(iv) Insurance and indemnity certificates must be current and valid to cover the period outstanding works are being completed.

(c) Acceptable security

(i) Cash bonds.

(ii) Unconditional bank guarantees.

(A) A bank guarantee must include:

- a binding contractual relationship between council and the guaranteeing bank;
- specific requirements for renunciation of the guarantee; and
- a requirement of adequate notice of renunciation.

(B) Bank guarantees must not have expiration dates.

(2) Incomplete works bond

(a) Incomplete works condition

In addition to the standard bond conditions:

(i) Where council consents to the early release of a Plan of Survey in line with the minimum requirements listed in Section 3, the developer will be required to lodge a security (bond) and an undertaking to complete the works within an agreed timeframe. These works must be completed to the satisfaction of council and the security submitted in a format as detailed in this sub-section. Security bonds for incomplete works will be subject to a minimum value of $15,000.

(ii) Outstanding works must be itemised, valued and certified by an RPEQ.

(iii) Potential purchasers of lots must be advised of the arrangements.

(b) Required information

The RPEQ must provide the following information:

(i) certification of the value of incomplete works;

(ii) detailed schedule of the scope and cost of the incomplete works for auditing purposes;

(iii) certification that all external and internal works can be completed and accepted on maintenance within the timeframes detailed elsewhere in this Policy sub-section;

(iv) certification that the contract has been let for the construction of the remaining internal and external works and the name of the Contractor;

(v) proposed finish dates for remaining internal and external works; and

(vi) security lodgement form completed clearly indicating that the purpose of the bond is for incomplete works.

(3) Revegetation bonds

Revegetation bonds may be required where conditioned by a development permit. At the time of on maintenance council may accept the drains and earth batters within a subdivision whereby the vegetation is not in accord with the objectives of this and other SC6.4 Development manual planning scheme policy sub-sections, subject to the following requirements.

(a) Revegetation performance bond

(i) A bond for the incomplete revegetation must be included as a performance bond for incomplete works along with all other bonds for incomplete works upon that subdivision.

(ii) The bond for the revegetation works must be 150 per cent of the approved estimated cost of the revegetation works to allow for the typical seasonal weather encountered in the region, due to the risk of erosion and scouring in areas of exposed earth.

(iii) The revegetation performance bond will be considered for acceptance on and off maintenance separate to the general subdivision works.

(b) Revegetation maintenance bond

(i) The revegetation performance bond will be reduced to a revegetation maintenance bond upon achievement of a minimum scour protection, which is deemed as 40 per cent vegetal coverage, which includes 15 per cent of the total area having the specified species. The revegetation maintenance bond must be equal to the approved estimate of the value of the works required to achieve the specified grass coverage by the off maintenance date.

(ii) The acceptance of revegetation on maintenance will correspond with the reduction of the performance bond for revegetation works. The acceptance of the revegetation works off maintenance and release of the revegetation maintenance bond will require the specified grass coverage to be completed but will not occur prior to the remainder of the development being accepted off maintenance.

(4) Sewer pump station bonds

(a) Where a sewage pump station is a pump station identified by council in the Priority Infrastructure Plan (PIP) and that sewage pump station is identified as minor trunk infrastructure, then consideration will be given to the release of the Plan of Survey prior to the completion of the works associated with that pump station.

(b) The pump station must be located upon land that is or will be under the control of the council upon the registration of the subject Plan of Survey.

(c) The working drawings and specifications must have been completed and approved by council for construction.

(d) The Consultant Engineer acknowledges that with respect to the nominated works that they are working for council and not the developer, and that the specifications nominate council as the Principal of the Contract.

(e) The tenderers must have been reported to council and council must have approved the successful tenderer.

(f) The Contract must have been let, and a submitted works program must indicate that the trunk

infrastructure is programmed to be completed prior to when the commencement of dwelling construction is envisaged, including provision for a normal wet season.

(g) The developer must enter into a Deed of Agreement with council, as detailed in SC6.4.7.3 Sewer pump-out agreements that includes provision for a pump-out service and a security for this pump-out. The template in Attachment A of SC6.4.7.3 Sewer pump out agreements may be used for the Agreement.

SC6.4.7.1.4 Early release of the plan of survey

(1) Justification for early release

Council may elect to release plans of survey prior to satisfaction of the development permit on the basis that critical works are provided and security is afforded for the outstanding works. This process requires the developer to request the early signing in writing at the time of lodging a survey plan and payment of a fee, demonstrating how conditions of the development approval are satisfied or secured.

Early approval and dating of the Plan of Survey does not discharge the developer from obligations to satisfy the conditions of development approval, and the development may be subject to enforcement action for non-compliance with the development permit(s) and/or the undertaking given to complete the outstanding works.

The aim of this clause is to enable the developer to have the Plan of Survey released from the council as early as possible while at the same time ensuring that the allotments being constructed will be fully serviced at the time that the Plan of Survey is registered and subsequent sales of the allotment takes place.

(2) Early release of survey fees

A fee for the early release of the Plan of Survey in accordance with council's schedule of fee's and charges at the time of payment will also be required as payment separate to the incomplete works bond.

(3) Minimum requirements

Council will not sign any Plans of Survey where the relevant works or matters are incomplete, unless the following are completed:

(a) Early Plan of survey on maintenance inspection

An on maintenance inspection must be satisfactorily completed in accordance with SC6.4.7.1.2(4) and as detailed below, however some minor defects may be outstanding, with minor defects defined as those not impacting on public safety and/or the ability of council to operate and maintain the infrastructure.

(b) Earthworks

All allotment preparation work and earthworks on allotments to be 100 per cent complete in accordance with the requirements of SC6.4.6.10 Earthworks (construction), with finished surface levels, the degree of compaction achieved and geotechnical assessments required on any of the allotments submitted and approved by council. All works within allotments must be fully completed and no further disturbance required on the allotments. Appropriate erosion and sediment control measures must also be in place for all disturbed areas.

(c) Sewerage

All sewerage works including pump stations, rising mains, trunk mains and the proposed sewers have been inspected and certified by the supervising engineer as being 100 per cent complete and in full working order. Sewer systems must be installed, tested and operational. (Bonding of pump stations may be accepted; refer to SC6.4.7.1.3(4)). Conduit inspection must be undertaken in accordance with SC6.4.2.2.6 Conduit assessment.

(d) Water

All works associated with water supply on site are 100 per cent complete, and all reticulation has been pressure tested, sterilised, completed and connected to an existing supply. All water pumping stations must be certified by an RPEQ as being 100 per cent complete and in full working order.

(e) Roads

Roads must be completed to the point where the pre-seal inspection has been carried out by council's inspectors and the pavements are approved for application of bitumen or asphalt.

(f) Stormwater

(i) Stormwater drainage works must be installed with all erosion controls in place and able to function without detriment to the system. Allotments must be provided with the nominated flood immunity. All stormwater systems must be constructed, including kerb and channel. Downstream drainage easements must have been executed in favour of council, necessary drainage, other easement documentation must have been submitted, and required reserves for drainage, parkland, etc. must have been provided.

(ii) This excludes large WSUD measures such as bio-retention basins and wetlands, where the acceptance of the asset and ongoing maintenance requirements is to be in accordance with SC6.4.3.9 Water sensitive urban design guidelines.

(g) Services

Evidence must be provided of street lighting, telecommunications and electrical supply works commitments. Satisfactory evidence must be provided to council of a negotiated agreement with service providers for telecommunications and broadband infrastructure, reticulation of electricity (e.g. Letter of Supply) and the provision of street lighting and gas service providers for provision of gas (if gas is provided).

(h) Payments and bonds

(i) The full payment of fees and bonds, including the maintenance bond and any bonds for incomplete works. The maintenance bond will be 5 per cent of the value of the works as certified by the RPEQ and accepted by council, and must be lodged with council until the development is accepted as off maintenance.

(ii) All outstanding levied rates are paid.

(iii) All infrastructure charges required by the conditions of approval must be paid.

(iv) Accompanied by the prescribed form and fee of an amount in accordance with council's fees and charges current at the time of payment.

(i) Land

The developer must covenant that all transfers of land and interests in land to council are free of encumbrances and registered in the Title's Office at the same time as the Plan of Survey is registered at no cost to council.

(j) As constructed plans

As constructed plans must be submitted in accordance with SC6.4.7.1.2(2) showing all works completed to date, including as a minimum, the requirements above in parts (a) – (i). All works not shown on the as constructed drawings at the time of submission for early release of Plan of Survey, will be required to be bonded in accordance with the requirements of this section.

(4) Timing

All incomplete works must be completed and ready for council inspection within 1 month of council releasing the Plan of Survey. Should the developer not be able to meet this requirement they must submit justification to council detailing exceptional circumstances. The RPEQ must submit for the approval of council, a program of works to certify that the incomplete works can be completed within 1 month (or longer as agreed by council).

(5) Sewer pump stations

Early release of the Plan of Survey may be considered if council developed sewer pump stations are almost complete. See SC6.4.7.1.3(4) for more information.

SC6.4.7.2 On maintenance/final completion/off maintenance requirements

SC6.4.7.2.1 Introduction

This sub-section provides guidance and advice for the requirement for on maintenance/final completion/off maintenance to facilitate the release of the plan of survey (see SC6.4.7.1 Release of the plan of survey).

SC6.4.7.2.2 Lodgement

(1) Requirements for on maintenance:

(a) building approval for all buildings/structures, where required by the *Building Code of Australia* (BCA);

(b) a supervision certificate from the Consulting Engineer and request to have the works accepted on maintenance;

(c) a workmanship guarantee from the Contractor;

(d) submission to and acceptance by council of as constructed information. The RPEQ must certify the "as constructed" drawings by including the following statement on each drawing:

I/We (Name) of (Firm) hereby certify that the works as shown on the as constructed drawings reflect any changes that were made during the course of construction (signed with RPEQ No and dated);

(e) a Registered Surveyor must certify that the locations, surface and invert levels of all works and infrastructure presented on the as constructed drawings and digital submissions have been surveyed and are true and accurate representations of the works by including the following statement on each relevant as constructed drawing:

I/We (Name) of (Firm) hereby certify that this drawing accurately describes and records the nature and the location of the works depicted hereon as they have been constructed for the purposes of the development (signed and dated);

(f) infrastructure agreements, if required, must be in place for the provision of and/or connection to trunk infrastructure;

(g) approval by other authorities, e.g. evidence of NBN Agreement, or Certificate of Acceptance from Ergon;

(h) the works must remain on maintenance for a minimum period of 12 months;

(i) the works subject of other approvals for which the works of this approval are dependent must also have been accepted on maintenance; and

(j) where on maintenance can be achieved within 1 month of the release of the plan of survey then the date for the on maintenance will be backdated to the date of the release of the plan of survey. Otherwise, on maintenance will be from the date that all requirements have been satisfied.

SC6.4.7.2.3 Sewer

(1) Requirements for on maintenance:

(a) pressure test all sewers and manholes in accordance with WSA to ensure the requirements of the specification are met;

(b) check by internal examination (closed circuit television) that all sewers are straight, clean and to grade. Conduit inspection must be undertaken in accordance with SC6.4.2.2.6 Conduit assessment;

(c) check that all manholes are sound, smooth and clean and benched as per the required standard;

(d) check that house connection "jump up" construction complies with council's standards;

(e) performance testing of pumping equipment. This testing will require the connection of the electricity supply and water to the pump station;

(f) certified results of pressure tests on all mains;

(g) certified results of field tests on pumping equipment;

(h) operations manual, performance specifications and maintenance requirements for all pump stations; and

(i) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications.

SC6.4.7.2.4 Water

(1) Requirements for on maintenance:

(a) pressure test and supervise the swabbing and sterilisation of the water mains (if necessary);

(b) check location of hydrants and valves to ensure they are in their correct location;

(c) check that all valves and hydrants are working satisfactorily(include lid arrangement as per SD-350;

(d) when water mains have been constructed, mains must be commissioned in accordance with council requirements;

(e) certified results of pressure tests on all mains;

(f) certified results of field tests on pumping equipment;

(g) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications; and

(h) no concrete footpaths installed over water main where property connections are yet to be constructed.

SC6.4.7.2.5 Earthworks

(1) Requirements for on maintenance:

(a) all survey pegs placed; and

(b) compaction results of each layer of earthworks on roads and on each allotment where depth of fill exceeds 0.5 m. The maximum depth of fill on each lot must be indicated on the as constructed drawings. Allotment fill must be in layers no greater than 200 mm and compacted a minimum standard of 95% standard compaction for residential subdivision and 98% standard compaction for commercial subdivision. The fill material must be free of vegetation and organic material.

SC6.4.7.2.6 Roads

(1) Requirements for on maintenance:

(a) roads must be completed and fully sealed;

(b) all tests and hold point documentation completed and finalised;

(c) pavement line markings completed, including passing and turning lanes at major intersections;

(d) where a double coat bitumen seal has been used, copies of bitumen spray sheets and calculated average spray rate and aggregate spread rate are required;

(e) where asphaltic concrete surfacing has been used, test results on samples of the material supplied to the site must be taken at the Asphalt Plant together with field tests to confirm asphalt depth and percentage of voids filled;

(f) all traffic control devices, including traffic islands, to be completed;

(g) all traffic signage to be in place and completed in accordance with *Manual of uniform traffic control devices'* requirements;

(h) traffic signals, if present, to be installed, completed and fully functional in accordance with the relevant requirements and legislation;

(i) retaining walls within road reserve to be completed and maintenance requirements documented;

(j) fences and noise abatement or screening walls to be completed and maintenance requirements documented;

(k) compaction results of subgrade and each course of pavement; and

(l) grading, Atterberg limits and a California Bearing Ratio (CBR) test of each course of pavement material in accordance with SC6.4.5.3 Quality management system.

SC6.4.7.2.7 Stormwater

(1) Requirements for on maintenance:

(a) stormwater drainage works must be installed with all erosion controls in place and able to function without detriment to the system. Allotments must be provided with the nominated flood immunity. All

stormwater systems must be constructed, including kerb and channel. Downstream drainage easements must have been executed in favour of council, necessary drainage and other easement documentation must have been submitted, and required reserves for drainage, parkland, etc. must have been provided;

(b) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications. Conduit inspection must be undertaken in accordance with SC6.4.2.2.6 Conduit assessment;

(c) performance testing of pumping equipment. This testing will require the connection of the electricity supply and water to the pump station;

(d) certified results of field tests on pumping equipment;

(e) operations manual, performance specifications and maintenance requirements for all pump stations; and

(f) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications.

This excludes large water sensitive urban design (WSUD) measures such as bio-retention basins and wetlands, where the acceptance of the asset and ongoing maintenance requirements is to be in accordance with SC6.4.3.9 Water sensitive urban design guidelines and SC6.4.6.1 Water sensitive urban design construction and establishment guidelines.

SC6.4.7.2.8 Landscaping and irrigation

(1) Introduction

This clause outlines the conditions and timeframes associated with acceptance by council of landscape and irrigation works (Works) constructed as part of a Development Permit.

(2) Principles

(a) the establishment period will be included within the maintenance period;

(b) council will accept works on maintenance that have reached practical completion and have met the relevant conditions of the Development Permit, but may still require time to establish;

(c) the establishment date will be used to determine satisfactory establishment;

(d) council will accept responsibility for maintenance of hard landscape assets from the on maintenance date;

(e) the Developer will remain responsible for maintenance of soft landscape assets during the maintenance period;

(f) the Developer is responsible for all defects in the works until the off maintenance date; and

(g) council will accept responsibility for maintenance of soft landscape assets from the off maintenance date.

(3) Terminology

In addition to the terms previously defined in SC6.4.7.1.1(2) the following terms and definitions apply to this clause, specific to landscape and irrigation works:

Contractor	A person or company who has entered into a contract with the developer to supply and install infrastructure, landscaping and/or an irrigation system.

Establishment period	The period of time between when council accepts the works on-maintenance until when council accepts the works as established (the established date). Works are deemed established when: (i) all the defects identified at the on-maintenance and practical completion; (ii) defects identified at inspection have been rectified unless agreed otherwise; (iii) all turfed areas have "taken root" and there are no obvious gaps between strips of turf; (iv) all turfed areas have been rolled and/or topdressed to fill any depressions; (v) all plants are showing signs of healthy, new growth, and that the planting design intent is starting to take shape; (vi) generally, the landscape works indicate that they are being maintained in accordance with the Development Permit; and (vii) revegetation areas have achieved specified cover.
Hard landscaping	Structures, paths and facilities such as playground equipment constructed from building materials (but excluding irrigation systems).
Maintenance period	The period of time between when council accepts the works on-maintenance until council accepts the works off maintenance. This includes any establishment periods and the defect liability period. This is to be: (i) a minimum of 12 calendar months; and (ii) include the establishment period and the defect liability period.
Off maintenance date	The date the works are fully accepted by council following an inspection by council, which considers that all works are satisfactory, and the defects liability period concludes. This date must be: (i) after the established date; (ii) after all defects have been remedied; (iii) at least 12 months after the on maintenance date; (iv) after an inspection by council which considers that all works are satisfactory.
Soft landscaping	Trees, plants, grass and vegetation generally and any irrigation system associated with such vegetation.

(4) Ownership and responsibilities

The ownership of the works transfers to council on the earlier of:

(a) the date when the land on which the works are constructed is transferred to council; or

(b) the on maintenance date.

(5) Typical timelines

(a) Construction

(i) achieve practical completion;

(ii) conduct inspections to determine the on maintenance date; and

(iii) release Plan of Survey if applicable.

(b) 0 weeks

(i) on maintenance date.

(c) 12 weeks

(i) normal established date;

(ii) landscape inspection to be carried out; and

(iii) if works are unsatisfactory, establishment date will be deferred.

(d) 52 weeks

(i) normal off maintenance date;

(ii) landscape inspection to be carried out; and

(iii) if works are unsatisfactory the off maintenance date will be deferred.

(6) Landscape works on maintenance/practical completion

(a) Requirements for on maintenance:

(i) maintenance inspection;

(ii) the Registered Landscape Architect must certify as constructed drawings by including the following statement on each drawing:

I/We (Name) of (Firm) hereby certify that the works as shown on the "as constructed" drawings reflect any changes that were made during the course of construction;

(iii) all asset transfer documentation is submitted and approved by council including the following:

(A) Open Space Asset Data Collection Form – This form contains the asset information relating to the construction of new assets; or

(B) Asset Change Form – This form contains information about minor changes to existing assets; and

(C) warranty details for all items with a value greater than $500.00. This information is required by council to assist in future warranty claims;

(iv) plantings, gardens and turfed areas must be exhibiting a "strike", but compliance with full establishment requirements is not essential at on maintenance;

(v) the defects liability period for soft landscape works shall be concurrent with the defects liability period for any associated irrigation system; and

(vi) the defects liability period for landscape works shall not commence until:

(A) the associated irrigation system has been commissioned; and

(B) all requirements of the Special Conditions of Approval have been met.

(7) Landscape works defects liability period

(a) Establishment

(i) All soft landscaping will be subject to a 12 week landscape establishment period. The landscape establishment period is included in the 12 month maintenance period. The Developer is responsible for establishing the works during the establishment period until the established date as advised by council.

(ii) The developer may be required to undertake additional works during the establishment period such as additional watering, formative pruning, topdressing, turfing, replenishment of mulch and replacement of plants.

(iii) At the conclusion of the landscape establishment period a landscape establishment inspection may be conducted, and if the landscaping establishment is not satisfactory additional works may be requested and/or the maintenance period may be extended.

(b) Landscape maintenance period requirements and responsibilities

(i) Council is responsible for maintenance of hard landscaping during the maintenance period.

(ii) The developer is responsible for maintenance of soft landscaping during the maintenance period until the off maintenance date.

(iii) Water costs

(A) The developer is responsible for the cost of water during the maintenance period.

(B) Council is responsible for cost of water from the off maintenance date.

(iv) Vandalism, theft and damage caused by unexpected events or third parties

(A) For soft landscaping, the developer is responsible for rectification works to remedy vandalism, theft and damage caused by unexpected events during the maintenance period.

(B) For hard landscaping, the council is responsible for rectification works to remedy vandalism, theft and damage caused by unexpected events during the maintenance period.

(v) Extended maintenance periods

(A) In addition to provisions detailed, where negotiated as conditions of the development approval, extended maintenance period beyond the 12 month period may apply.

(B) Where the landscape maintenance period is extended as a condition of development approval or due to provisions within this policy, this extension may concurrently apply to any irrigation system associated with the landscape works.

(vi) General maintenance activity requirements

(A) All maintenance activities must be undertaken in accordance with council's public open space maintenance specifications. Any maintenance activities that deliver a level of service above and beyond council's specification is at the discretion and cost of the developer.

Editors Note - council's Public open space maintenance frameworks are currently under development.

(B) Maintenance activities include, but are not limited to mowing, top dressing, litter collection, watering, pruning, fertilising, weeding, mulching, pest and disease control.

(C) All maintenance work to new and existing landscaping shall be carried out in accordance with the best horticultural practices.

(vii) Watering requirements

(A) All soft landscaping shall be watered regularly (either by hand watering or by irrigation) to ensure the continuing healthy establishment and growth of all plants taking into account soil type, plant type and size, prevailing weather conditions and seasonal variations.

(B) Watering methods are to be suitable for watering the root ball of newly planted plants during the critical first several weeks of establishment.

(C) Watering shall not cause displacement of mulch or erosion of garden mix soil.

(viii) Weeding, pest and disease control

(A) Gardens and turf shall be regularly weeded. Six weeks prior to the end of the defects liability period ("off maintenance"), the area shall be inspected for weed growth and treated with an appropriate selective herbicide. All chemicals shall be used in accordance with the manufacturer's recommendations.

(B) Plants shall be regularly inspected for pest and diseases throughput the defects liability period. Any pest or disease detected shall be reported to the Superintendent. Acceptable horticultural techniques shall be employed by the Contractor to manage any infestations as directed by the Superintendent. 12 weeks prior to the end of the defects liability period ("off maintenance"), the area shall be inspected for pests and disease and treated with an appropriate pest and disease control.

(ix) Planting and tree maintenance

(A) All maintenance work to new and existing trees shall be carried out by an arborist with formal qualifications or at least 5 years recognised experience in Arboriculture. The works shall be carried out in accordance with the AS 4373 *Pruning of Amenity Trees* and shall not proceed without the written approval of the Superintendent.

(B) Stakes and ties and guying shall be checked for firmness and support and shall be adjusted as necessary to prevent any damage to the bark or roots of the tree. Stakes and ties or guying shall be removed when the tree is self-supporting and/or as directed by the Superintendent.

(x) Planting, trees, turf and hydroseed failure and replacement

(A) Plants and trees lost through vandalism, theft or that have died shall be replaced by the Contractor on a monthly basis.

(B) Plants, trees, and turf supplied by the Contractor that have failed to become established during the defects liability period or are diseased and/or dying shall be removed and replaced by the Contractor twelve weeks prior to the end of the defects liability period ("off maintenance") and at no cost to council. If the loss is significant, it will be at the discretion of the Superintendent if an extension on the defects liability period for the failed landscaping is warranted.

(C) Areas of hydro seeding/mulching that have failed to become established or have died during the defects liability period shall be removed and retreated by the Contractor at no cost to council. If the area is of significant size it will be at the discretion of the Superintendent if an extension to the defects liability period for the failed area is warranted.

(8) Landscaping inspections during the defects liability period

In addition to the requirements outlined in SC6.4.7.2.8(2) Principles, the following requirements apply to landscaping works:

(a) any work inspected that does not comply with the specification and/or the design plans or has not been adequately maintained in accordance with SC6.4.7.2.8(2) will not be accepted by council and will be noted for rectification. The contractor is required to rectify these items as soon as is practical and as a minimum before the next scheduled inspection; and

(b) failure by the Contractor to rectify unacceptable items prior to the next inspection may result in the defects liability period for those items being extended by the number of weeks that have lapsed prior to the rectification work being completed.

(9) Landscaping off maintenance/final completion

(a) Final inspection and completion

(i) Soft landscaping shall be inspected by the Superintendent for acceptance ("off maintenance") at the end of the defects liability period, subject to any special conditions of approval.

(ii) In addition to the requirements outlined in SC6.4.7.2.8(2), the final inspection and completion requirements apply as detailed below.

(b) Final acceptance criteria (Gardens)

The acceptance criteria for gardens shall be:

(i) gardens shall be free from weeds, stones, roots, sticks, rubbish and other deleterious material;

(ii) gardens shall be free of disease and pests;

(iii) mulch shall be to the minimum thickness specified;

(iv) plants shall be as specified; and

(v) plants shall be placed at the spacings nominated and in the quantities nominated as detailed on the drawings or as specified.

(c) Final acceptance criteria (plantings)

The acceptance criteria for plants shall be:

(i) plants shall exhibit signs of healthy active growth;

(ii) plants shall show no signs of yellowing or wilting;

(iii) plants shall be well formed;

(iv) plants shall be free of disease and pests;

(v) plants shall have healthy root systems and shall not be root bound; and

(vi) plants are true to cultivar, type or form as specified.

(d) Final acceptance criteria (turf)

The acceptance criteria for turf areas shall be:

(i) the achievement of an even green colour with a dense sward over the entire area with no open joints;

(ii) turf shall exhibit signs of healthy active growth;

(iii) turf shall be free from weeds, stones, roots, sticks, rubbish and other deleterious material; and

(iv) turf shall be free of disease and pests.

(e) Final acceptance criteria (hydro seeding/mulch)

The acceptance criteria for hydro seeding/mulch areas shall be:

(i) the achievement of an even green colour over the entire area and exhibiting healthy active growth with acceptable vegetative cover. Of this cover 95% shall be the nominated dominate grass species with the remaining 5% made up of annual and perennial grasses;

(ii) free from weeds, stones, roots, sticks, rubbish and other deleterious material;

(iii) free of disease and pests; and

(iv) the area shall not be mowed for at least 5 days prior to the inspection.

(f) Final inspection documentation

(i) Following the final inspection (off maintenance) council will issue a site inspection report (defects list). Any items not acceptable to council will be noted for rectification.

(ii) The Contractor is required to rectify these items and apply for a re-inspection when all rectification items have been completed.

(iii) A certificate off final completion will be issued by council following the rectification of all defects noted at the off maintenance inspection.

(10) Irrigation works on maintenance/practical completion

(a) Requirements for on maintenance:

(i) all as constructed drawings and documentation nominated in SC6.4.7.2.8(2) is submitted and approved by council;

(ii) all asset transfer documentation including the following:

(A) Irrigation Asset Data Collection Form – This form contains the asset information for the construction; or

(B) Irrigation Asset Change Form – This form contains information about minor changes to existing assets;

(C) Irrigation Network Controller Setup Request Form – This form is used to provide information to the infrastructure Services Irrigation Technician who will configure the telemetry network. The form shall be submitted to council a minimum of 4 working days prior to commissioning of the system;

(D) Irrigation Program Setup Request Form – This form is used to provide information to the infrastructure Services Irrigation Technician who will setup the irrigation controller program. The form shall be submitted to council a minimum of 4 working days prior to commissioning of the system. After the program has been set up, the Infrastructure Services Irrigation Technician will issue a copy of the program to the Contractor;

(E) Warranty details for all irrigation components with a value greater than $500.00 excluding GST. This information is required by council to assist in future warranty claims; and

(F) Plumbing and Drainage Application Forms 1, 2 and 7 are to be completed by a licensed plumber and submitted to the Hydraulic and Building Services Unit of the Townsville City Council. The Backflow Test Certificate must be lodged with Hydraulic and Building Services Unit of the Townsville City Council. A copy of the Backflow Test Certificate must also be supplied to Infrastructure Services; and

(iii) commissioning of the irrigation system shall not proceed until all of the above documentation is submitted and approved by the council.

(11) Irrigation defects liability period

(a) A defects liability period applies to all irrigation systems installed by contractors. The defects liability

period shall be undertaken in accordance with this policy and any special conditions of approval.

(b) If applicable the defects liability period for the irrigation system shall be concurrent with the Defects Liability Period for any associated landscaping works.

(c) The defects liability period for an irrigation system shall not commence until:

(i) all of the documentation nominated in SC6.4.7.2.8(10)(a) above is submitted and approved by council;

(ii) all requirements of the special conditions of approval have been met;

(iii) if applicable the associated landscaping works are accepted “on maintenance”;

(iv) the irrigation system has been commissioned; and

(v) the site has been jointly inspected by the council and contractor and the irrigation system is free of defects at the time of inspection.

(12) Irrigation inspections during the defects liability period

During the defects liability period, council may require access to the site to undertake the following tests:

(a) main lines pressure test – the main line is pressurised to test for leaks. All valves are shut and the pressure is taken over a determined length of time;

(b) sprinkler pressure test – the sprinkler pressure is taken at the nozzle using a pitot pressure gauge and is then compared to manufacturer recommendations;

(c) dripper pressure test – measurement at flushing valves are taken and the pressure gauged to make sure it conforms to the manufacturer recommendations. The inlet pressure is then tested under the same conditions to check it does not exceed 300Kpa; and

(d) lateral pressure loss test – the first and last sprinklers of the lateral line are pressure tested. The variation in flow is then calculated and compared with the limits nominated in the specification.

(13) Irrigation off maintenance/final completion

(a) Final inspection and completion
Final completion shall be managed in accordance with this policy and any special conditions of approval.

(i) Following the final inspection, council will issue an irrigation inspection defects list detailing items that do not comply with the specification and/or design plan.

(ii) The contractor is required to rectify these items and apply for a reinspection when all rectification work has been completed.

(iii) After reinspection of the rectification work, and if the work is satisfactory to council an Irrigation Inspection Report (Defects List) will be issued with the status noted as “Ready to proceed to off maintenance”.

(iv) A Certificate of final completion will be issued by the Superintendent when the Contractor has met all obligations under the Contract.

SC6.4.7.2.9 Quality assurance documentation

(1) Requirements for on maintenance

(a) Copies of the Test Certificates from a National Association of Testing Authorities (NATA) registered laboratory; and

(b) A single quality control document must be submitted, including but not be limited to:

(i) pavement levels;

(ii) compaction tests;

(iii) pavement materials tests;

(iv) concrete tests;

(v) asphalt tests;

(vi) sewer pressure tests;

(vii) water pressure tests;

(viii) water bacteriological tests;

(ix) landscaping soil tests;

(x) playground and fitness equipment certification;

(xi) softfall under surfacing certification;

(xii) structural certification (forms 15, 16 and 21);

(xiii) electrical safety, testing compliance certification; and

(xiv) backflow certificate.

SC6.4.7.2.10 Defects liability period

The defects liability period for all works is a minimum of 12 months from the date of the release of the formal plan of survey or from the date of acceptance on maintenance, whichever is later, at which time the bond will be refunded subject to the off maintenance requirements being completed to the satisfaction of council. If for any reason during the maintenance period, a defect of substantial proportions is discovered then council reserves the right to extend the defects liability period for a further 12 months from the date of correction of the defects, or as negotiated e.g. infrastructure is required to be reconstructed after a significant failure due to deficiency in design/construction.

SC6.4.7.2.11 Bonds and fees advice

(1) Requirements for on maintenance

(a) A works inspection fee (at the rate applicable at the time of payment) must be paid prior to the works being accepted.

(b) A reinspection fee (at the rate applicable at the time of payment) will be applicable where an additional inspection is required due to works being incomplete or unsatisfactory at the initial inspection. The reinspection fee must be paid prior to the additional inspection being conducted.

(c) A maintenance bond (5% of the value of the works as determined and certified by a Registered Professional Engineer of Queensland (RPEQ) or Registered Landscape Architect) and supporting Schedule of Works with costs certified by the RPEQ or Registered Landscape Architect must be lodged with council. The bond must be in favour of council and in the form of cash or an unconditional bank guarantee (non-expiring). If the security is in the form of a bank guarantee, the guarantor must be a bank or financial institution acceptable to council.

(d) In the event of a default by the developer relating to defects, council may undertake whatever action required to secure compliance with the conditions of approval and may apply the security for that purpose. The security (or balance) will be returned to the developer upon satisfaction of the conditions of approval relating to maintenance responsibility.

SC6.4.7.2.12 On maintenance inspection and final inspection and compliance check

(1) Requirements for on maintenance:

(a) The developer must provide council at least 5 business days' notice, requesting the works be checked for compliance with the approvals and be accepted on maintenance.

(b) A report must be submitted, showing the scope of works, date and outcome of works inspected by the supervising Registered Professional Engineer of Queensland or supervising Registered Landscape Architect.

(c) Council must be satisfied with the results of an on maintenance inspection and compliance checks against the development approvals. Council will issue an On Maintenance Certificate, identifying the relevant works and any defects applicable.

(d) Prior to requesting an on maintenance inspection, the developer must correct any defects arising from faulty workmanship, materials or design identified in the On Maintenance Certificate or during the maintenance period (or extended period following rectification of such defects).

(e) The on maintenance date may be backdated to the date of the initial on maintenance inspection date or the release of the plan of survey (whichever is the latter), if all outstanding requirements were met within 4 weeks of identification.

SC6.4.7.2.13 Off Maintenance

(1) The works will become off maintenance subject to:

(a) rectification of all defects identified at on maintenance or during the maintenance period;

(b) council being satisfied with the results of an off maintenance inspection and compliance check against development approvals conducted by council officers following the end of the maintenance period;

(c) the development will only be accepted off maintenance in its entirety and all works must be performing satisfactorily at this stage;

(d) the developer, or their representative, must arrange with council an inspection of all defects 1 month prior to the work being due off maintenance;

(e) the whole of the works must be inspected at the off maintenance inspection. The consulting engineer is responsible for thoroughly inspecting the development and any necessary remedial work prior to the off maintenance inspection; and

(f) acceptance of the works off maintenance does not discharge the developer from their obligation to provide a development free of defects. Any defect that is discovered after the acceptance off maintenance, which attributed to the failure to deliver a development in accordance with the conditions of the development permit, must be repaired at the developer's expense.

SC6.4.7.3 Sewer pump-out agreements

SC6.4.7.3.1 Introduction

(1) Purpose

In accordance with SC6.4.7.1 Release of the plan of survey, council may consider early sealing of the survey plan for a development if:

(a) incomplete or non-commissioned trunk infrastructure is preventing the developer providing infrastructure from being fully commissioned; and

(b) the non-delivery of this trunk infrastructure is impacting on council's process for signing of the survey plan.

(2) Scope

This sub-section sets out the circumstances in which a sewage pump out agreement may be entered into, and the mandatory requirements that will be included in such an agreement under the *Sustainable Planning Act 2009.*

(3) Reference and source documents

This section shall be read in conjunction with the following standards and legislation:
Environmental Protection Act 1994
Local Government Act 2009
Plumbing and Drainage Act 2002
Sustainable Planning Act 2009
Water Supply (Safety and Reliability) Act 2008
WSA 02-2002 2.3 *Sewerage Code of Australia*
WSA 04-2005 2.1 *Sewerage Pumping Code of Australia*

SC6.4.7.3.2 Sewage pump-out deed of agreement requirements

(1) A Deed of Agreement relating to the incomplete or non-commissioned trunk infrastructure must be entered into. The agreement must ensure that all risks associated with the temporary pumping out and disposal of sewage are adequately addressed by the developer. The following sections must be addressed within the Deed of Agreement at a minimum:

(a) Timing

The trunk infrastructure must be programmed to be commissioned prior to when the completion of dwelling construction is envisaged.

(b) Supply of electricity

(i) Sewer pump stations must be provided with a continuous and reliable electrical supply. Details of the provision of power supply must be provided with the sewage pump station design.

(ii) Alternatively, if temporary power supply is proposed to be supplied by a generator, details of this arrangement must be included as part of the agreement.

(c) Lawful effluent disposal and access arrangements

Access arrangements for pump stations and/or other wastewater maintenance holes required for the pump-out service must be specified, and the wastewater maintenance hole or licensed septic disposal facility designated. The disposal of all sewage must be as directed by Townsville Water from time to time by a registered operator following agreed transport routes, for the duration of the agreement, and under the supervision of a suitably qualified engineering consultant.

(d) Developer's provision of pump-out service
A minimum standard for the developer's provision of a pump-out service must be specified.

(e) Management of odour complaints, fish kills and wastewater spills
Details of management of overflow/spills or environmental harm must be included in the Deed of Agreement and actions undertaken in accordance with the *Environmental Protection Act 1994.*

Click here to obtain a copy of the following form.

SC6.4.7.3.3 Template agreement

Council's Template Agreement for Sewage Pump-Out may be used to assist in the preparation of the Deed of Agreement (see SC6.4.7.3 Attachment A).

SC6.5 Economic impact assessment planning scheme policy

SC6.5.1 Introduction

Short Title - The planning scheme policy (PSP) may be cited as the Economic impact assessment PSP.

SC6.5.1.1 Purpose

(1) The purpose of this planning scheme policy is to provide applicants with direction on how to undertake an economic impact assessment which council request to inform the proper assessment of a development application. Particularly, the policy provides direction on the standard information requirements expected to be incorporated within an economic impact assessment report.

An economic impact assessment report may be required to demonstrate compliance with the Townsville City Plan particularly for significant in-centre or out-of-centre development of a commercial nature. It is likely to be required where there is potential conflict with the Townsville City Plan, or for impact assessable development of a commercial nature in any zone.

SC6.5.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016.*

SC6.5.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan.

SC6.5.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 – Definitions, is to be interpreted in accordance with Part 1.3.1 terminology.

SC6.5.2 Planning scheme policy details

SC6.5.2.1 Terms of Reference for an economic impact assessment report

(1) Council intends to protect the economic viability and the intended role and successful functioning of centres. An economic impact assessment report will need to demonstrate that the proposed development will meet the relevant performance outcomes in the planning scheme codes and the intentions expressed in the strategic framework. Where the development is inconsistent with the planning scheme the assessment may form part of the basis for determining whether sufficient grounds exist to approve such a development.

(2) The standard requirements for the preparation of an economic impact assessment report should typically provide the following information:

(a) an outline of the purpose of the study;

(b) a description of the methodology used;

(c) a description of the proposed size, function and tenancy mix of the proposed development, together with details of any pre-commitment;

(d) the identification of the proposed development's trade area, supported by the reasoning and methodology behind the identification of the area;

Note—Refer to section SC6.5.2.2 Trade Area of this policy for guidance on identification of trade areas.

(e) an examination of the population growth prospects and socio-economic characteristics of the trade area, including socio-economic factors such as expenditure potential;

(f) the identification of any approved or proposed development that may affect the proposed development or be affected by the proposed development;

(g) the identification of the location, size, nature, function and tenancy mix of competitive business, commercial or centre uses likely to be affected by the proposed development;

(h) evidence that any feasible alternative, appropriately zoned location/s have been investigated and discussed so that reasoning behind the selection of the preferred site is clear;

(i) an estimation of the demand, or likely future demand, for business, commercial or centre floor space in

the trade area;

(j) an estimation of the market share of the proposed development;

(k) where an out-of-centre development is proposed, demonstration as to why the proposed development is required, including why the development cannot be accommodated within the existing centres;

(l) commentary on changes to the supply/demand balance upon approval of the proposed development, including whether the proposal represents an excess of supply for the community;

(m) a calculation of the quantitative economic impact upon competitive centres likely to be affected by the proposed development including a description of the consequent effects on the competitive centres;

(n) the identification of the impacts the proposed development would have on the successful trading of other centres (including the period of time) and the identification of the impacts on the Townsville hierarchy and functionality of activity centres;

(o) the changes, if any, to the range of services that existing centres will continue to provide; and

(p) a summary of the overall need for the proposed development including a description of the community benefits.

(3) The economic impact assessment report referred to in (1) above must be prepared by a suitably competent person.

Note — For the purpose of this section of the planning scheme policy, a competent person is an appropriately qualified and experienced economist or economic analyst with appropriate and proven technical experience in providing advice about the economic impacts of development.

SC6.5.2.2 Trade Area

For developments that are trade area based, the definition of the trade area should have due consideration to the following:

(1) the existing centres hierarchy and other relevant competition;

(2) the nature, scale and functionality of the proposed development;

(3) the nature of the potential users of the development (e.g. residents, workers, students, other businesses);

(4) typical travel routes of potential users of the development; and

(5) the attracting capacity of any neighbouring uses.

A map(s) of the trade area should be included in the economic impact assessment report, which clearly defines the trade area boundary, identifies relevant existing centres, identifies the site of the proposed development and includes key transport corridors. The economic impact assessment report should include a justification of the proposed trade area boundary.

SC6.6 Emerging community planning scheme policy

SC6.6.1 Introduction

Short Title - The planning scheme policy (PSP) may be cited as the Emerging community PSP.

SC6.6.1.1 Purpose

The purpose of this planning scheme policy is to provide applicants with direction on how to undertake structure planning for a greenfield development area contained within an emerging community zone. Such a structure plan is likely to be required to demonstrate compliance with the zone code and reconfiguration of a lot code.

The provision of this planning scheme policy may also be relevant to other large scale development within the city.

SC6.6.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016.*

SC6.6.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in Parts 6 and 9. The Emerging community planning scheme policy specifically relates to the assessment of any development application for a material change of use or reconfiguring a lot within the Emerging community zone.

SC6.6.1.4 Terminology

Terms used in this planning scheme policy are as defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 - Definitions is to be interpreted in accordance with Part 1.3.1.

SC6.6.2 Planning scheme policy details

SC6.6.2.1 Structure planning framework

A structure plan prepared under this planning scheme policy will address the following aspects at a minimum:

(1) type of development and land uses proposed;

(2) scale, density and height of development;

(3) servicing of the development by transport and other infrastructure;

(4) how the proposal addresses the relevant planning scheme overlays; and

(5) integration of the development with the local context.

SC6.6.2.2 Structure plan contents

A structure plan should identify the major elements of the locality surrounding a development that can impact on the planning and design of the site. It does not constitute an approval for land outside the development site but ensures the continuation of corridors, networks and linkages.

The major components of the development are to be designed with consideration of this broader context. It must be clear how the proposed development will integrate with the surrounding community and with the existing parks, centres, service and infrastructure networks and the movement system (road network, public transport facilities and pedestrian and cyclist paths) in the area. Where necessary, the structure plan will identify upgrades to infrastructure which are required to achieve the development outcomes proposed in the structure plan.

(1) Preparing a structure plan:

The steps that should be followed and information provided when preparing a structure plan are outlined below. Separate maps and reports may be provided for each step.

(a) Step 1—Site context:

Prior to preparing the structure plan an assessment of the site and its context must be undertaken and a site description of the land prepared, supported by a map containing the following features as a minimum:

(i) topography—contours and levels;

(ii) the street network, intersections and treatments, and public transport routes and stops;

(iii) existing and approved land uses on surrounding sites (including subdivision layouts) and including the location of nearby schools, activity centres, employment generators and other community facilities; and

(iv) the existing and proposed park network and pedestrian and cyclist paths.

(b) Step 2—Constraints mapping (identification):

Land may possess attributes or be subject to constraints which affect the development on the site. State planning regulatory provisions and overlays must be considered as part of the constraints mapping process.

(c) Step 3—Constraints analysis, land use allocation and infrastructure provision:

The site context mapping (step 1) and identification of constraints (step 2) will inform a further detailed analysis of the conditions on the site. This process will seek to 'ground truth' the sites constraints. It will involve technical investigation to identify specific constraints and their implications on future development of the land. The outcomes of the constraints analysis will determine which land is able to be developed for urban purposes and will also provide guidance to suitable uses of the land.

The design response should consider:

(i) the proposed layout and land use mix are integrated appropriately with surrounding land;

(ii) constraints are reflected on the structure plan and are in accordance with their relevant values;

(iii) an appropriate and well-designed proposed transport network;

(iv) the development incorporates appropriate provision for infrastructure (water, sewer, stormwater, parks and community services) for the land and demonstrates how the infrastructure is able to be coordinated with adjoining development where applicable; and

(v) where needed, land uses buffers to other uses or values.

(d) Step 4—Documenting the structure plan:

The structure plan for the land may include the following, as relevant to the land:

(i) the vision and principles for the structure plan area;

(ii) appropriate controls for land use and density, connectivity, open space and public realm and built form and design;

(iii) identification of specific precincts with individual characteristics and development outcomes, as relevant to the land and the site constraints;

(iv) levels of assessment where this is proposed to be altered through a preliminary approval; and

(v) any alternative code provisions where these are proposed to be altered through a preliminary approval. Any proposed code is to be constructed to be consistent with the format of codes within the Townsville City Plan.

SC6.7 Flood hazard planning scheme policy

SC6.7.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Flood hazard PSP.

SC6.7.1.1 Purpose

The purpose of the planning scheme policy is to:

(1) provide background information on the derivation of the Flood hazard overlay identified as overlay maps OM-06.1 and OM-06.2; and

(2) provide applicants with additional information and guidance in meeting the requirements of the Flood hazard overlay code.

SC6.7.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016.*

SC6.7.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan and applies to the whole of the local government planning scheme area. Flood hazard PSP specifically relates to the assessment of Flood hazard overlay code.

SC6.7.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 – Definitions, is to be interpreted in accordance with Part 1.3.1 Definitions.

SC6.7.2 Background information

SC6.7.2.1 Flood mapping

The flood hazard overlay maps show flood hazard derived from numerous sources and include:

(1) Detailed flood modelling studies identified in SC6.7.2.1.1 of this planning scheme policy; and

(2) Interim flood assessment overlay mapping completed by the Queensland Reconstruction Authority and amended for local constraints by Townsville City Council.

SC6.7.2.1.1 Flood modelling studies

Flood modelling studies are complex technical investigations requiring a detailed understanding of catchment hydrological processes and floodplain hydraulic controls. Computer simulations are used to quantify runoff from rainfall and evaluate flow patterns and flooding extents around floodplains. There are numerous flood modelling studies which have been completed for the Townsville local government area. Results from these flood modelling studies have been combined to provide the Flood overlay maps.

At the commencement date of the planning scheme, the flood modelling studies that have contributed to the Flood overlay maps are:

(1) Alligator and Whites Creek Flood Study (Alligatorcreek);

(2) Althaus Creek Flood Study - Baseline Flooding Assessment (AlthausCk);

(3) Townsville Flood Hazard Assessment Study (Arcadia, NellyBay and PicnicBay);

(4) Balgal Beach Infrastructure Master Planning Report (BalgalBeach);

(5) Black River Flood Study - Baseline Flooding Assessment (BlackRiver);

(6) Bluewater Creek Flood Study (Bluewater);

(7) Captains Creek Flood Study - Baseline Flooding Assessment (CaptainsCreek);

(8) Deeragun Flood Study - Baseline Flooding Assessment (Deeragun);

(9) Douglas/Annandale Flood Study - Baseline Flooding Assessment (DougAnnan);

(10) Gordon Creek Flood Study - Baseline Flooding Assessment (GordonCreek);

(11) Horseshoe Bay Flood Study - Baseline Flooding Assessment (HorseshoeBay);

(12) Little Bohle River Flood Study - Baseline Flooding Assessment (LittleBohle);

(13) Lousia Creek Flood Study - Baseline Flooding Assessment (LousiaCreek);

(14) Lower Bohle Flood Study - Baseline Flooding Assessment (LowerBohle);

(15) Townsville State Development Area - Flood Modelling (LowerStuart);

(16) Middle and Upper Bohle Flood Study - Baseline Flooding Assessment (MiddleBohle and Upper Bohle);

(17) North Ward Flood Study - Baseline Flooding Assessment (NorthWard);

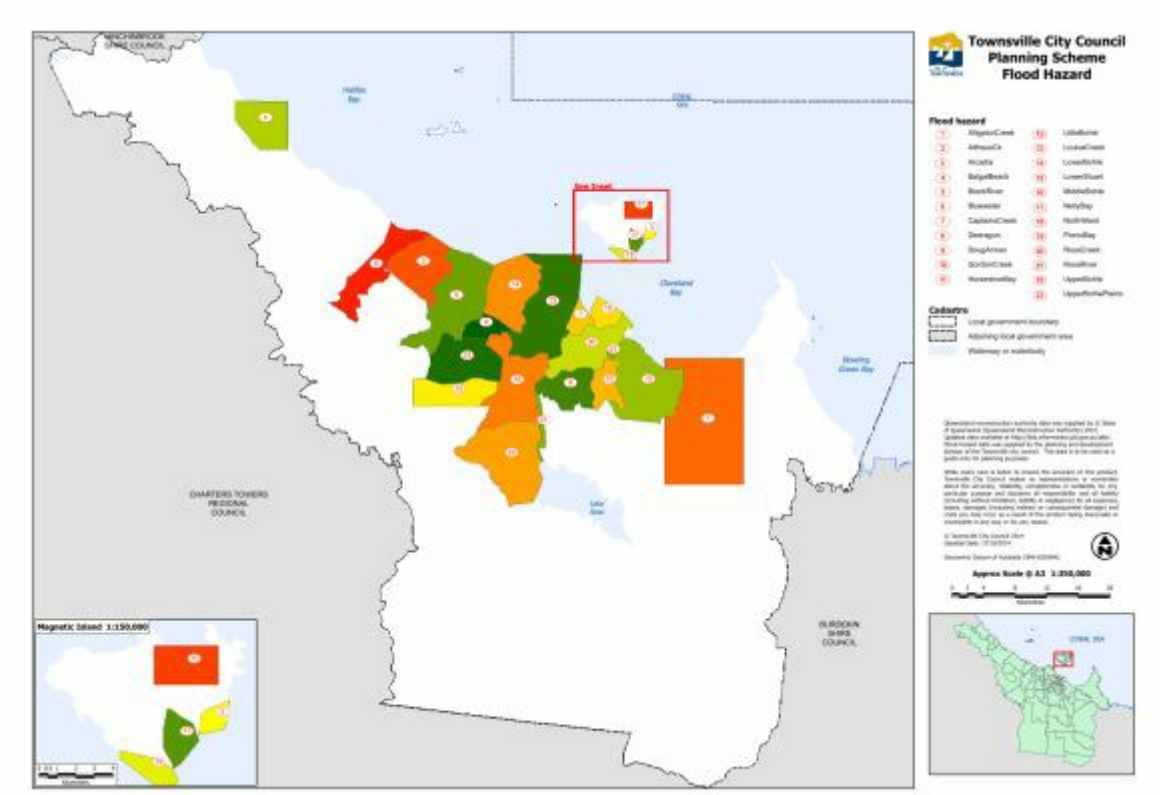
(18) Ross Creek Flood Study - Baseline Flooding Assessment (RossCreek);

(19) Ross River Flood Study - Baseline Flooding Assessment (RossRiver); and

(20) Upper Bohle Plains Flood Study - Baseline Flooding Assessment (UpperBohlePlains).

The area of applicability for each of the flood modelling studies identified in the aforementioned have been graphically presented on Figure SC6.7.1– Flood modelling study areas.

Flood modelling studies are under constant development due to the construction of infrastructure and the acquisition of new data. This information is available on Townsville City Council's website and contains digital copies of the latest and current flood modelling studies.



Click here to view PDF high resolution map.

Figure SC6.7.1 - Flood modelling study areas

SC6.7.2.2 Flood hazards

The Flood hazard overlay maps OM-06.1 and OM-06.2 have the following flood hazard ratings identified:

(1) high flood hazard;

(2) medium flood hazard;

(3) low flood hazard; and

(4) medium flood hazard – further investigation.

SC6.7.2.2.1 High and medium flood hazard

Both the high flood hazard and the medium flood hazard areas mapped on the Flood hazard overlay maps OM-06.1 and OM-06.2 are based on the 1% AEP flood. A velocity-depth criterion is used to distinguish between high flood hazard and medium flood hazard areas. High flood hazard areas are characterised by faster flowing and/or deeper floodwaters.

Figure SC6.7.2 – Flood hazard categorisation on 1% AEP flood (below) - shows the velocity depth criteria for designating the high flood hazard and the medium flood hazard areas from the 1% AEP flood. Velocity and depth information for the 1% AEP flood has been determined from flood modelling studies (refer SC6.7.2.1.1).

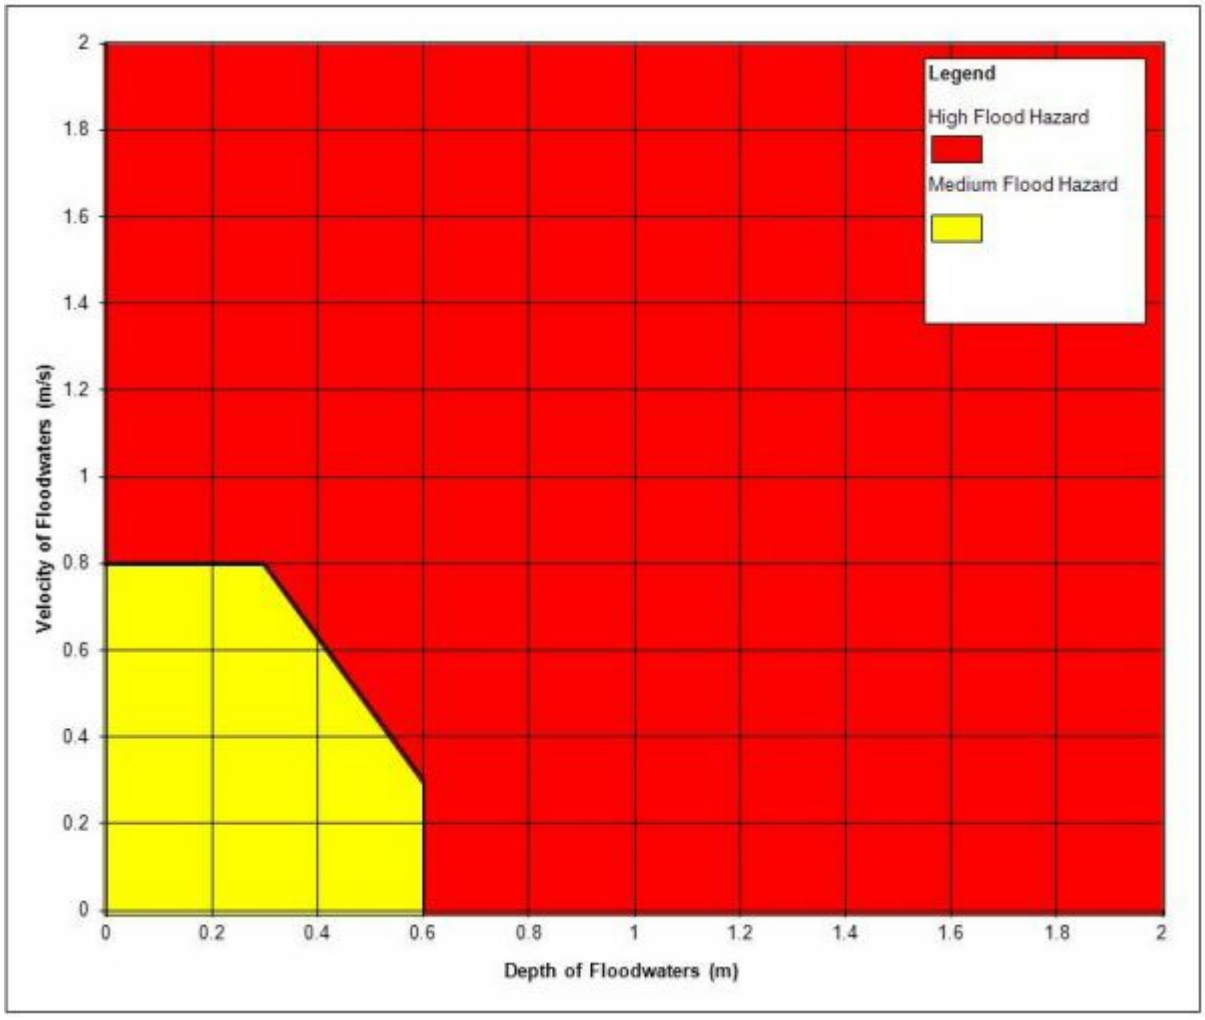


Figure SC6.7.2 - Flood hazard categorisation on 1% AEP flood

SC6.7.2.2.2 Low flood hazard

Areas of the floodplain outside the 1% AEP flood extent are still susceptible to flooding in rarer, more extreme flood events. Within the Flood hazard overlay maps OM-06.1 and OM-06.2, the low flood hazard area is identified as areas inundated by the probable maximum flood outside the combined extent of the high and medium flood hazard areas. The extent of the probable maximum flood has been determined from flood modelling studies (refer SC6.7.2.1.1).

SC6.7.2.2.3 Medium flood hazard - further investigation

Areas identified as medium flood hazard – further investigation on the Flood hazard overlay maps OM-06.1 and OM-06.2 are areas outside the extent of flood modelling studies and have been mapped by the Queensland

Reconstruction Authority. The Interim flood assessment overlay mapping produced by the Queensland Reconstruction Authority has been reviewed and amended by Townsville City Council to reflect local conditions. This information is less reliable than the other areas mapped on the flood hazard overlay maps OM-06.1and OM-06.2. Limited information is available on the flood characteristics in these areas as there is no information about flood depths, levels or velocities.

Within areas identified as medium flood hazard – further investigation, assessable development is likely to require further detailed flooding investigation, involving:

(1) development of a base-line flood study in accordance with Attachment 1 - Guidelines for preparation of flood studies and reports at a scale suitable to represent relevant floodplain process and site specific features;

(2) assessment of the potential impacts on flooding of the proposed development;

(3) identification of suitable measures to mitigate any adverse impacts on flooding; and

(4) demonstration of how the proposed development layout reduces the risk of flooding.

SC6.7.2.3 Defined flood level

Most development applications for which the Flood hazard overlay code is triggered will require details of the defined flood event (DFE). The DFE is the 1% AEP flood, which is spatially represented by the combined extent of the high flood hazard and the medium flood hazard areas mapped on the Flood hazard overlay maps OM-06.1 and OM-06.2.

For development which is accepted subject to requirements, it is most likely that existing information from flood modelling studies for the DFE will be adequate to address the acceptable outcomes of the Flood hazard overlay code. Information on the DFE derived from the flood modelling studies can be obtained from council's website.

SC6.7.3 Application requirements

This section provides information for a development application, guidance and advice for addressing assessment benchmarks.

SC6.7.3.1 Addressing assessment benchmarks

SC6.7.3.1.1

Development that is accepted subject to requirements and triggers the Flood hazard code only has to address the acceptable outcomes for performance outcomes 1 and 2 of the code.

Performance outcome 1
Development in medium and high hazard areas is designed and located to minimise susceptibility to and potential impacts of flooding.

Other than in the medium hazard - further investigation, council will be able to make available the height of the flood level for any particular location, upon request, where flood modelling studies have been undertaken (refer SC6.7.2.1.1).

In some areas, storm tide hazard areas will also co-exist with flood hazard areas. In these instances, the floor levels and other design responses will need to be sufficient to comply with both the Coastal environment overlay code, the Flood hazard overlay code and the *Building Regulation 2006*. Typically, floor levels will need to be based on the highest of either the defined flood level or the defined storm-tide level as depicted in Figure SC6.7.3.1.1.1-Floor control levels for both flooding and storm tide (below).

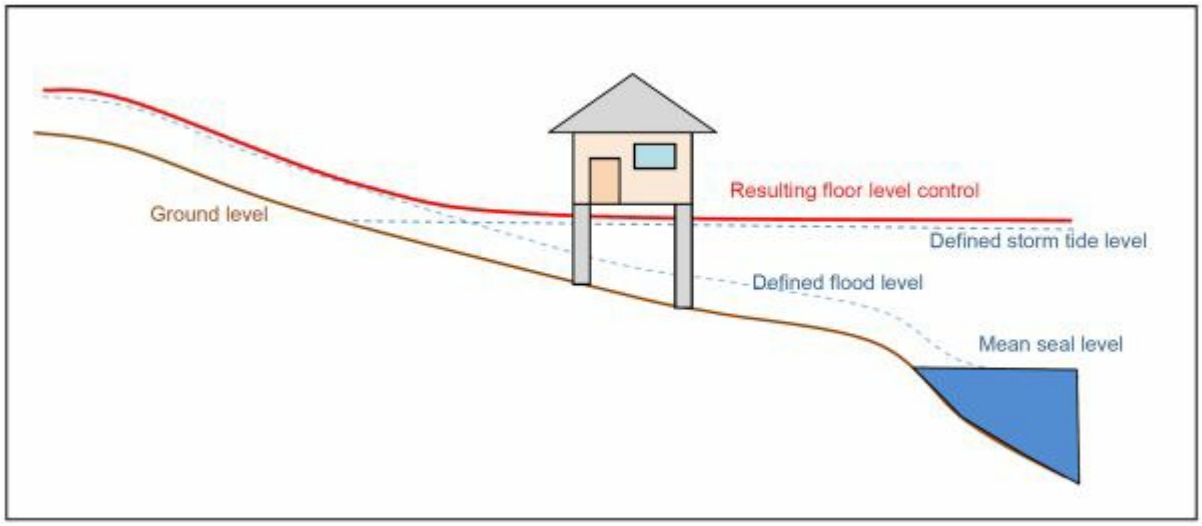

Figure SC6.7.3.1.1.1 - Floor control levels for both flooding and storm tide

Performance outcome 2

Development in high hazard areas does not significantly impede the flow of flood waters through the site or worsen flood flows external to the site.

The delineation of the high flood hazard areas on Flood hazard overlay maps OM-06.1 and OM-06.2 allows for clear identification of areas where performance outcomes 2 is applied.

Performance outcome 3

Development does not intensify use in high hazard areas, in order to avoid risks to people and property.

The delineation of the high flood hazard areas within Flood hazard overlay maps OM-06.1 and OM-06.2 allows for identification of areas where performance outcome 3 applies. Where flood flows are potentially altered by the development, a flood study will likely be required and the revised extent of the high flood hazard area will need to be mapped.

Performance outcome 4

Siting and layout of development maintains the safety of people and property in medium hazard areas.

Other than in the medium hazard – further investigation, council will be able to make available the height of the flood level for any particular location, upon request, where flood modelling studies have been undertaken (refer to SC6.7.2.1.1).

Alternatively, council's online flood mapping service can be used to obtain the height of flood levels for any particular locations.

Where flood flows are potentially altered by the development, a flood study will likely be required and the revised extent of the medium flood hazard area will need to be mapped.

Performance outcome 5

Signage is provided within high and medium flood hazard areas to alert residents and visitors to the flood hazard.

Signage will need to clearly state the nature of the flood hazard, with regards to inundation depths and flow velocities. Signage should also be able to function during a flood event and be practically visible.

Performance outcome 6

Development within high and medium flood hazard areas ensures any changes to the depth, duration, velocity of flood waters are contained within the site.

A flood modelling study, completed by a suitably qualified and experienced Registered Professional Engineer of Queensland (RPEQ), in accordance with Attachment 1 - *Guidelines for Preparation of Flood Studies and Reports*, will likely be required.

As a minimum, evaluating the impacts on floods up to the defined flood event will require a flood modelling study to evaluate the minor drainage system capacity event and the defined flood event for the catchment-wide critical duration and the site-specific critical duration. In addition, certain areas of the Townsville Local Government area will require evaluation of other frequency floods to assess adverse impacts on flooding. Attachment 2 – *Adverse Flooding Impacts Assessment – Additional Design Floods for Assessment* outlines areas where impact assessment and flood mitigation works will need to consider additional design floods to the minimum requirements.

To confirm adverse impacts on flood levels/depths, flow velocities and time of inundation are contained to the site; a pre- and post-development scenario will need to be assessed. Where possible, council requires the base-line flood modelling study that was used for deriving the flood hazard overlay to be used for evaluating development impacts. The RPEQ undertaking the impact study will need to determine if there is a need to update the base-line flood modelling with site specific survey/detail to adequately describe the hydrologic or hydraulic controls.

Performance outcome 7

Development within high and medium flood hazard does not directly, indirectly or cumulatively worsen flood characteristics outside the development site, having regard to:

(a) increased scour and erosion; or

(b) loss of flood storage; or

(c) loss of or changes to flow paths; or

(d) flow acceleration or retardation; or

(e) reduction in flood warning times.

To adequately assess the impacts of development on flooding regimes may require a hydrological and hydraulic assessment to be carried out by a suitably qualified and experienced hydrologist or engineer in accordance with Attachment 1 - *Guidelines for Preparation of Flood Studies and Reports.*

As a minimum, evaluating the impacts on floods up to the defined flood event will require a flood modelling study to evaluate the minor drainage system capacity event and the defined flood event for the catchment-wide critical duration and the site-specific critical duration. In addition, certain areas of the Townsville Local Government area will require evaluation of other frequency floods to assess adverse impacts on flooding. Attachment 2 – *Adverse Flooding Impacts Assessment – Additional Design Floods for Assessment* outlines areas where impact assessment and flood mitigation works will need to consider additional design floods to the minimum requirements.

To evaluate the potential for worsening flooding outside the development site; a pre- and postdevelopment scenario will need to be assessed. Where possible, council requires the baseline flood modelling study that was used for deriving the flood hazard overlay to be used for evaluating development impacts. The RPEQ undertaking the impact study will need to:

(a) determine if there is a need to update the base-line flood modelling with site specific survey/detail to adequately describe the hydrologic or hydraulic controls; and

(b) undertake analysis to adequately assess the potential for directly, indirectly or cumulatively impacting on flooding.

Figure SC6.7.1 – Flood modelling study areas of this PSP identifies which flood study has derived the flood hazard overlay in given areas.

Performance outcome 8

Facilities with a role in emergency management and vulnerable community services are able to function effectively during and immediately after flood events.

It is appropriate to have a higher level of flood immunity for critical community infrastructure. Table 8.2.6.3(b) within the Flood hazard overlay code outlines the required immunity for critical community infrastructure with a role in emergency management. The identified flood immunities within Table 8.2.6.3(b) should be used for setting flood levels as well as designing building services associated with the facility.

Performance outcome 9

Public safety and the environment are not adversely affected by the detrimental impacts of flooding on hazardous materials manufactured or stored in bulk.

The delineation of the low, medium and high flood hazard areas are shown the Flood hazard overlay maps OM-06.1 and OM-06.2 and allows for clear identification of areas where performance outcome 9 is applied.

Other than in the medium hazard – further investigation, council will be able to make available the height of the flood level for any particular location, upon request, where flood modelling studies have been undertaken (refer to SC6.7.2.1.1).

Alternatively, council's online flood mapping service can be used to obtain the height of flood levels for any particular locations.

SC6.7.4.1 Introduction

A flood study consists of the following parts:

(1) the hydrological determination to calculate the likely volume of water that results from the storm under consideration;

(2) the hydraulic determination to calculate the inundation levels and flow velocities that will most likely occur from the flow of water determined in the hydrological determination; and

(3) subsequent modelling to determine development impacts for the proposed development along with evaluation of works to mitigate the impacts of development.

Flood studies will be accepted based on approved inundation estimation calculation procedures and on observed historical records that can be quantified and related to an Average Recurrence Interval (ARI) by the use of the appropriate statistical flood frequency analysis procedure. It should be noted, use of historical records may allow for determination of inundation levels, however, will not be able to quantify the impacts on flooding of a development.

For analysis purposes a specific storm event is nominated as the benchmark event or standard to which council requires immunity against inundation for a development. That event is called the Defined Flood Event (DFE).

This guideline provides guidance on the appropriate use of given methods as well as some guidance on parameter values within the Townsville Local Government Area. There are numerous industry technical documents that detail the methods that should be consulted when completing flood studies including:

(1) Australian Rainfall and Runoff (AR&R); and

(2) Queensland Urban Drainage Manual (QUDM).

SC6.7.4.2 Catchment land use

Catchment land use is an important consideration for flood studies. The level of urbanisation within a catchment influences the volume of runoff and magnitude of peak discharges by:

(1) increasing the impervious fraction of the catchment which reduces the volume of infiltration and increases the total volume of runoff; and

(2) decreasing the time to peak discharge due to construction of open drains and stormwater networks which

concentrates flows and may increase the magnitude of peak discharges.

Strategies to avoid and increase in flooding as a result of any works may include:

(1) mitigation of flows at the individual development;

(2) catchment wide approach to mitigation of flows; or

(3) allowance for additional flow capacity within flow paths.

The strategy for accommodating flows will depend on existing land uses within the catchment and the environmental value of the watercourse. In preparing a flood study, **council must be consulted to identify the proposed approach to flood mitigation within the catchment.** The flood study may require assessment beyond the planning horizon in the current planning scheme, and make a determination of potential ultimate possible development or at least into the future for a period of 50 years, and even possibly 100 years.

As a general principle, drains are an opportunity to have several functions including providing flood mitigation for an area, however for the rest of the time they can be quite an effective open space for the community.

SC6.7.4.3 Hydrological determination

SC6.7.4.3.1 General

The hydrological process that is to be used for determining the design flows for the hydraulic modelling is to be cognisant of the proposed land uses. When calibration is being undertaken based on historical events, then the model being calibrated is to be based on the land use at the time of the storm event under calibration.

The choice of hydrologic method must be appropriate to the type of catchment and the required degree of accuracy. Simplified hydrologic methods such as the Rational Method should not be used whenever a full design hydrograph is required for flood mapping or to assess flood storage issues. Instead the more reliable runoff-routing techniques presented in publications such as Australian Rainfall & Runoff (ARR) should be adopted. Chapter 4 of the Queensland Urban Drainage Manual (QUDM) provides detailed guidance on the selection of an appropriate hydrologic method.

SC6.7.4.3.2 Hydrologic method

The hydrologic method adopted for the required analysis should be appropriate to the type of catchment and the design problem being assessed. Designers should be aware of the limitations, for each of the methods.

Approach	Applicability	Notes
Rational method	• Regular shaped catchment; • Homogenous catchments (generally uniform land use within the catchment); • Storage or timing issues are not relevant; • Rural catchments smaller than 25km^2; • Urban catchments smaller than 5km^2; • Time of concentration is likely to be less than 30 minutes; • **Rational method should only be used for drainage design as it is not appropriate for impact assessment at master planning stage.**	An appropriate method for calculating the time of concentration is essential to applying the rational method.
Synthetic unit hydrograph procedure	• Rural catchments; • Larger flood events where overbank flows are developed; • Rainfall can be assumed to be uniform across the catchment; • **Synthetic Unit Hydrograph Procedure has limited practical application in development assessment.**	Use of synthetic unit hydrograph procedures is not preferred and should preferably be undertaken by an experienced hydrologist with an extensive knowledge of the catchment.

Non-linear runoff-routing models (RORB, RAFTS, WBNM, URBS)	• Rural and Urban catchments (Rural only for RORB and all others should be used with caution in urban areas); • Storage or timing issues are relevant. • **Non-linear Runoff Routing Models are appropriate for drainage design or impact assessment at master planning stage, particularly for areas comprising both rural and urban land uses.**	Council uses RAFTS and requires any flood studies completed within the Townsville LGA to be completed using RAFTS. Models should be generally developed by suitably experienced practitioners, with appropriate verification / calibration of the models.
Time area runoff-routing models (DRAINS, ILSAX)	• Urban catchments with significant underground pipe network; • Storage or timing issues are relevant. • **Time Area Runoff Routing Models are appropriate for drainage design or impact assessment at master planning stage, particularly for areas only urban land uses.**	Models should be generally developed by suitably experienced practitioners, with appropriate verification / calibration of the models.
Direct rain on grid application in hydraulic model (MIKE FLOOD, TUFLOW)	• Flatter areas to prevent instabilities forming from flows down steep surfaces; • Study area needs to be small enough so that the model grid cell is not too large. • Storage or timing issues are relevant. • **Rain on Grid approach is appropriate for drainage design or impact assessment at master planning stage, and can represent areas comprising both rural and urban land uses.**	Although these methods are a component of hydraulic determination, they supplement the need for hydrologic determination and are gaining wider acceptance within the industry. Models should be generally developed by suitably experienced practitioners, with appropriate verification / calibration of the models.

Any hydrologic method using emerging technologies needs to clearly demonstrate:

(1) The approach and the principles it employs;

(2) Assumptions and limitations; and

(3) Appropriate calibration or verification.

SC6.7.4.3.3 Catchment parameters

Discussion on catchment parameters is required in particular:

(1) Overall catchment area and sub-catchment areas;

(2) (Sub-) catchment roughness and how the roughness or retardance was developed (may include a photographic record);

(3) Fraction impervious and how values have been derived including reference to what date values represent;

(4) Rainfall losses; and

(5) (Sub-) catchment slopes and how these have been derived.

All information used to define catchment parameters should be clearly referenced. A site assessment in the selection of some parameters is essential.

Catchment roughness

Catchment roughness or surface retardance accounts for the influence of vegetation and surface roughness on the generation of flows from sub-catchments. Ideally, values should be determined from calibration of the hydrological model to stream gauging. Values should be in the ranges presented below:

Catchment land use	Roughness coefficient (n*)
Urban impervious areas	0.010-0.030
Bare soil	0.010-0.050
Sparse vegetation	0.050-0.130
Heavily vegetated areas	0.080-0.200

Note that a sub-catchment may consist of numerous surface types that need to be accounted for in the specification of the catchment roughness.

Rainfall Losses
Rainfall losses account for rainfall which does not contribute to stormwater runoff because of infiltration and storage in surface depressions. Rainfall losses can vary from event to event and depend on antecedent rainfall conditions. Loss values for historical floods should be determined from calibration with loss values within the range of values as follows:

Surface type	Loss values
Pervious	Median initial loss 15 – 35 mm Median continuing loss – 2.5 mm/h Initial loss 0 – 140 mm Continuing loss 0.1 to 8 mm/h
Impervious	Initial loss 1mm Continuing Loss 0 mm/h

It should also be noted that loss values can vary between design storms of different frequencies. Guidance on appropriate loss values for different ARI storms can be obtained by matching peak discharges with peak flows determined from flood frequency assessment.

Sub-catchment slope
Sub-catchment slope can be derived from topographic maps or survey. Slopes applied should be representative of the sub-catchment and the modeller should ensure:

(1) The appropriate slope schematisation is applied when assigning values (equal area slope, vectored slope,); and

(2) Limitations of slope within the hydrological calculation method (i.e. Laurensen's method – minimum slope 0.3-0.5%, maximum slope 15%).

SC6.7.4.3.4 Rainfall intensities
Design Intensity-Frequency-Duration (IFD) Rainfall - IFD relationships shall be derived in accordance with the methodologies outlined in Australian Rainfall & Runoff, for the particular catchment under consideration. Input parameters shall be shown in the calculations submitted to council.

SC6.7.4.3.5 Partial area effects
If the Rational Method is being used, then there should always be checks to ensure that flows of greater magnitude are not apparent for partial catchment areas with faster runoff characteristics. These partial areas should be checked with the higher intensities relating to the shorter times of concentration.

Likewise, when using hydrograph techniques (such as runoff routing or Rain on Grid procedures), a range of storms of different duration for the same ARI should be checked to ensure that the worst event for the ARI is calculated and adopted. It should be noted that a range of storm durations may be required to evaluate sites that cover longer reaches of watercourses or numerous watercourses.

SC6.7.4.3.6 Calibration and verification of hydrological models
Calibration of results based on observed inundation events is desired. There are many pluviograph stations located within and adjacent to the City. Information from these is generally available from the Bureau of Meteorology or relevant Queensland Government department(s). Records from stream gauging stations will be required to match to hydrologic calculations and are generally available from the relevant Queensland Government department(s).

If observed data is not available to assist in the study, then it is suggested that the estimation of discharge flows from several methods will be considered with greater confidence in the result than the estimation of flows from one method alone.

SC6.7.4.3.7 Assessment of development impacts

When undertaking an assessment of the potential for development impacts on flooding, the development must be appropriately accounted for in the hydrological assessment including:

(1) Changes to imperviousness and expected rainfall losses;

(2) Changes to catchment layouts or extents;

(3) Changes to catchment roughness;

(4) Changes to slopes; and

(5) A re-evaluation for the potential for partial-area effects.

SC6.7.4.3.8 Preparation of reports

Reporting requirements

The method chosen should be adequately referenced and values derived should be substantiated by defining procedures used in their derivation. Where parameters are chosen or assumed, references and reasons should be supplied. The preferred method of setting out the hydrology is to describe in the text of the report the method to be used, and then to set the calculations out in a clear and concise table with sufficient data to enable quick verification of the results. The time of concentration or critical duration storm from the hydrological assessment should be clearly identified for areas relevant to the site.

Where computer methods for calculation of flows are used, the text of the report should describe the method that is utilised by the computer programme. Parameters that have been chosen should be referenced with reasons stated for any assumptions. A figure should be used to clearly demonstrate the layout of the model. Output from software should be tailored to produce concise tabular results to enable quick verification of the results. Where recognised computer programmes are utilised, council may require the electronic data files to be provided in acceptable format.

Where insufficient data is supplied then delays will occur while studies are returned to enable the additional data to be provided.

Catchment maps

Most hydrological techniques will require a catchment analysis and stream slope analysis. The catchment analysis should be presented on as large a scale map (smallest reduction ratio) as possible. The following scales for catchment sizes are recommended for use:

Scale	Catchment area
1:1000	up to 0.5 sq. kms (50 ha)
1:2000	up to 1.0 sq. kms (100ha)
1:5000	up to 1.5 sq. kms (150ha)
1:10000	up to 50 sq. kms (5000ha)
1:25000	limited to 300 sq. kms per sheet

Maps should be well presented with catchments contained upon one sheet where possible. Standard sized sheets should be used. Sub-catchments should be boldly defined and the contours should be clearly defined to enable easy verification of the catchments in relation to the contours. Where sub-catchments are not consistent with the contour information then reasons should be stated in the text and clearly labelled on the map. Good drafting standards should be maintained in the presentation of these maps.

SC6.7.4.4 Hydraulic determination

SC6.7.4.4.1 General

The hydraulic determination involves the calculation of flood levels and velocities for the flood flows from the hydrological determination. Australian Rainfall and Runoff and the Queensland Urban Drainage Manual set out

aspects of hydraulic calculations that can be utilised to determine the water levels for design discharges.

Unless the channel consists of long lengths of uniform section and uniform flow, the Mannings equation cannot be used in its simple form. This equation describes flow in a uniform channel at non-varying steady state flow conditions.

Australian Rainfall and Runoff describes methods for flood level determination in gradually varied flow conditions. The method for hydraulic determination will be dependent on the hydraulic controls of the study area. In general, it is appreciated that these methods will use computer applications.

SC6.7.4.4.2 Hydraulic method

The hydraulic method adopted for the required analysis should be appropriate to the hydraulic controls of the study area and the design problem being assessed. Designers should be aware of the limitations, for each of the methods.

Approach	Applicability	Notes
Steady state – one dimensional (HEC-RAS)	• Storage or timing issues are not relevant; and • Flows are one-dimensional, largely within a watercourse and the immediate overbank area.	Generally only suitable for small site scale hydraulic determination.
Fully dynamic – one-dimensional (MIKE11, ISIS, SWMM)	• Storage or timing issues are relevant; • Flows are one-dimensional, largely within a watercourse and the immediate overbank area.	Suitable for smaller onedimensional watercourses. Provides stability advantages over 2D models for steeper areas. Council uses MIKE11 and requires any flood studies completed within Townsville using a fully dynamic – onedimensional model, to use MIKE11.
Fully dynamic – two dimensional (MIKE21, TUFLOW)	• Storage or timing issues are relevant; • Flows are two-dimensional,	Flood maps are generally direct output from models. Council uses MIKE21 and requires any flood studies completed within Townsville using a fully dynamic – two-dimensional model, to use MIKE21.
Fully dynamic–coupled one & two dimensional (MIKE FLOOD, TUFLOW)	• Storage or timing issues are relevant; • Flows are combination of one and two- dimensional; • Large areas need to be represented in combination with fine detail	Council uses MIKE FLOOD and requires any flood studies completed within Townsville using a fully dynamic – one & two-dimensional model, to use MIKE FLOOD.

SC6.7.4.4.3 Topographic data

Topographic data used for the hydraulic determination will be dependent on hydraulic method:

(1) One-dimensional models employ cross-sections along branches to represent the study area topography; and

(2) Two-dimensional models employ digital elevation models to represent the study area topography.

The accuracy of the topographic data governs the accuracy of the hydraulic determination.
The accuracy of the topographic data should be clearly stated.

Cross-sections

Cross-sections are required at representative locations along a stream reach and at locations where changes occur in discharge, slope, shape, or roughness, and at bridges, culverts or control structures such as weirs. Where abrupt changes occur, several cross sections should be used to describe the change in shape regardless of the distance between sections. Cross-section spacing is also a function of stream size, slope and uniformity of cross section

shape. For one-dimensional models, the cross-sections should be wide enough so that the water surface is contained within the extent of the cross-sections. The accuracy of the hydraulic modelling will be dependent upon the spacing of cross-sections and the accuracy of the cross-section survey.

Digital elevation models

Digital elevation models used for two-dimensional models should use a grid spacing fine enough to resolve watercourses within the study area. As a general rule, a watercourse should be represented by a minimum of 5 grid-cells across the width of the watercourse. Coupled models can be used as an alternative to maintain the resolution within the watercourse.

The digital elevation model should be orientated to minimise disturbance of flows by the grid cell orientation. Aligning grid cells with streets (often part of the major drainage system) helps to achieve an appropriate orientation.

Digital elevation models are often captured from aerial surveying methods such as LiDAR or Photogrammetry. These methods can lose accuracy in areas of dense vegetation. It should be clearly demonstrated what steps (including ground survey) have been taken to improve the accuracy in areas potentially obscured by vegetation.

SC6.7.4.4.4 Roughness values

Based on the procedure developed by Cowan (1956), stream roughness values are a combination of influences from:

(1) Bed material;

(2) Surface irregularities;

(3) Variations in channel cross-section;

(4) Obstructions;

(5) Vegetation and flow conditions; and

(6) Meandering.

Different methods for hydraulic determination such as fully dynamic and fully dynamic twodimensional modelling will account for some of these influences within the underlying digital elevation model or solution scheme of the model.

Suggested ranges for roughness values based on the hydraulic method are provided below:

Land use	Roughness values (Manning's n)		
	1D Steady state	1D fully dynamic	2D fully dynamic
Natural watercourse	0.03-0.08	0.025-0.06	0.02-0.05
Riparian corridor	0.15-0.2	0.08-0.16	0.06-0.12
Open grassland	0.04-0.08	0.035-0.06	0.03-0.05
Low density vegetation	0.06-0.12	0.045-0.08	0.04-0.06
Medium density vegetation	0.08-0.18	0.06-0.1	0.05-0.08
High density vegetation	0.1-0.25	0.08-0.15	0.06-0.12
Roads	0.03-0.06	0.025-0.05	0.02-0.04
Open channels	0.03-0.05	0.025-0.05	0.02-0.04
Rural residential	0.06-0.1	0.05-0.08	0.04-0.07
Urban residential	0.06-0.15	0.05-0.12	0.04-0.1
Parks	0.04-0.18	0.035-0.1	0.03-0.08

Where possible, roughness values should be determined from calibration. Often, calibration will not be possible and sensitivity analysis to variations in roughness should be undertaken.

In the case of a one-dimensional model, roughness should be appropriately defined across the cross-sections based on the land use. In the case of a two-dimensional model, roughness should be appropriately defined using a grid to

represent the study area based on the land use.

SC6.7.4.4.5 Bridges and culverts
Australian Rainfall and Runoff and Queensland Urban Drainage Manual provide useful information and references for the determination of afflux levels and water profiles at bridges and other structures.

Head-losses across major drainage structures assessed within fully dynamic models should be verified by hand-calculations or assessment with a steady state model.

SC6.7.4.4.6 Tailwater conditions
Tailwater conditions for hydraulic models will be dependent on the location of the downstream extent of the model. Tailwater conditions may be one of the following:

(1) Sea levels for a coastal boundary;

(2) A gauged rating curve;

(3) Flood levels from the same ARI flood based on a previously accepted flood study; or

(4) Flood levels calculated from simplified means in the absence of other information (e.g. normal depth or critical depth).

In using flood levels calculated from simplified means, the method of calculation should be justified and sensitivity to input parameters should be evaluated. The downstream boundary should be located so that the boundary conditions do not influence results at the study site. Ensuring the boundary is sufficiently far enough downstream from the study site will reduce the impact on results at the site.

Requirements for some specific boundary conditions are discussed below.

Coastal boundaries
When calibrating hydraulic models, tailwater conditions should be based on observed sea levels for the event. Sea-levels are monitored at the Townsville port, with the information available through the Bureau of Meteorology.

To maintain the probability of the assessed flood event for design purposes, the tailwater condition adopted should not have a frequency of occurring any less than once a year. A fixed tailwater condition equal to the height of the Mean High Water Springs (MHWS) tide should be adopted. For storm events greater than 24 hours, a representative tidally varying water surface level between MHWS and Mean Low Water Springs (MLWS) can be adopted.

Backwater effects in tributaries from larger streams
Where a smaller stream discharges into a larger stream, it will be most probable that the larger stream will experience more severe flooding for storms of longer duration and hence lesser intensity for the same average recurrence interval. The tributary is to be checked for a storm of the same duration and intensity as that causing the peak flow in the larger stream.

The hydraulic assessment should assess the flooding for both the storm duration critical for the larger stream and the local tributary. Flood levels in the area will be based on the highest flood level determined from both storm durations. Peak velocities in the area will be based on the fastest velocity determined from both storm durations regardless of whether the storm duration that generates the fastest velocities produced the highest flood levels.

It is acknowledged that runoff routing models combined with fully dynamic hydraulic models will adequately account for these processes.

Estuary boundaries
Sometimes downstream boundary conditions for hydraulic models will be required in reaches of watercourses that are influenced by tides, but are not located at the coastline. In this instance, it is inappropriate to use neither a tidal water level boundary condition nor a rating curve boundary condition alone. The downstream boundary condition must account for both the tidal conditions and the ability for water levels to be elevated due to flood flows. Typically, this would involve the development of a rating curve with flows below MHWS set to zero and flows above MHWS to be calculated based on an appropriate water surface slope.

SC6.7.4.4.7 Impact of climate change

The impacts of climate change on flooding are likely to manifest from increased sea levels and changes in extreme event rainfall intensities. As part of understanding the risk associated with climate change, a sensitivity assessment should be undertaken as part of a flood study. The sensitivity should account for the latest projections in sea-level rise and increased rainfall intensities, specific to the area from leading authorities including relevant Queensland Government department(s), Australian Rainfall and Runoff, Commonwealth Scientific and Industrial Research Organisation, Bureau of Meteorology or Intergovernmental Panel on Climate Change. At the time of preparing this PSP appropriate values were:

Parameter	Value
Sea level rise to 2100	0.88m
Extreme rainfall Intensities to 2100	+15%

The DFE should be assessed in combination with the maximum sea-level rise applied to the MHWS level and the increase in rainfall intensities to evaluate the additional risk associated with climate change. The results from the climate change sensitivity should be assessed with commentary provided about:

(1) Areas where the floor level freeboard above the DFE would be exceeded;

(2) Any new flow paths that are formed; and

(3) What is the AEP of the climate change DFE relative to existing conditions.

SC6.7.4.4.8 Determination of impacts of development

Developments have potential to cause significant adverse impacts on flooding due to:

(1) Increasing the impervious fraction, reducing amount of infiltration and generating a larger volume of runoff;

(2) Providing more efficient conveyance of flows through the site so that flows are concentrated faster at the downstream end of the site producing larger peak flows; and

(3) Removing floodplain storage due to filling which reduces the natural flow attenuation of the floodplain and increases flood levels.

It will be necessary to carry out studies of the catchment in the pre-developed state (base case) and the developed state to determine increased amounts of flow and flood levels. The pre-developed state should represent the state of development within the catchment and floodplain immediately prior to time of construction of the proposed works.

Adverse impacts on flooding may preclude development unless appropriate flood mitigation measures are proposed as part of the development. As a result of developments:

(1) Flood levels should not increase beyond the accuracy of the method of hydraulic determination (generally 0.01 m) either upstream, downstream or adjacent to the site;

(2) There should be no significant change in flow patterns so that new flow paths on adjacent land are formed; and

(3) Any changes in flow velocities should be shown to have minimal impact on erosion potential.

Mitigation works such as levees or detention basins, involving embankments, need to be shown to have a safe overtopping failure. Such works should be modelled for the Probable Maximum Flood (PMF) to demonstrate safe passage of these flows without catastrophic failure of embankments.

Any mitigation measures recommended beyond the subject site will need to undergo the development assessment process including:

(1) Clear identification of the land parcels impacted;

(2) Development applications (material change of use, reconfiguration of a lot or operational works) - as required; and

(3) Identification of maintenance measures including responsibilities and funding sources.

Mitigation measures should generally be on the subject site unless prior discussions have been entered into with council and the landholder and there is an agreement for works outside of the subject site.

Hydraulic modelling of development

When representing development typically the hydraulic model is updated by:

(1) Changing the topography (cross-sections/DEM) to represent the development;

(2) Updating inflows to represent changes in hydrological response; and

(3) Updating roughness to represent the development.

Roughness values should only be changed to reflect the change in land use resulting from the development. These changes need to be clearly identified and justified. In assigning roughness values within new drainage channels or areas impacted by flooding, there should be consideration given to the way regrowth can occur within these areas. Areas below Highest Astronomical Tide (HAT) are likely to have mangrove regrowth occur. In areas further upstream, regrowth by tea-tree is likely to occur and can create a significant impediment to flows. Also, most flood events within Townsville occur towards the end of the wet season (January to March), when earlier rain has enabled grass in drains to grow with minimal ability to mow. Roughness values within drainage corridors for development assessment should be adopted towards the higher end of the range of values to account for regrowth, which may have minimal maintenance.

Freeboard for existing areas

Within some existing urban areas, design criteria have changed over time and have resulted in freeboard to existing buildings being less than is required in new development. To ensure the freeboard for existing areas is maintained, there should be no adverse impacts on flooding for all events floods up to the DFE. As a minimum, the assessment should demonstrate that there are no adverse impacts on flooding for the minor system drainage capacity AEP and the DFE.

SC6.7.4.5 General matters

SC6.7.4.5.1 Presentation of reports

As stated in the previous sections all reports and tabulations are to be printed on A4-sized sheets, and drawings presented on standard size sheets prepared using good drafting standards. The expected content of the reports is as discussed in SC6.7.4.2, SC6.7.4.3 and SC6.7.4.4 above. In summary the contents of a study report must include:

Hydrology section

(1) catchment Map - large as possible;

(2) report on procedure (brief), including hydrologic method, catchment characteristics, assumptions and discussions on results including critical duration /time of concentration as detailed in SC6.7.4.3 above; and

(3) calculations and model results - tabulated where possible and attached in appendix if significant in volume.

Hydraulics section

(1) report on procedure including hydraulic method, stream/floodplain characteristics and assumptions as detailed in SC6.7.4.4 above;

(2) model Results – Clearly presented as maps and tabulated values;

(3) stream Flood profile and bed profile of the study area;

(4) drawings/figures of topographic data used for the model (Digital Elevation Model map or plan of cross-section locations and cross- sections with X and Z coordinates included);

(5) a plan containing the proposed works showing any filling and excavation associated with development; and

(6) model results updated on the basis of including the development with the revised flood extents and impacts on flooding.

General

(1) discussion on sensitivity analysis for critical parameters (e.g. roughness, infiltration etc.);

(2) discussion on accuracy of inundation mapping and the resulting required flood line;

(3) recommendations as to methods of flood mitigation within the site;

(4) recommendations as to method of flood mitigation beyond the site together with development approvals,

construction proposal and funding proposals; and

(5) electronic data for both the hydrology and hydraulics in an agreed format (modelling platforms and GIS).

Drawings should be bound into the report where sizes are A3 or A4. Larger drawings are to be appropriately folded and inserted in a pocket in the back cover.

Recognition by the consultant, that the assignment of data to council, and use of the studies by council for its sole use, is a mandatory requirement before a study is commissioned and/or the results of any study will be accepted by council.

All studies, reports and submissions forwarded to council shall be prepared by, or at least certified by, a Registered Professional Engineer Queensland (RPEQ) who is registered in the specific area of engineering in which the study or report has been prepared e.g. an RPEQ (Structural) shall not certify a stormwater report.

SC6.7.4.5.2 Preference of computer models

It is acknowledged that where no modelling has been undertaken, then any modelling will provide a more accurate estimation of inundation levels than collated levels from observed inundation events.

Modelling studies where the results have been calibrated using observed levels and measured rainfalls will be recognised as providing a more representative result for the study area.

The hydrologic and hydraulic methods adopted should be suitable for purpose as indicated in SC6.7.4.3.2 and SC6.7.4.4.2. Townsville City Council requires that any flood studies completed within the Townsville Local Government Area uses software that is run internally which includes:

(1) Non-linear Routing – XP-RAFTS;

(2) 1D Steady State – HEC-RAS;

(3) 1D Fully Dynamic – MIKE11;

(4) 2D Fully Dynamic – MIKE21; and

(5) Coupled 1D/2D Fully Dynamic – MIKE FLOOD.

SC6.7.4.5.3 Copyright of reports, studies and drawings

Prepared directly for council

It is acknowledged that intellectual capacity has been demonstrated in the preparation of the report. However, the report is prepared and based on accepted engineering fundamentals and principles. In addition, the practices adopted are those developed by the engineering profession through initiative and ingenuity and ratified through the professions recognised body “The Institution of Engineers, Australia” currently trading as “Engineers Australia”.

All reports and studies (including drawings, tables, model files etc.) prepared for council under direct commission will become the sole copyright of council, and those reports will be used by council in a manner that will provide the optimum benefit to the community. All reports adopted by council will also be available for public and professional perusal on council’s website.

In any reference to the report, the author of the report will be acknowledged by council and should be acknowledged by any authorised third party user.

Submitted as part of a development application

Submitted as part of a Development Application and adopted as supporting the application only

When a technical report or study is submitted to council as part of a development application, this report/study, along with all components of the submission, can be made available to the public as part of the notification stage. The report can be provided to anyone seeking the report during this stage and following the approval. Use of the report for any third-party use will be at the complete risk of the third party. It should be noted that it will be only the approved report including any council requested amendments, which should be referred to in future.

Submitted as part of a Development Application and adopted by council as a benchmark report for future development or other purposes

From time to time, reports etc. submitted as part of a development application, or supporting an application, could provide a wider ‘regional’ significance and importance than just the development site for which they were prepared. Council may choose to open discussions with the developer to determine if obtaining all supporting digital and electronic data along with software input/output files would allow the option of adopting the report as a ‘base-line’ report for council. The decision as to whether a report has wider regional significance will be council’s alone.

Once these reports have been adopted by council as a ‘base-line’ report, the report assumes the status as if the report was prepared by or for council, and the copyright previously assigned by the author is released and the copyright provided to council. Council can use the report to achieve optimal outcomes for the wider community.

SC6.7.4 Attachment 2 - Adverse Flooding Impacts Assessment - Additional Design Floods for Asessment

Location	Design flood event
Ross River - Downstream *Within the immediate area around Ross River downstream of Ross River Dam and the lower Ross River Floodplain.*	0.2 % AEP
Ross River Upstream *Upstream of Ross River Dam*	0.5 % AEP

SC6.8 Mitigating bushfire hazard planning scheme policy

SC6.8.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Bushfire PSP.

SC6.8.1.1 Purpose

(1) The purpose of the planning scheme policy is to:

(a) support the outcomes presented in the Bushfire hazard overlay code; and

(b) provide guidance and information relating to the preparation of a Bushfire hazard assessment, and where necessary a Bushfire management plan.

SC6.8.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.8.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan, in particular, the Bushfire hazard overlay code.

SC6.8.1.4 Terminology

Terms used in this planning scheme policy are as defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 - Definitions is to be interpreted in accordance with Part 1.3.1 Definitions.

SC6.8.2 Planning scheme policy details

SC6.8.2.1 Bushfire hazard assessment

A Bushfire hazard assessment (and where necessary a Bushfire management plan) may be required as part of an assessable Reconfiguring a Lot or Material Change of Use development application as determined by assessment under the Bushfire hazard overlay code.

Where a Bushfire hazard assessment is required or is submitted, assessments are to be prepared and undertaken by a suitably qualified and experienced professional.

As a guide, the features sought by council to achieve a comprehensive Bushfire hazard assessment are addressed below.

The Bushfire hazard assessment should have regard to the following –

(1) Australian Standard AS3959 - 2009: Construction of buildings in bushfire prone areas.

(2) State Planning Policy and supporting guidelines.

Editor's note—A detailed guide on how to undertake this type of risk assessment is provided in QRA (2012) publication. Although this focuses on flooding the evaluation process can be applied for any natural hazard.

(1) A bushfire hazard assessment should provide:

(a) the name and qualifications or experience of the person(s) preparing the assessment;

(b) the use description;

(c) location of the extent and level of bushfire hazard in relation to the spatial extent of existing and forecasted land uses;

(d) details of the storage of any dangerous or hazardous goods to be kept on the site;

(e) details of existing vegetation, including slope and aspect characteristics of the site;

(f) details of weather conditions that influence bushfire intensity; and

(g) details of existing bushfire records and local knowledge.

(2) Risk appropriate development;

(a) mapping details of the proposed development through GIS overlays or comparison of hard copy mapping;

(b) a determination of the consequence of a bushfire hazard for each lot within the study area, and a qualitive assessment of

  (i) vulnerability;

  (ii) tolerability;

  (iii) a bushfire risk assessment to identify how development mitigation measures will work in conjunction with other risk management measures including building controls, mitigation infrastructure, early warning systems, community awareness and emergency managements to address the risk of bushfire, should it not be classed as a low hazard on the subject site; and

  (iv) recommendations.

SC6.8.2.2 Bushfire management plans

Where a bushfire management plan is required to respond to the risk, these are to be prepared and undertaken by a suitably qualified and experienced professional.

Where required, a Bushfire management plan is to include with the following:

(1) a discussion of proposed mitigation measures, the reduction of the hazard risk and the feasibility and reasonableness of these measures;

(2) identification of the key factors such as vegetation type, slope and aspect and include matters such as: likely direction of bushfire attack, environmental values that may limit mitigation options, location of evacuation routes and/or safety zones;

(3) an assessment of the specific risk factors associated with the development proposal, including matters such as the nature of activities and materials to be conducted or stored on the site, numbers and types of persons likely to be present, particular warning and/or evacuation requirements; and

(4) a plan for mitigating the bushfire risk. The plan should address all of the matters raised and recommend specific mitigation actions for the proposed development including:

  (a) road and lot layout and land use allocations;

  (b) firebreaks and buffers;

  (c) building locations or building envelopes;

  (d) landscaping treatments;

  (e) warning and evacuation procedures and routes;

  (f) firefighting requirements including infrastructure;

  (g) any other specific measures such as external sprinkler systems and alarms;

  (h) purchaser/resident education and awareness programs;

  (i) ongoing maintenance and response awareness programs; and

  (j) a description of the control measures that will be use to ensure compliance.

The level of detail required will vary with the nature of the development proposal and site, and with the type of development application.

The level of detail required to accompany a particular application should be determined in consultation with the assessment manager.

SC6.9 Natural assets planning scheme policy

SC6.9.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Natural assets PSP.

SC6.9.1.1 Purpose

(1) The purpose of the planning scheme policy is to:

- (a) support the use of the Natural assets overlay code;
- (b) provide background information on the derivation of the natural assets overlay maps;
- (c) outline information the council may request for a development application; and
- (d) provide guidance or advice about satisfying assessment benchmarks.

SC6.9.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.9.1.3 Relationship to Townsville City Plan

This planning scheme policy supports the assessment provisions specified in Townsville City Plan. Natural assets PSP specifically relates to the assessment of the Natural assets overlay code.

SC6.9.2 Natural assets

SC6.9.2.1 General guidance - environment protection

A healthy natural environment underpins the social and economic fabric of a sustainable city. Human modification of the natural environment interferes with physical and biological processes, natural cycles and energy flows. Natural systems can tolerate some amount of human modification however when the resilience level is exceeded, natural system break down and life support functions are diminished or damaged. In extreme cases damage may be irreparable as with endemic habitat loss, species extinction and desertification. Protecting the environment from human activities is a prerequisite for achieving ecological sustainability.

SC6.9.2.2 Land use and environment protection

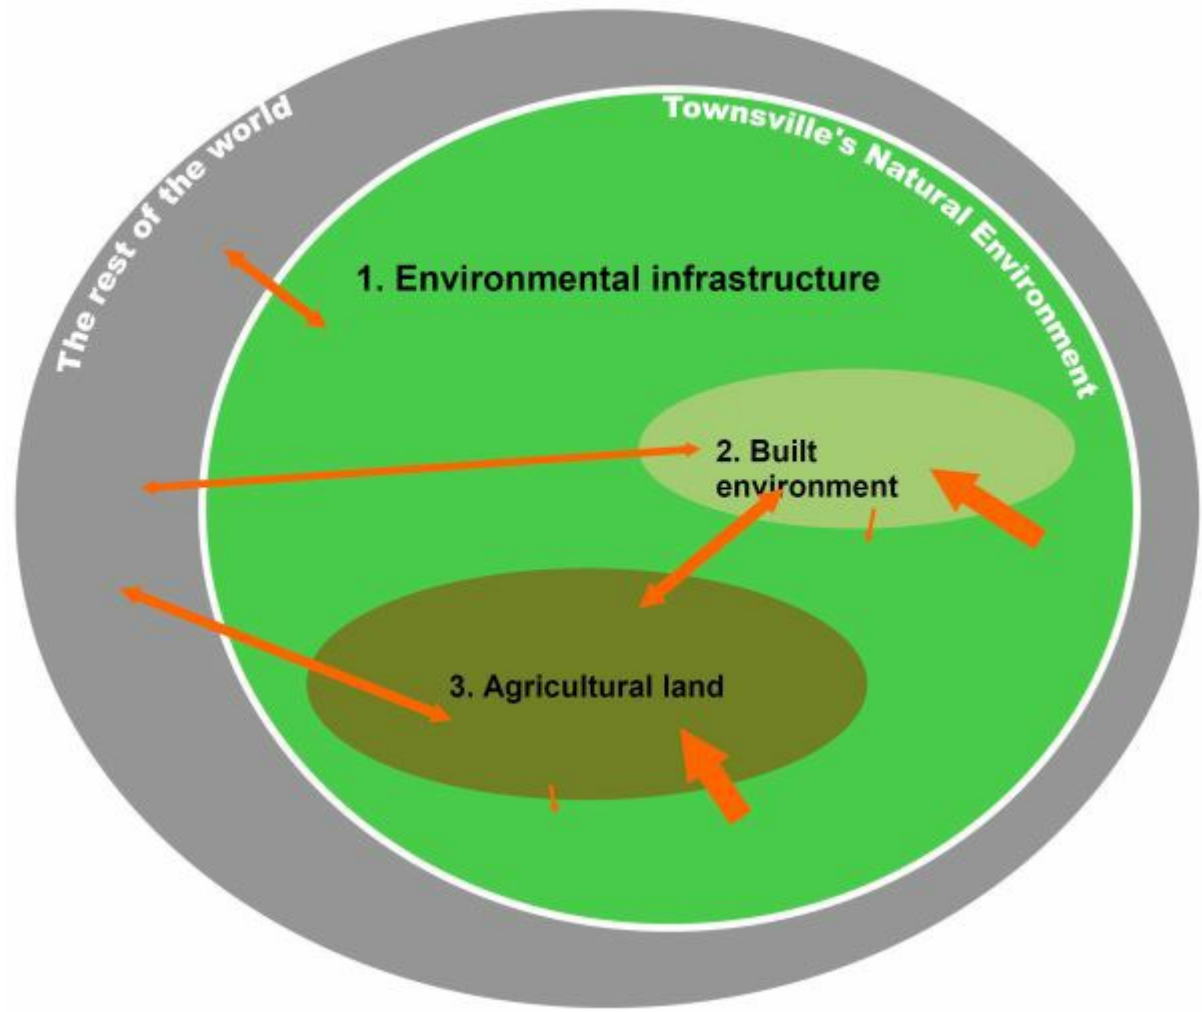
In broad terms, the three main functional land use units are:

(1) Environmental infrastructure;

(2) Built environment; and

(3) Agriculture land.

The three units are overlain on the single pillar of our existence - the natural environment, as illustrated conceptually in the diagram below.



SC6.9.2.3 Ecological planning

To seek to achieve ecological sustainability requires ecologically-based planning solutions. The underlying principle of ecological planning is the maintenance of our quality of life through the protection of our life support systems. This can best be done in a planning context through the recognition and protection of significant environmental areas.

Ecological planning takes an 'organic' approach to planning where the placement of built structures is dictated by environmental features and the need to protect and maintain natural assets and significant environmental infrastructure.

SC6.9.2.4 Environmental infrastructure

Environmental infrastructure is the basic framework or underlying foundation of the natural environment that contains the myriad of life support systems for all forms of life. Environmental infrastructure and function include:

(1) waterways/drainage systems (water drainage, water storage, seed transport, nutrient relocation, soil formation, sediment redistribution, habitat, connectivity, aquifer recharge, recreation, base flow, food source, biodiversity);

(2) wetlands (water filtering, water storage and aquifer recharge, habitat, seasonally high productivity, food source, biodiversity);

(3) riparian vegetation (shading, nutrients, ground cover; bank stabilisation, erosion prevention, water filtering, shelter/refuge, habitat, connectivity, recreation, food source, buffering, biodiversity);

(4) coastal dune systems (first line storm protection, buffering, water filtering, recreation, habitat, biodiversity);

(5) extensive forest in mid and upper catchments slopes >15% (erosion prevention, soil and slope stabilisation, soil formation, habitat, recreation, food source, aquifer recharge/intake, biodiversity, climate stabilisation);

(6) corridors and connections (wildlife movement, seed and vegetation dispersal, habitat, shade, shelter/refuge, food source, buffering, recreation, biodiversity);

(7) habitat/sustainable living space (biodiversity, connectivity, buffering, food source, recreation);

(8) native vegetation (biodiversity, habitat, wildlife movement, buffering, seed and vegetation dispersal, food source, recreation, soil health, shade, shelter/refuge, fuel, timber, erosion prevention;

(9) floodplains (habitat, biodiversity, nutrient and sediment dispersal, food source);

(10) aquifers (water storage, sub surface connectivity, hydraulic pressure); and

(11) protected areas (National Parks, Conservation Parks, Forest Reserves, Fish Habitat Areas and other socially delineated conservation areas).

Environmental infrastructure is unlikely to follow the same lines as appear on cadastral maps.

SC6.9.2.5 Ecosystem services

When planning and designing the built form we need to be aware of the intrinsic value of the surrounding environment and the ecosystem services operating in the background.

These services are provided without the need for any extra mechanical or chemical intervention and operate continually at variable rates determined by environmental conditions and climate. When we 'adjust' the environmental conditions we change the balance of ecological functions and ecosystem services at times beyond the resilience of the system to bounce back. If the change in environmental conditions is exacerbated by climate variability then a system may collapse due to the cumulative combination of natural and human impacts.

A risk management approach is adopted in ecological planning due to the uncertainties about how much of our natural assets (land, vegetation, water, soil, wildlife, soil microbes) is required to sustain an increasing human population and still maintain ecological processes at functional levels.

Determining or estimating the extent and influence of the ecological processes and ecosystem services is necessary in a planning context so that planning policies and intent can be applied to small areas (e.g. a house lot) as well as across broader landscape units such as regional ecosystems and land units.

SC6.9.2.6 Categories and components

The environmental importance ratings depicted on the Natural assets overlay map identify the likely significance of the natural environment and the likely extent of environment protection required to maintain habitat, species, vegetation communities, strategic habitat units, ecological processes, ecosystem services and hydrological function. Each of the three categories (medium, high and very high) are based on a variety of environmental and ecological components. The components associated with each category are listed in Table SC6.9.1—Environmental importance categories and components.

Table SC6.9.1 — Environmental importance categories and components

Category	Environmental importance components	General description
Very High	• Endangered ecological communities − semi evergreen vine thicket* − littoral rainforest and coastal vine thicket − broad leaf tea tree* • Endangered remnant vegetation (VMA vegetation management status) − Brigalow belt north bioregion − sub-regional (<10% left OR <300ha of pre-clearing extent remains) − local government area (<10% left OR <300ha of pre-clearing extent remains) • Remnant vegetation (VMA biodiversity status - endangered (dominant)) • Endangered high value regrowth (VMA) • Non bioregional ecosystems* • GBR wetland protection areas • Main connecting corridors • Mahogany glider habitat • Southern Cassowary habitat • Land units of limited extent* − Alligator Creek delta − *Eucalyptus acmenoides* lowlands − *Eucalyptus brownii* woodlands major occurrence − *Corymbia clarksoniana* alluvial fans − *Eucalyptus platyphylla — Melaleuca viridiflora* alluvial fan complex − *Eucalyptus tereticornis* on holocene deposits − *Grevillea striata* dominant − Land zone 4 grasslands − Pleistocene dunes − Terminal wetlands − *E. platyphylla — C. clarksoniana* woodlands on old levees and prior streams	This category includes endangered species habitat and vegetation communities along with the main connecting corridors (riparian, coastal and biogeographic units), land units of limited extent and Great Barrier Reef (GBR) wetland protection areas. These areas have been allocated as very high priority as they are the last examples of this type of vegetation community and/or habitat (generally less than 10% remains) and are the most vulnerable to loss and/or extinction in the short to medium term. Any further loss of these endangered elements could result in their loss from the landscape with little chance that they will recover or could result in their loss from the landscape with little chance that they will recover or could be restored.

Table SC6.9.1 — Environmental importance categories and components

Category	Environmental importance components	General description
High	• Of concern remnant vegetation (VMA vegetation management status) − Brigalow belt north bioregion − sub-regional (<10% left OR <300ha of pre-clearing extent remains) − local (30-50% of the pre-clearing extent remains) • Remnant vegetation (VMA biodiversity status - Endangered (sub dominant)) • High value regrowth − endangered (sub dominant) − of concern (dominant) • Wetland regional ecosystems (Estuarine, Palustrine, Lacustrine and Riverine) • Black-throated Finch habitat* • Essential habitat (regional ecosystems) • Very high ecosystem diversity (SDI >75% of the maximum value for the Bioregion) • A significant habitat for 'at risk' species • Waterways (buffered as per VMA bioregion codes) • Essential regrowth habitat (VMA)* • Wet tropics corridors* • Statewide corridors (remnant)* • Magnetic Island corridors (remnant)* • Magnetic Island lowland values(remnant)* • Land units of limited extent* − Castle Hill − (Sandy Creek and Double Barrel Creek) floodplain complex − watercourses (and associated areas subject to flooding)	This category includes the next most threatened suite of habitat, species and regional ecosystems (generally less than 30% of these components remaining in the landscape) along with strategically important connecting corridors, essential regrowth habitat, wetland regional ecosystems and endemically important landscape elements. It also includes a significant portion of the network of waterways and buffers (not included in the very high category) that are critical to the maintenance of ecological functions and ecosystem services. This category includes environmental elements close to the probable 'survival edge' as 30% is considered to be at the lower limit of ecological viability and function for habitat and vegetation communities. Any further reduction of extent is likely to result in a downward spiral that could ultimately lead to species endangerment and/or the endemic loss or degradation of vegetation communities and ecological processes. To take into account the relative importance of this category, if there are two or more environmental parameters with a high rating in a given polygon then the polygon was elevated to the very high category.

Table SC6.9.1 — Environmental importance categories and components

Category	Environmental importance components	General description

Medium	• Least concern remnant vegetation (VMA vegetation management status)
	  − Brigalow belt north bioregion
	• Remnant vegetation (VMA biodiversity status — Of Concern)
	• High value regrowth
	  − of concern (sub dominant)
	  − least concern
	• GBR wetland protection trigger areas (buffers)
	• Statewide corridors (nonremnant)*
	• Magnetic Island corridors (nonremnant)*
	• Magnetic Island lowland values (regrowth)*
		This category includes the widest range of environmental values from near threatened (30% remnant vegetation remaining) to relatively stable (100% remnant vegetation remaining). This category also includes some of the less tangible environmental and ecological functions, such as catchment protection, buffers, landscape connectivity and viable- sized habitat and ecosystems.
		
		This is the category that is likely to require the highest level of investigation prior to any development, as it is the least 'certain' in terms of priority for environmental protection. It is likely to have very high and high environmental value features, which have not been identified at the mapping resolution used for the categorisation. It may also include some low value features.
		
		If there are three or more environmental parameters with a medium rating in a given polygon then the polygon has generally been elevated to the high category.

Footnote—SDI is Simpson's Diversity Index

Footnote—*Denotes amendments/additions using DEHP mapping

It should not be assumed that any area has no environmental values. Areas not included in the overlay map (depicted without an infrastructure rating) generally consist of areas that have significantly less environmental value due to the level of disturbance resulting from anthropogenic activities, including clearing of native vegetation and the construction built form. The environmental values of some of these areas could be reinstated.

Applicants and landowners should be aware that other land not included in the overlay map may contain other remnant and non-remnant vegetation or other environmental value that is subject to the requirements of other state and/or federal legislative requirement.

In addition, there are provisions in some zone codes that require applicants to respond appropriately to any localised values that may exist outside the overlay area.

SC6.9.2.7 Mapping limitations

The general mapping resolution used for the environmental importance ratings map (Overlay Map OM-08) is 1:100,000. The Queensland Government's Regional Ecosystem mapping has been used as the base map for the environmental importance rating map and, while being the best available data source for this type of environmental categorisation, it is recognised that there are inaccuracies in the base map and therefore there will be inaccuracies in the resulting product - i.e. environmental importance ratings.

To overcome some of the inaccuracies, a review of the environmental importance ratings has been undertaken for the urban, rural and rural residential areas using 2011 aerial photography (the most recent available at the time of review). Further refinement of the mapping is required, for example, to accurately locate waterways, wetlands, riparian zones and buffers as the current Queensland Government mapping is not accurate at the local/urban scale and especially for order 1 and order 2 streams.

In light of these mapping limitations, it is imperative that an environmental assessment is undertaken for areas mapped with medium, high and very high environmental importance to ensure that development applications are assessed with the benefit of the best available information.

Council will continue to improve its environmental mapping, over time, to more accurately reflect environmental importance across the entire Townsville landscape, to reduce the incidence of unsustainable land use and development, and thereby contribute to the achievement of ecological sustainability and a sustainable Townsville.

SC6.9.2.8 Supporting maps

Supporting maps have been produced to assist applicants in using the Natural assets overlay code. The data presented on each of the supporting maps has been extracted from data contained on map OM-08 and are provided to assist applicants identify environmental and ecological features within the Townsville landscape.

Supporting maps may be used to assist applicants address relevant assessment benchmarks of the natural assets code.

Maps supporting the natural assets overlay code are:

(1) Figure SC6.9.1 – Natural assets – waterways represent the Queensland Government 1:100,000 waterways mapping. Waterways have been mapped to enable identification of stream orders specifically and are designed to allow applicants to identify the relevant stream order that affects a given location.

(2) Figure SC6.9.2 – Natural assets – wetlands include Great Barrier Reef wetlands of high ecological significance (wetland protection areas), riverine wetland regional ecosystems and other wetland regional ecosystems. Ramsar wetlands and wader roosts have also been shown to identify the presence of these areas at their given location.

(3) Figure SC6.9.3 – Natural assets – ecological corridors include:

  (a) priority corridors from the Environment and Biodiversity Study: Final Report (Chenoweth April 2011);

  (b) state corridors from data provided by the Department of Environment and Heritage Protection (DEHP); and

  (c) the state and priority corridors as major ecological corridors and the great eastern ranges conservation corridor. Major ecological corridors shown on the map consist of a 250m core corridor and a 50m buffer either side of the core corridor.

(4) Figure SC6.9.4 – Natural assets – core habitat includes Cassowary, Mahogany Glider and draft Black-throated Finch habitats in addition to essential habitat for other threatened species as mapped by DEHP including declared fish habitat areas.

SC6.9.2.9 Environmental assessments

An environmental assessment may be required to show what impacts the development activity may have on the environment and how potential adverse impacts on the environment can be mitigated. To demonstrate compliance with the Natural assets overlay code, such an assessment may need to include a detailed ecological assessment.

The required assessments should be undertaken by a suitably qualified and experienced professional and provide a site specific investigation of the values present and their significance to ground truth the data reflected on the overlay mapping. The level of investigation required and techniques utilised should be commensurate with the scale and nature of the proposed development and the type of values present on the site. The environmental assessment should provide the appropriate level of information to assess the potential impact of a proposed development on the environment including:

(1) identification of the physical and ecological features of the site;

(2) identification of the ecological processes and ecosystem services associated with the site;

(3) identification of the physical and ecological connections between the site and the surrounding environment, including ecological processes and ecosystem services; and

(4) comparison of the environmental importance components and features identified on OM-08 to on ground findings.

The environmental assessment and reporting process also provides the development proponent with the opportunity to propose potential solutions that prevent or minimise potential environmental harm to natural assets and ecological processes associated with the proposed development. Potential solutions may include:

(1) environmental offsets;

(2) operational environmental management plans;

(3) succession plans and criteria for handover of natural assets to council;

(4) establishment of Nature Refuge areas;

(5) stormwater management plans incorporating water sensitive urban design (WSUD);

(6) resourced rehabilitation plans (in addition to or instead of environmental offsets); and

(7) innovative ideas for the progression of the development and protection of environmental values.

SC6.9.2.10 Environmental assessment report

The environmental assessment report should be set out in accordance with the framework provided below.

Physical and ecological features of the site including:

(1) Introduction providing information about:
   (a) the applicant;
   (b) tenure;
   (c) location; and
   (d) current land use and proposed land use.

(2) Site description including:
   (a) surrounding land use;
   (b) location in the water catchment;
   (c) proximity to HEV waters;
   (d) proximity to World Heritage Areas and other protected areas;
   (e) geology and soils; and
   (f) Regional ecosystems.

(3) Environmental importance components and features identified on OM-08 (Natural assets overlay).

(4) Likely ecological processes and ecosystem services associated with the site and adjoining areas.

(5) Social, physical and environmental constraints identified in other overlays including flooding, fire hazard, slope and visual amenity.

Physical and ecological features of the site (on ground site assessment results):

(6) The physical and ecological features of the site, based on on-ground assessment including:
   (a) soils and their geological derivation;
   (b) drainage and wetland features;
   (c) Other native vegetation and regrowth;
   (d) Regional Ecosystem type and extent;
   (e) habitat type and extent;
   (f) exotic species presence (terrestrial and aquatic – plant and animal); and
   (g) fauna sightings and signs (additional targeted survey work may be required where threatened species and ecological communities are likely to be present).

(7) Ecological processes and ecosystem services associated with the site.

(8) The physical and ecological connections between the site and the surrounding environment including ecological processes and ecosystem services.

Comparison of desktop review features with site assessment features:

(9) Comparison of the environmental importance components and features identified on OM-08 council's Natural assets overlay to on ground findings.

Suggestions for development impact avoidance or mitigation, including, but not limited to the following considerations:

(10) stormwater management including erosion prevention and sediment movement control;

(11) habitat management including weed control;

(12) maintenance of ecological processes; and

(13) maintenance or improvement of connectivity.

Environmental assessments and the preparation of management and rehabilitation plans are to be undertaken by a

person/people/organisation with the appropriate skills and experience. Where a person with less than four years' experience in field work is involved in the assessment, they should be supervised by an experienced environmental practitioner. Regardless of experience and qualifications, all work should be thoroughly reviewed as part of a quality assurance process prior to submission of studies, reports and plans to council.

SC6.9.2.11 Site-based management and rehabilitation plan

Where there is a requirement in the Natural assets overlay code, a site based management plan and/or a rehabilitation plan should be prepared to address the site specific situation. Generally, content should be in a format that identifies:

(1) the physical and biological condition of the site (from the Environmental assessment report);

(2) the issue/s being addressed and their location (from the Environmental assessment report);

(3) how and over what time scale the issue will be addressed (with input from Part 4 of the Environmental assessment report); and

(4) the commitment of resources allocated to implement the plan.

Plans need to provide enough information to show that the performance outcomes in the Natural assets overlay code will be met by the implementation of the plan. The use of maps and accompanying tables with management actions are encouraged to simplify the plan and reduce the size of documents.

SC6.9.2.12 Additional information

Additional material may be required as part of the environmental assessment depending on the environmental importance components and features identified in the Natural assets overlay. This involves proximity to areas of significant ecological or environmental value and requirements for vegetated buffers as well as the proximity to wader roosts. Additional information will be required if the proposed development is within:

(1) 200 metres of a wader roost area as indicated on Figure SC6.9.2 – Natural assets – wetlands;

(2) 200 metres of core habitat and endangered ecological communities;

(3) 200 metres of HEV waters;

(4) 200 metres of a wetland area;

(5) 100 metres of an ecological corridor;

(6) 100 metres of a declared fish habitat area; and

(7) 100 metres of a waterway.

Information derived from on ground investigations will be required to show:

(1) the actual distance from the environmental feature to the edge of the development and a comparison to the Natural assets overlay.

(2) the physical condition of the area between the environmental feature and the development including:

  (a) soils;

  (b) drainage patterns;

  (c) habitat type/s;

  (d) vegetation type and condition;

  (e) presence of exotic species;

  (f) observed fauna and signs of fauna; and

  (g) built infrastructure e.g. fences, drains and roads; and

(3) how buffer areas will maintain natural assets and ecological processes if a proposed buffer area/width is less than that specified in the Natural assets overlay code.

It is the responsibility of the development proponent to provide council with alternative solutions, when digressing from council's acceptable solutions, to ensure natural assets and ecological processes are not degraded as a consequence of the proposed development. Council may adopt the proponent's suggestions as conditions of development approvals.

SC6.9.2.13 Background information to assist environmental assessments

Council has compiled a range of environmental information to assist development proponents with the preparation of their environmental assessments. A list of the information is provided below with associated references:

(1) schedule of locally significant fauna, flora and vegetation/ecological communities along with those scheduled under legislation;

(2) landscaping guidelines expounding the use of local native species and excluding environmental weed species;

(3) local and regional movement requirements of wildlife (refine connectivity corridors based on species habitat location and known ecology);

(4) fauna survey techniques (e.g. types of trapping, call play back etc.) including the most appropriate targeted survey techniques and when these may be required for particular species;

(5) pest species (flora and fauna) specific to Townsville and appropriate management techniques; and

(6) Black Ross (Townsville) Water Quality Improvement Plan

SC6.9.2.14 Terminology

The following table provides a useful compendium of environmental terms, including terms used in this policy.

Word / Term	**Explanation**
Aquatic	Of the water, or living or growing in water.
Arboreal	Tree dwelling. Adapted to living in or among trees. Spending a significant part of the life cycle in trees or relying on arboreal habitats for shelter and/or food.
Avian	Birds. Of or pertaining to birds.
Biodiversity	The variety of all life forms: (1) *genetic diversity*—the variety of genetic information contained in individual plants, animals and other organisms. (2) *species diversity*—the variety of species. (3) *ecosystem diversity*—the variety of habitats, ecological communities and ecological processes. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Biodiversity values	As biodiversity is the variety of all forms of life biodiversity values are difficult to quantify. Biodiversity values are often based on a combination of biological and biophysical parameters including; habitat species richness and endemic anomalies. Some of these parameters have been included in the environmental importance rating map prepared for the Natural Assets Overlay.
Biophysical processes	Processes involving interaction between the biological (organic) world and the physical (inorganic) world e.g. soil formation and nutrient recycling.
Bioregion	As described in the *Vegetation Management Act 1999* (VMA).
BTF is Black-throated Finch	The Black-throated Finch BTF is an Endangered species under the *Commonwealth Environmental Protection and Biodiversity Conservation Act 2000* (EPBC Act) and Queensland's *Nature Conservation Act 1992*. BTF habitat mapping is draft and will require further investigation to determine actual core habitat. A greater level of assessment will be required for development applications in BTF habitat areas.
Buffer	The threat management space between a natural or environmental asset and the threat. Buffers can also act as ecological corridors and provide habitat for wildlife. [anything serving to neutralise the shock of opposing forces (The Macquarie Dictionary (2nd Edition) 1991, p.234)]

Buffering	The practice of providing a managed ecotone between the area of environmental significance and the threatening process/es.
Connectivity	The physical linkages serving to connect dissimilar or separated patches of habitat. The name given to the concept of landscape elements being connected. The capacity of landscapes or aquatic environments to allow ecological movement and function. The broad concept can be considered to have several main elements:*landscape connectivity*—the physical connection between areas with vegetation cover across a landscape. (1) *habitat connectivity*—the connection between patches of habitat suitable to a particular species. (2) *ecological connectivity*—the ecological processes that underpin the function of landscapes; for example, the transfer of pollen or seeds and the sequestration of soil carbon. (3) *evolutionary connectivity*—populations of species are able to interact naturally, sharing genes and adapting to changing environmental conditions. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Core area, core habitat area	An area of habitat that is of a suitable size, shape and condition for an assemblage of species or a single organism. Core habitat provides nutrients and water resources, and supports successful reproduction. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45- 49).
Corridors	Corridors are passageways that facilitate the movement of organisms and serve as habitat. Corridors exist at a range of scales depending on the organism and their ecological requirements. Corridors are not confined to linear strips of vegetation or riparian zones but rather include an interconnected network of native vegetation and habitat across the landscape. Waterways and wetlands provide ecological corridors for aquatic organisms.
Degraded	In a lessor state as a result of human interaction and natural causes e.g. storms.
Ecological communities	Assemblages of species (plants, animals, bacteria and fungi) that interact with each other in a common environment and often as part of a food chain or trophic web.
Ecological functions	Functions and processes involving the interaction of organisms with each other and their environments including , nutrient cycling, pollination, animal and plant breeding.
Ecological significance	The term used to describe areas that are important for maintaining biodiversity and ecological processes.
Ecotone	The gradation or transition zone between different habitats or vegetation communities.
Ecosystem	Ecosystem is “1. a community of organisms interacting with one another and with the environment in which they live.” (The Macquarie Dictionary (2nd Edition) 1991, p.555). A complex network or interconnected system or a biological community of interacting organisms and their physical environment; for example, combinations of plant, animal and other organisms in communities and their non-living environment (soil, water, climate, and so on) interacting as a functional unit, such as forest, wetland or grassland. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Ecosystem health	A measure of the condition of ecosystems from sustainable to threatened.

Ecosystem processes	Those life processes and interactions between organisms and the environment that (generally) contribute to the overall health of the ecosystem.
Ecosystem services	The multitude of resources and processes that are supplied by natural ecosystems. Collectively, these benefits are known as ecosystem services and include products like clean drinking water and processes such as the decomposition of wastes. The term is generally applied to benefits to human beings as with the Millennium Ecosystem Assessment 2005 definition “the benefits people obtain from ecosystems”. This is a narrow, anthropogenic definition that could restrict the protection of important ecosystem services if they are not seen as beneficial to humans. The definition has been broadened in the National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012 to read; “the processes or materials provided by ecosystems. Ecosystem services benefit biodiversity, humans and society through the provision of essential goods and services such as clean air, water, food, shelter, energy, nutrients, amenity values and cultural resources”. (pp.45-49)
Endemic	Refers to organisms that are native to a particular area or region. Having a limited distribution or habitat extent or confined to a specific area.
Environmental infrastructure	Environmental infrastructure is the basic framework or underlying foundation of the natural environment that contains the myriad of life support systems for all forms of life.
Hydrological function	The function of water moving through the landscape as part of a natural drainage process. Hydrological function is shaped by geological features and influences those features over time e.g. erosion. Hydrological function can be impeded by: (1) the placement of obstacles in waterways, (2) obstructing overland flow e.g. raised roads and rail lines, (3) reduced aquifer recharge.
Migratory species	Animals, especially birds and marine species, that travel significant distances (compared to remaining in a home range) to: (1) avoid climatic extremes and resource (food) depletion, (2) find sufficient resources to maintain physical health, (3) breed in more favourable conditions.
Native habitat	Habitat that is in a relatively natural state with minimal disturbance from human activities with a low incidence of exotic plant species.
Native species	Species (plant or animal) that would normally be found in the (Townsville) natural environment.
Natural areas	Those parts of the environment that have not been significantly altered from their natural state and that retain their ecological processes, biophysical functions and suite of native species.
Naturalised	Non-native species introduced to Australia that flourish and become part of the landscape.
Non-native	Not having evolved in Australia. Introduced into Australia from another country within the last 300 years.
Pest fauna and flora	Introduced species that threaten the viability and/or productivity of native ecosystems.

Refuge/refugia	An area that provides shelter, food or water for organisms when other parts of the landscape are inhospitable. For example, rocky areas can provide shelter during bushfires, while riparian areas might provide food and water during times of drought (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Resilience	The ability to recover after being impacted by threatening processes.
Riparian areas	Areas of vegetation alongside watercourses, lakes and wetlands. They often contain vegetation that differs from that in the surrounding landscape, providing important habitat and ecological resources (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012 pp.45-49).
Significant ecological communities	Those ecological communities that are limited in extent (endemic) or population, confined to specific habitats or have characteristics that result in a vulnerability to environment changes and threatening process.
Threatened species	Threatened wildlife means native wildlife that is prescribed under the *Nature Conservation Act 1992* as— (a) extinct in the wild wildlife; or (b) endangered wildlife; or (c) vulnerable wildlife.
Threatening processes	Human activities that adversely impact the environment, natural values and ecological processes and result in adverse impacts including habitat loss, native vegetation destruction and reduced populations of native and migratory species.
Wader roosts	As defined in the Environment and Biodiversity Study: Final Report (Chenoweth 2011) and represented as a 700 metre buffer trigger area around wader roosts.
Wetland mapping and classification methodology	The "A Method to Provide Baseline Mapping and Classification for Wetlands in Queensland (VERSION 1.2) published by the Environmental Protection Agency, Queensland Government and produced in conjunction with the Australian Government (Department of the Environment and Heritage) in 2005.

SC6.10 Parking rates planning scheme policy

SC6.10.1 Introduction

Short Title – The planning scheme policy (PSP) may be cited as the Parking rates PSP.

SC6.10.1.1 Purpose

The purpose of the planning scheme policy is to:

(1) define the particular rates of parking that provide the relevant acceptable outcome under the Transport impact, access and parking code in the Townsville City Plan.

SC6.10.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.10.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan, specifically the Transport impact, access and parking code.

SC6.10.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 - Definitions. A term which is not defined in Schedule 1 - Definitions is to be interpreted in accordance with Part 1.3.1 - Definitions.

SC6.10.2.1 Planning scheme policy content -parking rates

(1) Parking rates are provided on site in accordance with the following uses or combination of uses.

(2) Where the number of parking spaces calculated in accordance with this table is not a whole number, then the minimum number of spaces to be provided is to be rounded upward to the closest whole number.

(3) The number of car parking spaces required for people with a disability is to be in accordance with Table D3.5 of the Building Code of Australia. There is no requirement to designate car parking spaces for people with a disability where the total number of car parking spaces required is five (5) or less.

Use	Parking rates
Adult store	One (1) space per 25m² of GFA.
Agricultural supplies store	One (1) space per 100m² of total use area, but not less than five (5) spaces.
Air services	One (1) space per 80m² of GFA.
Animal keeping	One (1) space per 10 animals for which accommodation is provided for on the premises, OR 3 spaces, whichever is the greater.
Aquaculture	One (1) space per employee (FTE).
Brothel	One (1) space for each room in the brothel AND one (1) space per two employees (FTE) on the premises at any one time.
Bulk landscape supplies	One (1) space per 100m² of total use area, but not less than five (5) spaces.
Caretaker's accommodation	One (1) space.
Car wash	Two (2) spaces, AND queuing space within the site for 4 vehicles using or awaiting use of each washing bay.
Cemetery	Thirty (30) spaces plus one (1) space per two employees (FTE) on the premises at any one time.
Child care centre	One (1) space for every 6 children, and 1 space per employee (FTE).
Club	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Community care centre	One space per 20m² of GFA
Community use	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Crematorium	Thirty (30) spaces plus one (1) space per two employees (FTE) on the premises at any one time.
Detention facility	One (1) space per 2 employees (FTE); plus a minimum of ten (10) visitor spaces.
Dual Occupancy	Two (2) spaces per dwelling unit, which may be provided in tandem, of which one (1) space is to be covered per dwelling unit.
Dwelling house	Two (2) spaces, which may be provided in tandem, of which one (1) space is to be covered.
Dwelling unit	One (1) space.
Educational establishment	Primary – one (1) space per employee (FTE) AND one (1) space per 10 students for visitor parking AND sufficient spaces for loading and unloading of passengers in addition to other requirements. Secondary – one (1) space per employee (FTE), AND one (1) space per 10 students of legal driving age, AND one (1) visitor space per 50 students, AND sufficient spaces for loading and unloading of passengers in addition to other requirements. Tertiary – point five (0.5) spaces per employee (FTE) PLUS one (1) space per 10 students (FTE), AND sufficient spaces for loading and unloading of passengers in addition to other requirements.
Emergency services	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Environment facility	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Extractive industry	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Food and drink outlet	One (1) space per 10m² of GFA available to the public (including outdoor dining); One (1) space per 50m² of GFA for food preparation; AND One (1) space per 100m² of GFA used for storage.

Function facility	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Funeral parlour	One (1) space per employee; AND One (1) space per hearse; AND One (1) space per 4 persons capable of being seated in any chapel or accommodated in a function area with a minimum of ten (10) spaces.
Garden centre	One (1) space per 100m² of total use area, but not less than five (5) spaces.
Hardware and trade supplies	One (1) space per 40m² of GFA.
Health care services	One (1) space per 20m² of GFA, OR four (4) spaces per medical practitioner, whichever is the greater; AND one (1) space for ambulance vehicle pick-up and set down.
High impact industry	One (1) space per 100m² of GFA.
Hospital	One (1) space for each 4 beds, two (2) spaces for each 3 employees, AND one (1) space for each doctor.
Hostel	One (1) space for every 2 beds provided, one (1) space for every 4 employees (FTE), and an additional one (1) covered space for a resident manager, and a dedicated car washing bay (additional to visitor and tenant parking spaces). A dedicated car washing bay is not required where there are 5 or less dwelling units provided. A dedicated car wash bay may also be integrated with visitor parking to serve both functions.
Hotel	Licensed facilities: One (1) space per 2m² of bar area; and One (1) space per 5m² of the lounge and beer garden area. One (1) space for each guest suite; AND One (1) space for each resident manager or caretaker; AND For any drive-through facility, queuing space within the site for ten (10) vehicles being served or awaiting service.
Indoor sport and recreation	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Intensive animal industry	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Intensive horticulture	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Low impact industry	One (1) per 100m² of GFA.
Major sport, recreation and entertainment facility	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Marine industry	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Market	One (1) space per stall.
Medium impact industry	One (1) space per 100m² of GFA.
Motor sport facility	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.

Multiple dwelling	In the Principal centre zone: One point five (1.5) spaces per dwelling (and one (1) dedicated car washing bay* for the entire development). In the High density residential zone: One point five (1.5) spaces per dwelling (and one (1) dedicated car washing bay* for the entire development). In the Medium density residential zone: One point five (1.5) spaces per dwelling; Point two (0.2) spaces per dwelling for visitors (and one (1) dedicated car washing bay* for the entire development). All other zones: One point seven (1.7) spaces per dwelling; Point two (0.2) spaces per dwelling for visitors (and one (1) dedicated car washing bay* for the entire development). * A dedicated car washing bay is not required where there are 5 or less dwellings provided. A dedicated car wash bay also may be integrated with visitor parking to serve both functions.
Nature-based tourism	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Nightclub entertainment facility	One (1) space per 15m² for the first 1,500m² of GFA, then one (1) space per 25m² of GFA thereafter.
Non-resident workforce accommodation	One (1) space per employee (FTE).
Office	In the Principal centre zone: One (1) space per 70m² of GFA All other zones: One (1) space per 30m² of GFA.
Outdoor sales	Point seven five (0.75) spaces per 100m² of total use area AND four (4) spaces per work bay (for vehicle service facilities)
Outdoor sport and recreation	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Permanent plantation	No parking rate required.
Place of worship	One (1) space per 10 persons capable of being seated.
Port services	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Relocatable home park	One point five (1.5) spaces per relocatable home.
Renewable energy facility	No parking rate required.
Research and technology industry	One (1) space per 80m² of GFA.
Residential care facility	Subsidised developments (nursing and convalescent homes): One (1) space per 10 beds; AND one (1) space per 2 employees and one (1) space per ambulance Self-contained units: One (1) space per 10 units (residents) and one (1) space per 10 units (visitor)

Resort complex	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Retirement facility	One (1) space per 2 self-contained or service units, plus one (1) space per 5 nursing home beds of the premises.
Rural industry	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Rural workers accommodation	One (1) space per accommodation unit.
Service industry	One (1) space per 100m² of GFA.
Service station	One (1) space per 40m² of GFA.
Shop	In the Principal centre zone: One (1) space per 30m² of total retail area* available to the public and one (1) space for each 100m² of total storage GFA. All other zones: One (1) space per 25m² of total retail area * available to the public and one (1) space for each 100m² of total storage GFA. * The total retail area available to the public excludes: (a) building services, plant and equipment; (b) access between levels; (c) ground floor public lobby; (d) a mall; and (e) the parking, loading and manoeuvring of motor vehicles;
Shopping Centre	In the Principal centre zone: One (1) space per 30m² of total retail area * available to the public and one (1) space per each 100m² of total storage GFA. All other zones: One (1) space per 25m² of total retail area * available to the public GFA and one (1) space per each 100m² of total storage GFA. * The total retail area available to the public excludes: (a) building services, plant and equipment; (b) access between levels; (c) ground floor public lobby; (d) a mall; and (e) the parking, loading and manoeuvring of motor vehicles.

Short-term accommodation	In the Principal centre zone: 0.75 spaces per self-contained unit, and 0.25 spaces per non self-contained unit, AND one (1) space for each 10m2 of GFA available to the public and one (1) space per 50m2 of GFA kitchen and preparation areas, and point one (0.1) spaces per unit for visitors. All other zones: One (1) space for each guest suite, one (1) space for a restaurant manager or caretaker, AND one (1) space for each 10m2 of GFA available to the public and one (1) space per 50m2 of GFA kitchen and preparation areas.
Showroom	One (1) space per 40m² of GFA.
Special industry	One (1) space per 100m² of GFA.
Telecommunications facility	No parking rate required.
Theatre	One (1) space per 15m² of GFA or one (1) space for each 4 seats, whichever is the greater.
Tourist attraction	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Tourist park	One (1) space per van, relocatable home and cabin site (to be located adjacent to such site), one (1) visitor space per 10 such sites, one (1) space for each 2 staff members, and one (1) space for a resident manager.
Transport depot	Sufficient spaces to accommodate the amount and type of vehicle traffic likely to be generated by the particular use.
Utility installation	Sufficient spaces to accommodate the amount and type of vehicle traffic likely to be generated by the particular use.
Veterinary services	Five (5) spaces per veterinarian.
Warehouse	One (1) space per 100m² of GFA.
Wholesale nursery	One (1) space per 100m² of total use area.
Winery	One (1) space per 25m² of GFA.
Any other development	Sufficient spaces to accommodate the amount of vehicular traffic likely to be generated by the particular use.

Schedule 6 Planning scheme policies

SC6.1 Planning scheme policy index

The table below lists all the planning scheme policies applicable to the planning scheme area.

Table SC6.1.1 - Planning scheme policy index

Number	Planning scheme policy title
SC6.2	Character residential planning scheme policy
SC6.3	Cultural heritage planning scheme policy
SC6.4	Development manual planning scheme policy
SC6.5	Economic impact assessment planning scheme policy
SC6.6	Emerging community planning scheme policy
SC6.7	Flood hazard planning scheme policy
SC6.8	Mitigating bushfire hazards planning scheme policy
SC6.9	Natural assets planning scheme policy
SC6.10	Parking rates planning scheme policy

SC6.2 Character residential planning scheme policy

SC6.2.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Character residential PSP.

SC6.2.1.1 Purpose

The purpose of the planning scheme policy is to:

(1) provide advice about achieving outcomes in the Character residential zone code; and

(2) identify and provide guidance about information that may be required to support a development application where assessable against the Character residential zone code.

SC6.2.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.2.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan, specifically the Character residential zone code.

SC6.2.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 – Definitions, is to be interpreted in accordance with Part 1.3.1.

SC6.2.2 Planning scheme policy details

The Character residential zone identifies and defines parts of the city with a unique mixture of architecture and overall streetscape. The Character residential zone code regulates development within identified character precincts. This code ensures that the features of these neighbourhoods that make a positive contribution to each precinct's overall character are retained and appropriately managed.

There are twelve precincts in the Character residential zone code, each with its unique features (such as Workers Cottages, Grand Queenslanders and 1960s Defence Housing). The precincts provide for specific development outcomes over and above the general zone code outcomes. Individual properties are included within a precinct. The character features are described fully in the code.

The purpose of the Character residential PSP is to provide applicants with guidance in meeting the requirements of the Character residential zone code. Appendix 1 of this policy identifies non-contributing properties in the Character residential zone. Properties and buildings identified in the Character residential zone and not listed in Appendix 1 of this policy are considered to be contributing properties and buildings. Appendix 2 of this policy identifies contributing non-residential properties.

SC6.2.2.1 Understanding your precinct and your character building

Each character residential precinct is defined in the Character residential zone code. Townsville has defined character residential precincts; these precincts are rich in diversity, unique in character, and capture Townsville's history and North Queensland lifestyle.

(1) Your precinct

The buildings in your street create the character of your precinct. Properties are defined as either contributing character buildings or non-contributing properties. Non-contributing properties must still comply with certain provisions of the Character residential zone code, however; they are not to be used for comparative assessment.

Your street will provide the majority of the information you need to better understand the types of buildings, design, developments and architectural aspects that will be relevant to any new works on your property.

SC6.2.2.2 Finding your way around the policy

The policy is divided into the following eight sections:

(1) Key contributing character elements (SC6.2.3)

(2) Non-residential contributing character buildings (SC6.2.4)

(3) Reconfiguring a lot (SC6.2.5)

(4) Information that may support a development proposal (SC6.2.6)

(5) Preparing an assessment report (SC6.2.6.2)

(6) Preparing a condition report (SC6.2.6.3)

(7) SC6.2 Appendix 1: Non-contributing properties in the Character residential zone

(8) SC6.2 Appendix 2: Contributing non-residential properties

SC6.2.3 Key contributing character elements

SC6.2.3.1 Roofs

This section of the policy provides design principles and examples that may be considered when addressing the requirements of the Character residential zone code. Applicants may refer to this section for guidance on Character residential zone code outcomes regarding roof forms and pitch, material type and colour and depth of roof overhang.

(1) Figure SC6.2.3.1 below demonstrates acceptable roof pitch in relation to neighbouring properties. This may provide guidance in addressing roof pitch related outcomes of the Character residential zone code requirements in particular, in relationship to PO18, PO21, PO28, PO33, PO40, PO45, PO51, PO56, PO63, PO69, PO74 and PO80.

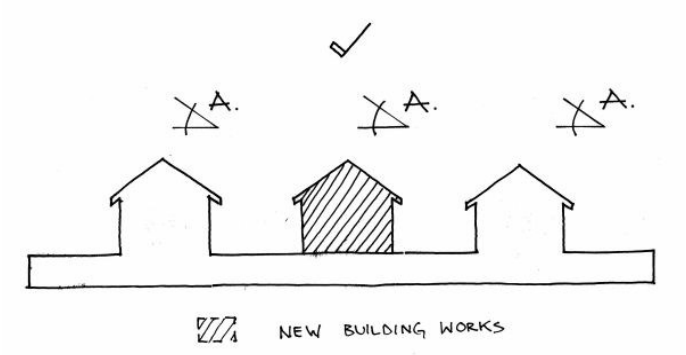

Figure SC6.2.3.1 Illustrates an example of acceptable roof pitch

(2) Figure SC6.2.3.2 below demonstrates an unacceptable roof pitch in relation to addressing roof pitch related outcomes of the Character residential zone code requirements in particular, in relation to PO18, PO21, PO28, PO33, PO40, PO45, PO51, PO56, PO63, PO69, PO74 and PO80.

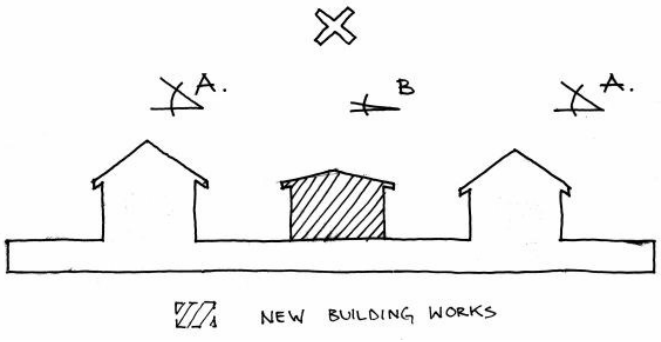

Figure SC6.2.3.2 Illustrates an example of unacceptable roof pitch

(3) Figure SC6.2.3.3a and Figure SC6.2.3.3b identifies some examples of compatible roof pitches found in various character residential precincts. These may be considered in addressing Character residential zone code requirements relating to roof pitch.

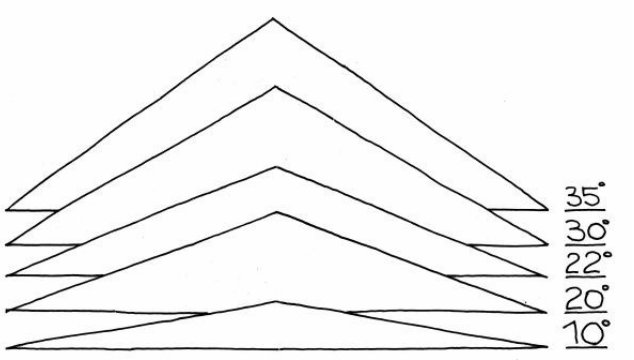

Figure SC6.2.3.3a Illustrates an example of common roof pitches in character residential precincts

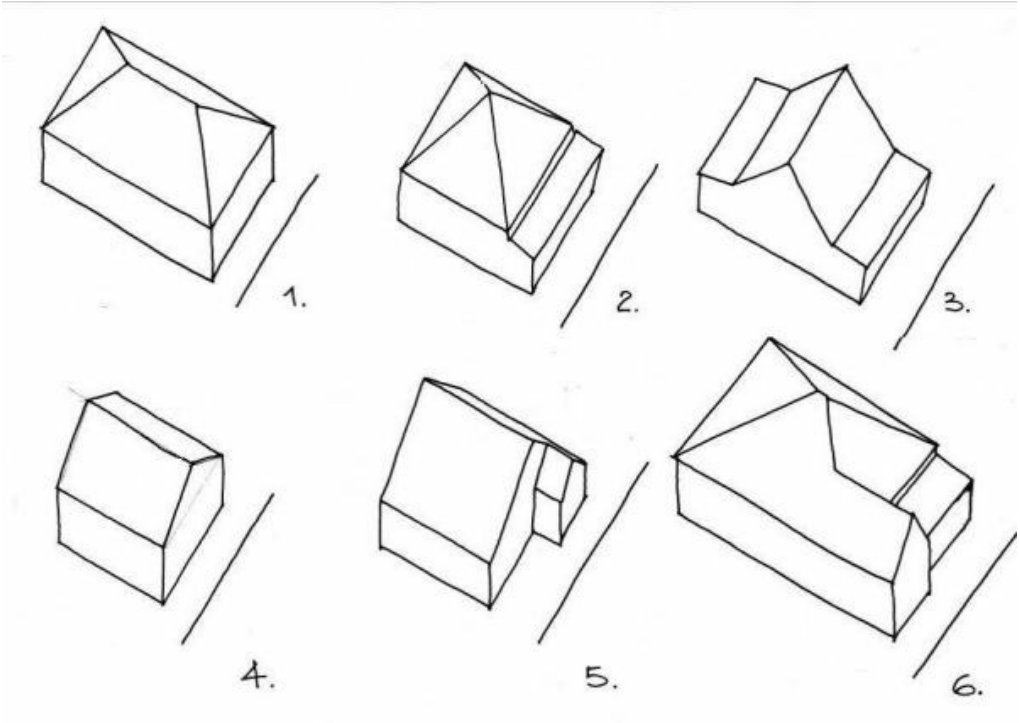

Note—the resulting roof may be expressed as a combination of any number of roof forms:

(1) hip roof;

(2) pyramid roof with skillion/lean-to verandah;

(3) side gable roof with skillion/lean-to verandahs;

(4) front gable roof;

(5) double gable roof (sometimes expressed as triple gable roof); and

(6) combination of gable and hip roofs, with skillion/lean-to verandah.

Figure SC6.2.3.3b Illustrates an example of common roof forms in character residential precincts

(4) Figure SC6.2.3.4 provides guidance on the identification of roof eave depth. This figure may assist in the determination of eave depth in particular, in relation to PO19, PO22, PO57, PO64, PO75 and PO81 of the Character residential zone code.

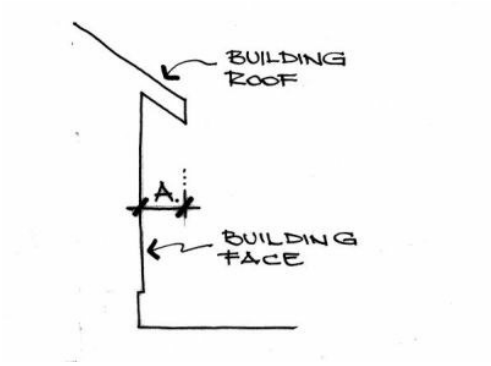

Figure SC6.2.3.4 Illustration of the roof eave depth which is shown by measurement "A"

SC6.2.3.2 Verandahs and front facades

A front verandah or an articulated front façade is commonly observed as a fundamental element of character within some precincts. This section of the policy provides examples of variation in verandah design, including scale (width, depth) enclosure, setback and height above ground level (see Figure SC6.2.3.5 for illustration of terms).

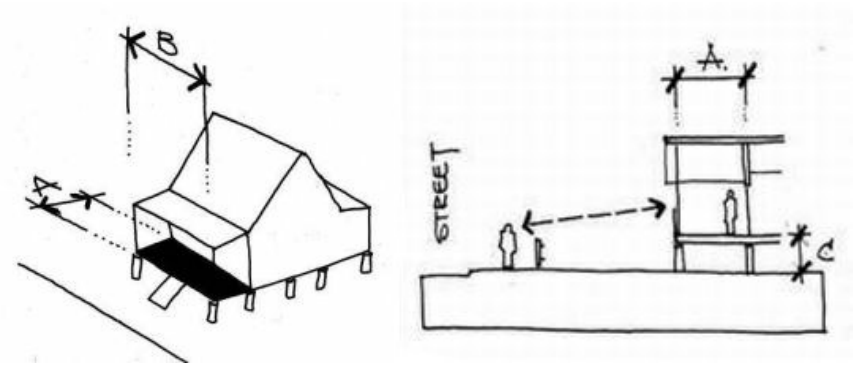

Figure SC6.2.3.5 - Demonstrating the width (B), depth (A), enclosure, setback, and height above ground level (C) of a front verandah

(1) Figure SC6.2.3.6 below illustrates 100% of the front façade width containing a verandah (left), and also an example of a property with a front façade including a verandah for a minimum 60% width of the front façade, wrapping down one side, and includes an asymmetrical projecting front gable (right). Both are open verandahs and are elevated above the natural ground level.

Figure SC6.2.3.6 Illustrates examples of a front verandah

(2) Figures SC6.2.3.7- SC6.2.3.9 illustrate examples of variation in verandah design including open, enclosed, and semi-enclosed and their supporting character elements.

Figure SC6.2.3.7 Illustrates an example of a front verandah, semi enclosed with screening and a door

Figure SC6.2.3.8 Illustrates an example of an open front verandah Workers Cottage style

Figure SC6.2.3.9 Illustrates an example of an open front verandah, Grand Queenslander style

(3) Figure SC6.2.3.10 and SC6.2.3.11 shown below, may be considered as a compatible outcome in relation to PO48, and PO71 and PO 78 of the Character residential zone code. The figures illustrate an example of projecting built forms that may be incorporated into building design in character precincts that do not include a verandah.

Figure SC6.2.3.10 Illustrates an example of a front façade with projecting gable features

Figure SC6.2.3.11 Illustrates an example of a front façade with single asymmetrical projecting gable

SC6.2.3.3 Windows

(1) Figure SC6.2.3.12 shown below, illustrates examples of sympathetic window scale and proportion. These examples provide guidance for addressing outcomes PO20, PO23, PO29 PO34, PO46,PO52, PO58, PO65, PO76 and PO82 of the Character residential zone code.

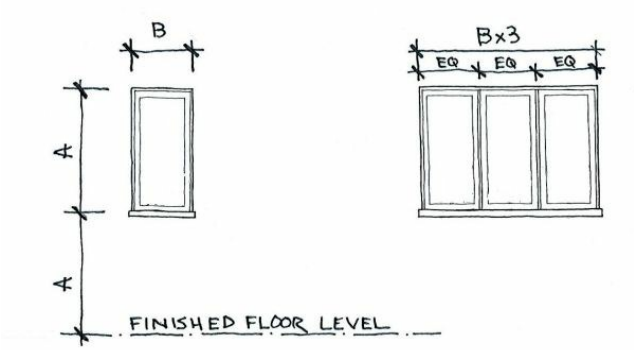

Figure SC6.2.3.12 Illustrates an example of half-height, vertically proportioned windows with one frame (left) and a set of three frames (right)

(2) Figure SC6.2.3.13 shown below, illustrates examples of window hoods in relation to the predominant character of the precinct. This information may be considered in addressing outcomes PO29 and PO34 Character residential zone code requirements regarding sympathetic window scale and proportion.

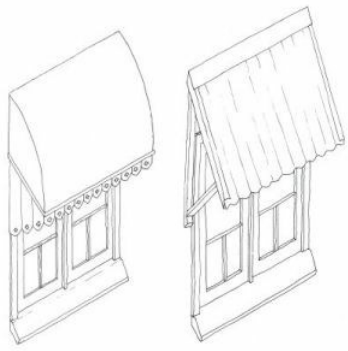

Figure SC6.2.3.13 Illustrates an example of traditional window with hood (left), and an acceptable new window with hood reflecting the same scale and proportions (right)

(3) Figure SC6.2.3.14 - SC6.2.3.17 shown below, illustrates examples of typical windows in character precincts. This information may be considered in addressing outcomes PO20, PO23, PO29 PO34, PO46, PO52, PO58, PO65, PO76 and PO82 of the Character residential zone code.

(a) casement windows and louvers;

Figure SC6.2.3.14 Illustrates an example of two vertically proportioned casements and louvers either side, centrally located under the apex of a gable projection

Figure SC6.2.3.15 Illustrates an example of five vertically proportioned casements located under the apex of a gable projection

(b) bay windows; and

Figure SC6.2.3.16 Illustrates an example of projecting bay window with four casement frames two located centrally and one either side

(c) full height windows.

Figure SC6.2.3.17 Illustrates an example of a full height window, acceptable in 1960's Defence Housing Precinct only

SC6.2.3.4 Building materials

Lightweight construction materials are typical within Townsville's character residential precincts. Lightweight construction materials are traditionally "timber and tin" products. New works within a character residential precinct can replicate lightweight construction using other materials, provided the appearance of lightweight construction is achieved. This section provides guidance on how to achieve PO15 of the Character residential zone code.

(1) Buildings and new works can use materials that are lightweight in appearance and sympathetic with the character of the streetscape. Where traditional lightweight materials are not able to used, non–lightweight materials are acceptable, provided the materials and methods used reflect the appearance of lightweight construction.

An example of an acceptable construction (Figure SC6.2.3.18, left) shows non-lightweight materials that reflect lightweight construction by referencing a raised appearance using textured cladding. An example of an unacceptable construction (right) shows a rendered wall that does not reference a lightweight appearance.

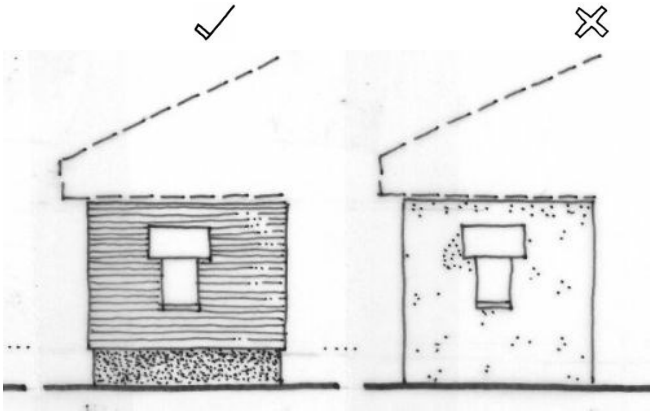

Figure SC6.2.3.18 An example of an acceptable construction (left), and an unacceptable construction (right)

(2) The design materials and principles below provide acceptable examples which can be considered for achieving PO15 of the Character residential zone code.

(a) Typical use of expressive materials in the Character residential zone precincts includes:

(i) chamferboard: A common exterior timber cladding. Several profiles of chamferboard exist, produced in several timber types, such as silky oak, cedar and hardwoods (as shown in Figure SC6.2.3.19);

Figure SC6.2.3.19 Illustrates traditional use of timber chamferboard on external walls

(ii) expressed studwork: Typical of traditional timber framed homes. A practice of fixing the weatherboards to the inner surface of the stud frame and leaving the outer surface uncovered. Evolved to be both functional and decorative (as shown in Figure SC6.2.3.20);

Figure SC6.2.3.20 Illustrates traditional use of expressed studwork walls

(iii) manufactured cladding: Exterior building veneer material. Can be used as an overlay to an existing exterior; some cladding products are known as siding. Manufactured cladding can be used to mimic traditional materials such as chamferboard (as shown in SC6.2.3.21);

Figure SC6.2.3.21 Illustrates new works using manufactured cladding in imitation of traditional lightweight materials

(iv) corrugated galvanised iron: A common roofing material in Australia (as shown in Figure SC6.2.3.22); and

Figure SC6.2.3.22 Corrugated galvanised iron is typical for roofing in Townsville Character buildings

(v) masonry is acceptable for use with external walls where it is finished in the appearance of lightweight construction, and/or used in conjunction with lightweight cladding materials (as shown in Figure SC6.2.3.23).

Figure SC6.2.3.23 Illustrates desirable outcome of a masonry constructed home with a "lightweight appearance"

SC6.2.3.5 Maintaining the street rhythm (scale and proportion)

Maintaining the street rhythm within a character residential precinct is paramount to preserving the character of any particular precinct. Street rhythm can be maintained by repeating the scale and proportions of the character buildings that are predominant in the streetscape. This can be achieved in terms of building heights, setbacks from the street, width of the front facades, and elevation of the floor levels.

Figure SC6.2.3.24 Illustrates an example of an acceptable ground floor enclosure

Figure SC6.2.3.24 illustrates an acceptable example; a raised character building that has been enclosed on the ground level, recessed the full width of the front verandah, using complementary materials and includes a valance in appropriate scale and proportion (this may be considered in addressing numerous Character residential zone code outcomes).

SC6.2.4 Non-residential contributing character buildings

SC6.2.4.1 Non-residential uses

This section of the policy provides guidance in relation to addressing outcome PO35 of the Character residential zone code. In particular, for those properties listed in Appendix 2 - Contributing non-residential properties.

In the South Townsville precinct, non-residential uses and buildings are a contributing element to the precinct's defined character. These non-residential buildings and uses reflect the early settlement and lifestyle of South Townsville.

(1) Typical elements of non-residential contributing character buildings in the South Townsville precinct include:

(a) no setback to street boundaries, and provide an awning and footpath for the full extent of the primary street frontage (as shown in Figure SC6.2.4.1 and Figure SC6.2.4.2); and

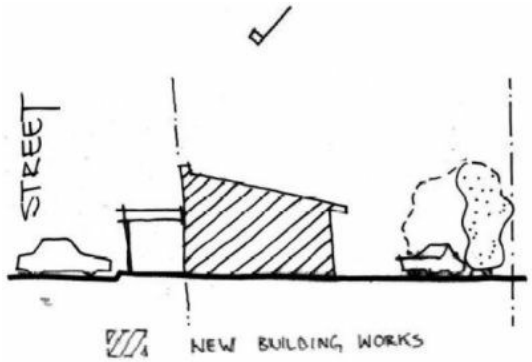

Figure SC6.2.4.1 Non-residential building with no setback to street boundary, awning over the footpath and parking on the street or behind the building

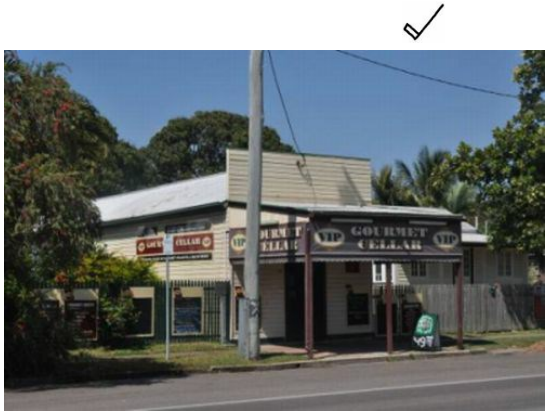

Figure SC6.2.4.2 Existing acceptable example of a non-residential use in an acceptable non-residential building (no setback to street boundary and awning over footpath)

(b) utilise on-street car parking, and/or on-site parking is behind the building and obscured by landscaping screen.

Note—where an existing non-residential non-contributing character building is not retained, the site may be converted to a residential use to match the scale and rhythm of adjacent contributing character residential buildings.

SC6.2.5 Reconfiguring a lot

The following design principle is provided as material for consideration when addressing PO11 of the Character residential zone code.

(1) To maintain the rhythm and consistency of the streetscape, the installation of a fence that is tapered in height from the street front to the front façade of the building may be considered (Figure SC6.2.5.1 illustrates an acceptable outcome).

Figure SC6.2.5.1 Illustrates access strip fencing tapered from the front façade of the building to the street boundary (measurements are provided only as an example)

SC6.2.6 Information that may support a development proposal

SC6.2.6.1 Elevations and streetscape

Development proposals should provide clear representations of the relationship between adjacent contributing character buildings and the proposed works to ensure that the design of development is undertaken with a clear understanding of the surrounding context.

Development applications should provide front/street elevations of the proposed works and of each adjoining contributing character building. References of key elements from adjoining contributing character buildings (roof type/pitch, floor elevations, windows, building materials, building height, setbacks, scale and proportions) should be made in all new works.

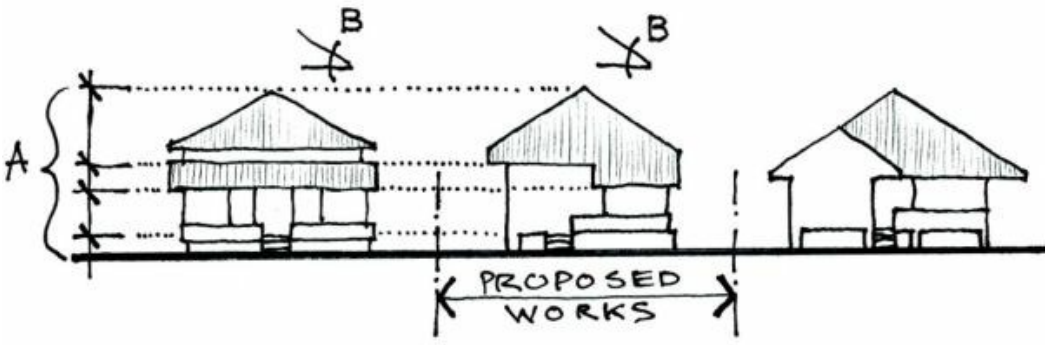

Figure SC6.2.6.1 Illustrates an example of clear elevations of the proposed works and adjoining contributing character buildings, with references made to key elements

SC6.2.6.2 Preparing an assessment report

The following is advice for preparing an assessment report for a property or building within the Character residential zone code. This may be required to demonstrate achievement with the relevant performance outcomes in the Character residential zone code.

An assessment report may provide specific information about how a proposed development will affect the character residential precinct.

The report should include the following:

(1) A brief description of the proposed development including:

- (a) type of development;
- (b) range and scope of work proposed;
- (c) timeframe for carrying out work; and
- (d) location of work in relation to the character residential precinct;

(2) A description of the setting and context of the place, including photographs and maps showing significant features that will be affected. Provide an analysis of the affect the development will have on the streetscape;

(3) A description of proposed changes to character including:

(a) what elements or aspects of streetscape are affected by the change;

(b) assessment of the proposal against the performance outcomes in the zone code;

(c) analysis of the impact of the change on the significance of the precinct;

(d) assessment of potential for detrimental impact on the significance of the precinct; and

(e) where the proposed change is assessed as having potential for detrimental impact, provide information about why the change is required, alternative solutions that were investigated, and what measures are included in the development to reduce detrimental impact that may result from the change; and

(4) References list documents referred to in the assessment report such as conservation policies, conservation management plan, condition report (i.e. demolition report), and specialist consultants' reports. (Adapted from Guideline: *Preparing a Heritage Impact Statement* Department of Environment and Heritage Protection, 2011).

SC6.2.6.3 Preparing a condition report

If an application is proposing demolition of a contributing character building, the applicant may be requested to provide a condition report. The condition report should, at a minimum, include consideration of:

(a) the structural stability of the building in the form of a structural engineer's report. The condition report must include a factual statement from an appropriately qualified structural engineer about the condition of the building; and

(b) a pest inspection report and other supporting documentation may also be provided.

Appendix 1

SC6.2 APPENDIX 1: Non-contributing properties in the Character residential zone

Precinct A – 1950's Post War Expansion

Address	Comments
79 Lancaster Street	Original house that has been re-clad with face brick, including brickwork fence. Original roof form and windows have been retained, however brickwork is out of character
18 Lockheed Street	Contemporary rendered blockwork slab on ground house with double garage facing the street and rendered masonry front fence.
62 Perroux Street	High-set house
10 McHardie Street	Blockwork house
14 McHardie Street	Blockwork house
29 Downs Street	Blockwork house

Precinct B – 1960s Defence Housing and 1960s Housing Commission

Address	Comments
55 Clements Crescent	Substantial tornado damage
2 Lancaster Street	Low-set house
3 Lancaster Street	"Ranch Style" high set house – different style to predominant character
4 Lancaster Street	Low-set house
46 Douglas Street	Oriented to other street – does not relate to rest of precinct

Precinct C – Worker's Cottages

Address	Comments
4 Fifth Street	Vacant Lot
6 Fifth Street	Vacant Lot
3 Fifth Street	High-set horizontally massed house with shallow pitched roof
2 Flowers Street	High-set horizontally massed house
16 Flowers Street	Low-set Blockwork house
26 Flowers Street	Horizontally massed with prominent carport
77 Ninth Avenue	High-set horizontally massed house
1A Doorey Street	Low-set rendered house with prominent carport to front boundary
66 Tenth Avenue	Low-set blockwork duplex
60 Eleventh Avenue	High-set horizontally massed house
63 Eleventh Avenue	High-set horizontally massed house
73 Eleventh Avenue	High-set fibre cement clad house
75 Eleventh Avenue	High-set horizontally massed duplex
12 Fourteenth Avenue	Low-set blockwork house
14 Fourteenth Avenue	Low-set blockwork house
13 Fifteenth Avenue	High-set horizontally massed house
40 Seventh Street	Low-set fibre-cement house with skillion roof
7 Third Street	Low-set blockwork house
9 Third Street	High-set horizontally massed house with shallow pitched roof
14 Third Street	Low-set blockwork house (obscured by garden)
19 Third Street	High-set horizontally massed duplex
31 Flowers Street	Low-set blockwork house
258 Boundary Street	Blockwork Duplex
288 Boundary Street	Horizontally massed high-set house
1 Cape Street	Blockwork House
2 Cape Street	Horizontally massed high-set house
2 Comet Street	Low-set fibre cement house with shallow roof pitch
6 Fourth Avenue	Low-set house with shallow roof pitch
30A Sixth Avenue	Horizontally massed house with blockwork arches
37 Sixth Avenue	Vacant Lot
26 Sixth Street East	Horizontally massed high-set house
52A Sixth Street East	Vacant Lot
53 Sixth Street East	Vacant Lot
55 Sixth Street East	Water Police Office
57 Sixth Street East	Vacant Lot
56-58 Sixth Street East	Vacant Lot
19 Eighth Avenue	Horizontally massed two storey house
26 Perkins Street	Low-set blockwork house
37 Davidson Street	Low-set block house with large setback
40 Davidson Street	Low-set coloured blockwork house
42 Davidson Street	Rendered low-set house with tiled roof and garage door on street
15 Baxter Street	Original character house – raised to two storeys and poorly enclosed front verandah.
21 Baxter Street	Low-set brick block of units
22 Baxter Street	Rendered low-set house with visually prominent garage
7A Garrick Street	High-set fibre cement house with shallow pitched front gable
12 Garrick Street	Low-set brick house
16 Garrick Street	Low-set blockwork house
9-11 Castling Street	High-set “Ranch” style fibro house with shallow pitched roof
8 Castling Street	Blockwork lowest house
15 Estate Street	Modern, unsympathetic new dwelling, inconsistent setback, subdivision not consistent with other blocks

15A Estate Street	Modern, unsympathetic new dwelling, inconsistent setback, subdivision not consistent with other blocks
17 Estate Street	Low-set house with shallow front gable
18 Estate Street	Horizontally massed house
26 Estate Street	High-set 1950s era house
28 Estate Street	Low-set masonry – only visible expression is front double carport
3 Townsville Street	High-set fibre cement clad with shallow pitched front gable
4 Townsville Street	High-set horizontally massed house
5 Townsville Street	Unsympathetically raised house
7 Townsville Street	Character house with blank blockwork wall in front
15A Townsville Street	Rendered low-set house with prominent front carport
27 Townsville Street	Vacant lot
2 Edwards Street	Low-set rendered house with very shallow roof pitch
7 Edwards Street	Recent house with disproportionate front setback and prominent front carport
7A Edwards Street	Recent house with disproportionate front setback and prominent front carport
17 Edwards Street	Gable fronted two storey units
18 Edwards Street	Low-set house with brick walls and single front gable
6 Lamington Road	Brick “six pack” unit block
12-14 Lamington Road	Blockwork units, tiled roof
13 Lamington Road	Blockwork units
6 Humphrey Street	Two storey brickwork units
14 Humphrey Street	Low-set blockwork units
15 Humphrey Street	Low-set blockwork house
25 Humphrey Street	Unsympathetically raised and renovated character house
5 Plant Street	Two storey blockwork “six-pack” units
6 Shaw Street	Oversized modern highest house with gable – out of scale
22 Shaw Street	High-set “Ranch” style
25 Shaw Street	Low-set blockwork duplex
9 Shaw Street	Blockwork units

Precinct D – South Townsville (Residential)

Address	**Comments**
66 Allen Street	Rendered two storey house with prominent carparking
75 Allen Street	Low-set blockwork house
30 Allen Street	Low-set rendered house
10 Bell Street	Low-set fibre cement house
15 Bell Street	Horizontally massed high-set house
17 Bell Street	Brick and tile house
21 Bell Street	St Andrews Villas – Brick low-set
37A Bell Street	Rendered duplex
37B Bell Street	Rendered duplex
183 Boundary Street	Horizontally massed high-set house
283-285 Boundary Street	Low-set blockwork house
1 Cannan Street	Contemporary house under construction
17 Hubert Street	Character house raised on disproportionately high stumps
41 Macrossan Street	Horizontally massed high-set house
55 Macrossan Street	Two storey blockwork house
5 Martin Street	Low-set duplex with very prominent garages
10 Martin Street	Low-set rendered duplex
7 Nelson Street	Brick and tile house
13 Nelson Street	Wide low-set rendered house
18 Nelson Street	Brick duplex with blank gable end facade
21 Nelson Street	Vacant lot
22 Nelson Street	Low-set blockwork house

43-45 Nelson Street	Brickwork units
46 Nelson Street	Contemporary skillion roofed house – lacks front verandah
50 Nelson Street	Brick and tile house
52 Nelson Street	Brick and tile house
54 Nelson Street	Low-set blockwork house
71 Perkins Street	Low-set rendered house
85 Perkins Street	Vacant lot
115 Perkins Street	Unsympathetically converted commercial building
8 Tully Street	Blockwork duplex
42 Tully Street	Two storey brickwork house
44 Tully Street	Mock heritage low-set house
73 Tully Street	Rendered two storey house – lacks shade elements
81 Tully Street	Two storey blockwork house
91 Tully Street	Low-set blockwork house
97 Tully Street	Low-set rendered house
105 Tully Street	Multiple units

Precinct D – South Townsville (Non-Residential)

Address	**Comments**
50 Allen Street	Rendered recent commercial building – built to front boundary, however lacks street activation and awnings to footpath
12-20 Bell Street	Large contemporary warehouse building – Sigma Pharmaceuticals
20A Bell Street	Shades By Prior – rendered recent commercial building built to boundaries, however lacks substantial awnings to footpath
22 Bell Street	Map to Mine – commercial offices with large front setback
8 Cannan Street	Sabre Marine – large light industrial shed with large setback to the street and front hardstand area
10 Cannan Street	Basic commercial building with large front setback and extensive front carparking area
12 Cannan Street	Basic commercial building with large front setback and extensive front carparking area
6 Hubert Street	NSS (Northern Stevedoring Services) Shed with large hardstand area to street
3-7 Macrossan Street	South Townsville Self-Storage – secure self-storage complex
11 Macrossan Street	Portside Self-Storage – secure self-storage complex
13-17 Macrossan Street	U-Store – secure self-storage complex
36 Macrossan Street	Home-grown Hardwoods – large setback to the street and prominent front hardstand and storage area
38 Macrossan Street	SSAF Sheetmetal – Light industrial shed built to front and side boundaries however lacks street activation or awnings to footpath. May be suitable for retrofitting or refurbishment to improve character values.
45 Macrossan Street	Black River Cattle Equipment – light industrial use and rear shed destroys character values of retained house.
47 Macrossan Street	Abraham Steel Fabrications – large light industrial shed.
53 Macrossan Street	C&C Motors Shed – light industrial shed
46 Morey Street	Furniture warehouse with relatively blank blockwork façade to street and lack of shade to footpath. Appears suitable for retrofitting or refurbishment to improve character values.
19 Perkins Street	Light Industrial shed setback from street with hardstand area to front
41 Perkins Street	Murphy Steel Fabrications – Open light industrial shed with general storage in fenced yard.
75 Perkins Street	Dick Yuen Wholesale – Large front setback and extensive front hardstand area
99 Perkins Street	Kirk's Automotive Service – Shed to street frontage – interrupts an otherwise consistent row of character houses. Shed to rear of site may have some character value however is not readily visible from the street.

113 Perkins Street	Hood the Sailmakers Offices – blockwork commercial building. Built to front and side boundaries however lacks street activation and awnings to footpath. Appears suitable for retrofitting or refurbishment to improve character values.
3 Tully Street	U-store – secure self-storage complex
17 Tully Street	Shed with large front setback
50 Tully Street	Commercial complex with relatively blank blockwork façade to street and prominent driveway.
58 Tully Street	Warehouse complex. Built to front and side boundaries, however blank blockwork façade and lack of shade to footpath. Appears suitable for retrofitting/refurbishment.
80 Tully Street	Woodfield Engineering – basic light industrial shed
102 Tully Street	Fenced site – otherwise vacant

Precinct E – Queenslanders

Address	**Comments**
12 The Avenue	3 storey blockwork “Six-pack” units
16 The Avenue	2 storey brick units
7 Ackers Street	Three storey blockwork units
16 Ackers Street	Brickwork units
24 Ackers Street	Blockwork units
26 Ackers Street	Blockwork units
29-31 Ackers Street	Blockwork units
32 Ackers Street	Blockwork units
39 Ackers Street	Brick and tile house
42 Ackers Street	Low-set duplex
57 Ackers Street	Blockwork units
64 Ackers Street	Low-set blockwork duplex
66 Ackers Street	Horizontally massed high-set house
68 Ackers Street	Horizontally massed high-set house
69 Ackers Street	Low-set fibre cement units
2 Ahearne Street	Vacant lot
19 Ahearne Street	Brickwork base, horizontally massed highset house
25 Ahearne Street	Horizontally massed high-set house
27 Ahearne Street	Horizontally massed high-set house
35 Ahearne Street	Blockwork units
36 Ahearne Street	Horizontally massed high-set house
38 Ahearne Street	modern duplex
47 Ahearne Street	Blockwork units
51 Ahearne Street	Two storey contemporary units – some sympathetic elements however overall bulk and prominent garages are detrimental.
52 Ahearne Street	Vacant lot
54 Ahearne Street	Blockwork Units
70 Ahearne Street	Brickwork house
7 Armstrong Street	Blockwork low-set units
16 Armstrong Street	Horizontally massed high-set house
18 Armstrong Street	Three storey blockwork units
27 Armstrong Street	Low-set brick units
28 Armstrong Street	Horizontally massed high-set house
30 Armstrong Street	Low-set brick units
39 Armstrong Street	Two storey brick units
41 Armstrong Street	Fibre cement building with shallow roof pitch – used as offices
44 Armstrong Street	Two storey blockwork with arches
50 Armstrong Street	Blockwork low-set house
54 Armstrong Street	Brickwork units

56-58 Armstrong Street	Blockwork units
64 Armstrong Street	Vacant lot
78 Armstrong Street	Low-set rendered house
36-38 Ackers Street	Two storey brick units
4 Campbell Street	Blockwork units
6 Campbell Street	Blockwork units
2 Marks Street	Horizontally massed high-set house
16 Marks Street	Two storey blockwork units
18 Marks Street	Two storey rendered units
13 Philp Street	Rendered low-set units
16 Philp Street	Blockwork low-set units
19 Philp Street	Two storey brick house
21 Philp Street	Low-set rendered house
27 Philp street	Brick two storey units
37 Philp Street	Vacant Lot, not gazetted address, part of 35 Philip but fenced off
42 Philp Street	Rendered two storey units
9 Campbell Street	Masonry rendered 2 storey house (actually rear of lot at 42 Philip St, but driveway is to Campbell & post-box has number 9 on it.
14 Summerfield Street	Vacant lot
2A Ralston Street	Low-set blockwork units
2 Ralston Street	Low-set blockwork units
16 Ralston Street	Two storey blockwork units
18 Ralston Street	Vacant lot
45 Henry Street	Two storey blockwork units
125-127 Francis Street	Church, modern brickwork
129 Francis Street	Masonry units
146 Francis Street	Low-set blockwork house with very shallow roof pitch
154 Francis Street	Low-set house with stipple render finish
36 Leigh Street	Two storey units – face brickwork with fibre cement chamfer boards
56 Leigh Street	Light industrial building
25 Stagpole Street	Prominent three storey blockwork units
30 Stagpole Street	Horizontally massed high-set house
32 Stagpole Street	Blockwork low-set house with shallow roof pitch
33A Stagpole Street	Newly reconfigured house
40 Stagpole Street	Low-set rendered units (“6 pack”)
43A Stagpole Street	Newly reconfigured house
49 Stagpole Street	Open light industrial shed
52 Stagpole Street	Low-set shallow pitched hipped roof house with high fence and low floor height
82 Stagpole Street	Horizontally massed high-set house
83 Stagpole Street	Shallow pitched skillion roofed fibre cement clad house
86 Stagpole Street	Low-set blockwork units
93 Stagpole Street	Horizontally massed 1960’s era high-set house. Front setback blocks views to “Wolverton”.

Precinct F – Interwar Gables and Queensland Bungalows

Address	**Comments**
14 Chubb Street	Rendered front parapet (addition) and tall rendered fence
16 Chubb Street	Rendered
15 Taylor Street	Horizontally massed high-set house
16 Taylor Street	Vacant lot
20 Taylor Street	Horizontally massed high-set house
12 McKillop Street	Brick house with prominent front carport
3 Mawai Street	Low-set blockwork house with high fence
8 Mawai Street	Horizontally massed high-set house

4 Mears Street	Horizontally massed high-set house
6 Mears Street	Horizontally massed high-set house
11 Mears Street	Horizontally massed high-set house
22 Mears Street	Brick and tile units
24 Mears Street	Street frontage dominated by double carport with roller doors
34 Mears Street	Two storey block of units with shallow pitched roof
30 Hammond Street	Horizontally massed high-set duplex

Precinct G – Interwar to 1950s Asymmetrical Gable

Address	Comments
34 Hooper Street	Low-set blockwork duplex
35 Hooper Street	Low-set skillion roofed house with prominent front carport
26 Hooper Street	Vacant lot
53 Princes Road	Units
14 Princes Road	Two storey units
29 Princes Road	Units
30 Princes Road	Units
16 Sussex Street	Blockwork low-set house
3 Batt Street	Modern rendered with skillion roof
9 Batt Street	Slab on ground, flagstone veneer
3 Purves Street	Slab on ground, rendered modern
21 Kenilworth Street	Low pitch mono gable horizontally massed
22 Kenilworth Street	Low-set render low pitched roof
23 Kenilworth Street	Brick veneer, two storey
24 Kenilworth Street	Not representative of character, but good tropical house
12 Kenilworth Avenue	Two storey unit development
6 Surrey Street	High-set fibre cement clad house
14 Surrey Street	Brick low-set house
16 Surrey Street	Brick low-set house
20 Surrey Street	Brick House
19A Surrey Street	High-set fibre cement clad house
21A Surrey Street	“Six pack” unit block
31 Townsend Street	Rendered blockwork house with prominent front garage
5 Burton Street	Low-set blockwork duplex
34 Townsend Street	Skillion roofed low-set house with rendered walls. Possible 1950s era
7 Burton Street	Low-set brickwork duplex
12 Burton Street	Low-set blockwork house
25 Burton Street	Low-set blockwork duplex
26 Burton Street	Horizontally massed high-set house
5 Ballard Street	Horizontally massed high-set house
11 Ballard Street	Horizontally massed high-set house
13 Ballard Street	Horizontally massed low-set house
15 Ballard Street	Rendered low-set house with shallow front gable
16 Ballard Street	Two storey, two car garage to front
40 Purves Street	Horizontally massed high-set house
51 Purves Street	Two storey unit building
55 Purves Street	Low-set blockwork house
57 Purves Street	Vacant lot
25 Mindham Street	Low-set rendered duplex

Precinct H – Churchill Street

Address	Comments
9 Churchill Street	High-set house with shallow pitched gable roof
11 Churchill Street	Low-set blockwork house with shallow pitched roof and lack of windows oriented towards street

Precinct I – Park Street

Address	Comments
22 Gladstone Street	Terrace Style Unit development. Width of building facing Park Street far exceeds character houses.
24 Gladstone Street	Pre 1946 house, however house faces Gladstone Street and does not contribute to Park Street Precinct streetscape.
20 Park Street	Unit Development. Incorporates some sympathetic features such as front verandah and fence.
21 Park Street	60's era High-set house with fake brick cladding
23 Park Street	Blockwork unit development with blank street frontage and no fence.

Precinct J – Grand Queenslanders

Address	Comment
17 Alexandra Street	3 storey brickwork units
26 Alexandra Street	Rendered house with shallow roof pitch and no front verandah
32 Alexandra Street	Low-set brick and tiled roof house
40 Alexandra Street	Two storey blockwork house
43 Alexandra Street	Two storey 1950s house with flush lower level and dominant rendered front retaining wall.
44 Alexandra Street	4 storey blockwork units
46 Alexandra Street	Rendered two storey units with tiled roof
1 Burke Street	4 storey blockwork units
2 Burke Street	Low-set masonry units
32 Paxton Street	Two storey rendered units with blank façade and prominent parking
21 Cleveland Terrace	Rendered Units – wide form/bulk, Mediterranean style
19 Cleveland Terrace	Brick unit building. Wide, horizontal massing.
11 Cleveland Terrace	Brick unit building. Setback from street does not align with neighbours
27 Cleveland Terrace	Building site – design appears to be modern house with materials that are not related to surrounding context.
34 Cleveland Terrace	Shallow gabled low-set house. Overly large front setback. Fibre cement wall cladding.
7-11 Hamilton Street	Very large site – Vacant apart from small 70s/80s era fibre cement clad dwelling.
3-5 Hamilton Street	Vacant
25 Melton Terrace	70's era fibre cement clad units. Dilapidated.
7 Victoria Street	Two storey rendered house with shallow roof pitch and prominent double garage
18-20 Victoria Street	Blockwork and tile duplex
15-19 Victoria Street	Ridgemont Motel – Blockwork and tiled roof
26-28 Victoria Street	Skillion roofed house
273 Stanley Street	Skillion roofed cottage
277 Stanley Street	Derelict cottage
279 Stanley Street	Brick units
37 Hale Street	Two storey fibre cement clad unit building – lacks front verandah.
39 Hale Street	Modest low-set house with large street setback and no front verandah.

Precinct K – French Street

Address	Comments
18 French Street	Blockwork unit block with large setback
16 French Street	Blockwork House with tiled roof
20 French Street	Modern unsympathetic units
27 French Street	Enclosed block work on ground floor and the removal of external front staircase
13 French Street	Low-set rendered masonry units

Precinct L – Mixed 1950's

Address	Comments
2 Goodwin Street	Blockwork low-set house
28 Goodwin Street	1960's era high-set house
56 Goodwin Street	Rendered contemporary low-set house
66 Goodwin Street	Horizontally massed high-set duplex
69 Goodwin Street	Blockwork low-set house
101 Goodwin Street	Blockwork low-set with tiled roof
3 McDougall Street	Horizontally massed high-set duplex
4 McDougall Street	Horizontally massed high-set duplex
27 Haig Street	3 storey unit development
3-5 Haig Street	Unit Development
2B Haig Street	Unsympathetic modern dwelling
6 Haig Street	Low-set house with prominent flat roofed extension facing Haig Street
10 Isley Street	Brick veneer, timber floor low-set house
12 Isley Street	Brick veneer on slab
146 Howitt Street	Three storey apartment complex
146 Mitchell Street	Two storey units

SC6.2 APPENDIX 2: Contributing non-residential properties

Address	Comments
38-42 Allen Street	Former Petrol Station – currently Motolec Auto Electrical. Current use of forecourt for fenced general storage is detrimental to precinct character; however, site contains former petrol station buildings that are part of the mixed precinct character. Site would benefit from refurbishment and new use with greater street activation.
39 Allen Street	Pre1941 commercial building built to front boundary with 2 shopfronts and awning over footpath.
34 Archer Street	Former basic light industrial shed – patina of weathered corrugated iron and surrounding gardens contributory.
25 Bell Street	Character house converted into two storey commercial building. No setback to front boundary and includes awning to footpath.
33 Bell Street	Pre 1941 commercial building built to front boundary. Character value reduced by added blockwork façade and lack of awning to footpath.
173 Boundary Street	Pre 1941 small chamferboard shop to street with awning. High chainlink fence to property boundary is detrimental to the character.
265 Boundary Street	Small row of shopfronts with awning to footpath. Parts appear to be pre1941. Unusual 1960's era two storey units on the same parcel of land – units appear to have potential for retrofitting/refurbishment.
32 Hubert Street	St Patrick's Catholic Church and former school building.
20 Macrossan Street	Commonwealth Hotel. Two storey corner hotel with wraparound verandahs over footpath. Very important contributor to local character.
30 Macrossan Street	St Johns Anglican Church
65 Morey Street	Bahai Community Centre
25 Perkins Street	Building materials site with pre 1941 twin gabled sheds built to Perkins Street Boundary. Current use of site for open storage is detrimental to precinct character however sheds have character value and appear suitable for retrofitting or refurbishment.
45 Perkins Street	South Side Engineering – light industrial gabled shed with some character values and appears suitable for retrofitting or refurbishment.
89 Perkins Street	Former 1950s era Art Deco influenced brick and tile house. Features curved walls and unusual plan. Currently used as offices for Family Emergency Accommodation Townsville – generally retains residential appearance.
115-147 Perkins Street	Heritage listed Warehouse building with brick components dating from 1899. Property is in relatively poor condition. Site is very large and mainly open hardstand – the heritage building occupies the Cannan Street end only. Sympathetic retrofitting or refurbishment will be required to retain the character values of this property.

SC6.3 Cultural heritage planning scheme policy

SC6.3.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Cultural heritage PSP.

SC6.3.1.1 Purpose

The purpose of the planning scheme policy is to provide applicants with additional information and guidance in meeting the requirements of the Cultural heritage overlay code and the Advertising devices code for signage in Flinders Street East.

SC6.3.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.3.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan, specifically the Cultural heritage overlay code and Advertising devices code.

SC6.3.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 – Definitions, is to be interpreted in accordance with Part 1.3.1.

SC6.3.2 Planning scheme policy details

The cultural heritage of Townsville continues to be a major contributor to the identity of the City and local communities. The Citation of Heritage Places Report provides information about each heritage place in Townsville. It highlights the criteria that were originally identified for each place and indicates its significant heritage features and eligibility for entry into Schedule 7 Places of cultural heritage value.

This planning scheme policy contains information to help individuals and groups identify, conserve and protect heritage places in Townsville. This policy provides applicants with guidance in meeting the requirements of the Cultural heritage overlay code and the Advertising devices code (where it relates to advertising devices for heritage places in Flinders Street East). The policy also details how to nominate to add a place to Schedule 7 Places of cultural heritage value and how to nominate to remove a place from Schedule 7 Places of cultural heritage value.

SC6.3.2.1 Finding your way around the policy

The policy is divided into the following nine sections:

(1) Information that may support a development proposal (SC6.3.3);

(2) Development adjoining a heritage place (SC6.3.4);

(3) Development within a heritage place, including advertising devices (SC6.3.5);

(4) Preparing a heritage impact statement report (SC6.3.6);

(5) Preparing a condition report (SC6.3.7);

(6) Preparing archival recording of a heritage place (SC6.3.8);

(7) Interpretive signage for the loss of a heritage place (SC6.3.8.3);

(8) Preparing an archaeological management plan (SC6.3.9); and

(9) Adding or removing a place to Schedule 7 Places of cultural heritage value (SC6.3.10).

SC6.3.3 Information that may support a development proposal

The information required for any development application will depend on the heritage significance of the heritage building, site or element and the proposed development. In addition to the requirements for development applications under the *Planning Act 2016* (PA) and the relevant Integrated Development Assessment System forms, the following additional information should generally be provided to council.

(1) To ensure that the design of the proposed development is undertaken with a clear understanding of the surrounding context and significance of "place", the proposed application should submit clear representations of the relationship between the heritage buildings and the proposed works.

(2) The applicant should submit a street elevation of the proposed development. The elevation is to be

(a) drawn to 1:200 scale;

(b) include the full width of the street frontage of the proposed development and the two adjacent neighbouring buildings (as shown in Figure SC6.3.3.1);

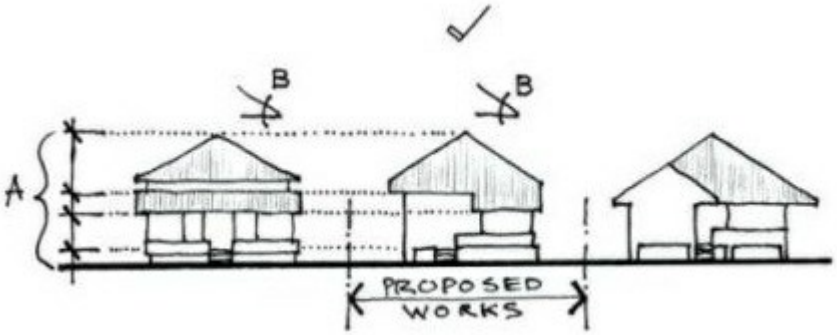

Figure SC6.3.3.1 Illustrates desirable outcome. 'A' denotes key building lines and 'B' is the referenced roof pitch. This may provide clear representations of relationship between the heritage place and the proposed works such as floor heights, dominant fascia lines, roof lines, roof pitch etc.

(c) provide accurate representations of the primary design considerations: setbacks, form, massing, height, materials, finishes, and key detail elements that contribute to the significance of the heritage place;

(d) for new buildings adjoining a heritage place, indicate key building lines in relation to the heritage place (as shown in Figure SC6.3.3.2); and

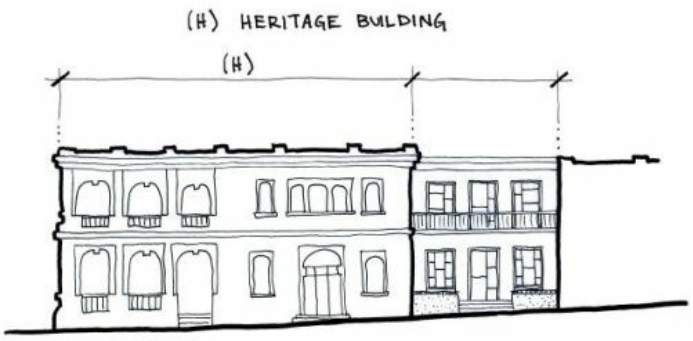

Figure SC6.3.3.2 Key building lines in relation to the heritage place

(e) for new works that are proposed to be visually obscured by a heritage feature, consider demonstrating view lines using a cross section drawing (as shown in Figure SC6.3.3.3).

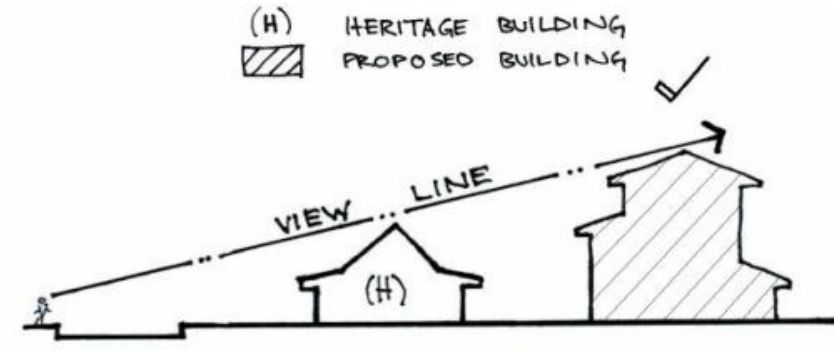

Figure SC6.3.3.3 View lines using a cross-section drawing

(3) In addition to the requirements above, for buildings with a height greater than 2 storeys, the applicant may be requested to submit:

(a) three dimensional perspective images inclusive of the adjacent neighbouring buildings; and

(b) in urban contexts in which the streetscape is of uniform height consistent with the height of the heritage place, provide an elevation drawing of the full width of the street block and nominate a "reference height".

SC6.3.4 Development adjoining a heritage place

This section of the policy provides guidance in achieving performance outcome PO13 of the Cultural heritage overlay code associated with setbacks for development, building height and scale and form of development adjoining a heritage place.

SC6.3.4.1 Setback for development

PO13 of the Cultural heritage overlay code requires that new buildings be consistent with the significant features and values of the heritage place, including, but not limited to, built form and setbacks, maintain significant views to and from the heritage place and ensure that new buildings are visually subservient.

(1) To achieve the requirements of the performance outcomes in the code and allow for significant views to and from a heritage place to be maintained, the following design guidance should be considered.

(a) in instances where the significance of the heritage place includes its setback in common with the established street pattern, the setback of new works ought to maintain this significance (as shown in Figure SC6.3.4.1);

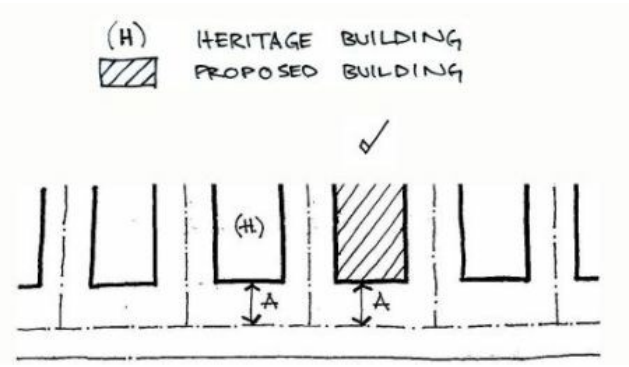

Figure SC6.3.4.1 Illustrates appropriate front setbacks for development adjoining a heritage place. "A" is the street setback distance.

(b) in instances where the significance of the heritage place includes its difference in setback to the established street pattern, the setback of new works ought to maintain this significance (as shown in Figures SC6.3.4.2- SC6.3.4.6); and

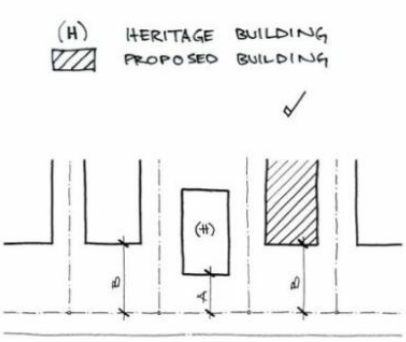

Figure SC6.3.4.2 Illustrates appropriate front setbacks for development adjoining a heritage place. "A" and "B" is the street setback distance.

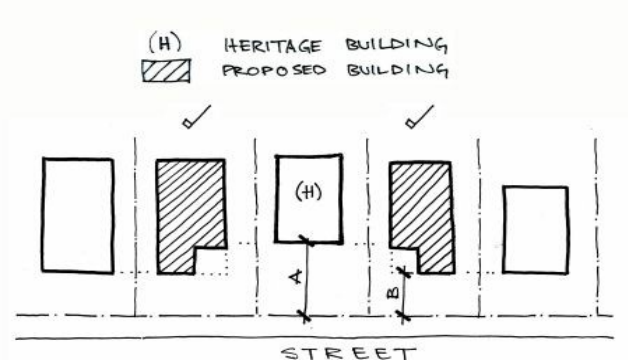

Figure SC6.3.4.3 Illustrates appropriate front setbacks for development adjoining a heritage place. "A" and "B" is the street setback distance

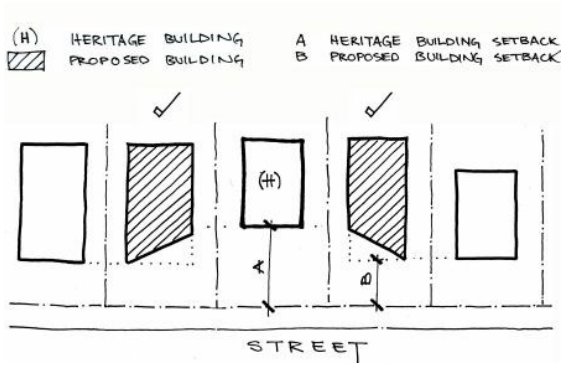

Figure SC6.3.4.4 Illustrates appropriate front setbacks for development adjoining a heritage place. 'A' and 'B' is the street setback distance

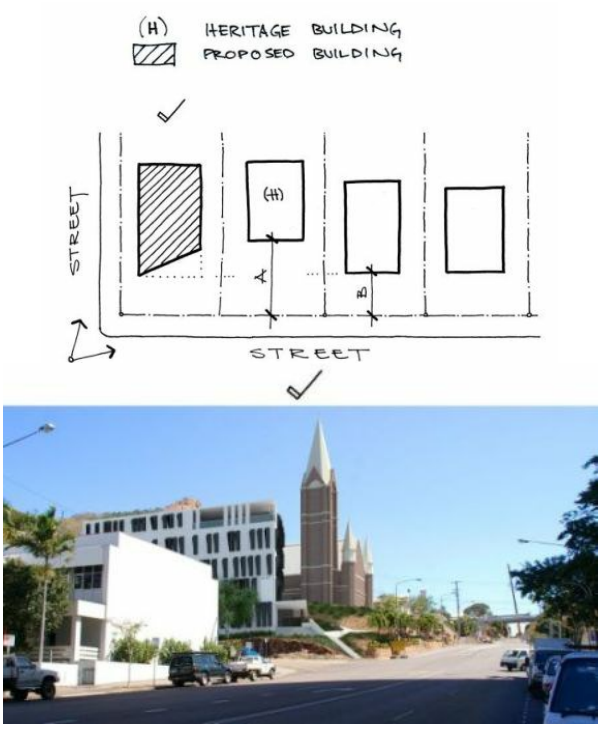

Figure SC6.3.4.5 Illustrates appropriate corner block front setback for development adjoining a heritage place. "A" and "B" is the street setback distance. The setback of new development is tapered to allow improved views to the heritage place.

(c) in order to achieve visual subservience to a heritage place in accordance with PO13, building form ought to be articulated into smaller elements to relate to scale, rhythm and spacing of the heritage place and its context (as shown in Figure SC6.3.4.6).

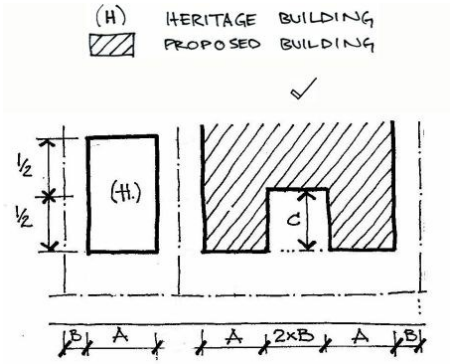

Figure SC6.3.4.6 Illustrates sympathetic building frontage rhythm. "B" is side setback; "C" (being the depth separation to get sympathetic building frontage rhythm) is 6m or ½ of "H" (heritage building depth)

SC6.3.4.2 Building height

(1) Where parts of the development are proposed to be taller than adjacent significant heritage elements, the following design guidance may be considered to demonstrate achievement of performance outcome PO13 of the Cultural heritage overlay code:

(a) proposed taller elements of the proposed new building are to be setback to diminish their impact (as shown in Figure SC6.3.4.7);

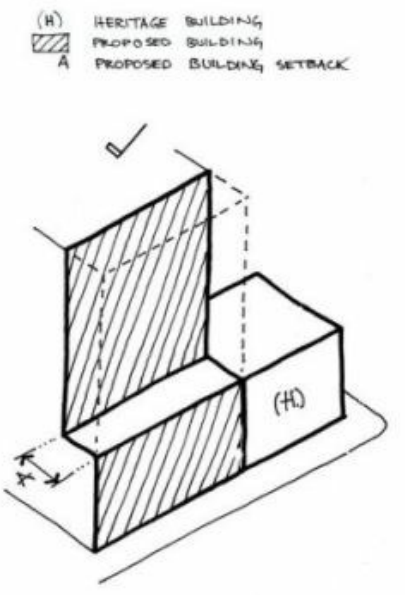

Figure SC6.3.4.7 Illustration of building setback of taller new building. "A" is equal or greater than 3m

(b) setback upper levels of the proposed new building to provide a transition between adjacent buildings of different scales (as shown in Figure SC6.3.4.8);

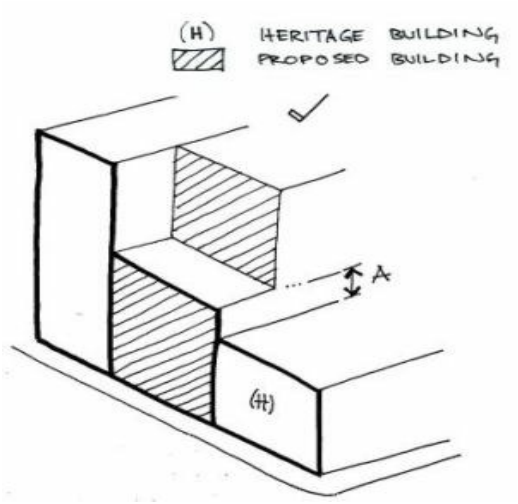

Figure SC6.3.4.8 Illustration of new building upper level setbacks. Dimension "A" is within 20% of the adjacent heritage building height

(c) provide an appropriate separation gap between the significant heritage elements and taller new elements (as shown in Figure SC6.3.4.9);

(d) building elements in the separation gap may be recessed and of lower height and/or different material than the heritage building, (as shown in Figure SC6.3.4.9); and

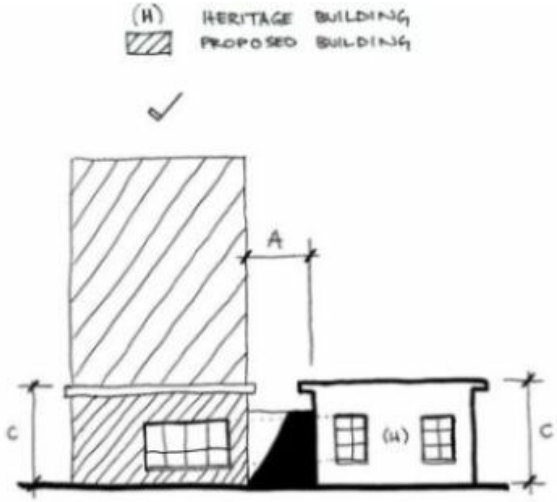

Figure SC6.3.4.9 Illustration of separation gap between contributing heritage elements and taller new buildings. "A" is Separation and "C" is the Common Reference Height

Figure SC6.3.4.10 An example of a desirable outcome – free standing tower provides a significant landscaped public piazza which acts as a separation adjacent to the heritage place

(e) new building works reflect a ‘reference height’ for the full width of the street frontage where the ‘reference height’ is consistent with the height of the adjacent heritage building (as shown in Figure SC6.3.4.11).

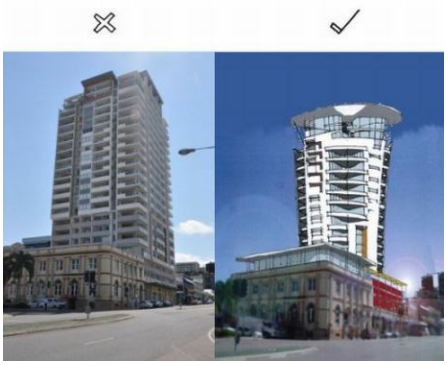

Figure SC6.3.4.11 An example of an undesirable outcome (left): tower element with no setbacks to the street boundary or adjacent heritage building which is detrimental to the otherwise uniform streetscape heights and the adjacent heritage building. An example of a desirable outcome (right): tower element setback from the street boundary and the adjacent heritage building to reduce the impact of its height and bulk. Podium element references the heights of the adjacent heritage building and streetscape.

SC6.3.4.3 Scale and form of development adjoining a heritage place

(1) The following design examples are associated with building scale and form and may be considered to demonstrate achievement of performance outcome PO13 of the Cultural heritage overlay code.

(a) in instances where the significance of the heritage place form includes its difference in scale to its setting, the scale of new works is to maintain this significance (as shown in Figure SC6.3.4.12); or

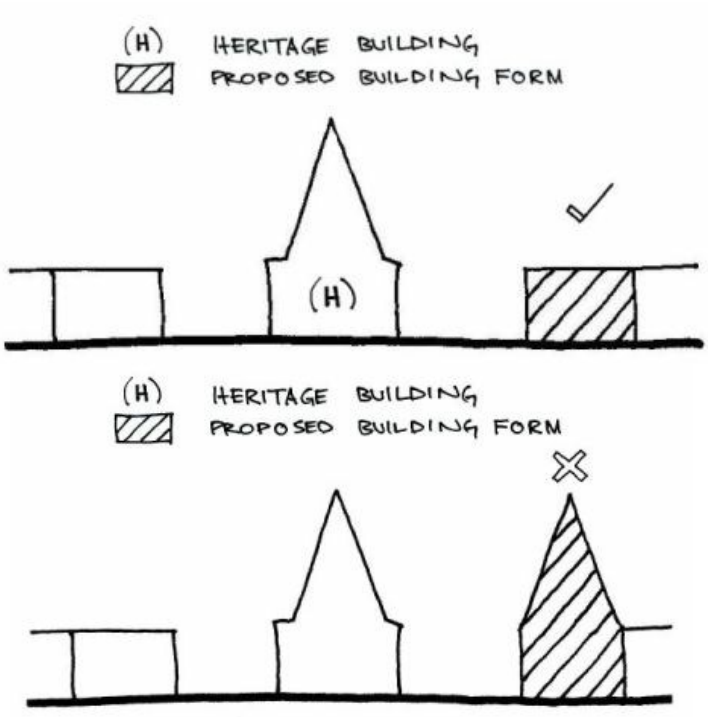

Figure SC6.3.4.12 Illustration of desirable and undesirable outcome

(b) in instances where the significance of the heritage place form includes its common scale and form to its setting, the scale and form of new works is to maintain this significance (as shown in Figure SC6.3.4.13); and

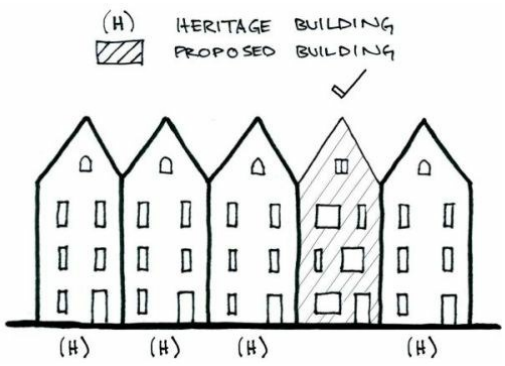

Figure SC6.3.4.13 Illustration of development maintaining common scale

(c) new building works should generally not directly copy the heritage place and as an example, should be readily distinguishable from it. Use of similar overall form, scale, proportions and materials is appropriate (as shown in Figure SC6.3.4.14 and SC6.3.4.15);

Figure SC6.3.4.14 Illustrates an example of appropriate scale and form

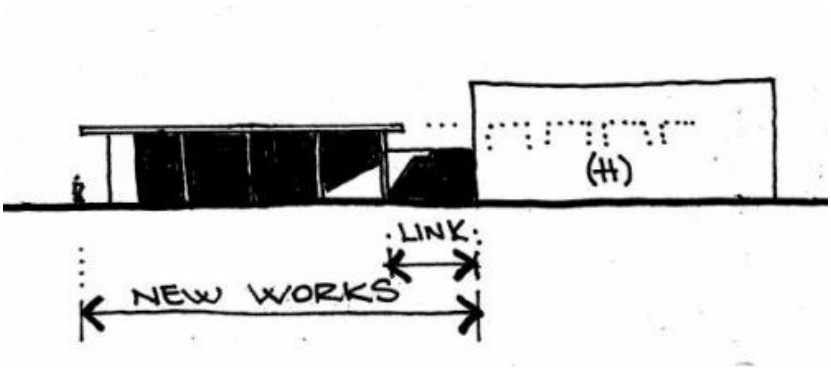

Figure SC6.3.4.15 Illustrates desirable outcome – pavilion type addition

(d) new building works should not reference non-significant features and atypical elements (as shown in Figure SC6.3.4.16 to SC6.3.4.17); and

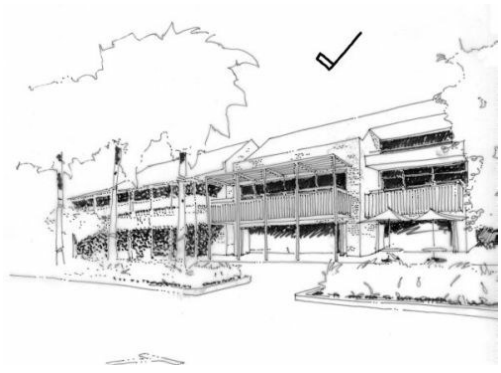

Figure SC6.3.4.16 Illustrates desirable outcome

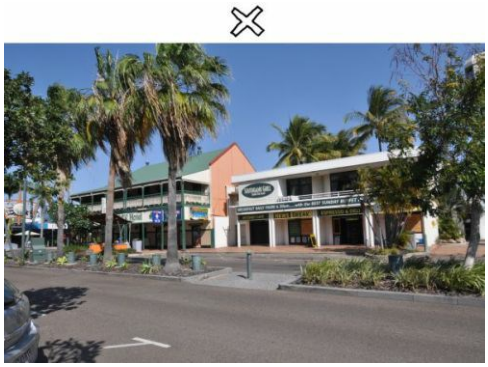

Figure SC6.3.4.17 Illustrates undesirable outcome - new building adjacent to a heritage place does not recognise characteristic articulation of materials, textures and colours (Palmer Street, Townsville)

Figure SC6.3.4.18 An example of an undesirable outcome: design of the new building referenced non-contributory features of the former streetscape, such as angled light poles that have subsequently been removed (Flinders Street East, Townsville)

(e) the quality of new materials is commensurate with those of the heritage place.

SC6.3.5 Development within a heritage place

This section of the policy provides guidance in achieving performance outcomes PO1, PO3 – PO6, PO8 – PO10 of the Cultural heritage overlay code associated with setbacks for development, building height, the scale and form of development, the heritage setting, landscaping and open space, building elements and advertising devices associated with development within a heritage place.

SC6.3.5.1 Setbacks for development

PO3 and PO4 of the Cultural heritage overlay code require that new buildings to be consistent with the significant features and values of the heritage place, including, but not limited to, built form and setbacks, maintain significant views to and from the heritage place and ensure that new buildings are visually subservient.

(1) To achieve the requirements of the performance outcomes in the code and allow for significant views to and from a heritage place to be maintained, the following design guidance should be considered.

(a) in instances where the significance of the heritage place includes its setback in common with the established street pattern, the setback of new works ought to maintain this significance (as shown in Figure SC6.3.5.1);

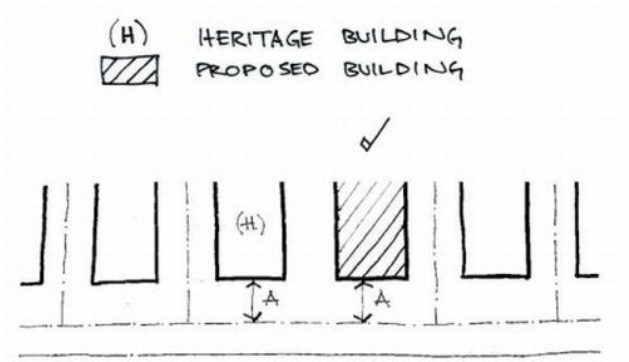

Figure SC6.3.5.1 Illustrates appropriate front setbacks for development within a heritage place, "A" is the street setbacks distance

(b) in instances where the significance of the heritage place includes its difference in setback to the established street pattern, the setback of new works ought to maintain this significance (as shown in Figures SC6.3.5.2 to SC6.3.5.3); and

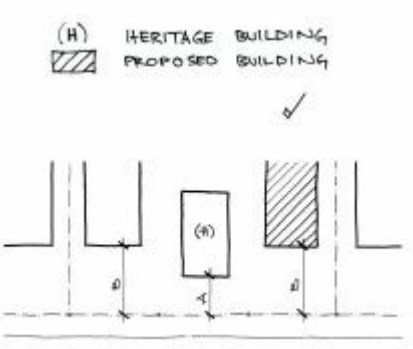

Figure SC6.3.5.2 Illustrates appropriate front setbacks for development within a heritage place, "A" and "B" is the street setback distance

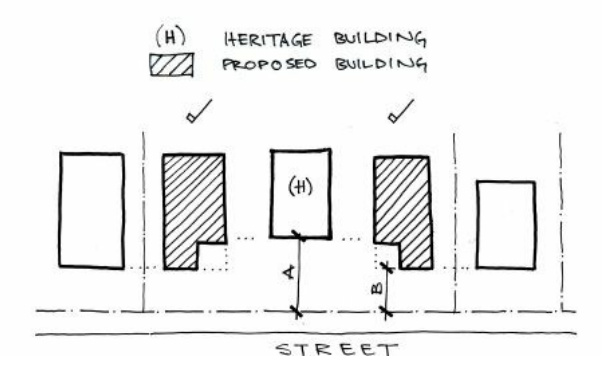

Figure SC6.3.5.3 Illustrates of appropriate front setbacks for development within a heritage place, "A" and "B" is the street setback distance

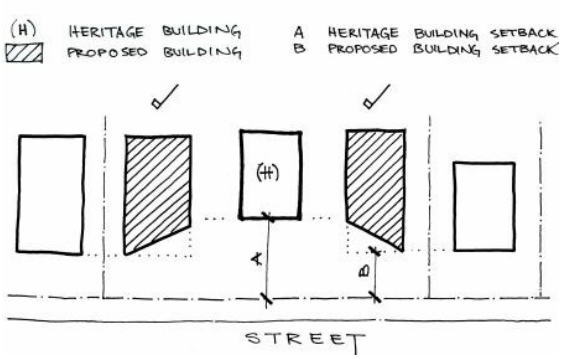

Figure SC6.3.5.4 Illustrates appropriate front setbacks for development within a heritage place and development adjoining a heritage place. "A" and "B" is the street setback distance

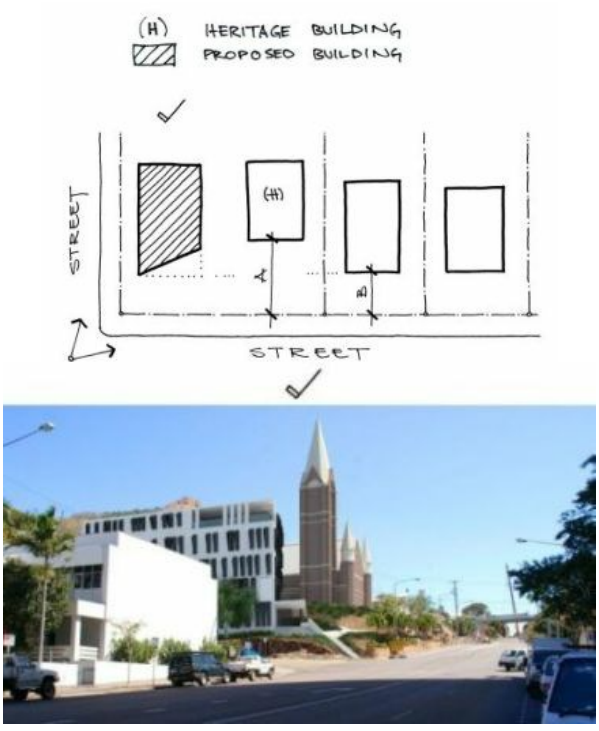

Figure SC6.3.5.5 Illustrates appropriate corner block front setback for development on a heritage place. "A" and "B" is the street setback distance. The setback of new development is tapered to allow improved views to the heritage place.

(c) new developments should adopt side setbacks that are common with the heritage place, unless this would diminish a significant feature of the heritage place (as shown in Figure SC6.3.5.6).

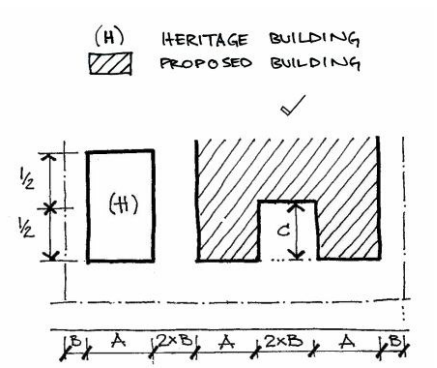

Figure SC6.3.5.6 Illustrates sympathetic building frontage rhythm, "B" is side setback and "C" (being the depth separation to get sympathetic building frontage rhythm) is 6m or ½ of "H" (heritage building depth).

SC6.3.5.2 Building height

(1) Where parts of the development are proposed to be taller than adjacent heritage elements, the following design guidance may be considered to demonstrate achievement of performance outcome PO3, PO4 and PO5 of the Cultural heritage overlay code.

(a) proposed taller elements of the proposed new building are to be setback to diminish their impact (as shown in Figure SC6.3.5.7); or

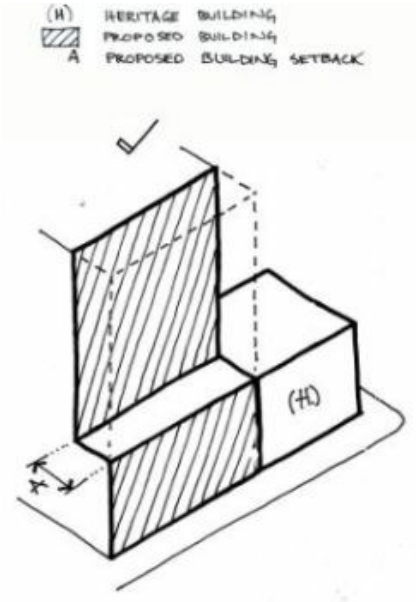

Figure SC6.3.5.7 Illustrates building setback of taller new building. "A" is equal or greater than 3m

(b) setback upper levels of the new building to provide a transition between adjacent buildings of different scales (as shown in Figure SC6.3.5.8);

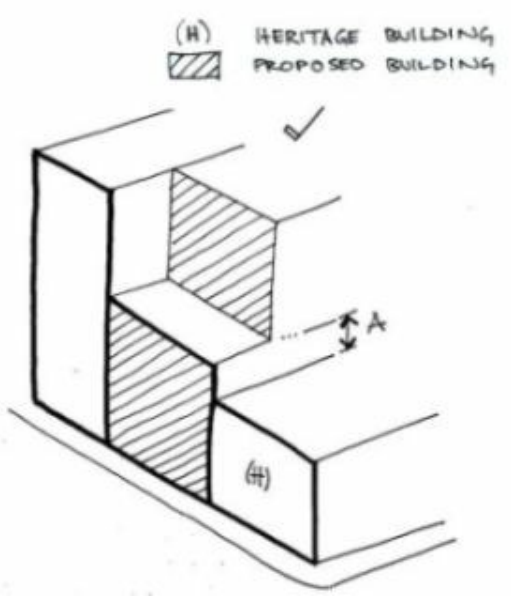

Figure SC6.3.5.8 Illustrates new building upper level setbacks. Dimension "A" is within 20% of the adjacent heritage building height

(c) provide an appropriate separation gap between the significant heritage elements and taller new elements (as shown in Figure SC6.3.5.9);

(d) building elements in the separation gap may be recessed and of lower height and/or different material than the heritage building (as shown in Figure SC6.3.5.9); and

(e) new building works may reflect a "reference height" for the full width of the street frontage where the "reference height" is consistent with the height of the adjacent heritage building (as shown in Figure SC6.3.5.9).

Figure SC6.3.5.9 Illustrates separation gap between contributing heritage elements and taller new buildings. "A" is the separation gap. "C" is the common reference height.

SC6.3.5.3 Scale and form development

(1) The following design examples are associated with building scale and form and may be considered to demonstrate achievement of performance outcome PO3 – PO6 of the Cultural heritage overlay code.

(a) in instances where the significance of the heritage place form includes its difference in scale to its setting; the scale of new works is to maintain this significance (as shown in Figure SC6.3.5.10); or

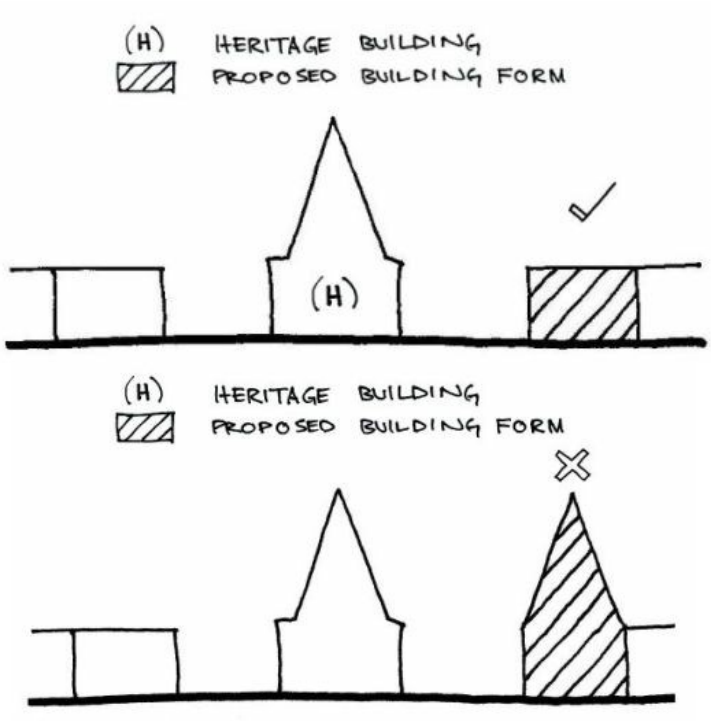

Figure SC6.3.5.10 Illustrates desirable and undesirable outcome

(b) in instances where the significance of the heritage place form includes its common scale, proportions and form to its setting, the scale, proportions and form of new works is to maintain this significance (as shown in Figure SC6.3.5.11);

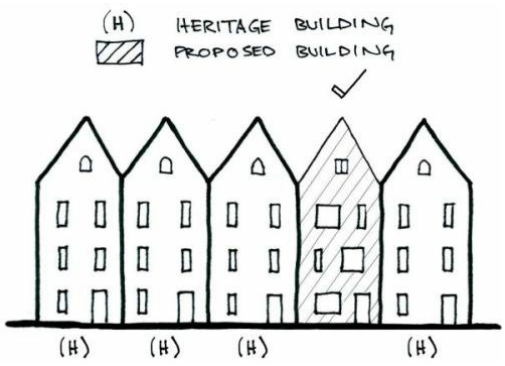

Figure SC6.3.5.11 Illustrates an example of appropriate scale and form

(c) the scale of new works should be compatible with, and not diminish the setting of the heritage place (as shown in Figures SC6.3.5.12 – SC6.3.5.14);

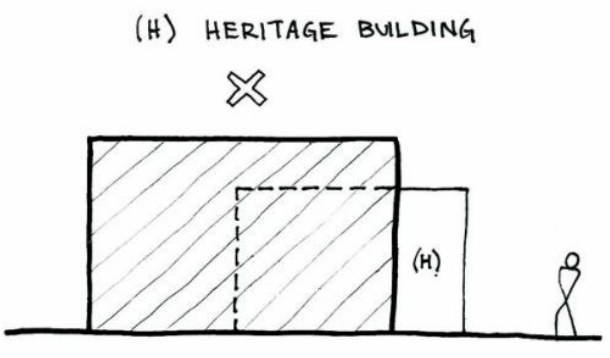

Figure SC6.3.5.12 Illustrates an example of an undesirable outcome – new works obscures the heritage place

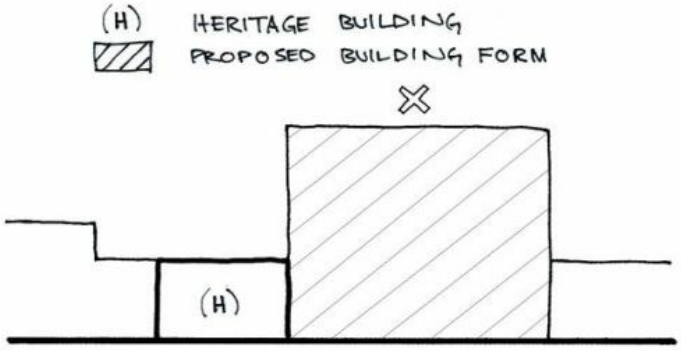

Figure SC6.3.5.13 Illustrates an example of an undesirable outcome: scale of new works dominates the heritage place and is detrimental to the settings of the heritage place

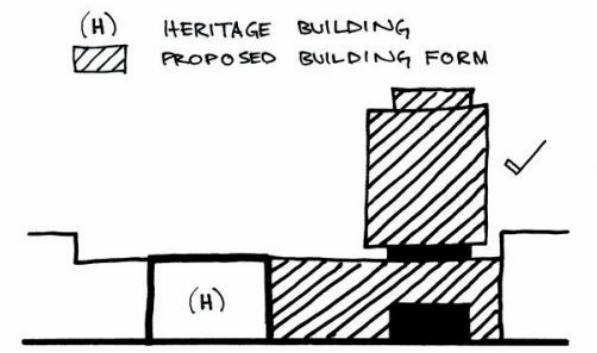

Figure SC6.3.5.14 Illustrates an example of a desirable outcome with regard to scale and form

(d) in order to achieve visual subservience to a heritage place in accordance with PO4, building form ought to be articulated into smaller elements to relate to scale, rhythm and spacing of the heritage place and its context (as shown in Figure SC6.3.5.15);

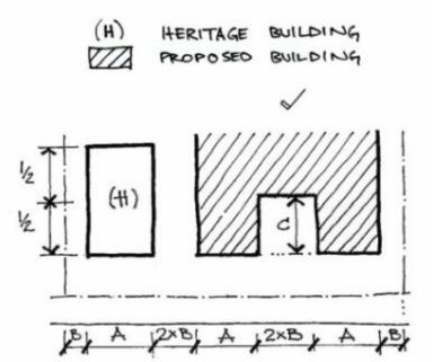

Figure SC6.3.5.15 Illustrates sympathetic building frontage rhythm, "B" is side setback and "C" (being the depth separation to get sympathetic building frontage rhythm) is 6 m or ½ of "H" (heritage building depth).

(e) new buildings should respond to existing ridge or parapet lines, roof slopes or other significant features of the heritage place (as shown in Figure SC6.3.5.16);

Figure SC6.3.5.16 Illustrates an example of an appropriate outcome. The proposed new development adopts ridge and parapet lines of the heritage place and enhances the continuity of the streetscape

(f) new building works should not reference non-significant features and atypical elements;

(g) new works should provide elements of design that are clearly distinguishable from heritage elements and that assist in representing the historical form of the heritage place (as shown in Figure SC6.3.5.17); and

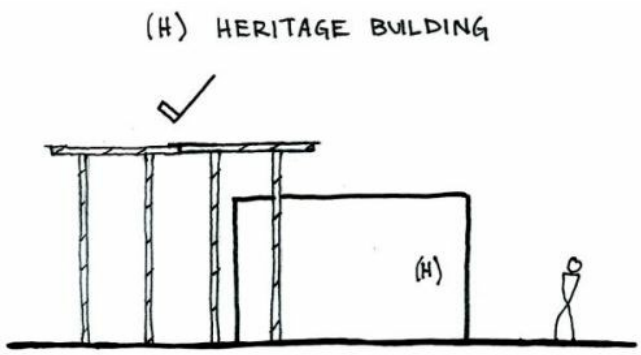

Figure SC6.3.5.17 Illustrates an example of an appropriate outcome, where new works are detached and expressed as a lightweight addition

(h) architectural expression of new works should avoid diminishing the setting of the heritage place (as shown in Figure SC6.3.5.18 and Figure SC6.3.5.19).

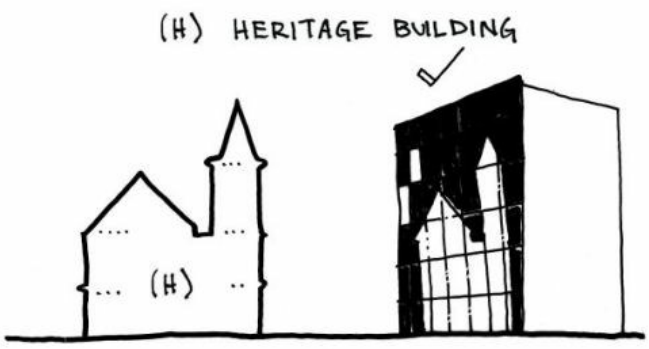

Figure SC6.3.5.18 Illustrates an example of a desirable outcome, in which a glazed or glass façade reflects the heritage place

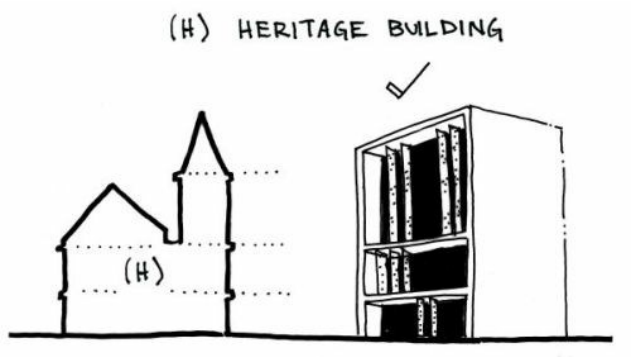

Figure SC6.3.5.19 Illustrates an example of an undesirable outcome, in which the contemporary expression of new works reference the heights of the heritage place

SC6.3.5.4 The heritage setting

The following is advice for achieving PO3, PO4 and PO5 of the Cultural heritage overlay code associated with the heritage setting.

(1) New buildings or works minimise visual impacts to the heritage place by:

(a) new buildings are set apart in a separate building (as shown in Figure SC6.3.5.20);

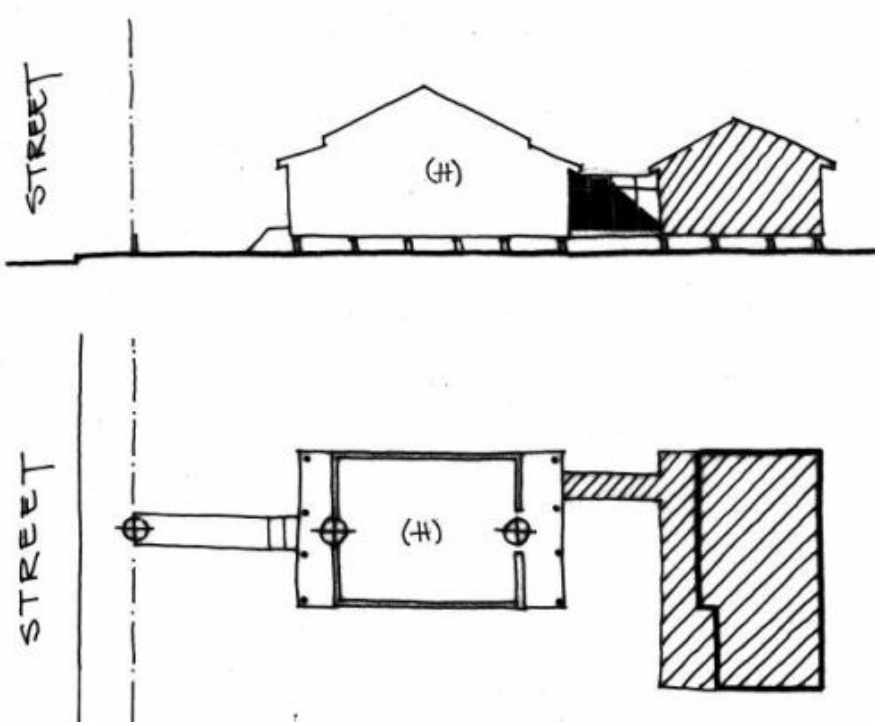

Figure SC6.3.5.20 Illustrates an example of a desirable outcome

(b) new works should design junctions between new and old fabric to be legible, reversible and may be incorporated into the overall architectural design (as shown in Figure SC6.3.5.21 and Figure SC6.3.5.22); and

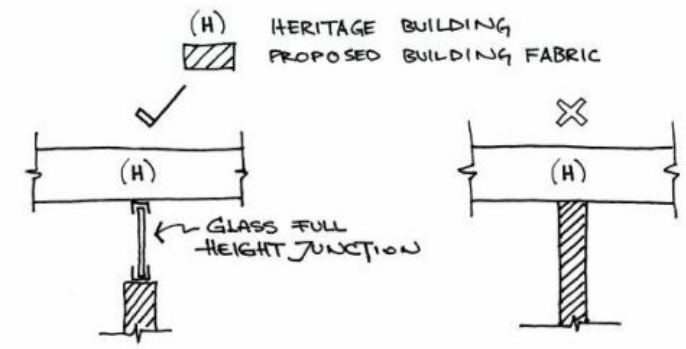

Figure SC6.3.5.21 Illustrates desirable and undesirable outcome: plan detail of old and new wall junction separation of new and old fabric using glass or other translucent light weight material

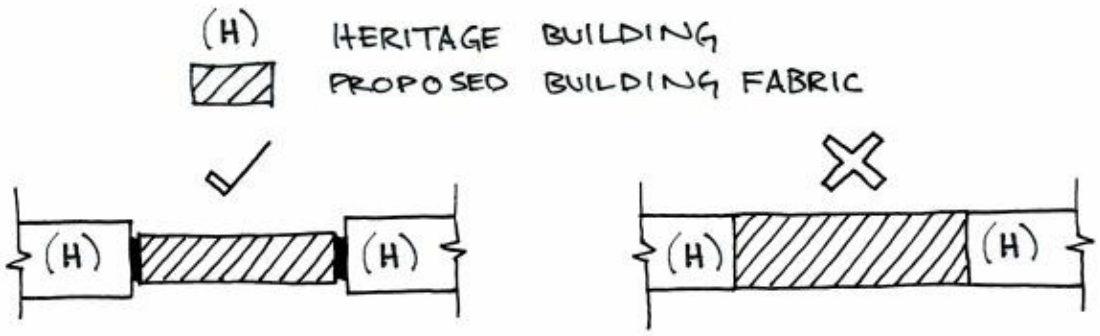

Figure SC6.3.5.22 Illustrates desirable and undesirable outcome - plan detail of the junction between the proposed/new development to the existing heritage wall opening. The new development requires a reduced wall depth to maintain the legibility of the original opening

(c) works are located within areas that are not visible from the dominant street views or other significant views, and do not diminish any significant features of the heritage place (as shown in Figure SC6.3.5.23 and SC6.3.5.24).

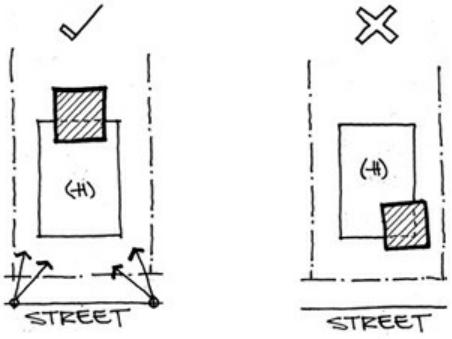

Figure SC6.3.5.23 Illustrates an example of desirable and undesirable outcome

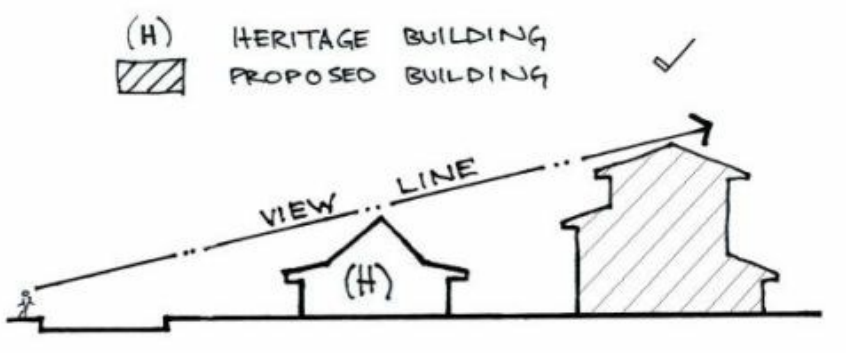

Figure SC6.3.5.24 Illustrates view line from the street. The new building at the back cannot be seen by a person standing across the street, which means that the view of the heritage building is not diminished

SC6.3.5.5 Landscaping and open space

The following advice is for demonstrating achievement of performance outcome P03 and PO8 of the Cultural heritage overlay code associated with landscaping and open space.

(1) Open space and landscaping features should maintain views to and from the significant heritage features of the heritage place (as shown in Figure SC6.3.5.25– SC6.3.5.28).

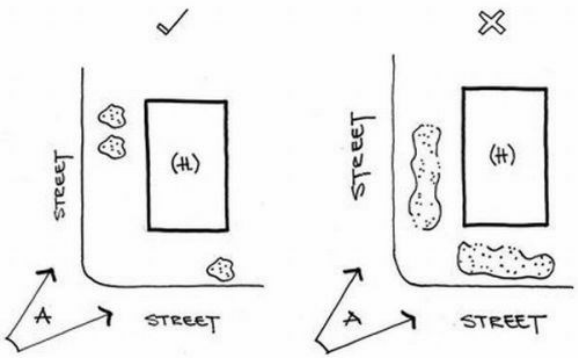

Figure SC6.3.5.25 Illustrates an example of desirable and undesirable outcome. "A" is principal view to and from heritage place

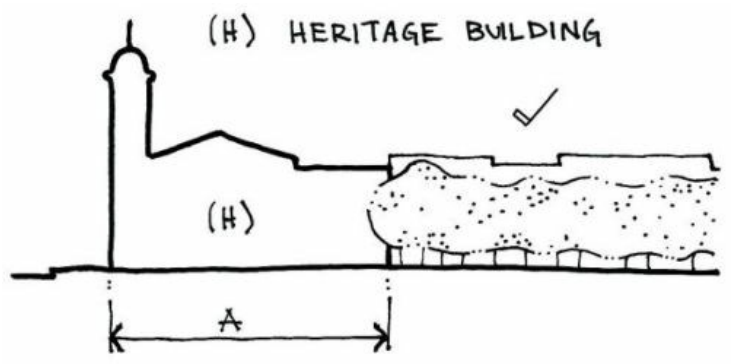

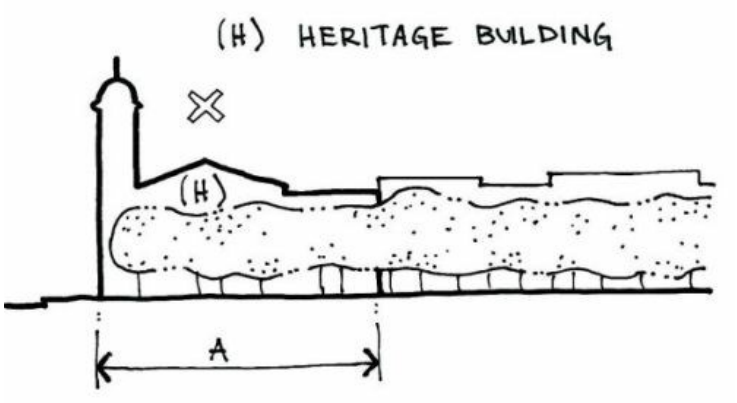

Figure SC6.3.5.26 Illustrates an example of desirable outcome "A" is street width

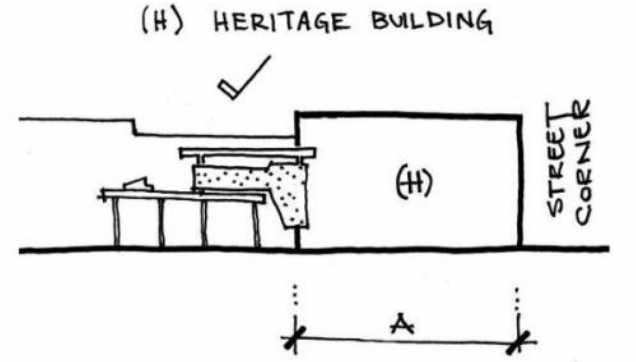

Figure SC6.3.5.27 Illustrates an example of a desirable outcome, tall street shelter element does not block views to and from the heritage place. "A" is street width of "H"

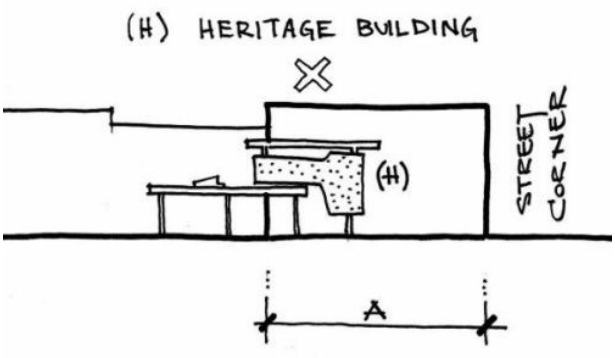

Figure SC6.3.5.28 Illustrates an example of an undesirable outcome, where a tall street shelter element blocks views to and from the heritage place. A' is street width of "H" (heritage place)

SC6.3.5.6 Heritage fabric

In order to protect the cultural significance of a heritage place, retaining the original fabric and significant fenestration patterns, finishes and decorative details should be a primary aim.

(1) The following should be considered in demonstrating achievement of performance outcomes PO1 and PO6 of the Cultural heritage overlay code.

(a) alteration or partial demolition of elements that do not contribute to cultural significance may be appropriate where there is no detrimental impact on significant features;

(b) buildings are to be retained in their three dimensional form. The inadequate retention of only the front façade may result in "facadism" and should be avoided (as shown in Figure SC6.3.5.29 and SC6.3.5.30);

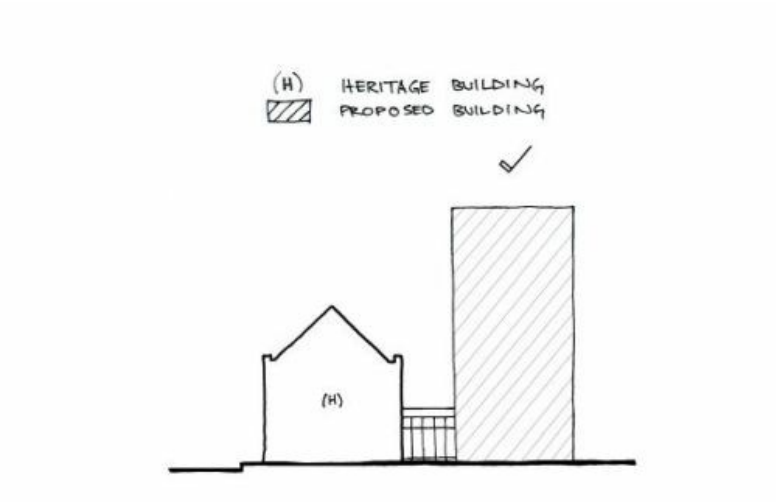

Figure SC6.3.5.29 Illustrates an example of a desirable outcome, new works with adequate retention of the three dimensional form. New works set back as a detached form.

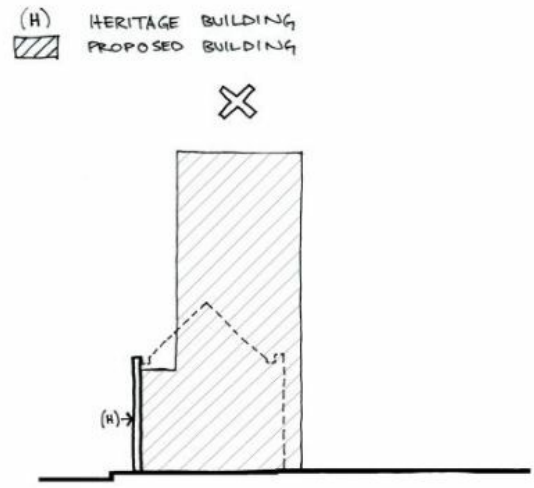

Figure SC6.3.5.30 An example of an undesirable outcome; new works have inadequate retention of the three dimensional form (only the front façade has been retained)

(c) the building fabric that contributes to the significance of the heritage place should be retained whether visible or not from the public realm (as shown in Figure SC6.3.5.31);

Figure SC6.3.5.31 "The Brewery", former Post Office (Flinders Street, Townsville). Significant features of the interior have been retained. This is an example of maintaining original building fabric.

(d) significant associations and meanings of the heritage place ought to be maintained (as shown in Figures SC6.3.5.32 and SC6.3.5.33); or

(e) new works provide interpretations for, associations and meanings of the heritage place, and its original use;

(f) where a new use is proposed for a heritage place, the new use is compatible with the cultural significance, significant features and values of the heritage place (as shown in Figures SC6.3.5.32 and SC6.3.5.33);

Figure SC6.3.5.32 Illustrates a desirable outcome: former Post Office building (Flinders Street, Townsville)

Figure SC6.3.5.33 Illustrates a undesirable outcome: former Customs House (The Strand, Townsville). Change of use to a private residence diminishes the associations and meanings of the heritage place

(g) building services may be concealed to render them not readily visible from the street or any significant views of the heritage place. If services are by necessity visible, they may be constructed using materials and details sympathetic to those of the heritage place (as shown in Figure SC6.3.5.34); and

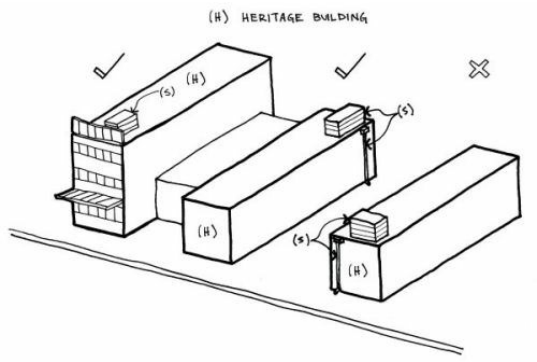

Figure SC6.3.5.34 Examples of desirable and undesirable outcome, "S" are air conditioning and drainage locations. An example of an undesirable outcome is at right, with air conditioning and drainage services positioned to the front of the building, which has a detrimental impact on visual amenity of the heritage place

(h) any changes to significant fabric necessary to accommodate a new use are reversible.

SC6.3.5.7 Building elements

This section will assist you to demonstrate achievement with PO3, PO5 and PO6 of the Cultural heritage overlay code.

Building elements refer to the components of a building which contribute to the overall character and heritage significance of the building, site or area, and may include the materials, colours and details used.

(1) Materials, colours and details used in a development should complement rather than reproduce the heritage place. The following design guidance illustrates how this might be achieved:

(a) the design of new works recognises characteristic materials, textures and colours used locally and in adjacent buildings. These may be re-interpreted and incorporated in the design of the new building (as shown in Figure SC6.3.5.35);

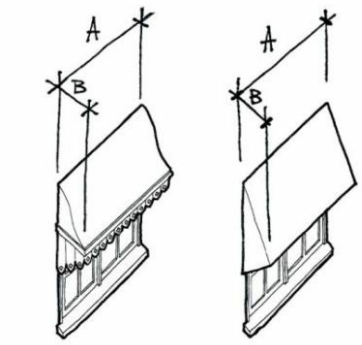

Figure SC6.3.5.35 Illustrates (left) contemporary interpretation of a typical heritage awning hood (right) where dimensions "A" and "B" have similar proportions.

(b) materials and colours of surrounding buildings generally should not be copied but used as a point of reference. Modern materials may be used if their proportions and details are sympathetic within the adjacent heritage place;

(c) colour, texture and tonal contrast of new building elements may be utilised as a unifying element with heritage features. Details that contribute to the significance of the heritage place may inform or inspire the design of new building works;

(d) modern details may be designed to reinterpret traditional details and create new relationships between new and old; and

(e) the quality of new materials is of the same quality as those of the heritage place.

(2) New materials introduced to a heritage place should generally be intentionally varied from the original and be distinguishable from the original fabric by a date stamp (as shown in Figure SC6.3.5.36).

Figure SC6.3.5.36 Illustrates an example of a desirable outcome - date stamp on new or introduced fencing panel

SC6.3.5.8 Advertising devices

(1) Advertising devices should be designed to ensure that they do not dominate the heritage place or obscure significant views or features of the heritage place. The following is advice for achieving performance outcome PO8, PO9 and PO10 of the Cultural heritage overlay code associated with advertising devices.

Note— there are specific requirements when dealing with State Heritage listed buildings. Advertising devices on heritage buildings listed on the Queensland State Heritage Register is subject to the provisions of the *Queensland Heritage Act 1992*.

(a) advertising devices should be readily removable without damaging the building fabric, (as shown in Figure SC6.3.5.37);

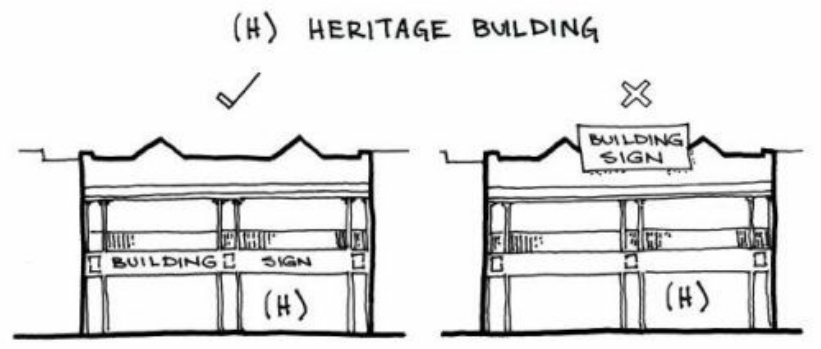

Figure SC6.3.5.37 Illustrates a desirable outcome (left) and undesirable outcome (right)

(b) advertising devices may be clearly modern yet respectful of the heritage context, associations and meanings of the heritage place;

(c) advertising devices should consider enhancing a building's architecture and setting;

(d) integrate advertising devices with architectural features of the building wherever possible;

(e) unless there is adequate evidence – physical and documentary – to reconstruct original advertising devices, new advertising devices on a heritage place should complement, not replicate, a "period" style. "Old fashioned" imitation signage would be inappropriate. Any form of signage may be considered, as long as visual and physical impacts on the heritage building are minimised;

(f) the appropriate size of signage may be relative to the specific architectural characteristics of the heritage place (as shown in Figure SC6.3.5.38); and

(g) table SC6.3.5.1 identifies advertising devices which are not suitable on a heritage building.

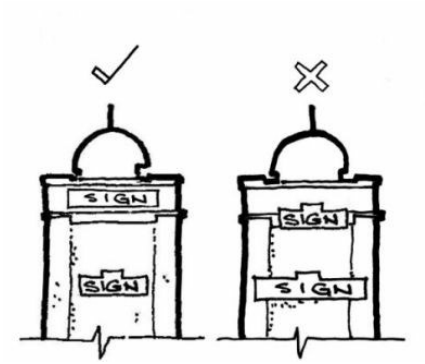

Figure SC6.3.5.38 Illustrates a desirable outcome (left) and undesirable outcome (right)

Table SC6.3.5.1 Advertising devices which are not suitable on a heritage building

Device type	An example of an undesirable outcome
Roof signs	
Above awning signs	Wall sign	Inflatable sign	
In accordance with AO3 of the Advertising devices code, Table SC6.3.5.2 identifies the desirable outcomes for heritage places on Flinders Street East. Advertising devices are in accordance with the advertising device types and design parameters set out within Table SC6.3.5.2.

Table SC6.3.5.2 Design parameters for supported advertising devices on Flinders Street East

Device type	Design Parameters additional to those set out in the advertising devices code	An example of an desirable outcome
Awning fascia sign		
Blind/canopy		Under awning sign		
Under Awning sign (where an under-awning sign is affixed between posts of a footpath awning)	The under-awning sign must be contained within the spacing of posts and must not exceed 600mm in height.	
Wall sign		
Window sign		

SC6.3.6 Preparing a heritage impact statement report

A heritage impact statement may be required to demonstrate compliance with the Cultural heritage overlay code, in particular performance outcomes PO1, PO3, PO4, and PO7.

A heritage impact statement provides specific information about how a proposed development will affect the heritage place. The purpose of a heritage impact statement is to identify any potential detrimental impacts that the development may have on the significance of the place. Ultimately, a heritage impact statement should demonstrate compliance with the Cultural heritage overlay code.

A heritage impact statement is to be produced by a suitably qualified architect or cultural heritage professional, and should include the following at a minimum:

(1) Description of the proposed development
Provide a brief description of the proposed development including:

- (a) type of development;
- (b) range and scope of work proposed; and
- (c) timeframe for carrying out work.

(2) Setting and context of the place
Describe the setting or context for the place, including photographs and maps showing significant features that will be affected. Provide an analysis of the affect the proposed development will have on the setting of the heritage place.

(3) Proposed changes to the heritage place
List the changes required to the heritage place as a consequence of the proposed development and provide the following information about each change:

- (a) what elements or aspects of the heritage place are affected by the proposed change;
- (b) list the work required to effect the proposed change;
- (c) analysis of the impact of the change on the cultural heritage significance of the place;
- (d) assessment of potential for detrimental impact on the cultural heritage significance;

(e) if the proposed work will directly affect a heritage element of the place – provide details of proposed work methods; and

(f) where the proposed change is assessed as having potential for detrimental impact, provide information about the following:

(i) why the proposed change is required;

(ii) alternative solutions that were investigated; and

(iii) what measures are included in the proposed development to reduce detrimental impact that may result from the change.

(4) Applicable conservation policies

(a) some heritage places already have conservation management plans that include conservation policies. Where a heritage building has a current conservation management plan, the heritage impact statement will need to list the conservation policies that relate to the proposed development and describe how they have guided the development;

(b) where conservation policies have not been followed, give reasons why the conservation policies were not used and describe the process that is proposed to be followed; and

(c) where conservation policies are not already available, an architect or heritage consultant can provide conservation advice to help inform the planning and guide development of places.

(5) References
List documents referred to in the heritage impact statement such as conservation policies, conservation management plans, condition report (i.e. demolition reports), and specialist consultants' reports.

(Adapted from *Guideline: Preparing a heritage impact statement' Department of Environment and Heritage Protection*, 2011).

SC6.3.7 Preparing a condition report

If an application is proposing the demolition of a structure of heritage significance the applicant may be requested to provide a condition report. The condition report should, at a minimum, include consideration of:

(1) the structural stability of the building in the form of a structural engineers report. The condition report must include a factual statement from an appropriately qualified structural engineer about the condition of the building; and

(2) a pest inspection report and other supporting documentation may also be provided.

SC6.3.8 Preparing archival recording of heritage place

Archival recording may be required to demonstrate achievement of performance outcome PO2 of the Cultural heritage overlay code. Where demolition, change or relocation of a heritage building is allowed, a photographic record and measured drawings in accordance with the following of the place should be submitted to council prior to the commencement of the demolition works or relocation of the heritage building.

SC6.3.8.1 Guideline for photographic recording

The following guidelines are intended as a checklist for making an accurate photographic record of sites, buildings, objects, gardens or structures of heritage significance prior to major alterations or demolition. The recording process must be comprehensive and cover the parts specified in the approval conditions.

(1) Aim
The aim of the photographic record is to provide a sufficient number of photographs to fully illustrate the subject for which the photographic archival record is required. The purpose of the record is to provide permanent documentation of places so that future generations can benefit from and gain an understanding of Townsville's cultural history that is no longer possible to pass on to them.

(2) Method
The photographer should be informed by any available plans and documentary evidence and should have an

understanding of the history and operations of the place. If necessary the photographer should be accompanied on the site by a person familiar with the site's heritage significance and the processes related to it. The project should be planned before commencement and the photographer aware of the appropriate sequence.

The preferred shooting method is to proceed from the overall or general through to the detailed or specific. The photographic record should consist of:

(a) general views of the place.
Note—to provide its context and overall coverage of all slides – oblique shots are useful for general reference;

(b) elevation of all sides;

(c) details of all key elements including windows, doors, eaves, cornices, rainwater goods, skirtings and decorative elements;

(d) interior elevations of each space to include floor and ceiling finishes;

(e) the relationship of the elevations to any equipment or relics housed in each space;

(f) any significant items should be photographed;

(g) any features particular to the place internally and externally should be fully recorded; and

(h) when photographing landscape elements:

(i) an overall photograph is required; and

(ii) any unusual or distinguishing features should be fully recorded.

(3) Key plans
The photographic record shall include a plan or plans indicating the direction in which the photographs were taken. The positions, with a direction arrow, should be numbered and cross referenced to the photographs.

(a) The following information should be included:

(i) date of record production;

(ii) name of photographer; and

(iii) description of place (e.g. building, name, species of tree, etc.).

(b) Form

(i) photographs are to be colour and of professional quality. Digital format will be accepted. An electronic copy on CD, USB or of the like format acceptable to council, are to be submitted;

(ii) archival quality ink should be used for annotation and cross referencing. A 6B pencil should only be used for annotating on the back of prints; and

(iii) the photographic record should be submitted in an A4 archival album with photographs in archival quality plastic sleeves or pockets.

(c) Size

(i) minimum size of prints should be 100 x 150 mm, to a maximum A4 size.

(d) Report

(i) a very brief report or introduction explaining the purpose of the report, a brief description of the subject and detailing the sequence in which the photographs were taken should be included;

(ii) the report may also address the limitations of the photographic record and make recommendations for future work; and

(iii) sources of original work should be acknowledged.

SC6.3.8.2 Guideline for measured drawings
Measured drawings provide an accurate record of buildings, structures or objects and depict the physical features that contribute to their heritage significance. Measured drawings should be easy to read and suitable for reproduction. Australian Standard AS 1100 *Technical Drawing*, Part 301 and *Supplement 1*, *Architectural Drawing* provides a guide to suitable graphics.

The following guidelines are intended as a checklist for making an accurate record of a building, part of a building, or other subject at the time of production. The recording process must be comprehensive and cover the parts specified in the approval conditions.

(1) Aim

The aim of producing a measured drawing is to provide a record that is measured and drawn accurately to scale. It should be a true reflection of the existing condition and not an interpretation of a previous state (i.e. missing elements should not be included and elements which are not plumb should be recorded as such).

(2) Drawings:

(a) the measured drawings should be cross-referenced to each other, clearly titled and show scale, orientation and date of execution;

(b) drawings should not include any conjectural detail such as inaccessible elements that cannot be measured such as footings or framing;

(c) the drawings can also be annotated or hatched to reveal more about the heritage significance of the site or object – to differentiate between dates of construction, materials and finishes;

(d) record to the same standard all major fixtures such as machinery or building services; and

(e) for industrial sites, recording the position, relationship and function of all fixtures, machinery and services is particularly important and maker's names, model numbers etc. should be included.

For further information refer to *Measure for Measure: A Practical Guide for Recording Buildings and Landscapes*, published by the RAIA in 1990.

(3) Requirements

A typical measured drawing package for a build structure should include:

(a) location plan;

(b) site plan (1:500 or 1:200);

(c) floor plan/s (1:1:100 or 1:50) including basement or mezzanine levels;

(d) roof plan/s (1:100 or 1:50);

(e) elevations – showing all sides of the building (1:100 or 1:50);

(f) sections – two sections, through the building in different planes (not parallel) (1:100 or 1:50);

(g) ceiling and joinery details (1:20 or 1:10) – cornice, verandah posts, skirtings, mouldings;

(h) other significant details (rainwater heads, construction joints); and

(i) machinery and services details.

(4) Sheet sizes

Drawings should be on standard metric sheet sizes – A1, A2, A3 or A4.

SC6.3.8.3 Interpretive signage for the loss of a heritage place

In addition to archival recording, where a heritage place is to be lost, interpretive signage is to be provided. In particular:

(1) the sign should be placed at the front of the property boundary, integrated with a wall or fence;

(2) the sign should provide a photographic record and brief history of the heritage place;

(3) the sign should have a 330 mm diameter, a 3 mm thick aluminium plate with weatherproofed finish, refer to Figure SC6.3.8.57; and

(4) sign production i.e. colours used and branding should be consistent with the Townsville Heritage Trail Signage.

Figure SC6.3.8.1 Illustrates an example of a desirable outcome, an example of a Heritage Trail sign (Flinders Street, Townsville)

SC6.3.9 Preparing an archaeological management plan

The following is advice for demonstrating achievement of performance outcome PO11 of the Cultural heritage overlay code associated with archaeology.

(1) Any development with potential impact on archaeological values should provide for the following at a minimum:

- (a) the potential impact on archaeological deposits on the site is to be monitored and assessed during earthworks by an appropriately qualified person;
- (b) where archaeological deposits are identified, an archaeological management plan is to be prepared by an appropriately qualified person and approved to the satisfaction of the relevant authority, prior to the commencement of ground works; and
- (c) any archaeological management plan that is prepared should follow best practice.

SC6.3.10 Adding or removing a place from Schedule 7 Places of cultural heritage value

(1) The places of cultural heritage value in Townsville are contained in Schedule 7 Places of cultural heritage value and overlay map OM04.1 – OM04.4 of the Townsville City Plan. The process of entering and removing a heritage place from Schedule 7 and the overlay involves:

- (a) identification;
- (b) application;
- (c) assessment; and
- (d) notification.

(2) Council assesses a place based on the place fulfilling one or more cultural heritage criteria listed below. There are approximately 325 places in Townsville that meet one or more of the cultural heritage criteria stated below. These places have been incorporated into Schedule 7 Places of cultural heritage value of the Townsville City Plan. The Citation of Heritage Places Report provides information about each heritage place in Townsville. It highlights the criteria that were originally identified for each place and indicates its heritage significance and eligibility for entry into Schedule 7 Places of cultural heritage value. It should be noted that a building, site or place may be entered into Schedule 7 Places of cultural heritage value of the Townsville City Plan if it meets one or more of the cultural heritage criteria listed below.

- (a) It is important in demonstrating the evolution or pattern of Townsville's history.
- (b) It demonstrates rare, uncommon or endangered aspects of Townsville's cultural heritage.

(c) It has potential to yield information that will contribute to the knowledge and understanding of Townsville's history.

(d) It is important in demonstrating the principal characteristics of a particular class or classes of cultural places.

(e) It is important because of its aesthetic significance.

(f) It is important in demonstrating a high degree of creative or technological achievement at a particular period.

(g) It has a strong or special association with the life or work of a particular community or cultural group for social, cultural or spiritual reasons.

(h) It has a special association with the life or work of a particular person, group or organisation of importance in Townsville's history.

(i) It was constructed prior to 1910.

(3) For a heritage place to be removed from Schedule 7 Places of cultural heritage value of the Townsville City Plan the applicant must highlight that there is evidence to sufficiently demonstrate that a place has no cultural heritage significance, based on the Criteria listed Schedule 7 Place of cultural heritage value in the Townsville City Plan.

Following the lodgement of the application form titled, "Application form to add or remove a place from Schedule 7 Places of cultural heritage value of the Townsville City Plan," council will make a decision as to whether to enter, not enter, or remove a place from Schedule 7 Places of cultural heritage value. It should be noted that if a place is nominated to be included on, or to be removed from Schedule 7 Places of cultural heritage value, council will be required to undertake an amendment to the Townsville City Plan as required by the *Planning Act 2016*.

For more information refer to:

(a) Application Guide: Entering a place to Schedule 7 Places of cultural heritage value.

(b) Application Guide: Removing a place from Schedule 7 Places of cultural heritage value.

(c) Application form to add or remove a place from Schedule 7 Places of cultural heritage value of the Townsville City Plan.

SC6.4 Development manual planning scheme policy

SC6.4.1 Introduction

Short title -The planning scheme policy may be cited as Development manual PSP.

SC6.4.1.1 Purpose

The purpose of the Development manual PSP includes:

(1) specifying standards for the design and construction of development infrastructure;

(2) providing guidance and advice regarding administrative arrangements for development and development infrastructure;

(3) providing information the council may request for development applications, including standards and guidance on the preparation of specialists reports; and

(4) providing guidance or advice about satisfying an assessment benchmark in the Townsville City Plan which identifies this planning scheme policy as providing that guidance and advice.

SC6.4.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.4.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan. This planning scheme policy applies to the whole of the Townsville City Council planning scheme area and specifically relates to the assessment of any relevant development application.

SC6.4.1.4 Terminology

Terms used in this planning scheme policy are as defined in Schedule 1 – Definitions of Townsville City Plan. A term used in this planning scheme policy which is not defined in Schedule 1 - Definitions is to be interpreted in accordance with Part 1.3.1 Definitions of Townsville City Plan.

In addition to the definitions presented in Part 1.3.1 of the Townsville City Plan, each sub-section of the Development manual PSP may contain a list of terminology that is referenced in support of that specific policy sub-section.

For clarity, a reference in Development manual PSP to any act includes any regulation or instrument made under it and where amended or replaced, means the amended or replaced act. A reference in the Development manual PSP to a specific resource document or standard means the latest version of the resource document or standard.

SC6.4.1.5 Structure

The policy is arranged around seven major sections. Each major section is designed to group common themed sub-sections to improve usability of the entire document.

The seven major sections are:

SC6.4.1 Introduction – an introduction to the policy, including the purpose of the policy and relationship to the Townsville City Plan;

SC6.4.2 Development application guidelines – contains information for the preparation of reports that may be requested by council in support of development applications;

SC6.4.3 Design standards – a series of policy sub-sections that establish specific design standards, advice and guidelines for development;

SC6.4.4 Design specifications and standard drawings – technical standards for the design of infrastructure and development;

SC6.4.5 Construction management – this section sets out the broad auditing responsibilities of council, setting out procedural matters of development and the standards for construction management for development works, covering pre-construction, construction and quality management systems for the construction of development works;

SC6.4.6 Construction standards – the construction technical specifications of council; and

SC6.4.7 Acceptance of completed works – this section sets out the standards, advice and guidance to manage the donation of completed assets and works.

SC6.4.2 Development application guidelines

SC6.4.2.1 Introduction

This section provides standards, advice and guidelines for development applications, including well made application details along with design requirements to assist applicants in achieving council's design objectives.

SC6.4.2.1.1 Definition of major and minor developments

(1) A major development consists of a combination or some or all of the following:

(a) more than six residential, commercial or industrial lots; or

(b) a single or multi-storey mixed/high density dwelling unit complex of more than six dwellings; or

(c) a multi-storey development of more than three stories; or

(d) a commercial structure where the ultimate Gross Floor Area (GFA) exceeds 2,000m^2 and is two equivalent stories or more; or

(e) a development where site filling and/or excavation exceeds 2,500m^3; or

(f) a development where site filling impacts on a known or designated 'floodplain' and requires compensatory earthworks to cater for the flows from the defined flood event in the adjacent or nearby watercourse without increasing flood levels upstream and downstream of the development site; or

(g) a development that requires more than 300 carparking spaces.

(2) A minor development consists of a combination of some or all of the following:

(a) more than two and less than six residential, commercial or industrial lots; or

(b) a single storey (or higher) mixed/high density dwelling unit complex of six or less dwellings; or

(c) a mulit-storey development of not more than three stories of approved use; or

(d) development where site filling and/or excavation is less than 100m^3; or

Editor's note—where the site filling/excavation exceeds 100m^3, but is less than 2500m^3, the combination with other criteria will determine whether the development is classified as major.

(e) a development where twenty or less carparking spaces are required.

Editor's note—where required carparking spaces exceeds 20, but is less than 300, the combination with other criteria will determine whether the development is classified as major.

Editor's note–where a development does not meet any or only one of the criteria listed in major or minor development above, council retains the prerogative to determine whether the development is major or minor.

SC6.4.2.2 General

Council's general procedures when lodging development applications are set out below.

SC6.4.2.2.1 Pre-lodgement advice guidelines

(1) Council will facilitate pre-lodgement meetings when requested to discuss development proposals prior to lodgement. Pre-lodgement meetings can comprise of informal discussions or alternatively a formal response can be arranged for more complex applications. The latter will require advanced lodgement of details including reports, drawings and any information pertinent to the proposal to ensure an effective response to an applicant. A team of specialists will attend a formal meeting followed by written minutes of the proceedings.

Editor's note—A sliding fee will be applicable where stated in council's applicable fees and charges schedule.

Editor's note—Planning and Development's Schedule of fees and charges can be found on council's website.

Pre-lodgement discussions may include, but is not limited to, consideration of the following matters:

(a) environmentally significant areas;

(b) stormwater discharge (legal point of discharge);

(c) impacts of flooding/inundation;

(d) conceptual stormwater quality requirements and tailwater conditions/levels;

(e) overall water supply and pressure;

(f) overall sewerage reticulation;

(g) existing site conditions/constraints such as steep slopes, proximity to identified watercourses, existing utilities;

(h) lot and road layout design including existing traffic issues;

(i) traffic management strategy;

(j) landscape/streetscape;

(k) building setbacks and access requirements;

(l) relevant development permit conditions e.g. preliminary approvals or identify other required approvals e.g. referral to other agencies;

(m) variation to council standards and guidelines to explore possible solutions to design issues;

(n) design and layout; and

(o) building form and layout.

It is expected that resolving the above matters may significantly reduce the time for council officers in assessing the application and expedite the approval of the designs, presupposing all other requirements are submitted in order.

The pre-lodgement process is a without prejudice meeting designed to allow an exchange of information in respect to the intended development prior to submitting a formal development application. It is not intended to provide a detailed assessment audit against applicable planning scheme codes, planning scheme polices, or to determine the likely outcome of the proposed development. Furthermore, pre-lodgement meetings cannot take into consideration other third party interests such as referral agencies or anticipate possible adverse comments received from submitters in the notification stage.

(2) Meeting minutes will normally be taken at the meeting by a council officer, which can be forwarded to the applicant after the meeting (upon request) and registered in council's records system. However, attendees are encouraged to make their own notes.

(3) Pre-lodgement meetings are conducted by appointment only and would normally be of 1-2 hours duration depending on the complexity of the proposal. To request a pre-lodgement meeting, the applicant must complete a Pre-Lodgement Meeting Request Form (refer to SC6.4.2.2 Attachment A Pre-lodgement meeting request form), which can be submitted either by email or to the Planning and Development Counter, Level 2, Council Administration Building – Walker Street. The request must be accompanied with all relevant material including concept, layout or design plans and a brief covering letter or report detailing any specific issues.

SC6.4.2.2.2 Design requisites and quality assurance guidelines

(1) The developer/applicant is encouraged to engage and nominate appropriately qualified consultants/individuals with the required expertise to undertake design work on their behalf. The consultants are expected to have systems in place to assure the quality of the designs and the reports that they produce. It is the consultant's responsibility to ensure that the design complies with and has satisfied all relevant council requirements and conditions of the associated development approval.

Concept and detailed designs must comply with the relevant conditions of the Development Approval, council policies, Townsville City Plan and relevant provisions of this Development manual planning scheme policy. All designs must be prepared and certified by an appropriately qualified professional with relevant experience.

Quality assurance personnel shall be:

(a) engineering works - Registered Professional Engineer of Queensland (RPEQ) as defined under the *Professional Engineers Act 2002*;

(b) landscape works - Registered Landscape Architect with the Australian Institute of Landscape Architects (AILA) or a Landscape Designer with the Australian Institute of Landscape Designers and Managers (AILDM); and

(c) irrigation works - Certified Irrigation Designer or Certified Irrigation Agronomist where irrigation works are within the public realm.

(2) The Consultant must retain appropriate design records including calculations in a format such that they can be understood readily by design staff with no prior knowledge of the particular design. The design file must be maintained by the developer/applicants or the developer/applicant's consultant containing records of calculations, approvals and decisions, geotechnical data and other design data which could be relevant in reviewing aspects of the design or planning future maintenance responsibilities. Copies of records are to be made available to council on request and without charge.

(3) Council retains the right to audit all processes and documents related to the development design. The developer/applicants and the developer/applicant's consultant must provide council officers all reasonable

assistance in inspecting records of designs submitted to council for acceptance.

SC6.4.2.2.3 Documentation guidelines

To further assist developers in the process of lodging development applications, a well-made application checklist has been prepared by council and the completion of a particular checklist, and submission of all relevant accompanying information, will expedite the assessment process (refer to SC6.4.2.4 Well-made application checklists).

(1) Portable long service leave (PLSL)

Development Approvals for Operational Works cannot be issued by council until appropriate evidence of payment of the Portable Long Service Leave fees are provided as prescribed by the B*uilding and Construction Industry (Portable Long Service Leave) Act 1991*

(2) Certification and design reports

All designs to be accompanied with certification and design reports which must be signed by a qualified professional with relevant experience (see SC6.4.2.2.2(1)). The Certification Report will comprise the Certificate (SC6.4.2.2 Attachment B – Certification Report) and Design Report. The Design Report must contain documentation as required by SC6.4.2.2.3(4) and SC6.4.2.2.3(5) below.

The certification and design reports will be required with preliminary designs and will require resubmission with updates when final drawings are submitted. Certification is not required with sketch plans or concept plans.

The consultant must provide a detailed justification for each variation to or non-compliance with council's design and construction requirements, local laws, Townsville City Plan planning scheme policies and Townsville City Plan and relevant development approval conditions, as part of the Certification Report.

(3) Design drawings and work specifications

The consultant on behalf of the developer must present all design drawings and specifications for the development works to council for audit purposes.

The design drawings must be complete and clearly set out so as to present the design concepts in such a way that the project can be understood, specified for construction and satisfactorily built. Unless noted otherwise, the submission should comprise a full set of plans for proposed works (1 x A3 drawings and a digital copy in PDF format correctly scaled as per council-preferred sheet size).

All work specifications must be prepared by the consultant and submitted to council for review, specifying requirements not covered by council's standard work specifications.

Full design drawings and work specifications covering all aspects of the proposed works must be submitted to council for acceptance. Standard drawings and works specifications (if available) from the following sources are to be included in order of preference:

(a) Standard drawings (SC6.4.4.8);

(b) Council design specifications (SC6.4.4) and Construction standards (SC6.4.6); and

(c) Department of Transport and Main Roads.

Where council's standard specifications are used unaltered, they may be referenced as such in the documents and may be omitted from the submitted set of specifications.

All Design drawings and work specifications must be certified by an appropriately qualified professional with relevant experience (see SC6.4.2.2(1)).

(4) Design documentation for material change of use applications

Applicants should submit the following documentation where necessary in support of the proposal:

(a) site analysis plan;

(b) elevation plans, floor plans (if necessary);

(c) traffic impact assessment, hydraulic report, geotechnical reports, acoustic report, stormwater quality

management plan, waste management safety in design report and other specialist reports necessary to support the development application;

(d) water and sewer modelling (if necessary) refer to SC6.4.3.23 Water and sewer network modelling guidelines; and

(e) landscape and irrigation plans.

(5) Design documentation for reconfiguring a lot applications
Applicants for staged developments should submit master plan documentation where necessary showing a subdivision's overall design concept for:

(a) sewer and water (including pump stations);

(b) stormwater quantity and stormwater quality (SC6.4.3.8 Stormwater quality management plans for development);

(c) earthworks including conceptual erosion and soil control plan (refer to SC6.4.4.5 Earthworks (design));

(d) road network (includes hierarchy, road and carriageway widths, noise impact and traffic studies);

(e) acoustic report, geotechnical report and any specialist report necessary to support the development application;

(f) public transport;

(g) servicing details (utilities);

(h) pedestrian and cycle network;

(i) Safety in design reports for all infrastructure that does not comply with relevant sections of the Development manual; and

(j) landscape and irrigation.

For non-staged developments; applicants should submit:

(k) lot layout;

(l) proposed road and access network;

(m) servicing details (utilities);

(n) stormwater management;

(o) Safety in design reports for all infrastructure that does not comply with relevant sections of the Development manual;

(p) Safety in design reports that demonstrate that sewer connection points and maintenance structures located at rear of lots are still accessible at all times; and

(q) any specialist report necessary to support the development application.

(6) Documentation for operational works and compliance applications
Applicants should submit where necessary to support the application the following documentation as part of the application (depending on scope of development works):

(a) design drawings (1x A3 size and an electronic copy in PDF);

(b) work specifications (one copy);

(c) copy of the associated Development Approval (if any);

(d) certified detailed Schedule/Bill of Quantities by a suitably qualified and experienced professional (see SC6.4.2.2.2(1));

(e) landscape statement of intent (see SC6.4.2.5(7)(1)(c) Landscape statement of intent);

(f) landscape and irrigation plans (see SC6.4.2.5(7) Landscape drawings and SC6.4.2.5(8) Irrigation drawings);

(g) stormwater drainage design calculations including design of structures (e.g. open drains, detention basin), catchment plans (internal and external);

(h) stormwater quality management plan including the design criteria and details;

(i) water network analysis (refer to SC6.4.3.23 Water and sewer network modelling guidelines);

(j) sewer network analysis (refer to SC6.4.3.23 Water and sewer network modelling guidelines);

(k) subgrade test results and pavement designs;

(l) engineering certification of structural designs;

(m) preliminary erosion and sediment control plan (refer to SC6.4.2.2.7 Conceptual and preliminary erosion and sediment control plan);

(n) traffic management plan (if required);

(o) traffic report (if required);

(p) geotechnical reports (where relevant);

(q) conduit assessment of existing infrastructure (refer to SC6.4.2.2.6 Conduit assessment) Safety in Design; and

(r) any other information required by the associated development approval and under relevant legislation, or relevant to support the assessment of the application.

SC6.4.2.2.4 Council's acceptance of design - advice

Council does not guarantee that the submitted designs for the proposed development have been checked in detail. Upon council's acceptance of designs for the proposed development, it is assumed that the certifying professional has performed sound judgement in preparing the designs taking into consideration existing site conditions and council requirements.

Council does not accept any responsibility for the accuracy of the submitted design and that any deficiencies and non-complying works identified by council must be rectified at the cost of the developer, notwithstanding council's prior approval.

If council's audit of the design reveals the Design Certificate Report to be inaccurate or incomplete, the submission may be returned to the consultant for resubmission. A resubmission review fee may be charged.

SC6.4.2.2.5 Preparation of design drawings guidelines

The information set out in SC6.4.2.3 Design checklists, SC6.4.2.4 Well-made application checklists and SC6.4.2.5 Details on drawings should be used as a guide to prepare design drawings. The information should be used in the preparation of plans for each group of drawings to assist council in the assessment process.

SC6.4.2.2.6 Conduit assessment

Any development which proposes to construct a structure, building or undertake earthworks in the vicinity of or within the "zone of influence" of an existing conduit may be required to identify the condition of the conduit for assessment of serviceability and structural compatibility with the proposed development work. Any upgrading or replacement determined by council will be carried out at the developer's expense prior to the commencement of any development works.

(1) CCTV inspection criteria - general criteria for closed circuit television (CCTV) sewer and stormwater assessments for operational works/compliance permits are as follows:

(a) sewer:

(i) major developments (refer to SC6.4.2.1.1(1)):

(A) prior to commencement of the defects liability period; and

(B) if defects are identified they must be rectified, and the sewer, for the entire length between the upstream and downstream maintenance holes (MHs),must be assessed again prior to completion of the defects liability period.

(ii) minor developments (refer SC6.4.2.1.1(2)):

(A) systems containing two or more sewer lengths, or systems containing sewer lengths that exceed a combined service length of 60 m measured centre to centre between manholes require assessment prior to commencement of the defects liability period;

(B) if defects are identified they must be rectified, and the sewer, for the entire length between the upstream and downstream maintenance holes (MHs),must be assessed again prior to completion of the defects liability period; and

(C) where a defects liability period does not apply, CCTV assessment is mandatory prior to acceptance.

(b) stormwater:

(i) inter-allotment systems located on private property are exempt;

(ii) rubber ringed jointed pipe systems with flexible joints immediately outside chambers (includes PVC and Polythene pipe systems) will be visually assessed and are exempt subject to the system presenting defect free;

(iii) CCTV assessment of flush end RCP pipe systems is mandatory;

(iv) major developments (refer to SC6.4.2.1.1(1)):

(A) prior to commencement of the defects liability period; and

(B) prior to completion of the defects liability period.

(v) minor developments refer to SC6.4.2.1.1(2)):

(A) systems exceeding a service length of 60 m require assessment prior to commencement of the defects liability period; and

(B) where a defects liability period does not apply, CCTV assessment of the system is mandatory prior to acceptance.

(2) Qualification and training of CCTV operators and supervisors - the assessment must be undertaken by a suitably trained and qualified contractor, in accordance with the relevant sections of the current version of Water Services Association of *Australia's Conduit Inspection Reporting code of Australia* (WSA05) and the results are to be submitted to council in CD, DVD or any digital storage device acceptable to council accompanied by a written condition assessment report to be approved in writing by council prior to the issuance of any Development Approvals.

In the event of non-compliance in preparation and submission of the conduit assessment, council may require the developer to re-perform the inspections and re-submit. All costs incurred conducting these additional conduit assessments will be the responsibility of the contractor.

(3) Site establishment – the contractor is responsible for the following requirements:

(a) any necessary approvals from statutory authorities in order to complete the required work;

(b) any temporary electric light, power installations and water supply including all charges incurred;

(c) public notification if necessary – contractor must notify affected residents/adjacent property owners/commercial business owners and council (including if the area to be closed is public open space). Additional requirements may be necessary if closures are to be over an extended period of time. Notification is required prior to commencement of work;

(d) plans of existing services are to be verified by the contractor. Council does not guarantee the accuracy of the information on these plans;

(e) environmental management plan – if necessary, the contractor must prepare and implement a site specific environmental management plan, for inspections which would involve interference to live services e.g. sewer line which poses an environmental risk. The Plan must detail activities and measures to ensure that the inspection is performed in a manner which minimises risk of causing environmental nuisance or harm;

(f) reinstatement – clean-up, repair and reinstate any areas affected or impacted by the works, at their own cost;

(g) maintaining the service in all conduits being inspected;

(h) pipe cleaning – conduits being inspected must be sufficiently clean to allow proper visual identification of existing defects. The proper disposal of debris from the cleaning shall be the responsibility of the

contractor;

(i) traffic management – where the diversion of vehicular and pedestrian traffic is required, the contractor is responsible for implementing an appropriate traffic management plan; and

(j) occupational health and safety – the contractor is required to comply with all statutory and other current regulations relating to occupational health and safety.

(4) Inspection report – The production of reports (including mandatory information), detailing the condition of surveyed conduits, all coded and scored to standards that satisfy the requirements of current WSA 05 Code.

(5) Inspection software – The preferred software for use in reporting on conduit inspections is the current of WinCan, set up to report as per the current WSA 05 code. If a contractor proposes to use alternative software, a full detail of the software must be provided to council for approval which includes the capabilities must be provided and must be fully compatible with the WinCan software.

(6) Data ownership – Full ownership of the survey and report data including intellectual property rights to the digital visual records and its contents must be with council.

SC6.4.2.2.7 Conceptual and preliminary erosion and sediment control plan

Soil disturbance is inevitable in any development; it is fundamental to develop measures to reduce the impact of soil erosion in every stage of construction to an acceptable level of sediments leaving the development site.

For reconfiguring a lot, material change of use, operational works and compliance assessment applications, depending on the scope of development, associated environmental impacts, site constraints (e.g. land use, lot layout site topography, proximity to bodies of water) and other factors, the developer should identify the erosion risk level of the proposed development, which can be determined by assessing the erosion hazard of the intended development site outlined in SC6.4.3.8 Stormwater management plans for development and *Appendix F – Erosion Hazard Assessment* of the International Erosion Control Association's *Best Practice Erosion and Sediment Control (IECA BPESC).*

Where a development site of a development application was assessed as being a high-risk site, the developer should provide a conceptual erosion and sediment control plan (CESCP). The conceptual document should take into consideration the key principles of erosion and sediment control detailed in this clause, and the site planning aspects and guideline in preparing conceptual plans in SC6.4.3.8 Stormwater management plans for development.

Where a development site was assessed as being a low-risk site and where a CESP has been accepted by council, a preliminary erosion and sediment control plan (PESCP) must be submitted to council as part of the operational works or compliance applications. The PESCP must be prepared in accordance with the design standards and technique selection outlined particularly in:

(1) Chapters 2 – Principles of erosion and sediment control;

(2) Chapter 4 – Design standards and technique selection;

(3) Chapter 5 – Preparation of plans; and

(4) also including the appropriate Model Code of Practice and Specific Guidelines in:

(a) Appendix G – Model code of practice;

(b) Appendix H – Building sites;

(c) Appendix I – Instream works;

(d) Appendix J – Road and rail construction;

(e) Appendix K – Access tracks and trails; and

(f) Appendix L – Installation of services of *IECA BPESC.*

During the Pre Start Meeting, the applicability and appropriateness of the PESCP will be reviewed on-site and revisions will be required if necessary.

For general guidance in implementation of erosion and soil control plan refer to SC6.4.3.8 Stormwater management plans for development.

SC6.4.2.5 Details on drawings guidelines

SC6.4.2.5.1 General requirements guidelines

(1) The information shown on the drawings must be logically collected on discrete sheets to avoid illogical and onerous effort in cross referencing between sheets in order to find information. This policy section details

minimal information requirements for plans and drawings submitted for assessment.

(2) Drawings should not be overcrowded with information and should not rely on colour printing or colour wash to impart information.

(3) The preferred submission method is uploading to the Townsville Online Lodgement System (TOLS). The preferred sheet sizes of drawing sheets are:

(a) A1 size (841 mm x 594 mm); and

(b) A3 size (420 mm x 297 mm).

(4) The preferred scales for use should generally conform with the recommendations of AS 1100.101 *Technical Drawing – General principles*. Generally the following scales are to be used 1:10, 1:20, 1:50 and multiples of 10 of these scales.

(5) Electronic and hard copies of drawings should be true to scale A1 size sheets and be suitable for black and white printing, copying and photo reduction to A3 size without loss of clarity.

(6) The drafting should be of a standard generally in accordance with the requirements of AS 1100.

(7) Title block – All drawings must, within the boundaries of the title block, clearly indicate the following:

(a) project title e.g. estate name (if any);

(b) real property description;

(c) locality;

(d) developer's name;

(e) details on contents of drawings e.g. sewer reticulation;

(f) scales – bar scales;

(g) plan and sheet number;

(h) schedule and date of revisions;

(i) survey datum;

(j) street names;

(k) date of initial issue;

(l) legend and north point; and

(m) signed design certification.

(8) Typical scales – the following scales are suggested for particular uses but these may be varied as appropriate to the works concerned:

(a) plans – 1:1000 (rural) and 1:500 (urban);

(b) longitudinal section horizontal – 1:1000 (rural) and 1:500 (urban);

(c) longitudinal section vertical – 1:100 (rural) and 1:50 (urban);

(d) intersection details - 1:250 or 1:100; and

(e) cross sections – 1:100.

(9) Survey datum – Level information should be referenced to the Australian height datum (AHD). Position coordinates should be tied to the GDA94 datum based on the Mapping Grid of Australia (MGA) coordinate system.

(10) Dimensioning

(a) Units - All units should be expressed in metric units. Linear dimensions on all roadworks plans, with the

exemption of some details of small structures and standard details which may be in millimetres.

(b) Chainages – Chainages on plans should be expressed to three decimal places of a metre e.g. 0.123 m.

(c) Cross section intervals – Road cross sections should be provided at 20 metre intervals, with further subdivision to 10 metre or 5 metre intervals where necessary due to horizontal or vertical curvatures.

(d) Grades – Road and pipe grades should be shown to three significant figures in percentage e.g. 1.234%.

SC6.4.2.5.2 Layout and stage plan guidelines

(1) For large developments, the layout plan shows the relationship of all new roads to each other, and to existing roads adjoining the development.

(2) Where development is planned in stages, the boundaries of proposed stages are shown on the plan, and the stages identified by numbering.

(3) Existing and proposed streets which are adjacent to or fronting the proposal are included on the layout plans.

(4) All services, natural features, significant trees and the like are shown on existing road reserves.

(5) Details of the permanent survey mark, including the AHD level from which the levels were transferred, are included.

SC6.4.2.5.3 Roadworks and associated drainage drawings

(1) Plan – drawing should include the following details:

(a) road reserve boundaries;

(b) lot boundaries, both existing and proposed (levels provided at each boundary corner) and easements;

(c) centreline or other construction line;

(d) chainages on centreline or construction line or set out co-ordinates;

(e) bearings of the centreline or construction line;

(f) offsets (in tabular form) if the construction line is not the centreline;

(g) tangent point chainages or co-ordinates of each curve;

(h) radius and tangent length and superelevation of each curve;

(i) road reserve boundaries, centreline, and bearing of each intersecting road;

(j) chainage or co-ordinates of the intersection point of road centrelines;

(k) kerb lip lines, kerb types, kerb face (setout) radii and chainage or co-ordinates of all tangent points of kerb face (setout) lines;

(l) edge of pavement, where no kerb and channel is proposed;

(m) dimensioned road reserve, verge, concrete footpath and pavement widths, where these differ from the standard cross section;

(n) location and details of signs and road markings proposed;

(o) drainline locations(including interallotment drainage), diameters and class of pipes or size of box culverts, open drains and easements and invert levels;

(p) the defined flood event levels;

(q) manhole locations, chainage and offset or co-ordinates and invert and kerb levels;

(r) stormwater flow arrows;

(s) inlet pit and manhole locations tabulated to include type, type of jointing chainage;

(t) culvert/channel and other structures details;

(u) location of existing utilities or other existing works within the site;

(v) limits and levels of lot filling or grading;

(w) cut or fill depths and earthwork quantities;

(x) co-ordinates of all set out points;

(y) retaining wall (including details);

(z) location and levels of bench marks and reference pegs;

(aa) service conduits locations;

(ab) details of all existing construction on or adjoining the proposed works; and

(ac) longitudinal and cross sections with invert levels and the required flood levels including existing and proposed surface contours of constructed or natural open channels (e.g. table drains) and waterways (including landscape, construction details and maintenance).

(2) Detail plans of intersections, turnaround areas, property accesses, cul-de-sac, traffic calming (LATM) devices (if required) and the like.

(a) Intersection detail plans include all relevant information required for plans together with additional details such as tangent point chainages, kerb lip levels on all kerb returns, pavement contours and channelisation works.

(b) The plans should also include relevant information as listed for standard cross section SC6.4.2.5(3)(4)).

(3) Longitudinal sections of roads – the longitudinal section of each road includes:

(a) chainages;

(b) datum RL, existing surface and peg levels;

(c) design road centreline and lip of kerb levels and grades;

(d) cut or fill depths and earthwork quantities;

(e) design grades, length and radii of vertical curves;

(f) chainage and level of grade intersection points and tangent points of vertical curves;

(g) sight distance diagram for each direction of travel for collector or higher order roads only;

(h) line marking (where applicable);

(i) details of superelevation (where possible);

(j) drainage lines and manholes intersecting centre line;

(k) table drain grading and levels where no kerb and channel;

(l) sight distance diagram for each direction of travel;

(m) horizontal curve details;

(n) existing and proposed services; and

(o) pavement design and design speed.

(4) Type cross sections of road - a standard cross section is shown for each road, including:

(a) road reserve width;

(b) pavement widths (lip to lip dimension);

(c) road verge widths;

(d) concrete footpath and cycle paths;

(e) crossfalls of pavement and road verges;

(f) pavement depth (including subsoil drainage);

(g) type of kerb and channel;

(h) type of pavement surfacing;

(i) batter slopes; and

(j) pegged or shift centre line.

(5) Cross sections of roads – a cross section is shown for each chainage on each road.

(a) A cross section should be shown at a minimum spacing of 20 m. Where roads are in steep terrain, cross sections may be required at closer intervals. Cross sections are to be extended into the allotments for the limit of batters. The cross-section plans are to include:

(i) road reserve boundaries;

(ii) pavement centreline, and shift centre line or other construction lines;

(iii) natural surface;

(iv) design cross section;

(v) crossfall of pavement and road verge, pavement and road verge widths, and pavement depths, wherever these differ from the standard cross section, e.g. superelevation and curve widening;

(vi) pavement and subsoil drainage; and

(vii) chainages.

(b) When existing bitumen sealed roads are widened, cross sections include the full existing sealed pavement cross section at not more than 10 m intervals.

(c) Each cross section shows the percentage crossfall on the existing bitumen surface and the design crossfall to the lip of the proposed kerb and channel.

(d) Notations on drawings also require the Supervising Engineer to check for any errors between the design and the set out of the kerb and channel before the kerb and channel is constructed.

(6) Traffic signs and pavement markings plan – all required signage and pavement markings (including temporary works) are to be provided in accordance with the current version of the MUTCD, Queensland.

(7) Longitudinal sections of drainlines – a longitudinal section of each drainline should be drawn along the centre line of the drainline and should show:

(a) chainages;

(b) existing and proposed surface levels;

(c) design invert levels, hydraulic grade lines, velocity, discharge;

(d) manhole chainages, inlet and outlet invert levels, and finished surface levels of structures;

(e) distances between manholes;

(f) grade in percent, diameter, type and class of each pipe or size of each box;

(g) references to the Council's current standard drawings;

(h) class of each pipe, length and type of pipe;

(i) existing and proposed service locations and levels;

(j) all piped drainlines and constructed or natural channels used to convey run-off as part of the development are shown on drawings;

(k) longitudinal sections and cross sections of all channels show the calculated hydraulic grade line for the design frequency; and

(l) piped drainlines are included either on the road longitudinal sections where applicable or detailed separately.

(8) Stormwater drainage catchment plan – the catchment plans should indicate all catchments including external catchments contributing to the stormwater drainage design and the following:

(a) full external catchment;

(b) development layout plan showing the roads and allotment boundaries;

(c) existing and finished surface contours (in different line types). Contour intervals are to be sufficient to enable sub-catchments to be defined;

(d) contours must be extended external to the site to enable the limits of all external catchments to be fully defined;

(e) subcatchment boundaries, labels and areas;

(f) location of drainlines, manholes, inlet/gully pits, outlets, open drains etc.; and

(g) labelling of stormwater structures.

SC6.4.2.5.4 Bicycle, pedestrian and shared path drawings guidelines

(1) All plans for bicycle, pedestrian and shared paths are to be presented at the reduction ratio 1:500 minimum or 1:200 preferable. The plans are to include details of the signs and pavement markings to be used and any barriers, fences, holding rails, ramps, etc. The landscaping treatment should also be included in the plans.

(2) The cycleway bicycle path plan sheet may be incorporated into the road plan where clarity permits. Specific details are to be provided at reduction ratio 1:200.

(3) Longitudinal sections will be required for all off-road pathways where grades are greater than or equal to 3%.

(4) Longitudinal sections will have reduction ratios of 1:500 horizontal and 1:50 vertical.

(5) Cross sections will be presented at 1:100 reduction ratio (natural) and transition tables will be required where cross falls vary or superelevation is provided.

(6) A typical cross section will be detailed to indicate pavement materials and layer depths.

SC6.4.2.5.5 Sewerage drawings guidelines

(1) Sewerage layout plan - the sewerage layout plan includes:
For development consisting of two or more stages, a preliminary master layout plan showing boundaries of all stages. The plan shows proposed locations and sizes of all trunk mains, pumping stations and sewage treatment plants, where relevant.
In addition, the sewerage layout includes:

(a) boundary of the development, lot layout and numbers, easements (if required), finished surface contours;

(b) non-sewered areas;

(c) references to the council's current standard drawings;

(d) location, grades of all sewer lines, manholes (numbered) and other services where they cross;

(e) indicate trunk mains;

(f) pumping stations, maintenance structure numbers and sewer diameters;

(g) site plan for sewerage pump stations; and

(h) details of water and electricity supply, landscaping, access and control buildings, if applicable.

(2) Sewerage longitudinal sections - the longitudinal section of each sewer line includes:

(a) upstream and downstream invert levels;

(b) existing and finished surface levels, depth to invert;

(c) grade expressed as 1 in XX;

(d) diameter, type and class of pipe;

(e) chainage;

(f) distance between maintenance structures;

(g) concrete stops, where required;

(h) manhole and/or shaft number;

(i) manhole type and drop type;

(j) location and depth of all underground services; and

(k) the design invert level of each house connection branch, type and invert level of the branch.

SC6.4.2.5.6 Water drawings guidelines

(1) Water reticulation layout plan
For developments consisting of two or more stages, a master layout plan showing stage boundaries should be provided. Locations of existing or proposed trunk mains, treatment plants or reservoirs are to be shown on plan.

In addition, a water reticulation layout plan showing:

(a) pipe location;

(b) pipe material, diameter, type, class and joints, including fittings;

(c) fire hydrant, valve, bends, junction locations;

(d) size and location of all concrete anchor blocks, thrust blocks, and diaphragm walls;

(e) cut-in details;

(f) cross-road conduit locations;

(g) specific notes and instructions;

(h) boundary of the development, lot layout and numbers, including easements;

(i) proposed location for any pump stations, showing access details;

(j) references to council's current standard drawings (SC6.4.4.8 Standard drawings);

(k) dimension from road alignment boundary/property boundary;

(l) minimum clearances to other services;

(m) pipe and fitting, internal and external protection details including at road pavement crossings;

(n) trench cross section detail showing the pipes as well as bedding and filling materials for each size and type of pipe;

(o) pump curves if appropriate;

(p) complete pipe work and structural details of any pump stations, including complete details of valves and other fittings and electrical details; and

(q) technical specifications for pumps and pump stations.

SC6.4.2.5.7 Landscape drawings guidelines

(1) Applications including landscape works, detailed plans and documentation containing the following minimum amount of information should to be provided, as applicable and in support of the proposal:

(a) Demonstration of design preparation and certification by qualified personnel (refer SC6.4.2.2.2(1)).

(b) Landscape plans, providing the following minimum amount of information, as applicable:

(i) specification notes for plant establishment period and maintenance;

(ii) existing site information, boundaries, contours, underground/overhead services, easements, drainage lines, or the like;

(iii) adjoining structures that overshadow the site;

(iv) details of protected vegetation, significant trees that are proposed for retention and trees proposed for removal due to the development;

(v) the canopy height and spread of any major tree or building footprint on adjoining property which the proposed development may affect in any way. The incorporation of a qualified arborist's findings may be relevant where adjoining tree root zones or canopy extends into the development site;

(vi) specification notes either on the drawings or in an associated report that adequately outlines the quality of construction materials, and all other relevant information;

(vii) proposed location of buildings/structures including finished floor levels;

(viii) roadways, car parks, footpaths, driveways with description of materials and finishes;

(ix) all areas and their proposed treatment such as surface treatments, planting layout, planting schedule, including botanical names, stock sizes, quantities, staking and planting details;

(x) fences and screens indicating materials, heights and construction details;

(xi) location and details of street or park furniture, fixtures and lighting;

(xii) indicative cross-sections of important features or areas of the site such as entrances, waterways and retaining walls;

(xiii) details of irrigation system;

(xiv) proposed design levels and original ground levels/contours;

(xv) design details and materials of all surfaces, retaining walls, edging, embankments, furniture,

planting, lighting and other structures including entry statements;

(xvi) typical cross sections through the site; and

(xvii) construction details for planting, paving, edging and retaining structures.

(c) Landscape statement of intent, describing:

(i) how the proposed landscaping meets the intent of the (SC6.4.3.6 Landscape policy) ;

(ii) how the proposed landscaping address the sites opportunities and constraints; and

(iii) the underpinning concepts incorporated into the landscape design and how these relate to and deliver cost-effective sustainable outcomes.

(d) locality map illustrating surrounding reserves/natural areas, roads and local features.

(e) existing site conditions and base information including:

(i) site boundaries, levels and contours;

(ii) description and location of built elements, including “off street car parking”;

(iii) site analysis identifying opportunities and constraints;

(iv) description of all remnant vegetation present and any landforms (for example dunes, gullies, wetlands, waterways, rock formations);

(v) location of existing trees and identified vegetation to be retained including Vegetation Protection Zone/s and protection and management provisions as per SC6.4.5.2.1(18) Work adjacent to trees and protection of environmentally significant vegetation;

(vi) canopy height and spread of any major tree or building footprint on adjoining property which the proposed development may affect in any way. The incorporation of a qualified arborist’s findings and implementation Vegetation Protection Zone of may be relevant where adjoining tree root zones or canopy extends into the development site;

(vii) location of existing trees and identified vegetation for removal;

(viii) existing driveways, footpaths, adjoining driveways etc. including finished surface/s;

(ix) adjoining structures that overshadow the site;

(x) significant features pertaining to the application e.g. the location of refuse collection areas;

(xi) existing grading and drainage in relation to the landscaping (overland flows to be identified) with inlet and discharge points clearly shown; and

(xii) underground and overhead services (water, power, telecom and gas) easements and drainage lines.

(f) landscape details and schedules including:

(i) proposed design levels and original ground levels/contours;

(ii) typical cross sections through the site including surface grades;

(iii) method of erosion control for slopes steeper than 1:4;

(iv) grading and drainage in relation to the landscaping (overland flows to be identified) including surface and subsurface drainage, collection points, and discharge points clearly shown;

(v) surface treatment for hardscape areas including accurate location, dimensions, construction notes, details and finishes of concrete footpaths, paving, roadways, car parks, driveways, boardwalks and the like;

(vi) existing and proposed levels of building slab, hard surfaces, drainage grates and landscaped areas, especially adjacent to trees to be retained;

(vii) indicative cross-sections of important features or areas of the site such as entrances, waterways and retaining walls;

(viii) location and details of furniture, fixtures and lighting, where applicable;

(ix) fencing and screening locations including height, material and finish, to boundaries and pool area (if applicable);

(x) details and soil depth of planter boxes and podiums including inlet and discharge points for drainage;

(xi) location, dimensions and construction details for any other proposed works or structures or external elements;

(xii) calculation of the square metre area of landscape and recreation area;

(xiii) surface treatment for all softscape areas including accurate location, dimensions, planting notes, details and methods of establishment or transplanting for garden beds, lawn areas, and other softscape elements;

(xiv) planting bed preparation details/notes including excavation, cultivation, imported topsoil depths, mulch type and depth, fertiliser or soil additive type and application rate where the council specification is not being applied;

(xv) planting plan including planting layout, plant code, stock sizes, quantities, staking and planting details;

(xvi) plant schedule containing plant code, plant species, location, quantity and spacing and size of container (and approximate size of the plant if requested as part of a condition) as per Table SC6.4.2.1 below;

Table SC6.4.2.1 Example of plant schedule

Plant code	Plant name	Location	Qty	Spacing	Container size
1	Rhoeo spathacea	Garden 1	30	500mm centres	140mm
2	Carpentaria acuminata	Garden 2	3	As per plan	25 Litre
3	Callistemon Capt Cook	Garden 1 & 2	10	1 metre centres	150mm

(xvii) specification notes (either on the drawings or in an associated report) that adequately outline the quality of construction materials, and all other relevant information; and

(xviii) specification notes for the plant establishment period and maintenance including responsibility for plant replacement and maintenance.

(2) For public open space, streetscaping or works that will become council assets, council may request more detailed information including:

(a) General details such as:

(i) demonstration of design preparation and certification by qualified personnel (see SC6.4.2.2.2(1));

(ii) designer's name and/or company;

(iii) drafter's name and/or company; and

(iv) surveyor's name and/or company.

(b) Additional details pertaining to open space or streetscaping (existing and proposed) including but not limited to:

(i) geotechnical and soil test results;

(ii) site plan, including relationship to existing infrastructure and details and responsibilities relating to removal or modification of council assets;

(iii) details of type, manufacturer, materiality, and warranty of furniture, equipment and structures (such as play equipment, park furniture, shade shelters) including compliance with relevant standards where applicable;

(iv) the location and details of any stormwater quality management infrastructure to be constructed including maintenance access to the infrastructure;

(v) calculation of the square metre area of landscaping to be planted, broken down into turfed and mulched and planted areas;

(vi) other works proposed in the location/public open space, which do not form part of the detailed landscape plan, but may impact the landscape works or council assets (such as vegetation management, rehabilitation and environmental management plans);

(vii) the location and details of any stormwater discharge through or into a public open space or

waterway; and

(viii) where plantings are proposed in the road reserve, the provision of a plan showing an accurate footprint, including trunk diameter (at 1.2 m from ground level) and canopy spread of all existing trees and expected diameter at maturity for proposed street trees adjacent to the property and roads concerned, including any trees that are proposed to be removed.

(c) Maintenance plan pertaining to ongoing maintenance of public open space infrastructure or streetscaping, including but not limited to:

(i) schedule that lists the assets and associated maintenance activities, including locations, season of visit, schedule frequency and number of visits per year;

(ii) statement demonstrating alignment with council public open space management specifications;

(iii) Bill of Quantities (BOQ) that identifies the relevant types and quantities of each asset;

(iv) detailed specifications for specialist activities and/or infrastructure including, but not limited to, playground and fitness equipment, public art, ablution facilities, water features, stormwater quality infrastructure, bridges, and revegetation areas;

(v) that the landscape maintenance plan has been prepared by a suitably qualified horticulturist or landscape designer (or irrigation designer for any irrigation system component of the landscape management plan); and

(vi) an approved traffic management plan relating to all ongoing maintenance activities that will be required within the road reserve or require ongoing traffic management.

(d) Other applicable (written) approvals, including but not limited to:

(i) asset owner approval of works, including buildings and structure, where the works are within a designated parkland or affecting other council assets; and

(ii) all other approvals or certifications necessary for the completion of works in accordance with the Laws of Australia, Laws of the State of Queensland, Townsville City Council Local Laws and Ordinances.

SC6.4.2.5.8 Irrigation drawings guidelines

(1) For all irrigation works, detailed plans and documentation containing the following minimum amount of information are to be provided, as applicable:

(a) standard plan legend as shown in SC6.4.4.8 Standard drawings (Irrigation drawings).

Note—the symbols and line types shown in the Legend are the acceptable convention for design plans to be used to represent the components of the design. Additional symbols and line types may be introduced provided they are shown in the Legend on the drawing.

(b) valve key displaying the relevant information as shown in SC6.4.4.8 Standard drawings (Irrigation drawings);

(c) sprinkler key displaying the relevant information as shown in SC6.4.4.8 Standard drawings (Irrigation drawings);

(d) locality plan outlining the location of the site appropriately labelled with the suburb and street names;

(e) name of all adjacent roadways;

(f) location of water meter, backflow device, automatic controller, valve boxes;

(g) details of irrigation system and connection (town supply or bore water);

(h) irrigation design data displaying the relevant information as shown in SC6.4.4.8 Standard drawings (Irrigation drawings);

(i) irrigation cabling/wiring schedule displaying the relevant information as shown in SC6.4.4.8 Standard drawings (Irrigation drawings); and

(j) design notes detailing relevant design criteria e.g. Sprinkler Type A is to be Hunter PGP; all Solenoid valves are to be Hunter ICV; descriptions of the Symbols and Line Types used from the Plan Legend.

(2) For all irrigation in public open space works, streetscapes or works that will become council assets, council may request more detailed information in addition to the general irrigation works requirements previously outlined, including:

(a) general details such as:

(i) demonstration of irrigation design preparation and certification by qualified personnel being a Certified Irrigation Designer or Certified Irrigation Agronomist including certification number;

(ii) designers name and/or company;

(iii) drafters name and/or company; and

(iv) surveyors name and/or company;

(b) additional details pertaining to irrigation within public open space or streetscapes (existing and proposed) including but not limited to:

(i) details and responsibilities relating to removal or modification of council irrigation assets;

(ii) details of type, manufacturer, materiality, and warranty of irrigation system component including compliance with relevant standards where applicable;

(iii) the location and details of any irrigation associated with stormwater quality management infrastructure to be constructed including maintenance activities and access to the irrigation infrastructure;

(iv) calculation of the square metre areas of irrigation against the irrigation system type and profile levels;

(v) other works proposed in the location/public open space, which do not form part of the detailed irrigation plan, but may impact the irrigation works or council assets; and

(vi) where irrigation is proposed in the road reserve, the inclusion of offset details from lanes of traffic to irrigation infrastructure;

(c) maintenance plan pertaining to ongoing maintenance of irrigation infrastructure or streetscaping, including but not limited to:

(i) leak and blockage checks in irrigation lines and emitters;

(ii) reprogramming the irrigation controller and restationing of emitters as plants grow, die out and are replaced;

(iii) inspection of moisture sensors;

(iv) maintenance of tanks and cisterns;

(v) checking of water pumps; and

(vi) an approved traffic management plan relating to all ongoing maintenance activities that will be required within the road reserve or require ongoing traffic management; and

(d) other applicable (written) approvals, including but not limited to:

(i) asset owner approval of works, where the works are will affect council irrigation systems or other council assets; and

(ii) all other approvals or certifications necessary for the completion of works in accordance with the Laws of Australia, Laws of the State of Queensland, Townsville City Council Local Laws and Ordinances.

SC6.4.3 Design standards

SC6.4.3.2 Building over or adjacent to services

SC6.4.3.2.1 Introduction

(1) Purpose

This sub-section outlines council's standards and guidelines for building over or adjacent to council's services. This document will supplement the Queensland Development Code *Mandatory Part 1.4 – "Building over or near relevant infrastructure"* and identifies and provides additional guidance about any information that may be required to support a development application. This section does not replace or override any aspect of the QDC.

(2) Scope

This sub-section applies to all building work proposed to be carried out over or near to a council service or underground asset.

(3) Principles

The construction and erection of a structure or the creation of a residential allotment over or near to a council service must be carried out in a way that ensures that:

(a) the function of the service is not adversely affected;

(b) no additional load is placed on the service without council approval; and

(c) maintenance access (at all times) to the service is not interfered with or restricted.

SC6.4.3.2.2 Restricted development

(1) Without exception, council will not permit building a structure over or near to:

(a) sewer pressure mains and overflow pipework; or

(b) gravity sewer trunk mains; or

(c) sanitary drainage connection points; or

(d) water supply mains; or

(e) stormwater drainage conduits (pipes or culverts) with a capacity of less than 2% average exceedence probability (AEP) or stormwater pipelines with an internal diameter of less than 375 mm; or

(f) open drainage channels or overland drainage paths.

SC6.4.3.2.3 Allowable development over or adjacent to sewerage services

(1) Council may permit building a structure over or near to the following sewerage services:

(a) gravity sewer mains, other than gravity trunk mains excluded under section SC6.4.3.2.2. The applicant is to carry out an internal closed-circuit television inspection of the main and submit it to council, prior to commencing any construction activities over or adjacent to the sewer.

If the main is assessed to be in poor condition or liable to damage from the proposed construction, the applicant may be required to replace the main to the satisfaction of council prior to commencement of any construction activities over or adjacent to the sewer; and

(b) sewer maintenance holes in commercial or industrial buildings:

If approved, the chamber is to be raised to the floor level of the building. Maintenance holes must be sealed against gas leaks, bolted down and kept clear of obstructions for maintenance access by council at all times.

SC6.4.3.2.4 Allowable development over or adjacent to stormwater services

(1) Council may permit building a structure over or near to the following stormwater services:

(a) drainage conduit with a minimum 2% AEP and with an internal diameter greater than 375 mm. The applicant must carry out an internal closed-circuit television inspection of the stormwater conduit and submit it to council, prior to commencing any construction activities over or adjacent to the stormwater conduit. If the stormwater conduit is assessed to be in poor condition or liable to damage from the proposed construction, the applicant may be required to replace the main to the satisfaction of council

prior to commencement of any construction activities over or adjacent to the stormwater conduit. Council may permit a driveway or temporary or light steel framed structure to be constructed over a storm water drain where:

(i) maintenance access to the drain can be retained;

(ii) the drain does not also form part of an overland flow path; and

(iii) no other option is available.

SC6.4.3.2.5 Clearances

The following minimum clearances apply for structures permitted to be built over or adjacent to a service:

(1) a minimum clearance of 250 mm must be maintained between the outside edge of the service footprint and the nearest projection of the foundation of the proposed structure, excluding swimming pools. Swimming pools must be located to achieve a minimum clearance of 600 mm vertically and 1 m horizontally to the outer edge of the service footprint;

(2) a minimum horizontal clearance of 1.2 m must be maintained between the outer face of the service and the nearest point of the foundation of the structure;

(3) the foundation of any structure, excluding a swimming pool, located within the zone of influence must extend a minimum of 150 mm below the projected zone or on solid rock. Pier and beam footings are generally acceptable;

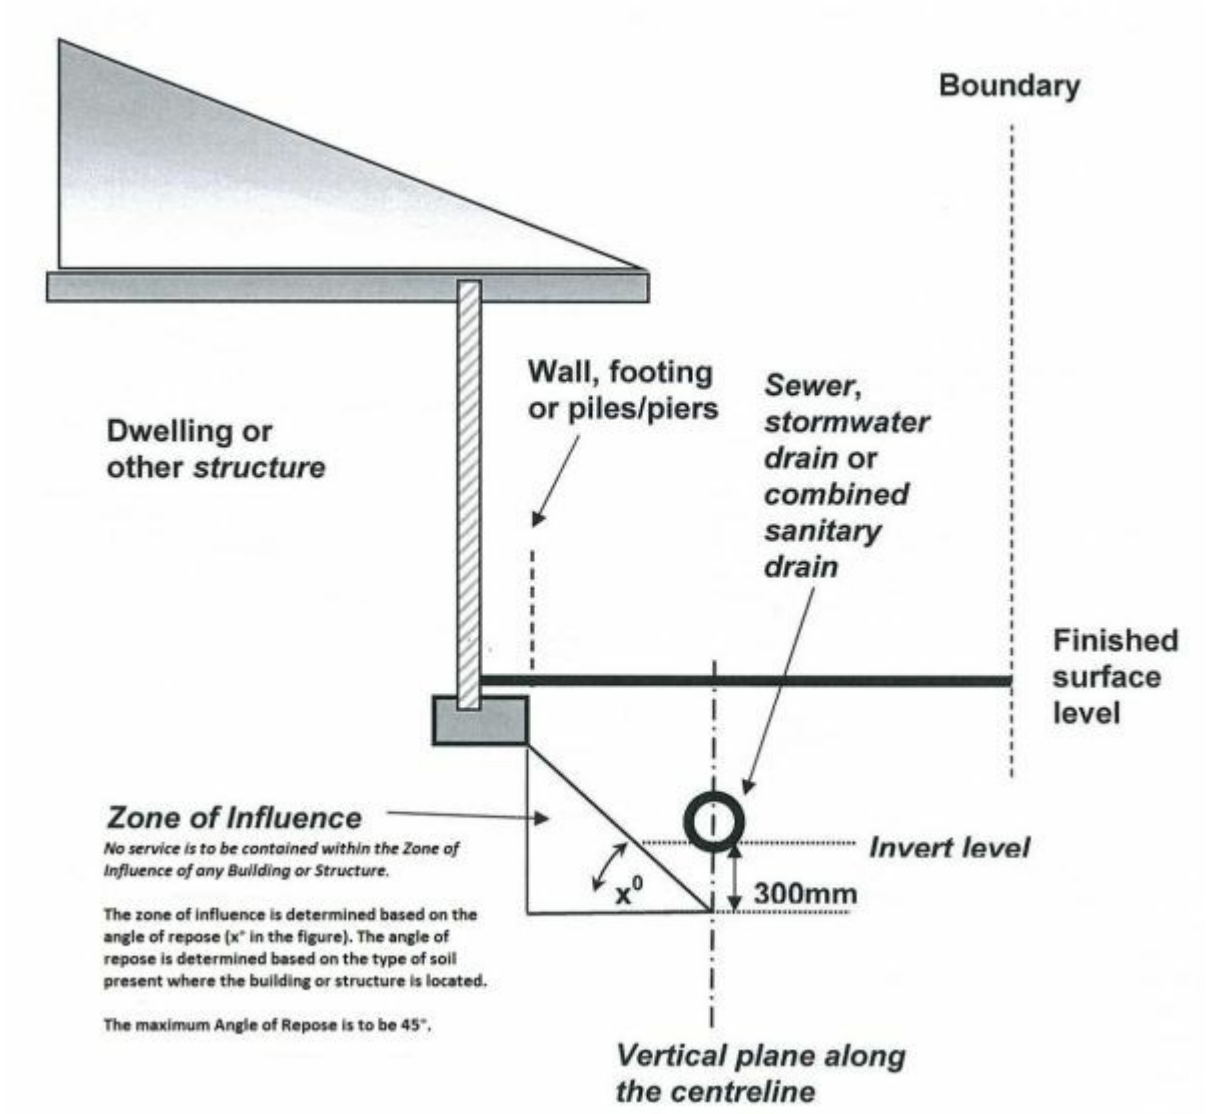

Figure SC6.4.3.2.1 Zone of influence

(4) a minimum clear vertical space above a sewer manhole of 2.4 m must be maintained above the finished ground

surface level for access purposes;

(5) a minimum horizontal clear space of 2.0 m must be maintained between structure and connection point on sewer, connection point on sewer refers to oblique branch (OB), vertical jump-up (VJU) and sewer maintenance structure; and

(6) a minimum horizontal clear space of 2.0 m must be maintained between structure and outside face of gravity trunk sewer.

SC6.4.3.2.6 Relocation of services

(1) Council will require that a service is relocated at the developer's expense where:

(a) no other site is reasonably available for the location of the proposed structure;

(b) the proposed structure is in conflict with, or likely to cause damage to, a council service.

(2) If council in its absolute discretion considers it necessary for a service to be relocated as a consequence of a proposed development, the re-design must consider:

(a) the feasibility of redesign or relocation;

(b) terrain;

(c) cost;

(d) importance of the service; and

(e) suitability for future maintenance access.

SC6.4.3.3 Footpath treatment policy

SC6.4.3.3.1 Purpose

(1) The purpose of the Footpath treatment policy is to achieve an appropriate footpath treatment and installation to achieve consistency of surfacing material located in key areas across Townsville, commensurate with the streetscape intent having regard to:

(a) the projected level of usage in a given location, such as shared-use or heavy traffic movements;

(b) activities anticipated to occur within the verge at the given location and safety requirements; and

(c) the desired streetscape character of the location, giving particular attention to the relevant zone code.

Editor's note—refer to SC6.4.3.3.7 Footpath treatment location maps for locations of treatments.

(2) Reference and source documents:

(a) This subsection should be read in conjunction with other sections of the Townsville City Plan and Development manual planning scheme policy including, but not limited to:

Part 4 Priority infrastructure plan
Part 9.3.3 Landscape code
Part 9.3.4 Reconfiguring a lot code
Part 9.3.6 Works code
SC6.4.2 Development application guidelines
SC6.4.3.4 Outdoor dining design
SC6.4.3.6 Landscape policy
SC6.4.3.20 Public lighting and utility services
SC6.4.4.1 Geometric road design
SC6.4.4.2 Pavement design
SC6.4.4.7 Bicycle, pedestrian and shared path design
SC6.4.6 Construction standards

(b) The following Australian Standards are also referenced and should be read in conjunction with this sub-section:

AS/NZS 1158.3.1 Lighting for roads and public spaces
AS 1170 Structural design actions (set)
AS 1428 Design for access and mobility (set)
AS 2890.3 Parking facilities – Bicycle parking facilities
AS 3996 Access covers and grates
AS 3727 Guide to residential pavements
AS/NZS 4586:2004 Slip resistance classification of new pedestrian surface materials

(c) Other:

The following documents are also referenced and should be read in conjunction with this subsection:
Austroads, Guide to Road Design (Set):
Aust Roads – Road Design Part 4 Intersections and Crossings, section 8 Pedestrian Crossings
Aust Roads – Road Design Part 4 Intersections and Crossings, section 9 Cyclist Crossings
Aust Roads – Road Design Part 6A Pedestrian and Cyclist Paths

Department of Transport and Main Roads, Manual of uniform traffic control devices (MUTCD), Queensland.
Department of Transport and Main Roads, Traffic and Road Use Management Manual, Volume 1 – Part 6: Intersections, Interchanges and Crossings, Section 3.4-1 Pedestrian crossing facility guidelines and prioritisation system user guide Queensland Government, Crime Prevention through Environmental Design, Guidelines for Queensland, Parts A and B, 2007.

SC6.4.3.3.2 Footpath treatment

(1) The standards and requirements of this policy sub-section will achieve compliance with Townsville City Plan where the planning scheme code notes this policy as providing compliance.

Editor's note— Part 9.3.3 Landscape Code, Part 9.3.4 Reconfiguring a lot code and Part 9.3.6 Works Code each have outcomes that can be achieved by this policy sub-section, in addition to the relevant zone code.

(2) The locations where footpath treatment standards of this policy are to be met are shown in SC6.4.3.3.7 Footpath treatment location maps. In general, the following locations require footpath treatment in accordance with this policy sub-section:

(a) the Principal central (CBD) and key development areas supporting the CBD;

(b) other key activity centres (generally those in the Centre zones category and Specialised centre zone), in particular along the supporting roads and streets where attractive pedestrian streetscapes are intended by the zone and precinct;

(c) key infill areas, including medium density and higher density residential areas where there is an emphasis on creating attractive and pedestrian-oriented streetscapes;

(d) facilities with high levels of public use warranting improved footpath treatment such as: educational establishments (schools, TAFE colleges), places of worship etc., the finish of the footpath treatment shall be at the discretion of the Townsville City Council;

(e) mixed use areas that have frequent pedestrian use have a highly visible frontage or where attractive pedestrian environments are intended by the zone and precinct;

(f) special footpath type areas such as Magnetic Island, The Strand, Palmer Street and Sir Leslie Thiess Drive; and

(g) any new centres, commercial, mixed use and community uses that are not identified in SC6.4.3.3.7 Footpath treatment location maps. In such instances, the above criteria shall be used to determine the most similar development to inform the particular treatment to be applied.

Editor's note—for any other areas not covered by SC6.4.3.3.7 Footpath treatment location maps see SC6.4.4.7 Bicycle, pedestrian and shared path design.
Editor's note—refer to SC6.4.3.3.7 Footpath treatment location maps for location of proposed treatments.
Editor's note—for land with the Townsville City Waterfront Priority Development Area (PDA) additional criteria applies, see the Townsville City Waterfront Priority Development Area Development Scheme.

SC6.4.3.3.3 Footpath treatment standards

(1) Footpath treatment standards for each of the nominated locations identified in SC6.4.3.3.7 Footpath treatment location maps are set out in the following Tables.

Editor's note—refer to SC6.4.3.3.7 Footpath treatment location maps for locations of proposed treatments.

FT1 – Footpath Treatment 1	
Statement of intent - FT1	
Footpath treatment 1 serves the core retail and entertainment areas of the Principal centre (CBD). The treatment provides the highest finish intended to support high levels of pedestrian use and may provide for on street dining, and informal and formal recreational and civic spaces.	
Body of footpath and driveway crossings: FT1	
Description:	• footpath treatment FT1 shall be full width from building line to the road kerb alignment. • two kinds of stone pavers of varying length and width set in mortar on mass concrete base (see SC6.4.6.14 Mass concrete sub-base and SC6.4.6.18 Segmental paving) • facing: split face finish to top (saw cut other edges) • image: refer to Figure SC6.4.3.3.2 Image FT1.

Pattern:	• staggered pattern as shown in Figure SC6.4.3.3.1 Conceptual diagram: FT1, and Figure SC6.4.3.3.2 Image FT1. • pavers shall be laid alternatively 200mm and 100mm wide with the basalt (darker) paver towards the building line and the granite (lighter) paver towards the kerb. • a staggered transition between the pavement types shall occur at approximately 70 per cent basalt 30 per cent granite, see Figure SC6.4.3.3.1 Conceptual diagram FT1.
Grout:	• product: CTA Polyblend G15 or approved equal. • colour: ‘Mid Grey’.
Pavers:	• basalt: 100% grey range (darker stone in Figure SC6.4.3.3.1 Conceptual diagram FT1) • granite: ‘Sindoor Brown’ (lighter stone in Figure SC6.4.3.3.1 Conceptual diagram FT1) • width: 200 mm or 100 mm (refer varying widths in Figure SC6.4.3.3.1 Conceptual diagram FT1) • length: 300 mm or 500 mm • depth: 40 mm
Driveway and pedestrian crossing point	
Description:	• driveway access through footpath shall be monolithic poured colored concrete slabs, colour to be matched to the basalt paver, with saw cut detailing to match adjacent paver pattern (scoring cuts only 5mm deep). See Figure SC6.4.3.3.3 Image FT1 driveway option. • driveway crossover shall be “plain natural” concrete with surface : broom finish. • pedestrian kerb ramp shall be "plain natural" concrete with surface: broom finish.

Figure SC6.4.3.3.1 Conceptual diagram: FT1

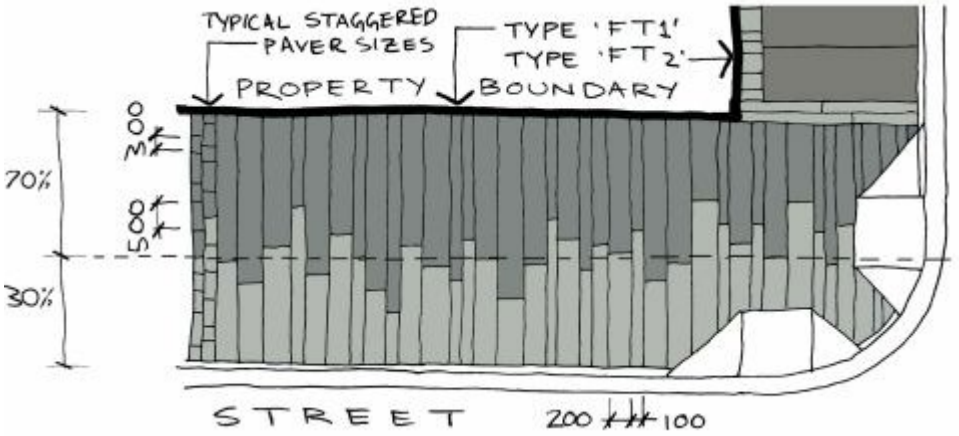

Figure SC6.4.3.3.2 Image: FT1

Figure SC6.4.3.3.3 Image FT1 driveway option

Editor's note—refer to SC6.4.3.3.7 Footpath treatment location maps for locations of proposed treatments.

FT2 – Footpath Treatment 2	
Statement of intent	
Footpath treatment 2 serves the remainder of the Principal centre (CBD), key areas which support the CBD and areas intended for medium and higher residential densities nearby the CBD. The treatment provides a nexus with FT1 and is of a high quality to support high levels of pedestrian use and may provide for the integration of civic spaces. A reduced width option may be permitted in the medium density residential areas as indicated on SC6.4.3.3.7 Footpath treatment location maps.	
Body of footpath: FT2	
Description:	• footpath treatment FT2 shall be full width from building line to the road kerb alignment. • monolithic poured concrete slabs in approximately 5 m lengths with decorative scoring pattern and perimeter stone paver banding on mass concrete base, see SC6.4.6.14, Figure SC6.4.3.3.4 Conceptual diagram: FT2, and Figure SC6.4.3.3.5 Conceptual diagram FT2, and Figure SC6.4.3.3.5 Image: FT2. • finish: 'light wash' 1 mm – 2 mm deep (2 mm max) using a water-based chemical retarder, see Figure SC6.4.3.3.8, Figure SC6.4.3.3.9, and Figure SC6.4.3.3.10. • standard drawings as noted in SC6.4.3.3.3(3)(b). • decorative scoring, see Figure SC6.4.3.3.4, Figure SC6.4.3.3.5, and noted in SC6.4.3.3.3(3) and SC6.4.3.3.3(3)(i). **Editor's note**—refer to Figure SC6.4.3.3.8 for maximum acceptable aggregate exposure and Figure SC6.4.3.3.9 and Figure SC6.4.3.3.10 for unacceptable, under and over, aggregate exposure.
Description reduced width option areas:	• reduced width which allows for a planting zone from back of curb and/or property boundary see Figure SC6.4.3.3.7 Conceptual diagram FT2 – Reduced width option. • monolithic poured concrete slabs with decorative scoring pattern and stone paver banding at approximately 5m intervals on a mass concrete base, see Figure SC6.4.3.3.7. • finish: 'light wash' 1 mm – 2 mm deep (2 mm max) using a water based chemical retarder, see Figure SC6.4.3.3.8, Figure SC6.4.3.3.9, and Figure SC6.4.3.3.10. • standard drawings as noted in SC6.4.3.3.3(3)(b). • decorative scoring: see Figure SC6.4.3.3.7, and noted in SC6.4.3.3.3(3) and SC6.4.3.3.3(3)(i). **Editor's note**—refer to Figure SC6.4.3.3.8 for maximum acceptable aggregate exposure and Figure SC6.4.3.3.9 and Figure SC6.4.3.3.10 for unacceptable, under and over, aggregate exposure.

Pattern:	• see Figure SC6.4.3.3.4 Conceptual diagram FT2 and Figure SC6.4.3.3.5 Conceptual diagram F2 and Figure SC6.4.3.3.7 Conceptual diagram F2 reduced width option for saw cut pattern.
Colour:	• concrete colour: CCS "Onyx" at 4% dose in a grey cement base. • aggregate: Hanson “salt and pepper” or approved equivalent.
Banding: FT2	
Description:	• granite stone pavers of varying length and width on mass concrete base, see SC6.4.6.14 Mass concrete sub-base and SC6.4.6.18 Segmental paving, SC6.4.3.3.5 Banding details. • facing: split face to top, saw cut finish to all other sides. • standard drawings as listed in SC6.4.3.3.3(3)(b).
Pattern:	• staggered pattern as shown in Figure SC6.4.3.3.4 Conceptual diagram FT2, Figure SC6.4.3.3.5 Conceptual diagram FT2, Figure SC6.4.3.3.6 Image FT2 and Figure SC6.4.3.3.7 Conceptual diagram FT2 reduced width option.
Grout:	• product: Polyblend G15 sanded grout from Construction Technologies Australia or approved equal. • colour: "Mid Grey".
Pavers:	• granite: "Sindoor Brown". • width: 200 mm or 100mm. • length: 300 mm or 500mm. • depth: 40 mm.
Driveway and pedestrian crossing points: FT2	
Description:	• driveway access through foothpath shall be monolithic poured concrete slabs with decorative scoring, see Figure SC6.4.3.3.3. • finish: light wash finish 1 mm – 2 mm deep (2 mm max), using a water-based chemical retarder (CCS "reveal" 1 mm or approved equal, do not use sugar), see Figure SC6.4.3.3.5, Figure SC6.4.3.3.9, and Figure SC6.4.3.3.10. • driveway crossover shall be “plain natural” concrete with surface: broom finish. • pedestrian kerb ramp shall be “plain natural” concrete with surface: broom finish. • standard drawings: as noted in SC6.4.3.3.3(3)(b)
Pattern:	• see Figure SC6.4.3.3.4 Conceptual diagram: FT2 and Figure SC6.4.3.3.5 Conceptual diagram: FT2 for sample crossover layout and decorative scoring pattern.
Colour:	• concrete colour: CCS "Onyx" at 4% dose in a grey cement base. • aggregate: Hanson "salt and pepper" aggregate or approved equivalent.

Editor's note—refer to SC6.4.3.3.7 - Footpath treatment location maps for locations of proposed treatments.

FT3 – Footpath Treatment 3	
Statement of intent	
Footpath treatment 3 serves many of the city activity centre areas, including major, district and local centres and some neighborhood centres, mixed use areas and specialised centres, where regular pedestrian use is anticipated for commercial and recreational purposes	
Body of footpath: FT3	
Description:	• footpath treatment FT3 shall be full width from building line to the road kerb alignment. • monolithic poured coloured concrete slabs in 5 m lengths with decorative scoring and perimeter cobble banding. • conceptual image: see Figure SC6.4.3.3.11 Conceptual diagram FT3. • finish: broom finish. • standard drawings: as noted in SC6.4.3.3.3(3)(b). **Editor's note —**for decorative scoring, see SC6.4.3.3.4, SC6.4.3.3.3(3)(g), and SC6.4.3.3.3(3)(i).
Description reduced width option areas:	• reduced width which allows for a planting zone from back of kerb and/or property boundary see Figure SC6.4.3.3.13 Conceptual diagram FT3 Reduced width option. • monolithic poured coloured concrete slabs with decorative scoring and cobble banding at approximately 5m intervals on a mass concrete base. • conceptual image: see Figure SC6.4.3.3.13 Conceptual diagram FT3 Reduced width option. • finish: broom finish. • standard drawings: as noted in SC6.4.3.3.3(3)(b). **Editor's note**—for decorative scoring, see SC6.4.3.3.4, SC6.4.3.3.3(3)(g), and SC6.4.3.3.3(3)(i).
Pattern:	• conceptual scoring pattern: see Figure SC6.4.3.3.11 and Figure SC6.4.3.3.13, • for variations such as corners, trees, doorways etc, refer: Figure SC6.4.3.3.22, Figure SC6.4.3.3.23, Figure SC6.4.3.3.24, Figure SC6.4.3.3.25, Figure SC6.4.3.3.26 and Figure SC6.4.3.3.27, • align scoring pattern with adjacent footpath scoring and/or saw cuts where applicable **Editor's note —**for decorative scoring, see SC6.4.3.3.4, SC6.4.3.3.3(3)(g), and SC6.4.3.3.3(3)(i)
Colour:	• CCS "paperbark" at 4% dose in a grey cement base
Banding: FT3	
Description:	• pressed concrete cobbles set in mortar on mass concrete base (see SC6.4.6.14 Mass concrete subbase, SC6.4.6.18 - Segmental Paving and SC6.4.3.3.5 Banding details) • finish: proprietary non-slip finish

Pattern:	• cobbles 3x wide in stack bond pattern • conceptual image: see Figure SC6.4.3.3.11 and Figure SC6.4.3.3.13,. • for variations such as corners, trees, doorways etc. refer: Figure SC6.4.3.3.22, Figure SC6.4.3.3.23, Figure SC6.4.3.3.24, Figure SC6.4.3.3.25, Figure SC6.4.3.3.26, Figure SC6.4.3.3.27, and Figure SC6.4.3.3.29.
Colour:	• CCS "ghost gum".
Pavers:	• 100mm x 100mm square x 60 mm to 65 mm deep.
Driveway and pedestrian crossing points: FT3	
Description:	• driveway access through footpath shall be monolithic poured coloured concrete slabs. • driveway crossover shall be “plain natural” concrete with surface: broom finish, see Figure SC6.4.3.3.24. • pedestrian kerb ramp shall be “plain natural” concrete with surface: broom finish. • standard drawings: as noted in SC6.4.3.3.3(3)(b). **Editor’s note —**for decorative scoring, see SC6.4.3.3.4, SC6.4.3.3.3(3)(g), SC6.4.3.3.3(3)(i).
Pattern:	• for pattern integration of driveways, refer: Figure SC6.4.3.3.24. • align driveway scoring pattern with adjacent footpath decorative scoring and/or crack control saw cuts. **Editor’s note —**for decorative scoring, see SC6.4.3.3.4, SC6.4.3.3.3(3)(g), SC6.4.3.3.3(3)(i).
Colour:	• CCS "paperbark" at 4% dose in a grey cement base, kerb transition: "natural" concrete colour.

Figure SC6.4.3.3.14 Image FT3 reduced width option

Editor's note—refer to SC6.4.3.3.7 - Footpath treatment location maps for locations of proposed treatments.

FT4 – Footpath Treatment 4	
Statement on intent	
Footpath treatment 4 serves many of the city's lower order activity centre areas, mixed use areas, key corridors and key infill areas intended for increased residential densities and attractive streetscape.	
Body of footpath: FT4	
Description:	• Footpath treatment FT4 shall be full width from building line to the road kerb alignment. • monolithic, poured, full depth coloured concrete finish: broom finish. • standard drawings: see standard drawings noted in SC6.4.3.3.3(3)(b).
Description reduced width option areas:	• Reduced width which allows for a planting zone from back of kerb and/or property boundary. • monolithic, poured, full depth coloured concrete finish: broom finish. • standard drawings: see standard drawings noted in SC6.4.3.3.3(3)(b).
Colour:	• CCS "paperbark" at 4% dose in a grey cement base.
Pattern	• divided by crack control joints as required and decorative scoring into equal sections of approximately 1 m wide throughout the length of the footpath.
Driveway and pedestrian crossing points: FT4	

Description:	• driveway access through footpath shall be monolithic, poured, full depth coloured concrete. • driveway crossover shall be “plain natural” concrete with surface broom finish, see Figure SC6.4.3.3.24. • pedestrian kerb ramp shall be “plain natural” concrete with surface: broom finish. • standard drawings: see standard drawings noted in SC6.4.3.3.3(3)(b)
Colour:	• CCS "paperbark" at 4% dose in a grey cement base.

FT5 – Footpath Treatment 5	
Statement of intent	
Footpath treatment 5 is a specialised treatment which serves the Palmer Street dining area.	
Body of footpath: FT5	
Description:	• footpath treatment FT5 shall be full width from building line to the road kerb alignment. • "Bluestone" stone pavers set in mortar on mass concrete base, see SC6.4.6.14 Mass concrete subbase and SC6.4.6.18 Segmental paving • Pattern: staggered pattern, see Figure SC6.4.3.3.15 and Figure SC6.4.4.3.16 facing: split face finish to top surface (all other sides sawn). • standard drawings: as noted in SC6.4.3.3.3(3)(b).
Pavers:	• stone type: "Bluestone" • size 1: 750 mm x 495 mm. • size 2: 495 mm x 495 mm. • size 3: 495 mm x 245 mm. • size 4: 495 mm x 155 mm. • depth: 40 mm.
Colour:	• natural stone colour.
Grout:	• product: CTA Polyblend G15 or approved equal colour: "Mid Grey".
Driveway and pedestrian crossing points: FT5	
Description:	• driveway access through footpath shall be ‘Bluestone’ cobble pavers set in mortar on mass concrete base see SC6.4.6.14 Mass concrete subbase and SC6.4.6.18 Segmental paving. • facing: split face finish to top with all other sides sawn. • pattern: continuous staggered pattern, see Figure SC6.4.3.3.15 and Figure SC6.4.3.3.16. • driveway crossover shall be “plain natural” concrete with surface: broom finish, see Figure SC6.4.3.3.24. • pedestrian kerb ramp shall be “plain natural” concrete with surface: broom finish.
Pavers:	• 100 mm x 100 mm square x 60 mm to 65 mm deep.
Colour:	• natural "Bluestone" colour.
Grout:	• product: Polyblend G15 sanded grout from Construction Technologies Australia or approved equal. • colour: "Mid Grey".

Figure SC6.4.3.3.16 Image FT5 body of footpath

Editor's note—refer to SC6.4.3.3.7 Footpath treatment location maps for locations of proposed treatments.

FT6 – Footpath Treatment 6	
Statement on intent	
Footpath treatment 6 is a specialised treatment area which serves the southern side of The Strand through to Ross Creek.	
Body of footpath and driveway crossings: FT6	
Description:	• footpath treatment FT6 shall be full width from building line to the road kerb alignment. • pressed concrete pavers set in stack bond pattern in mortar on mass concrete base see SC6.4.6.14 Mass concrete sub-base and SC6.4.6.18 Segmental paving. • image: see Figure SC6.4.3.3.18 • standard drawings: as noted in SC6.4.3.3.3(3)(b). • for property boundaries not parallel to kerb refer: Figure SC6.4.3.3.28
Pattern	• laid in stack bond parallel to the kerb line, see Figure SC6.4.3.3.17, and Figure SC6.4.3.3.18
Pavers:	• Havenpave 50. • width: 200mm. • length: 200mm. • depth: 50mm. • colour: "Charcoal"
Banding to footpath: FT6	
Description:	• pressed concrete pavers in soldier course pattern set in mortar on mass concrete base, see SC6.4.6.14 Mass concrete sub-base and SC6.4.6.18 Segmental paving. • for property boundaries not parallel to kerb refer: Figure SC6.4.3.3.28
Pattern:	• laid in soldier course perpendicular to the kerb line, see Figure SC6.4.3.3.17 and Figure SC6.4.3.3.18 below.
Pavers:	• Havenbrick 50. • length: 200 mm • width: 100 mm • depth: 50 mm • colour: CCS "Sunstone".
Driveway and Pedestrian Crossing Points: FT6	
Description:	• driveway access through footpath shall be pressed concrete pavers set in stack bond pattern in mortar on mass concrete base see SC6.4.6.14 Mass concrete subbase and SC6.4.6.18 Segmental paving. • Standard drawings: as noted in SC6.4.3.3.3(3)(b). • driveway crossover shall be "plain natural" concrete with surface: broom finish, see Figure SC6.4.3.3.24. • pedestrian kerb ramp shall be "plain natural" concrete with surface: broom finish.
Figure SC6.4.3.3.17 Pattern: FT6	

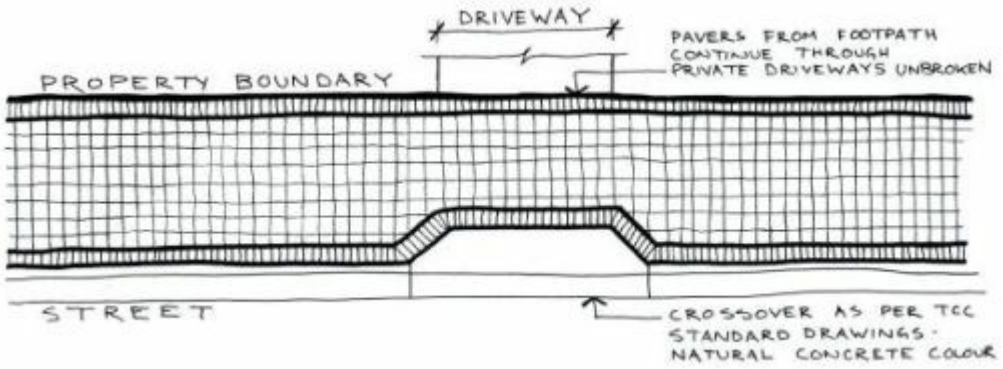

Figure SC6.4.3.3.18 Image FT6

Editor's note—refer to SC6.4.3.3.7 - Footpath treatment location maps for locations of proposed treatments

FT7 – Footpath Treatment 7	
Statement of intent	
Footpath treatment 7 is a specialised treatment area which serves the Sir Leslie Thiess Drive area and the east end of the southern side of The Strand.	
Body of footpath: FT7	
Description:	• monolithic poured concrete slabs in 5 m lengths • finish: lightly exposed aggregate, refer texture only of Figure SC6.4.3.3.8 • image: see Figure SC6.4.3.3.19. • standard drawings: refer to the standard drawings noted in SC6.4.3.3.3(3)(b).
Colour:	• CCS "Coco" 4% dose in a grey cement base • aggregate: Hanson "Burdekin Red" or approved equivalent.
Driveway and Pedestrian Crossing Points: FT7	
Description:	• driveway access through footpath shall be monolithic poured coloured concrete slabs. • driveway crossover shall be "plain natural" concrete with surface: broom finish, see Figure SC6.4.3.3.24. • pedestrian kerb ramp shall be "plain natural" concrete with surface: broom finish.

Figure SC6.4.3.3.19 Image FT7

Editor's note—refer to SC6.4.3.3.7 - Footpath treatment location maps for locations of proposed treatments

Editor's note—FT8 – Footpath Treatment 8 table describes the existing treatment, as noted on SC6.4.3.3.7 Footpath treatment location

maps this area is an investigation area. An alternate treatment is under development.

FT8 – Footpath Treatment 8	
Statement on intent	
Footpath treatment 8 is a specialised treatment area which serves the Gregory Street area in North Ward.	
Body of footpath: FT8	
Description:	• footpath treatment FT8 shall be full width from building line to the road kerb alignment. • pressed concrete pavers set in mortar on mass concrete base with perimeter banding, see SC6.4.6.14 Mass concrete sub-base and SC6.4.6.18 Segmental paving • for property boundaries not parallel to kerb refer: Figure SC6.4.3.3.28 image: see Figure SC6.4.3.3.20. • finish: proprietary non-slip finish. • sealant: two coats of penetrating sealer.
Pattern:	• stack bond as per existing adjacent pattern with alternating bands of coloured pavers separated by a 350 mm band of "natural" concrete • image: see Figure SC6.4.3.3.20.
Pavers:	• width: 400 mm. • length: 400 mm. • depth: 40 mm. • colours: CCS "Morocco", CCS "Onyx 21"
Banding: FT8	
Description:	• pressed concrete pavers set in mortar on mass concrete base see SC6.4.6.14 Mass concrete subbase and SC6.4.6.18 Segmental paving.
Pattern:	• 1x wide soldier course, see Figure SC6.4.3.3.20 • stack bond as per existing adjacent pattern with alternating bands of coloured pavers separated by a 350 mm band of "natural" concrete.
Colour:	• colour of banding pavers match colour of banded square pavers colours: CCS "Morocco", CCS "Onyx 21", natural grey concrete.
Pavers:	• length: 220 mm. • width: 110 mm. • depth: 40 mm.
Supplier:	• Boral or approved equal.
Driveway and Pedestrian Crossing Points: FT8	
Description:	• Driveway access through footpath shall be pressed concrete pavers set in mortar on mass concrete base with perimeter banding, see SC6.4.6.14 Mass concrete sub-base and SC6.4.6.18 Segmental paving. • Driveway crossover shall be “plain natural” concrete, with surface broom finish, see Figure SC6.4.3.3.24. • Pedestrian kerb ramp shall be “plain natural” concrete with surface: broom finish.
Figure SC6.4.3.3.20 Image FT8	

Editor’s note—refer to SC6.4.3.3.7 - Footpath treatment location maps for locations of proposed treatments

FT9 – Footpath Treatment 9	
Statement of intent	
Footpath treatment 9 is a specialised treatment occurring only on Magnetic Island.	
Body of footpath: FT9	
Description:	• monolithic poured coloured concrete slabs. • primarily in eucalypt with the secondary colour black used to highlight special features such as premises entries, dining areas, etc. • finish: 'light wash' 1 mm – 2 mm deep (2 mm max) using a water-based chemical retarder. • standard drawings: as noted in SC6.4.3.3.3(3)(b). **Editor's note**—refer to Figure SC6.4.3.3.8 for maximum acceptable aggregate exposure and Figure SC6.4.3.3.9 and Figure SC6.4.3.3.10 for unacceptable, under and over, aggregate exposure.
Description reduced width area:	• reduced width which allows for a planting zone from back of kerb and/or property boundary. • monolithic poured coloured concrete slabs. • primarily in eucalypt with the secondary colour black used to highlight special features such as premises entries, dining areas etc. • finish: 'light wash' 1 mm – 2 mm deep (2 mm max) using a water based chemical retarder. • standard drawings: as noted in SC6.4.3.3.3(3)(b). **Editor's note**—refer to Figure SC6.4.3.3.8 for maximum acceptable aggregate exposure and Figure SC6.4.3.3.9 and Figure SC6.4.3.3.10 for unacceptable, under and over, aggregate exposure.
Colour:	• primary - CCS "eucalypt" at 4% dose in a grey cement base Figure SC6.4.3.3.21 Image FT9. • secondary - CCS "black" at 4% dose in a grey cement base Figure SC6.4.3.3.21 Image FT9. • aggregate: Hanson "salt and pepper" or approved equivalent.
Pattern:	• divided by crack control joints as required.
Driveway and Pedestrian crossing Points: FT9	
Description:	• driveway access through footpath shall be monolithic poured coloured concrete slab. • driveway crossover shall be "plain natural" concrete with surface: broom finish, see Figure SC6.4.3.3.24. • pedestrian kerb ramp shall be "plain natural" concrete with surface: broom finish.
Colour:	• primary - CCS "eucalypt" at 4% dose in a grey cement base see Figure SC6.4.3.3.21 Image FT9. • Secondary - CCS "black" at 4% dose in a grey cement base Figure SC6.4.3.3.21 Image FT9. • aggregate: Hanson "salt and pepper" or approved equivalent.
Figure SC6.4.3.3.21 Image FT9	

(2) All concrete cobbles (border banding) and field pavers are to have a:

(a) depth of 60 mm to 65 mm for cobbles, 40mm for field pavers;

(b) compressive strength of 32 MPa for concrete cobbles and pavers;

(c) mass concrete subbase integral with adjacent concrete, see SC6.4.6.14 Mass concrete subbase;

(d) slip resistance in accordance with AS/NZS 3661.1, Table 5;

(e) 3 mm chamfer on the surface edges with a pressed finish for concrete pavers and cobbles; and be in accordance with AS1428.1 – Construction tolerances for abutment of surfaces;

(f) two coats of low VOC, water-based, 7-15 year recoat penetrating sealer system designed to repel grease and oil stains;

(g) cobbles and pavers are to be placed on concrete mortar; and

(h) edge of paver banding shall be filled with 10mm thick compressible filler board for full depth of slab and 20mm polyurethane based sealant.

(3) All concrete slabs shall be:

(a) integrally coloured for the full depth of the slab where colouring is noted in SC6.4.3.3.3 Foothpath treatment standards;

(b) Engineer Certified design drawings must be submitted to council for acceptance prior to approval being given showing site specific construction details of paver band designs and integrated construction joints at intervals that are generally in accordance with TCC Standard drawing SD-070. Pavements are to be constructed as per SC6.4.4.8 Standard drawings:
SD-015: Verge Service Corridors General Type Sections;
SD-020: Concrete Kerbing;
SD-025: Kerb Ramp;
SD-030: Driveway Access Urban Residential Properties;
SD-031: Driveway Access Commercial and Industrial Properties;
SD-032: Driveway Crossovers Urban Residential Properties;
SD-055: Road Crossing and Footpath Reinstatement for Trench Laid Services;
SD-060: Traffic Sign Installation;
SD-065: Street Name Sign and Installation Details;
SD-070: Concrete Pathway Reinforced Concrete (Mesh) Alternative;
SD-075: Concrete Pathway Reinforced Concrete (Fibre) Alternative; and
SD-500: Standard Bus Shelter and Footing Details,

(c) sealed with two coats of low VOC, water-based, 7-15 year recoat penetrating sealer system designed to repel grease and oil stains;

(d) proportioned in terms of 'width to length' as '1 to 1.5' between crack control joints as per standard drawings listed in SC6.4.3.3.3(3)(b);

(e) laid in accordance with standard drawings listed in SC6.4.3.3.3(3)(b);

(f) constructed so that all runoff, slurry and excess materials must be captured and disposed of appropriately, and all surrounding surfaces are protected from staining;

(g) constructed so that all decorative scoring cuts are five mm deep for the full length of the slab continuous through the end of the slab;

(h) constructed so that all crack inducing saw cuts are continuous through to the end of the slab;

(i) constructed so that all saw cuts:

  (i) are made approximately 24 hours after finishing (preferably the morning after the pour);

  (ii) are cut with a "Early Cut Saw" only;

  (iii) are cut with a "Dry Cut" method only (this requirement is to override conflicting specifications on standard drawing SD-070 (for coloured concrete only);

  (iv) are aligned where possible with any service penetrations, on at least one side of the penetration, or services to be located wholly within one saw cut square (see Figure SC6.4.3.3.32);

  (v) are constructed in accordance with standard drawings listed in SC6.4.3.3.3(3)(b) with the exception of SC6.4.3.3.3(3)(i)(iii);

  (vi) for footpath treatment type FT3, create a pattern comprised of:

    (A) both decorative scoring and crack inducing joints (as required) to create sub-panels approximately 1x1 m square or otherwise closely proportioned rectangular shapes evenly spaced throughout the panel (see Figure SC6.4.3.3.22);

    (B) minimum sub-panel dimensions of 0.8 m either width or length, generally creating rectangular, regularly spaced sub-panels evenly spaced through the primary panel; and

    (C) maximum sub-panel dimensions of 1.2 m either width or length, generally creating rectangular, regularly spaced sub-panels evenly spaced through the primary panel.

  (vii) for footpath treatment type FT2, create patterns comprised of both decorative scoring and crack inducing joints (as required) creating sub-panels approximately 1 m wide (4 cuts in 5 m lengths) evenly spaced throughout the panel (see Figure SC6.4.3.3.22, Figure SC6.4.3.3.23 and Figure SC6.4.3.3.24).

(j) coloured concrete slabs shall be grade S32 minimum. Where concrete is located in an aggressive environment (e.g. salt exposure, aggressive soils, etc.), concrete strength design shall be in accordance with AS3600;

(k) fibre reinforced concrete footing under banding shall be grade S20 minimum;

(l) concrete slab thickness shall be 100mm minimum. In areas where maintenance vehicular loading is expected, concrete thickness shall be 125mm minimum;

(m) concrete cover to steel reinforcement shall be 40mm unless otherwise noted;

(n) concrete shall be laid on minimum 50mm of compacted crusher dust / sand bedding with moisture barrier;

(o) all concrete shall be cured in accordance with the following:

  (i) AS3600;

  (ii) aliphatic alcohol must be used. The aliphatic alcohol shall be applied after screeding &and bull floating operations;

  (iii) no water shall be added to concrete;

  (iv) an impermeable membrane shall be applied. All joints in membrane are to be taped and the edges secured to prevent the ingress of air;

  (v) minimum curing period shall be not less than 7 days for strength grade S32 and not less than 4 days for high early strength concrete;

(p) exposed edges of formed concrete elements shall have a 20mm chamfer unless otherwise noted;

(q) all concrete shall be mechanically vibrated. Hand held vibrators must be held upright. Concrete must not be spread using vibrator; and

(r) all other requirements shall be in accordance with SC6.4.6.28 Minor concrete works.

(4) Tactile ground surface indicators (TGSI) where required shall:

(a) be stainless steel studs (CTA SureSteel or approved equal) with bright yellow plastic insert for type FT1, FT2, FT5 installed as per AS/NZS1428.4.1 providing slip resistance of R13 (wet/oil ramp);

(b) all other types not covered by SC6.4.3.3.3(4)(a) shall be yellow Polyurethane tactile indicator studs (warning tactiles), and bars (directional tactiles), drill and lock installation; and

(c) be supplied and installed in accordance with AS/NZS1428.4.1 providing correct illuminance contrast, and AS1428.1 and AS4586 Slip Resistance of Pedestrian Surfaces, and as per manufacturers specifications and in accordance with AS1884. Also to be in accordance with SC6.4.4.7(4) Bicycle, pedestrian and shared path design.

(5) footpath treatment shall not impede into private property.

(6) for all footpath treatment types the ground surface on the continuous accessible path of travel – construction tolerances for abutment of surface shall be in accordance with AS 1428.1. to eliminate the possibility of tripping hazards and non-compliance levels of abutting surfaces occurring.

SC6.4.3.3.4 General guidelines

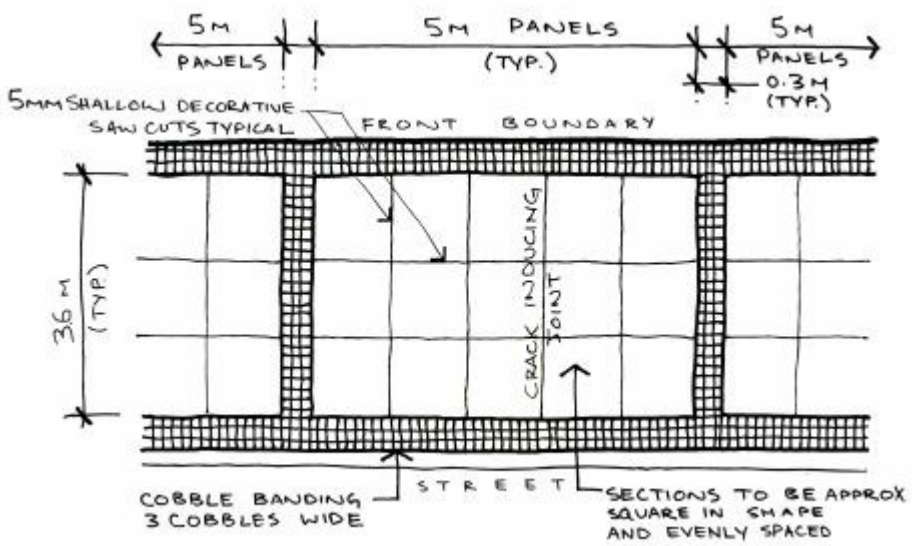

Figure SC6.4.3.3.22 Typical footpath treatment FT3

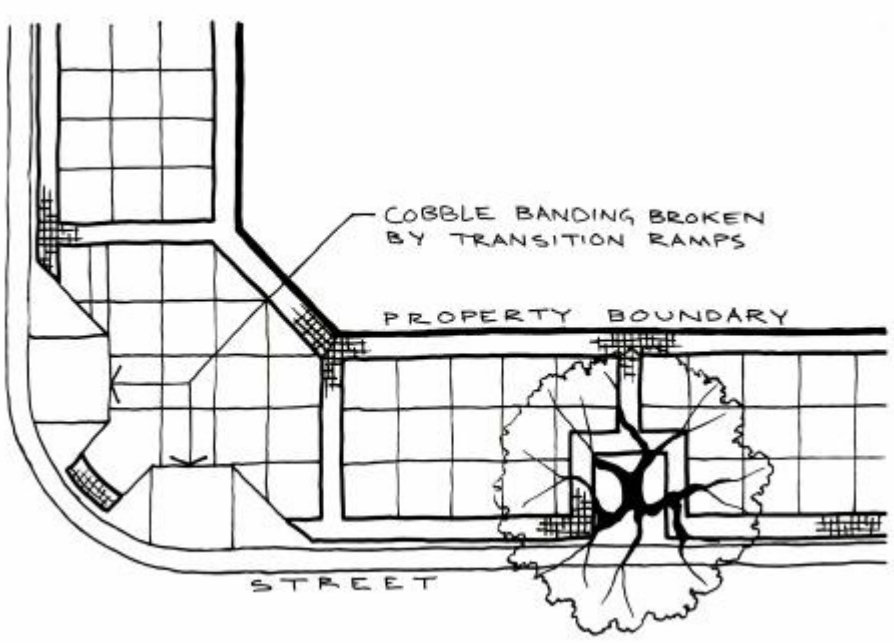

Figure SC6.4.3.3.23 Typical footpath treatment at street corners - banding is broken by kerb ramps

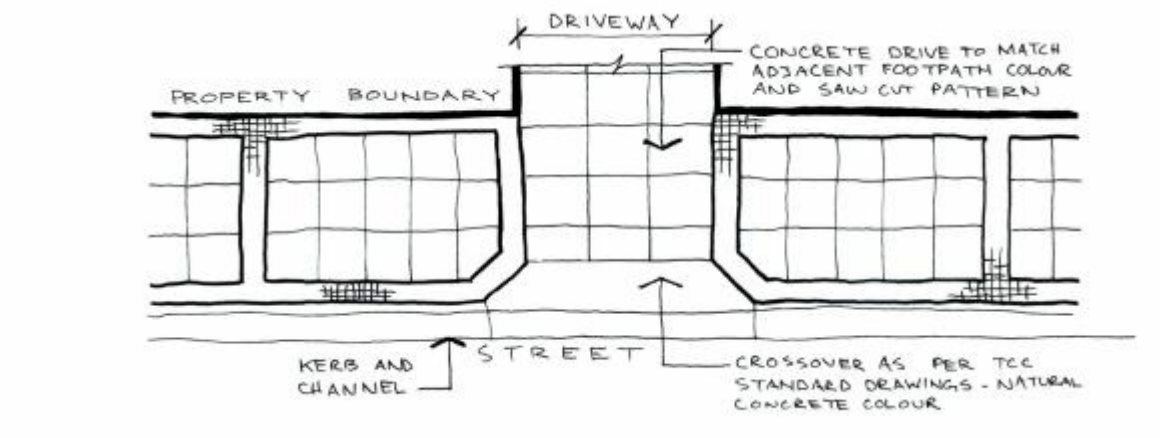

Figure SC6.4.3.3.24 Typical driveway treatment - banding to match angle of crossover

SC6.4.3.3.5 Banding details

(1) Banding is to be:

(a) continuous across tenancy or property boundaries at regular 5 m intervals (see Figure SC6.4.3.3.21 and Figure SC6.4.3.3.22) and is to retain a rectilinear alignment as illustrated in Figure SC6.4.3.3.25, Figure SC6.4.3.3.27 and Figure SC6.4.3.3.28;

(b) broken by minor built form intrusions, allowed to infill minor built form recesses, (see Figure SC6.4.3.3.25;

(c) continued around existing streetscape and landscape elements (see Figure SC6.4.3.3.26); and

(d) run parallel to property boundaries and kerb where property boundaries are not parallel to kerb, with cross-banding remaining perpendicular to line of kerb (see Figure SC6.4.3.3.27 and Figure SC6.4.3.3.28).

(2) Where banding is broken by driveways in footpath treatment types FT2, FT3, FT6 and, banding returns to the property line as per Figure SC6.4.3.3.24, Figure SC4.4.3.3.34 and Figure SC6.4.3.3.35.

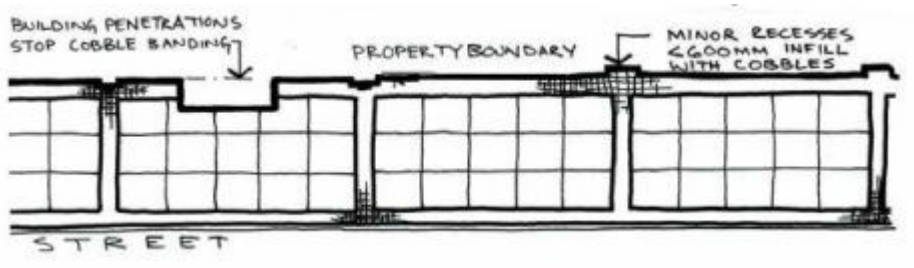

Figure SC6.4.3.3.25 Continuous footpath at uneven building lines

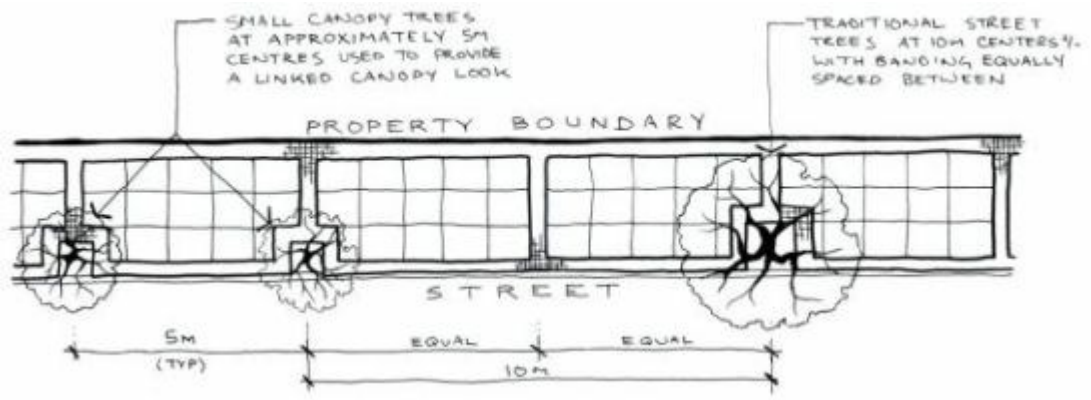

Figure SC6.4.3.3.26 Banding around landscape element

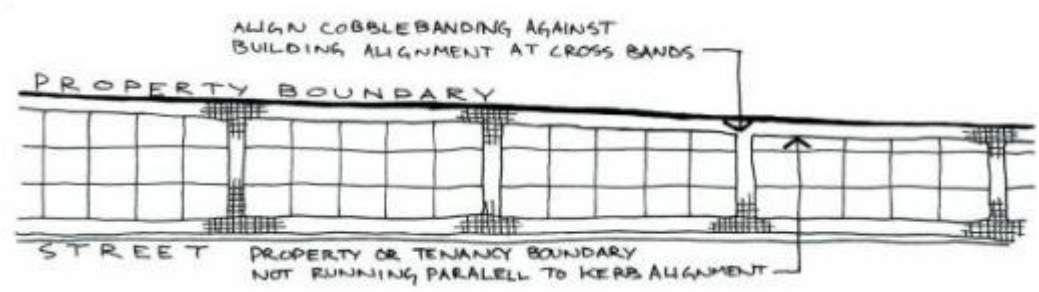

Figure SC6.4.3.3.27 Banding around poured concrete against property boundary where property boundary is not parallel to line of kerb

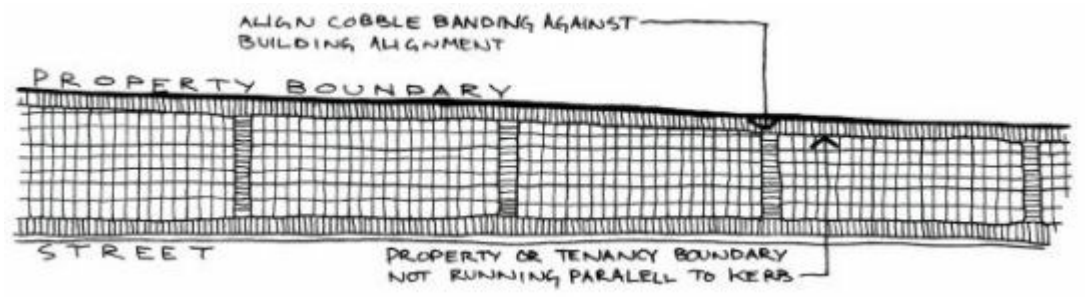

Figure SC6.4.3.3.28 Banding around pavers against property boundary where property boundary is not parallel to line of kerb

SC6.4.3.3.6 Footpath details

(1) Joint lines and trim courses are to be straight and as continuous as is practical along the footpath length regardless of individual property boundaries (see Figure SC6.4.3.3.29). Protect existing buildings as per Figure SC6.4.3.3.29.

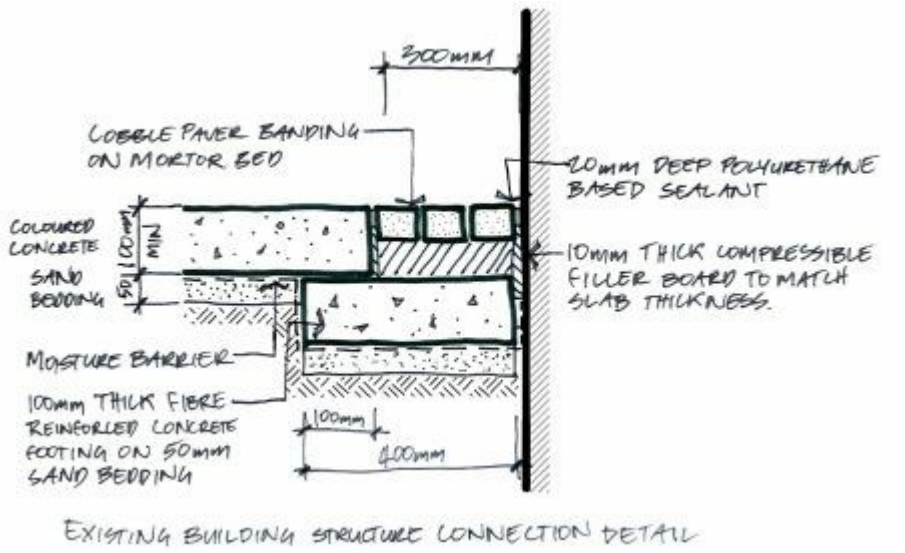

Figure SC6.4.3.3.29 Existing building structure connection detail

(2) Service access lids and inspection pits:

(a) installed within the footpath zone shall be finished and matched to the finished surface levels of the footpath treatment;

(b) which are manufactured shall be installed in accordance with manufacturer's installation instructions, having regard to the footpath pattern of the selected footpath treatment type;

(c) in footpath treatment areas FT1, FT5:

(i) be housed within an angle surround frame, which enables adjacent footpath treatments to be placed to the edge of the service penetration. The lid is to allow for matched pavers to be placed within, matching the adjacent paver material, colours and patterns flush with the top of the adjacent treatment (see Figure SC6.4.3.3.31);

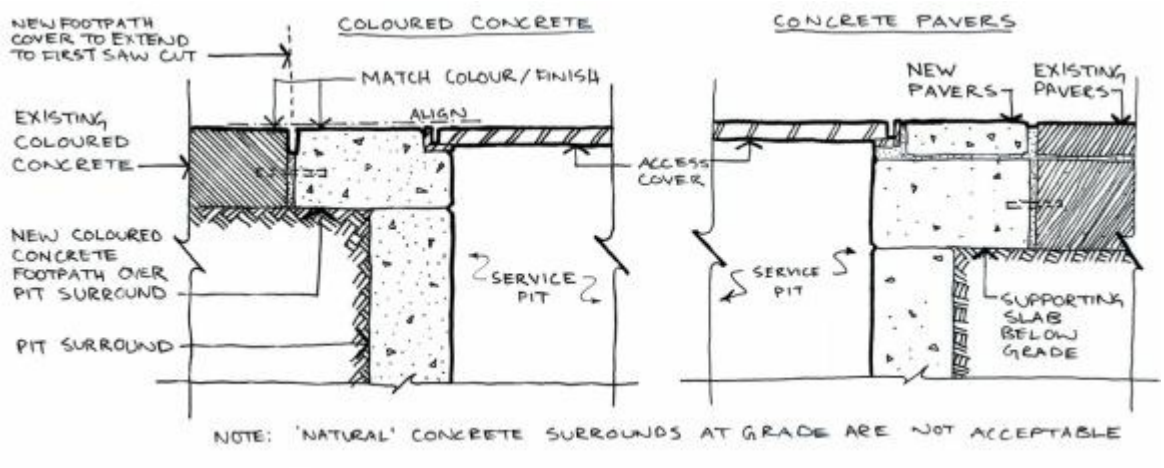
(d) in footpath treatments FT2, FT3, FT6, FT7 and FT8, have their perimeter supports resting on concrete slabs that are integral with the adjacent concrete slab without a separate surround (see Figure SC6.4.3.3.30):

(i) be housed within an angle surround frame, which enables concrete to be laid to the edge of the service penetration;

(ii) be located in and integrated with adjacent concrete slabs so service access structures limit or control cracking in surrounding concrete (see Figure SC6.4.3.3.32); and

(iii) are located where possible so future replacement or alteration of service access structures minimises disruption to adjacent concrete panels, and are aligned with existing or proposed concrete crack control saw cuts where possible, or are located wholly fully within the saw-cut panel (see Figure SC6.4.3.3.32); and

(e) when penetrating a cobbled area of FT3, be installed such that the cobbles continue to the edge of the new service access lids and inspection pits (see Figure SC6.4.3.3.31).



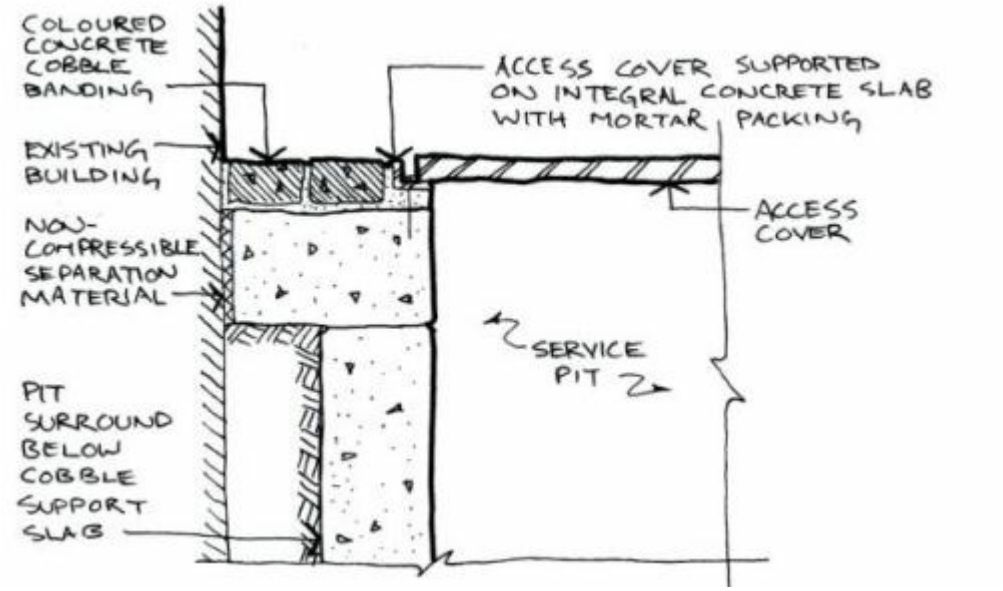


Figure SC6.4.3.3.30 Edge treatments to service access lids and inspection pits for footpath treatment areas FT2, FT3, FT4, FT6, FT7and FT8

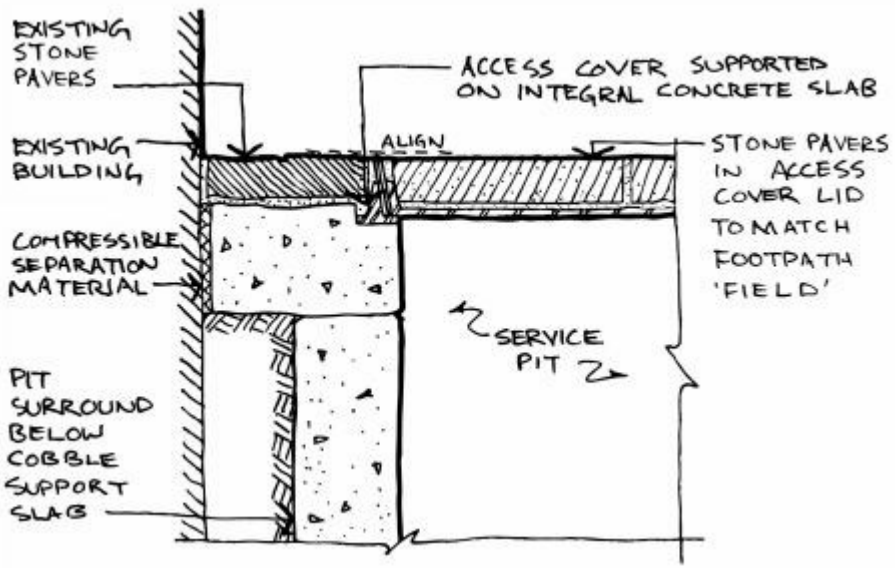

Figure SC6.4.3.3.31 Edge treatment to service access lid and inspection pits adjacent to pavers for type FT1 and FT5

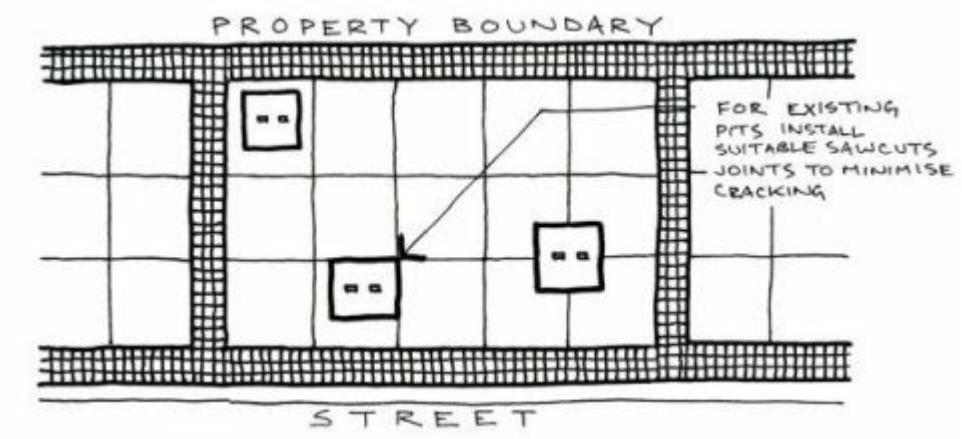

Figure SC6.4.3.3.32 Incorporate service access lids and inspection pits into decorative saw cut pattern

(3) All footpaths (see Figure SC6.4.3.3.33) shall have maximum:

(a) cross fall of 1:40 (for cross fall greater than 1:40 liaise with council); and

(b) slope of 1:20 (for slopes greater than 1:20 liaise with council).

(4) Kerb and channelling is to be provided if not currently installed for all footpath treatments covered by this policy, and shall be constructed in accordance with standard drawings listed in SC6.4.3.3.3(3)(b).

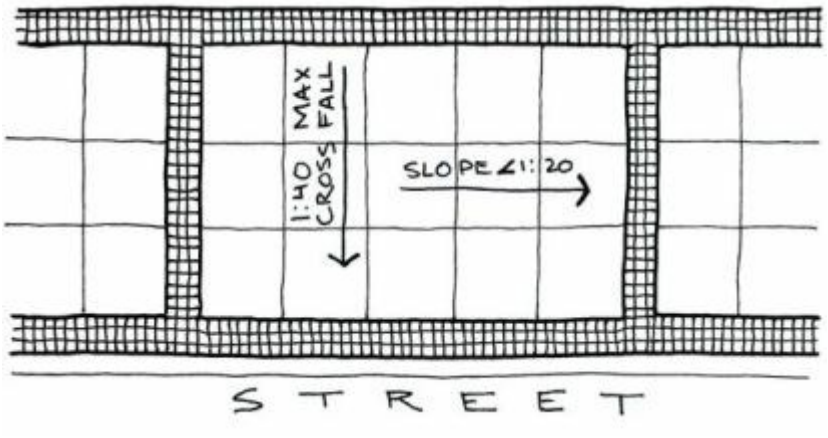

Figure SC6.4.3.3.33 Slope and cross fall

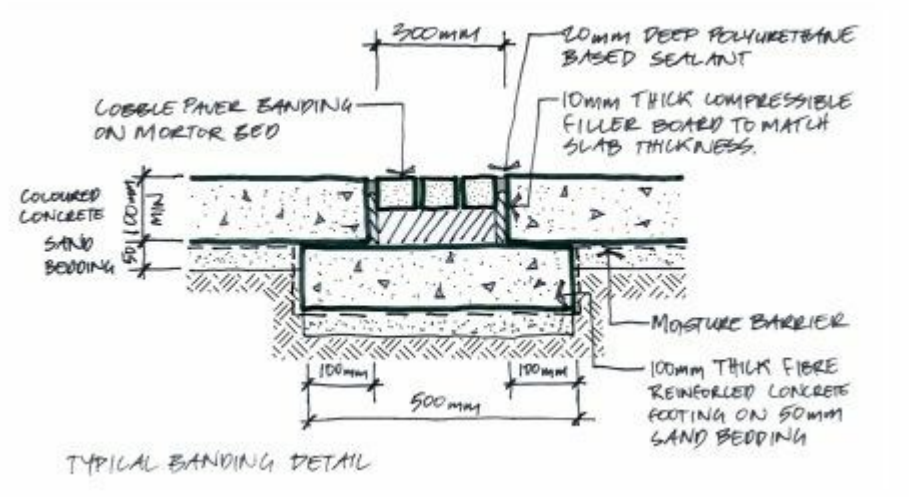

Figure SC6.4.3.3.34 Typical banding details

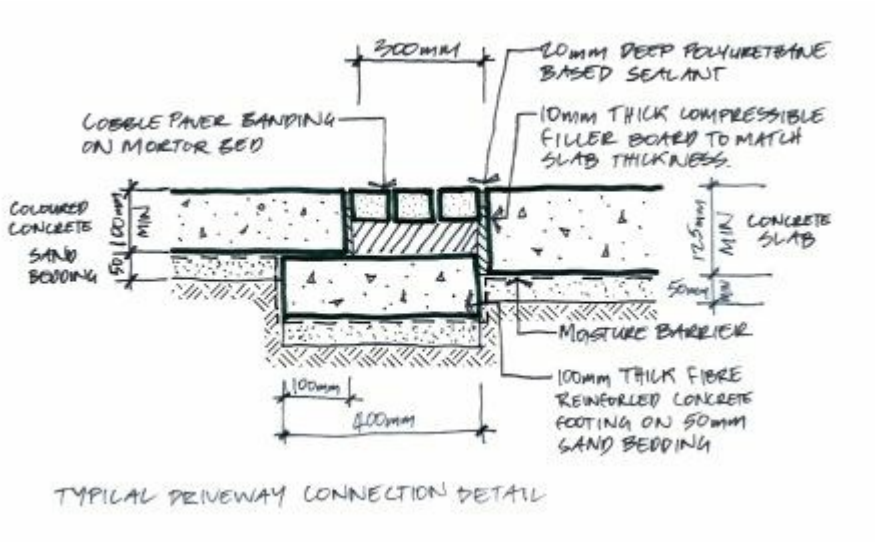

Figure SC6.4.3.3.35 Typical driveway connection detail

(5) Kerb ramps are to be:

(a) in accordance with the standard drawings see SC6.4.3.3.3(3)(b) - SD025 – Kerb Ramp,

(b) in accordance with AS1428.1 *Design for Access and Mobility, Part 1: General requirements for access – New Building Works;*

(c) installed facing the direction of travel and aligned parallel and perpendicular with opposite kerb ramp;

(d) located to suit the flow of pedestrian traffic and the position of the signal button;

(e) constructed of surface broom finished plain natural concrete;

(f) installed with sharp transitions between adjacent surfaces (top and bottom); and

(g) installed with Tactile Ground Surface Indicators (TGSIK) in accordance with AS/NZS1428.4.1 Design for Access and Mobility Part 4.1: Means to assist the orientation of people with vision impairment – Tactile ground surfaces indicators.

(6) Where the existing kerb edge is uneven:

(a) the cobble banding is to be set along a straight line. A cementitious infill material shall be used to make up for the irregularities of the kerb, as indicated in Figure SC6.4.3.3.36;

(b) ensure suitable concrete admixture (Fosroc Renderoc or approved equal) is used to create a straight and true edge if irregularity in kerb is less than 50 mm deep, see Figure SC6.4.3.3.36 and standard drawing SD-020: Concrete Kerbing; and

(c) infill is not to be formed so a tripping hazard occurs. In accordance with AS1428.1 Construction tolerances for abutment of surfaces.

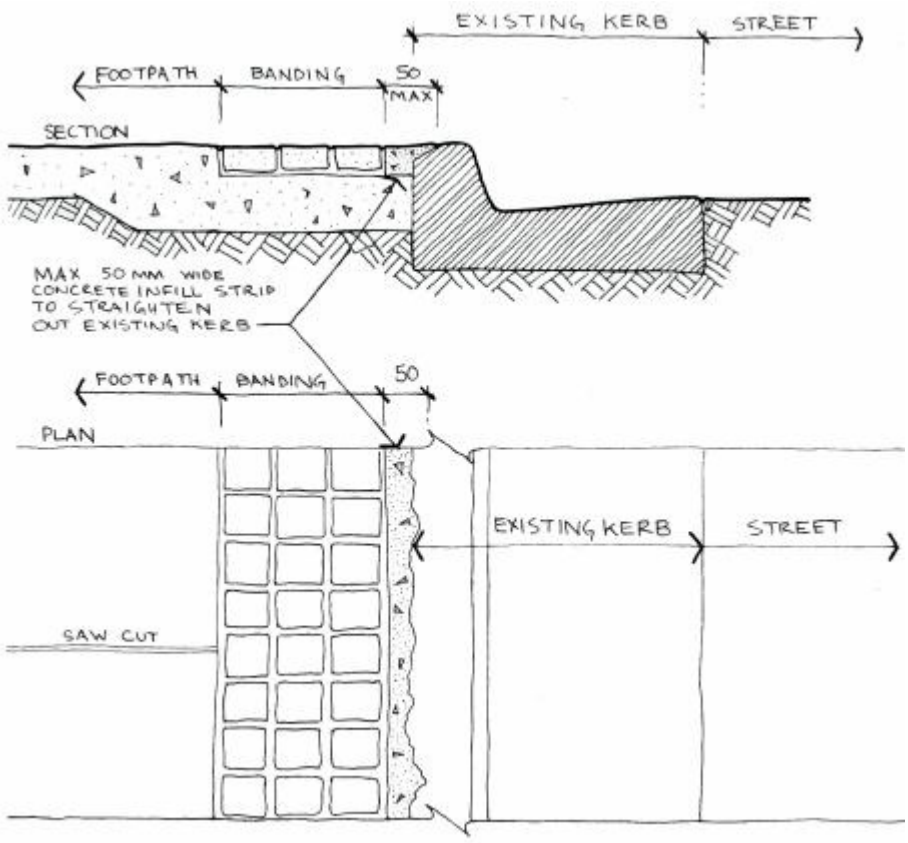

Figure SC6.4.3.3.36 Concrete infill strip for uneven existing kerb lines

(7) When providing reinstatement from trenching:

(a) where trench passes through segmented paver footpath treatment areas:

(i) remove intact pavers and store securely and safely on site;

(ii) allow for replacement and installation of any broken, cut or otherwise damaged pavers or deteriorated;

(iii) ensure paving support slabs removed for trenching purposes are reinstated in accordance with standard drawings noted in SC6.4.3.3.3(3)(b) flush with adjacent support slabs to allow level reinstatement of pavers over; and

(iv) replace original and/or new pavers over reinstated slab.

(b) where trench passes through concrete footpath treatment areas:

(i) reinstate new concrete in accordance with standard drawings listed in SC6.4.3.3.3(3)b) flush with adjacent support surface/slabs to allow level reinstatement;;

(ii) ensure new concrete matches adjacent slab colour: refer to relevant footpath type in Tables SC6.4.3.3.3, for concrete colour, aggregate, finish, etc. for types as identified in SC6.4.3.3.7 - Footpath treatment location maps; and

(iii) allow for replacement and installation of any broken, cut or deteriorated or otherwise damaged footpath treatment caused by the removal.

(8) When incorporating existing trees into new works, installing new trees, or other landscape features:

(a) incorporate elements into the paving pattern, as shown in Figure SC6.4.3.3.37;

(b) modify installation where practical in accordance with the construction detail indicated in Figure SC6.4.3.3.38; and

(c) refer to SC6.4.3.6 Landscape policy for street tree spacing, selection, root barrier treatments, root development zone, tree grates or other tree surround treatments and lighting.

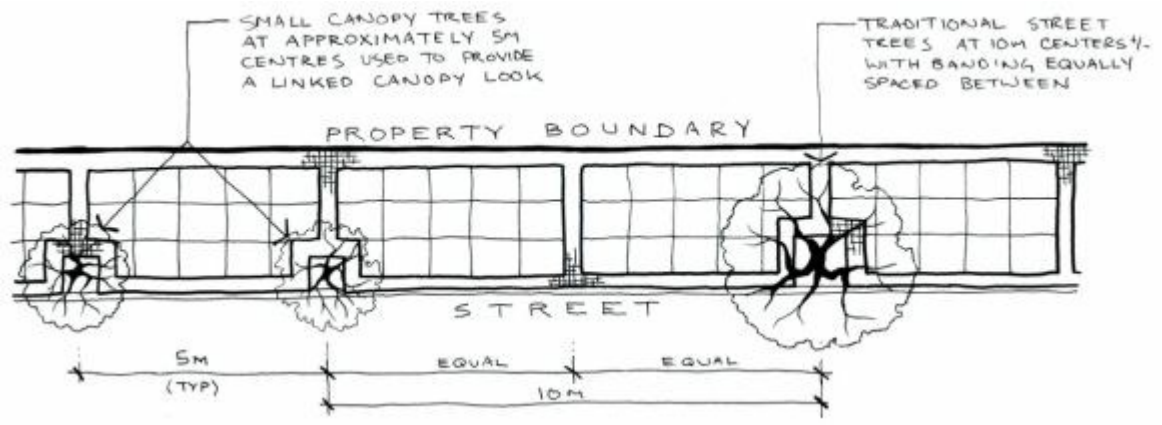

Figure SC6.4.3.3.37 Banding around tree planting

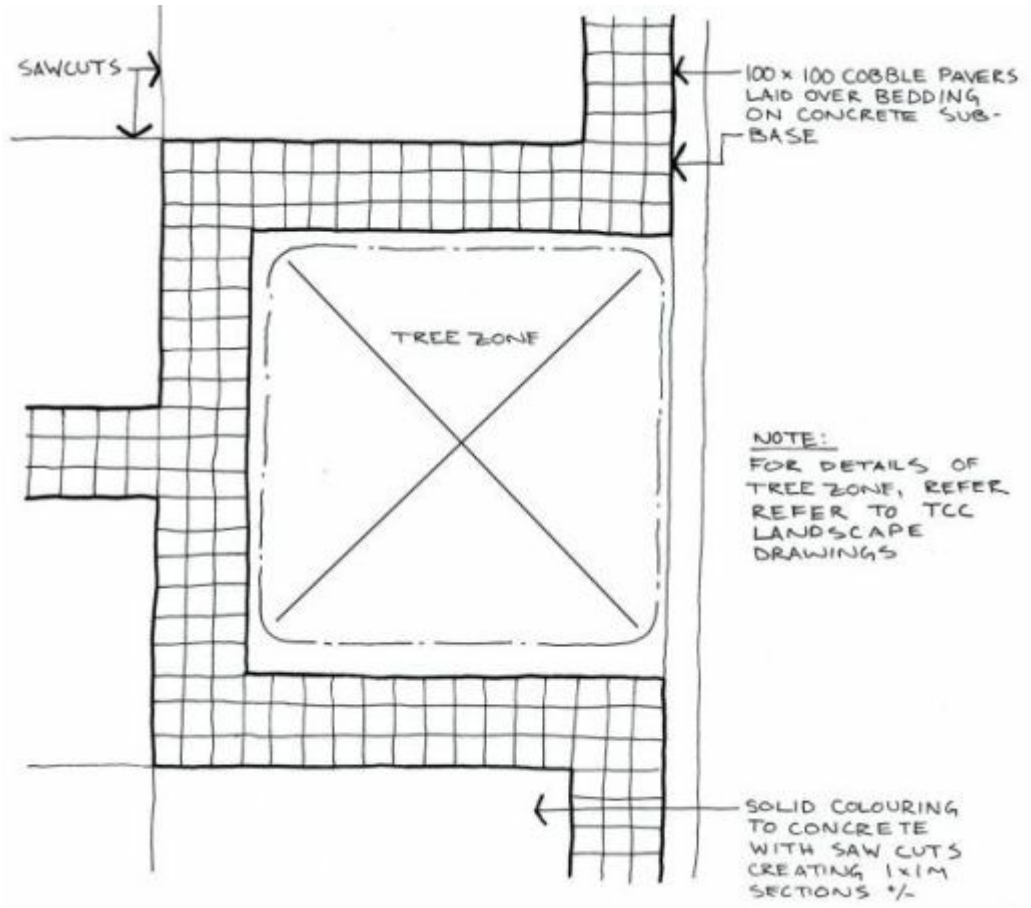

Figure SC6.4.3.3.38 Paver banding plan at tree surround

(9) When incorporating existing road transport- related infrastructure (such as bus stops, street signs and traffic signals) or providing for the placement of new road related infrastructure into any of the footpath treatment types:

(a) safety and visibility requirements shall be in accordance with the Manual of Uniform Traffic Control Devices (MUTCD) for the placement of new such infrastructure;

(b) footpath treatments and patterns shall be modified around existing elements in order to reduce disturbance to established infrastructure;.

(c) bus stops shall be in accordance with standard drawings listed in SC6.4.3.3.3.(3)(b). Bus stop concrete slab is a reinforced solid object supporting a large size structure, therefore required to be one whole slab undisturbed. Footpath treatment to be made flush with adjacent support slabs to allow level reinstatement;

(d) street signs and traffic signals shall be in accordance with Australian Standards and guidelines; and

(e) street signs shall be in accordance with standard drawings listed in SC6.4.3.3.3(3)(b).

(10) When incorporating the placement of street furniture (such as , seating, rubbish bins and bollards) :

(a) installation should not impede pedestrian movement along the footpath. There shall be a 1800mm minimum clear width for the continuous accessible path of travel along the building property line, building façade and fence lines for pedestrians, especially people with a vision impairment, .in accordance with AS2890.3; and

(b) the placement of street furniture shall give consideration to minimizing the disturbance to the footpath treatment type and paving patterns.

SC6.4.3.4 Outdoor dining design

SC6.4.3.4.1 Introduction

(1) Purpose

(a) To protect pedestrian traffic by the introduction of shared footpath management guidelines for the purpose of providing for improved use of the area and business opportunity.

(b) To effectively address risk management issues to facilitate which relate to the introduction of additional uses, cross pedestrian traffic, and items of infrastructure or street furniture, as well as the potential interaction with vehicles as outlined in SC6.4.3.4.2.

(2) Scope

(a) When assessing an application involving outdoor dining, council will consider all relevant issues, including, but not limited to:

(i) whether the proposed outdoor dining area is located immediately adjacent to the applicant's existing premises and/or connectedness to the development;

(ii) pedestrian usage of the area, including safety and passage;

(iii) vehicular usage of the area, including separation and safety matters;

(iv) the general safety of patrons of the proposed outdoor area;

(v) the contribution towards a high amenity area and creation of active and integrated spaces and places as identified by the relevant zone code; and

(vi) how the outdoor dining integrates with the character of the locality/zone and existing or intended streetscape, including specific footpath treatments.

Editor's note—Applicants should also refer to section 9.4.1 Advertising devices code of the Townsville City Plan for additional design requirements and Table 5.8.2 Operational work being placing an advertising device on premises for application requirements regarding the control of advertising devices in outdoor dining spaces.

Editor's note—Applicants should also be aware that there may be additional related approvals required, including Outdoor Dining Licence Applications from Townsville City Council (Subordinate Local Law No. 1.2 (Commercial Use of Local Government Controlled Areas and Roads) 2011), Food Premises Licence and any liquor licencing requirements required by the Queensland Government office of Liquor, Gaming and Racing and if the outdoor dining area is on state controlled land, including road, that the applicant shall lodge other necessary documentation to the required entity.

Editor's note— Any person wishing to use any council-controlled land for outdoor dining must lodge an application for an outdoor dining licence under council's Outdoor Dining Policy, which can be found on council's website.

(b) Outdoor dining is considered to include the following:

(i) the use of the council-controlled public land for the purpose of extending the services of premises whose main function is the provision of food and/or beverages to the public; and

(ii) premises may include restaurants, cafes, bars, deli and other food outlets, but does not include roadside stalls.

(3) Terminology

Back of kerb	The point of the kerb profile away from the road, as illustrated in Figure SC6.4.3.3.6.

Crash barrier	A longitudinal or roadside barrier that has the primary function of preventing penetration by a vehicle and for which the primary purpose is to prevent or reduce the injury to occupants of an errant vehicle and restaurant patrons by safely redirecting an errant vehicle away from a roadside hazard. All roadside crash barriers must be designed to meet AS3845:1999.
Kerbside zone	The area between the trading zone and the back of kerb.
Kerbside use zone	The area between the back of kerb and the vehicle through lane. Uses within the kerbside use zone may include parking, accessible parking, bus bays, taxi ranks, drop-off zones, loading zones, no standing zones, shoulders and bike lanes. Fencing legs should not create a tripping hazard.
Pedestrian fence	A fence provided to restrict the movement of pedestrians and restaurant patrons. This can include a permanent structure or may be a portable café-style fence. Pedestrian fences must be: • A minimum height of 800 mm; • Designed and constructed so that the fence does not present a spearing hazard and is of a level of quality and design acceptable to council.
Pedestrian zone	A 1.8m wide section of footpath for the through movement of pedestrians located adjacent to the property building line (shoreline).
Trading zone	The formally defined area within which outdoor dining is permitted by council. All furniture and commercial activities relating to outdoor dining must occur within this area. Pavement markers will be installed by council to define the extents of the approved dining area (trading zone).
Traffic lane	The area of the road that is used for the through passage of vehicles in normal driving conditions. The traffic lane does not include the shoulder, parking lane or other kerbside use area.

The relationship between the key terms above is shown in Figure SC6.4.3.4.1 - Summary of guidelines and requirements.

SC6.4.3.4.2 Risk considerations associated with outdoor dining

With respect to outdoor dining, risk is increased by four significant events. Risk management through design guidelines is provided for the following four risk events:

(1) a vehicle running off road when diners are present, without sufficient separation to allow the driver of the vehicle to recover (or for diners to react and clear the path of the vehicle);

(2) a vehicle running off road when diners are not present, without sufficient separation to allow the driver of the vehicle to recover, and the outdoor dining furniture penetrates the vehicle causing injury to vehicle occupants;

(3) a vehicle running off road at a location where a crash barrier has been provided for the specific purpose of protecting footpath diners, and the crash barrier has not been designed to safely and effectively redirect the impact of a vehicle, causing either injury to outdoor diners or injury of the vehicle occupants; and

(4) a diner/staff stepping or falling onto path of vehicle due to proximity of trading zone to the traffic lane (with no fence or barrier in place), for example due to placement of a chair too close to the kerb.

SC6.4.3.4.3 Design guidelines for kerbside risk management and use

In addition to risk management issues, the guidelines include recommendations for the separation of the trading zone to accommodate the various roadside elements such as parking, and access to public infrastructure and services. Table SC6.4.3.4.1 below summarises the content of these guidelines.

Table SC6.4.3.4.1 Summary of guidelines and requirements

Guidelines	Requirements
Speed zones	See Table SC6.4.3.4.2
Barriers and fences	See Table SC6.4.3.4.3
Intersection corner	Outdoor dining should not occur within an intersection corner as defined in Figure SC6.4.3.5
Kerbside uses	See Table SC6.4.3.4.4, Figure SC6.4.3.6
Public infrastructure clearances	In general, 1 m clearance from public infrastructure unless demonstrated otherwise. See SC6.4.3.4.8
Pedestrian access though trading zone to access kerbside uses	See clause SC6.4.3.4.7

SC6.4.3.4.4 Design guidelines for risk management

Because of the increase in risk associated with higher speed limits, different levels of outdoor dining protection and separation have been recommended to manage risk appropriately. In some speed zones, outdoor dining is generally not appropriate. In lower speed zones, outdoor dining is generally always appropriate provided suitable measures are taken to separate diners from traffic by distance or a physical barrier or fence. Table SC6.4.3.4.2 below summarises the recommendations for risk management in different speed zones.

Table SC6.4.3.4.2 Summary of recommendations for risk management

Speed zone (km/h)	Appropriate for outdoor dining	Provide crash barrier guidelines	Provide pedestrian fencing guidelines
Above 60	No	-	-
60	Yes	Yes	Yes
50	Yes	Yes	Yes
40	Yes	No	Yes

Table SC6.4.3.4.3 provides the detailed design guidelines for different speed zones. Note that in the majority of cases, the need for a crash barrier can be avoided by increasing the separation distance between the trading zone and traffic. Figures SC6.4.3.4.2 – SC6.4.3.4.4 illustrate these design guidelines.

Table SC6.4.3.4.3 Guideline for crash barriers, pedestrian fencing and separation distance

Speed zone (kph)	Trading zone 3m or more from traffic lane	Trading zone 1.2m to 3m from traffic lane	Trading zone less than 1.2m from traffic lane
Above 60	Not recommended for outdoor dining	Not recommended for outdoor dining	Not recommended for outdoor dining
60	No crash barrier or pedestrian fence required	Pedestrian fence required	Crash barrier required
50	No crash barrier or pedestrian fence required	Pedestrian fence required	Crash barrier required
40	No crash barrier or pedestrian fence required	No crash barrier or pedestrian fence required	Pedestrian fence required

SC6.4.3.4.5 Design guidelines for trading zones at an intersection

In general, outdoor dining is not appropriate in the vicinity of an intersection corner. This allows corners to be used by pedestrians and cyclists, and allows access to public infrastructure and services to be maintained at all times. In some circumstances it may however be appropriate to support the zone intent and specific demonstration for intersection driving will be required.

Figure SC6.4.3.4.5 shows the area at a corner that should not be used for a trading zone.

SC6.4.3.4.6 Trading zone setbacks for kerbside use

Different kerbside uses have different spatial requirements to facilitate the movement of vehicles and pedestrians. Table SC6.4.3.4.4 summarises the recommended separation distance between the back of kerb and the trading zone for each kerbside use. Figure SC6.4.3.6 illustrates these distances.

Table SC6.4.3.4.4 Setbacks for kerbside use

Kerbside use	Minimum setback from back of kerb
No Standing/traffic lane	0.3m (if no pedestrian fence provided)
Parking - angle	0.8m
Parking - Parallel	0.8 m
Accessible Parking (Parallel)	1.5m

SC6.4.3.4.7 Pedestrian access to kerbside use and through trading zones

The design of a trading zone and any required pedestrian fencing should accommodate access through or around the trading zone for pedestrians, including persons with a disability. Where a pathway is required through the trading zone, a minimum width of 1.2 m is required. Where the kerbside use has an accessible parking bay and kerb ramp to access vehicles in the kerbside zone, a 1.5 m wide access through the trading zone must be provided. In addition, the design should consider the need for the crossing of pedestrians where the proposed outdoor dining facility is not within 20 m of a pedestrian crossing or intersection. A minimum width of pedestrian zone of 1.8 m is recommended located adjacent to the property building line. This width should be increased to a minimum of 2.4 m at locations where high pedestrian volumes are expected.

SC6.4.3.4.8 Clearances to public infrastructure

It is recommended that with the exception of service pits, in general a clearance of 1 m is desirable from all public infrastructure with the following exceptions:

(1) where a pedestrian fence is provided which separates the infrastructure and the trading zone; or

(2) where the owner of the public infrastructure asset (including council) provides written permission to relax the minimum clearance requirement.

In the case of service pits, a minimum clearance is not specified. However, it is recommended that the applicant obtains the permission of the asset owner if the applicant wishes to install outdoor dining furniture over or in the immediate vicinity of the service pit.

SC6.4.3.4.9 Risk assessment for non-conforming designs

Outdoor dining proposed within a speed zone higher than 60 km/h, or if the applicant believes that the requirements of the design guidelines are not applicable to the specific location, a risk assessment will be required by council.

The risk assessment must be prepared by a person considered by the council to have appropriate expertise in traffic engineering, and will need to demonstrate that the proposed design meets the intent of this sub-section and the relevant provisions of the Townsville City Plan, particularly the relevant zone code.

SC6.4.3.4.10 Permanent outdoor dining structures

In the case where a permanent structure (for example concrete walls, decking, awnings) are proposed, details are to be provided on plans submitted for approval.

Structures, and associated services, must be designed and constructed by suitably qualified persons in accordance with the relevant Australian Standards and the requirements of the Townsville City Plan (i.e. relevant zone code) to maintain public safety, good amenity and ease of cleaning and maintenance.

Electrical supply should have an isolating switchboard to enable the operator of the outdoor dining service to isolate the electrical supply.

Editor's note—Works within council's road reserve will require separate approvals under the relevant local laws (e.g. Road Work Permit).

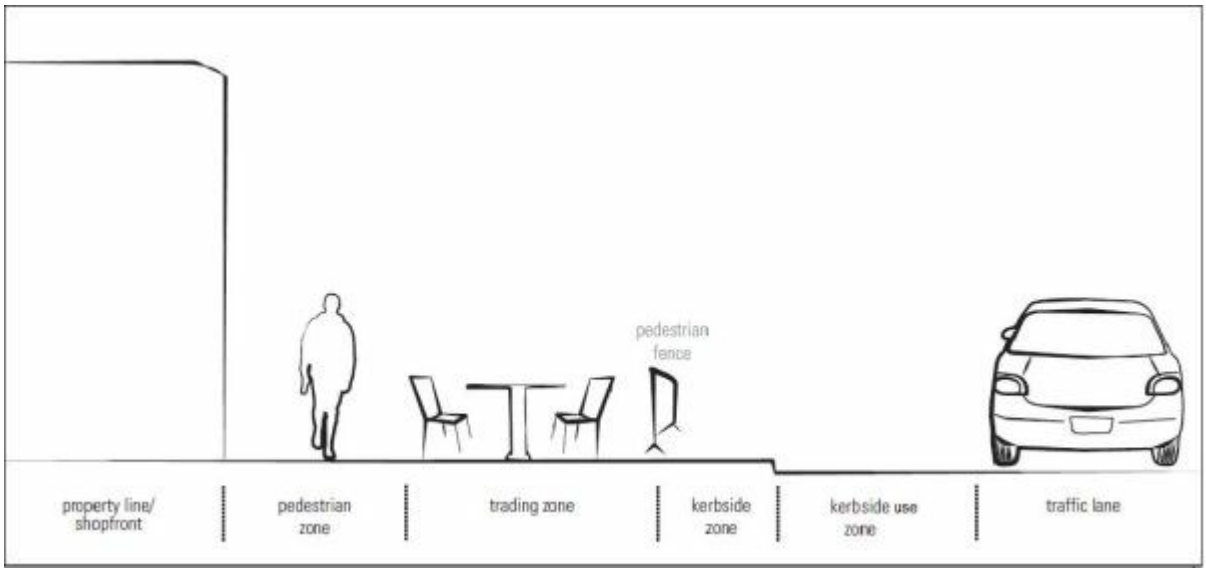

Figure SC6.4.3.4.1 Trading zone definitions

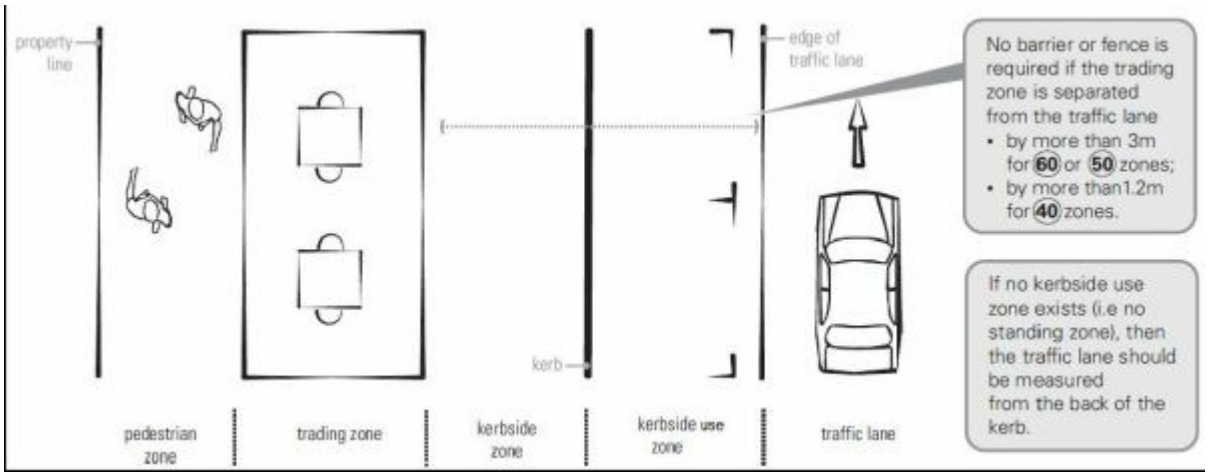

Figure SC6.4.3.4.2 Separation requirements (no barrier or pedestrian fence)

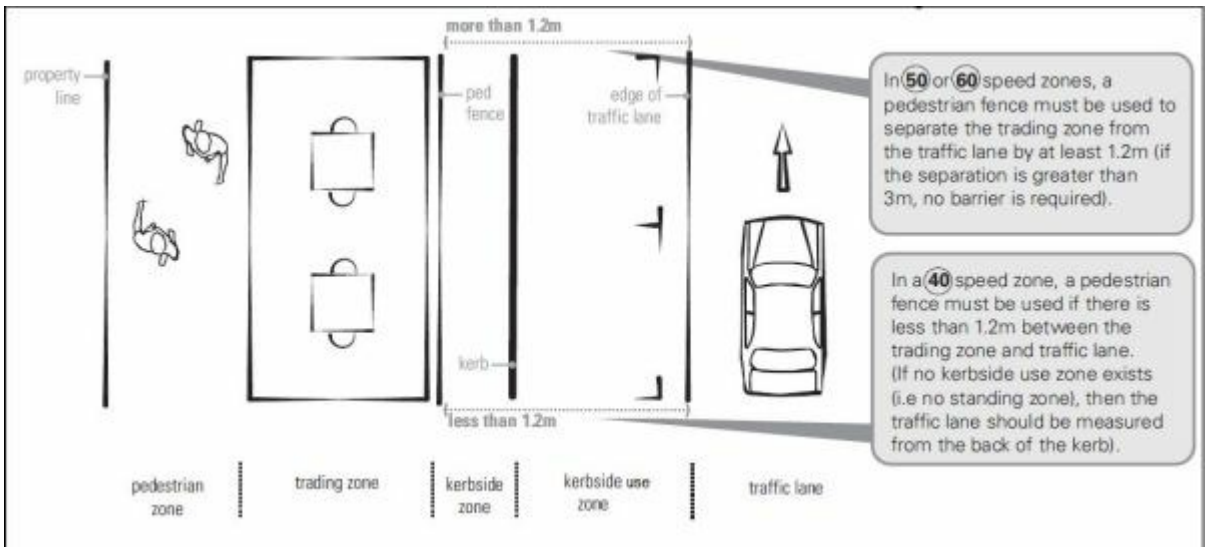

Figure SC6.4.3.4.3 Pedestrian fence requirements

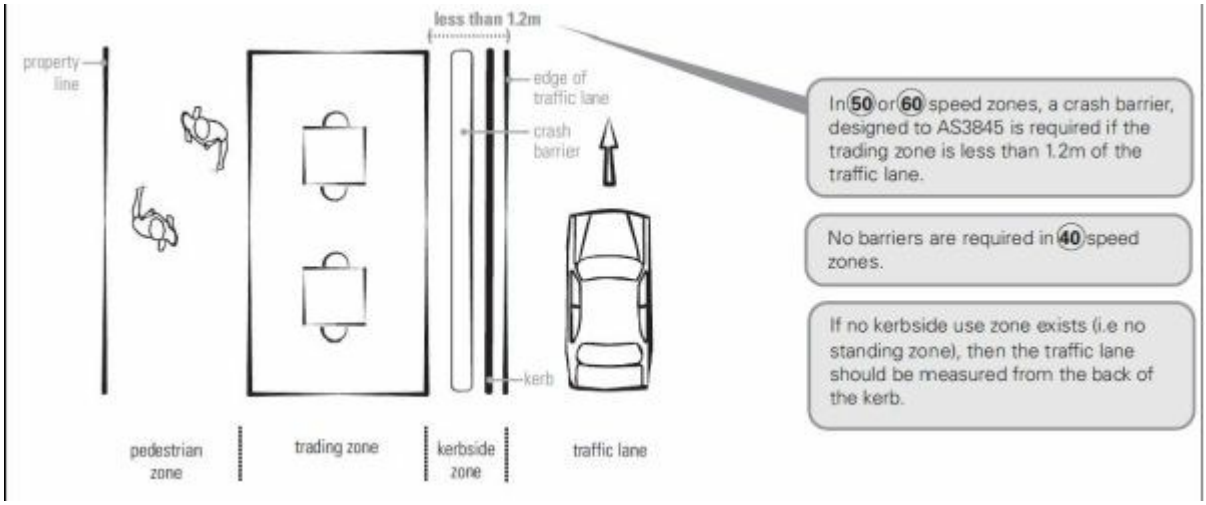

Figure SC6.4.3.4.4 Crash barrier requirements

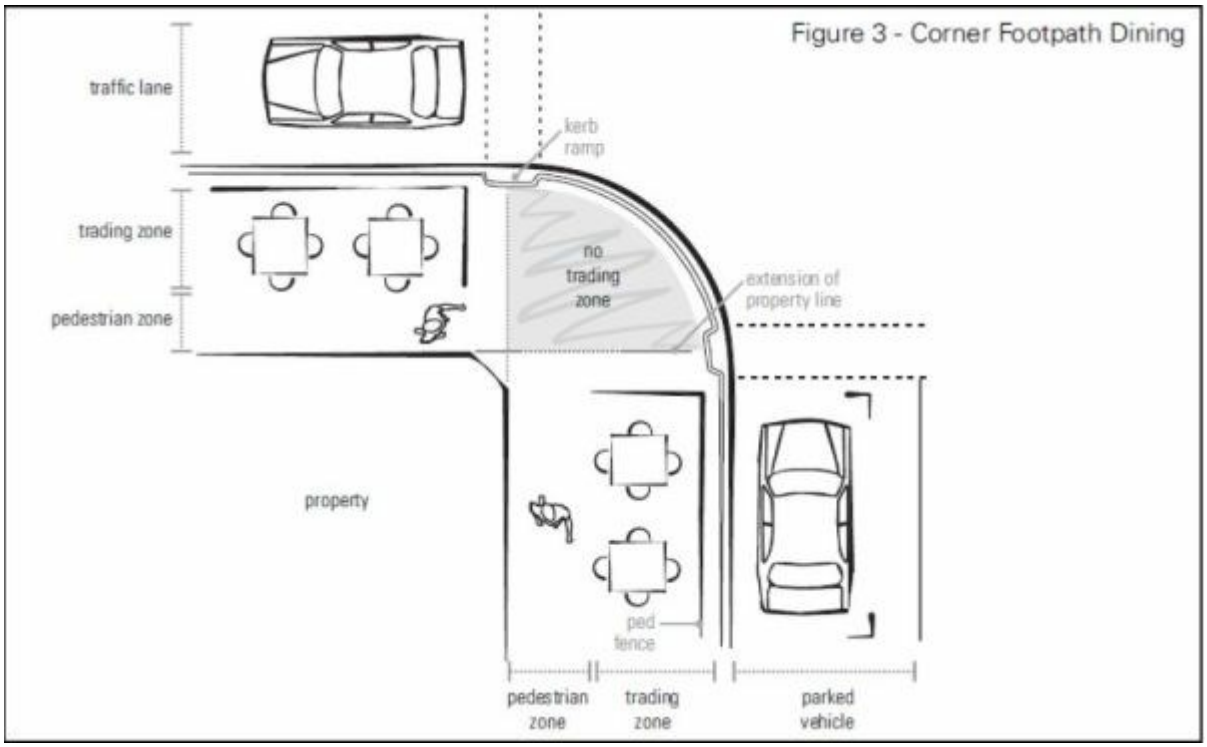

Figure SC6.4.3.4.5 Outdoor dining at intersections

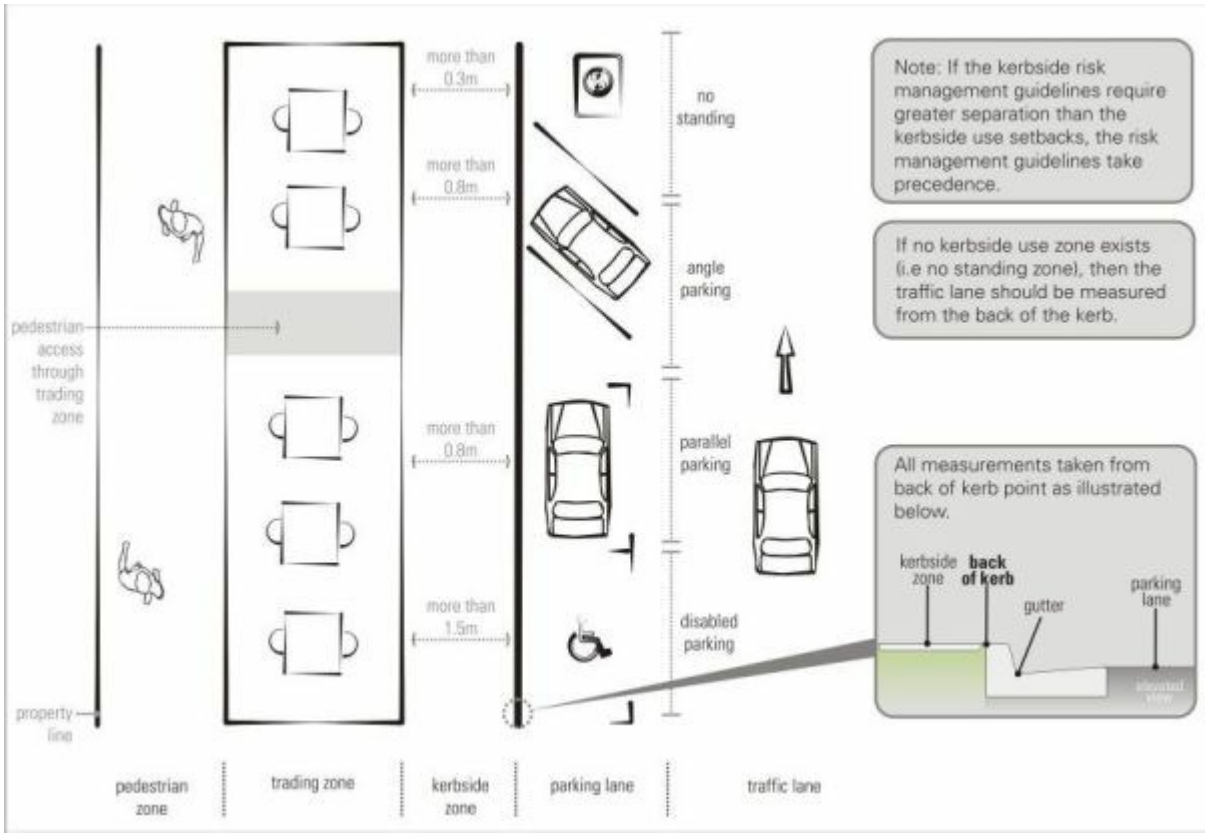

Figure SC6.4.3.4.6 Kerbside use setback requirements

SC6.4.3.4.11 Design and layout principles

(1) To ensure the safety of patrons using the indoor and outdoor areas of the business.

(2) To ensure safety and convenient passage of all pedestrians when using public footpaths.

(3) To ensure the maintenance of clear sight lines for both pedestrians and motorists, particularly near pedestrian crossings, street corners and key intersections as sought by the relevant zone code.

(4) To provide an active and integrated street front.

(5) To ensure adjoining premises are not adversely affected by any business use of footpath areas.

SC6.4.3.4.12 Plan of layout

(1) For any application involving outdoor dining, the applicant is required to provide a layout plan identifying the zones nominated in SC6.4.3.4.1(3) Terminolgy (and Figure SC6.4.3.4.1) above to a scale of 1:100.

The plan of layout must clearly identify the following:

(a) pedestrian zone - a clear pedestrian thoroughfare of not less than 1.8 m in width adjacent to the property building line;

(b) trading zone – an outline of the area intended to be used, including its dimensions;

(c) kerbside zone – area between trading zone and back of kerb;

(d) kerbside use zone – area between back of kerb and traveled path of vehicle;

(e) traffic lane – area of the road used for through passage of vehicles;

(f) any pedestrian fences that are proposed to be used;

(g) any crash barriers that are proposed to be installed;

(h) the access and exit points of the building near the intended outdoor dining area;

(i) details of any loading zones, bus zones, trees, planter boxes, fire hydrants, transformers, telephone booths, mail boxes, bus stops, bus seats and shelters, rubbish bins, pillars, posts and other obstructions; and

(j) If any structures are proposed the structures and, the location of any underground services (such as

water, electricity, etc.).

(2) In addition to submitting a plan of layout, the applicant is also required to submit:

(a) a colour photograph of the site frontage of the area; and

(b) details of all proposed signage and advertising.

SC6.4.3.4.13 Access guidelines

Outdoor dining should enrich the pedestrian experience and public life and support the purpose of the relevant zone. It is therefore important that they present an open, inviting image and are easily accessible from the public way. The layout and access must be ergonomically designed to allow safe operation of outdoor dining.

The streetscape must provide safe, equitable and dignified access for all, enabling all people to move around independently, safely and without restriction within an outdoor space. The edge of the building permits people who are visually impaired to easily locate entrances to buildings without encountering hazards. Hence, where possible and practical, the trading zone should be located on the kerb-side of the footpath, and the pedestrian zone should be located on the building side of the footpath adjacent to the property building line to provide a continuous accessible path of travel for all pedestrians.

In some locations, conditions may make siting of the trading zone on the kerb-side impractical, seriously disadvantageous or an unreasonable impediment to pedestrian traffic. In such situations, council will consider allowing the location of the trading zone adjacent to the building rather than against the kerb.

In all locations, an outdoor dining area must stay within the area identified as trading zone on the approved layout plan.

Details of required clearances to public infrastructure are provided in SC6.4.3.4.11.

Outdoor dining areas must be easily accessible from the footpath and must present an open and inviting image to entice participation. Pedestrians should not be forced onto the roadway by outdoor dining activities or other non-permanent items/structures on the footpath.

SC6.4.3.4.14 Furniture guidelines

Permanent outdoor furniture should make a positive contribution to the street environment. A furniture style that is practical and integrates well with the surrounding cityscape is encouraged.

(1) Outdoor furniture should enhance the character of the street.

(2) Outdoor furniture should be robust to withstand the wear and tear of outdoor commercial usage.

(3) Outdoor furniture should be safe in its design, compliant with Australian Standards, and not cause any hazards to the patrons, shopkeepers or pedestrians.

(4) Barricades, safety rails, bollards etc. may be required for safety reasons. All such barriers must be provided and maintained in accordance with this sub-section.

(5) The use of framed fabric or any other style of low-height barriers, including planter boxes, within public domain must be carefully designed and selected to ensure minimal impact on the use, enjoyment and safety of pedestrians and patrons.

(6) Removable furniture are to be removed when business is not open.

(7) No part of the footpath is to be used for storage.

SC6.4.3.4.15 Umbrellas/shade structure guidelines

(1) Fixtures that penetrate or damage the pavement on public footpaths will generally not be permitted. However, assessments will be undertaken on a case-by-case basis.

(2) In some cases, the applicant may wish to undertake streetscape works to accommodate an outdoor café. Such works may include footpath widening, paving, street tree planting, installation of permanent umbrellas/shade structures, pedestrian lighting and where such woks are in support of the relevant zone code of the Townsville City Plan.

(3) Umbrellas and other shade structures should not encroach upon, nor interfere with pedestrian movement or services.

(4) Umbrellas and other shade structures must have not less than 2.5 m clearance above the footpath within the obstruction free zone (AS1742.2 – 2009) from the lowest point of the extended arms (spokes) and not cause a hazard to pedestrians within a pedestrian zone.

(5) Umbrellas and other shade structures must be maintained in sound and aesthetically acceptable condition to the council's satisfaction.

(6) Umbrellas and other shade structures must be secured against high winds.

(7) Umbrellas and other shade structures must be removed when the outdoor seating area is not in use.

(8) Any advertising on umbrellas and other shade structures must comply with section 9.4.1 Advertising devices code (any relevant approval obtained for the placement of an Advertising device) and the relevant local law (*Local Law No. 1.4 Installation of advertising devices 2011)*.

SC6.4.3.4.16 Advertising guidelines

The Advertising devices code found in section 9.4.1 of the Townsville City Plan provides applicants with information regarding the placement of advertising devices. In some instances, separate approval for operational works for the placement of an advertising device may be required. Refer to Table 5.8.2 of the Townsville City Plan to determine levels of assessment for the placement of an advertising device.

SC6.4.3.4.17 Lighting

Any outdoor dining establishment approved to operate outside daylight hours must provide adequate lighting to Australian Standards, to ensure the safety and amenity of patrons and the general public. The use or reliance on council infrastructure is not permitted and the cost of maintaining, running and installing the lighting shall be the responsibility of the applicant/operator of the outdoor dining space. Any outdoor lighting must also comply with any light spillage requirements so as not to cause nuisance to adjoining properties or traffic movement areas. Lighting shall be safe and not cause obstruction or pose a hazard to pedestrians or traffic.

SC6.4.3.5 Car parking and public transport facilities

SC6.4.3.5.1 Introduction

(1) Purpose

This sub-section provides advice, guidance and standards with respect to car parking and public transport facilities to support an integrated safe, efficient and sustainable transport network.

(2) Scope

This sub-section includes the consideration of:

(a) transport impacts, including:

(i) demands for private and public transport, pedestrian and cycle usage;

(ii) impacts of future development on existing transport networks and infrastructure and the need for any improvements; and

(iii) assessment of the public transport services and the provision of facilities both on and off-site and specific high generator needs;

(b) pedestrian and cycle facilities integration with existing networks and for the provision of facilities both on and off-site;

(c) site access - accesses and driveways;

(d) parking area design provision of adequate and appropriately designed parking and circulation areas; and

(e) servicing - provision of appropriate loading/unloading facilities and manoeuvring areas both on and off-site and provision for emergency and service vehicle access.

(3) Relationship to codes

(a) Where a development application is assessable against Part 9.4.6 Transport impact, access and parking code, the application of this sub-section will assist the applicant to address the performance outcomes and acceptable solutions of that code as it contains advice, guidelines and standards.

(b) This sub-section can also be used as guidance and advice for other assessment criteria and codes including Part 9.4.4 Reconfiguring a lot code, Part 9.4.7 Works code, Part 9.4.5 Accepted works requirements code and Part 9.4.3 Landscape code.

(4) Reference and source documents that must be read in conjunction with this sub-section are as follows:

(a) Development manual planning scheme policy sub-sections
SC6.4.3.3 Footpath treatment policy
SC6.4.3.4 Outdoor dining design
SC6.4.3.6 Landscape policy

SC6.4.3.5.2 Public transport

(1) Transport network impact

(a) Applicants should assess the additional transport demands generated by the development and the capacity of the infrastructure to accommodate the additional demands by way of a traffic impact assessment report where all impacts, upgrades and alterations to the road infrastructure, including line marking and signage are identified.

(b) SC6.4.3.14 Traffic impact assessment guidelines must then be applied to the extent outlined in that report and information and plans provided on any new infrastructure or the proposed alterations/additions to the existing infrastructure for the consideration/approval of council which may be required as a result of this development. Provision should be made for the utilisation or extension of existing networks and services where required. The recommendations of the traffic impact assessment must be implemented with regard to the advice, guidance and standards identified in this sub-section. End of Trip facilities (on-site or off-site) must be provided as part of the development where identified by the relevant code and must take account of the particular characteristics of the user and service provider.

(2) Public transport

(a) Public transport demands should be assessed and consideration given to upgrading the existing transport network, services and facilities in accordance with the current and future demands.

(b) The developer is to provide council with a comprehensive assessment of the current and projected public transport demands for any new facility to be constructed as part of these works. This assessment is to be in the form of a detailed transport report and will include the particulars of any proposed upgrade to the existing transport services, routes and systems that adjoin the proposed project development. Taxi services are also considered a form of public transport and are to be considered in the model assessment of the site (if applicable). Taxi services should be integrated with other transport node facilities wherever it is possible to do so.

(c) Information and guidelines for providing public transport are provided in SC6.4.3.5 Attachment A of this sub-section. SC6.4.3.5 Attachment B of this sub-section provides advice on the consultation process with the necessary statutory authorities and service providers.

(3) Major developments

(a) Major developments which will result in high levels of public transport demand should give particular consideration to the provision and integration of services and the detail design of associated facilities on

or near the site. Facilities should be designed so as to be convenient and encourage public transport, walking or cycling. Generators may include uses such as schools, hospitals, event venues, shopping or employment centres, and high-density residential developments, aged care facilities, medical centres and retirement villages.

(b) If a development is a high level generator under SC6.4.3.14 Traffic impact assessment guidelines, a modal interchange should be provided which may include taxis. A set-back from the main road/route should be provided to ensure the site is serviced safely and directly for these facilities. Developments should present an active frontage to the transport interchange facility with wide footpaths and no conflicting vehicular accesses to ensure pedestrian and user safety is a priority.

SC6.4.3.5.3 Driveways

(1) Developments must provide for safe effective vehicular site access to and from the site, appropriate for the volume, frequency and type of vehicle usage and the function and characteristics of the surrounding road network. Separate, and clearly distinguishable, access for pedestrians should be provided where practicable.

(2) The location and characteristics of the access should be in accordance with the following documents:

(a) SC6.4.4.1 Geometric road design

(b) SC6.4.3.17 Driveways

(c) SC6.4.4.8 Standard drawings

(d) SC6.4.6 Construction specifications

(e) AS 2890 - *Parking Facilities Set*

(f) Austroads Guides

(3) The location and capacity of accesses must provide for safe and efficient pedestrian, cyclist and vehicular movement on adjacent and nearby road, and be appropriately designed so as to consider sight distances, grades, queuing, manoeuvring requirements, drainage and services. Any access must be structurally sound and built of aesthetically appealing materials for the circumstance. The impact of the access on neighbouring properties in terms of safety, streetscape and noise should also be considered.

SC6.4.3.5.4 Pedestrians and cyclists

(1) Developments are to make appropriate provision for the safe and convenient movement of pedestrians and cyclists, both on-site and to and from surrounding networks. Design should include the provision of suitable routes and end-of-trip facilities so as to encourage and facilitate these forms of movement.

(2) Major developments should provide end-of-trip facilities in accordance with the QDC Mandatory Part 4.1 *Sustainable Buildings* within the building or on-site.

(3) As well as to ensuring the safety of pedestrians, cyclists and other transport users, the design of pathways, roads, car parks and associated infrastructure (including lighting, landscaping etc) should in turn encourage overall public safety. The principles found in *Crime Prevention through Environmental Design Guidelines (Queensland)* must be given appropriate consideration for the specific development circumstances in addition to requirements of the relevant code.

SC6.4.3.5.5 Parking

(1) Parking on-site

(a) On-site parking must be provided to meet the demands of the development, including open space areas and meet the minimum rates set out in SC6.10 Parking Rates planning scheme policy (Table SC6.10.2.1 Parking rates). SC6.4.3.6 Landscaping policy provides further direction on the provision of parking to service open space areas.

(b) Any associated change to existing on-street parking controls or loading bays must also be appropriately addressed by the development. A parking layout plan must be submitted for the approval of council which accounts for the loss of any existing on-street parking bays to accommodate loading zones, bus

stops, taxi ranks or driveways required for the orderly operation of the proposed development.

(c) The design of the car park, its accesses and associated aisles are to be in accordance with AS/NZS 2890.

(d) Accesses must be designed in accordance with SC6.4.3.17 Driveways and SC6.4.4.8 Standard drawings.

(e) Where car parks are accessed through security barriers, doors or lifts, sufficient queuing space must be provided on site to accommodate all expected traffic during peak demand periods.

(f) Access ways adjacent to car park entries should have sufficient internal queuing space to prevent vehicles queuing into the street whilst waiting for a vehicle to manoeuvre into-out of a parking bay.

(g) Turning paths for cars and service vehicles must be provided in accordance with the Austroads' *Design Vehicles and Turning Path Template Guide*. Council may require the preparation of plans that demonstrate adequate turning paths in accordance with Austroads.

(h) Pavements must be sealed, line marked and constructed to a design appropriate for the anticipated vehicular loading.

(i) Parking for schools must comply with *Planning for Safe Transport Infrastructure at Schools*.

(j) Car parks must provide adequate manoeuvring and parking areas for the type of vehicles and functions served. They must be clearly signed and marked, accessible, safe and contribute aesthetically to the internal user and the streetscape character. Landscaping associated with parking facilities must be in accordance with the Landscape Code and with SC6.4.3.6 Landscape policy.

(k) All car parking spaces for people with a disability must be designed in accordance with AS/NZS 2890-6. Car parking spaces for people with a disability are to be largely located as close as possible to the point of entry into the proposed development. Provision for off-site parking may also be required. In this circumstance, the ability to safely provide this within the road reserve must also be demonstrated.

(l) Pedestrian access and movements within the car park should be separate from vehicular access and should be appropriately marked and signed and accessible by all abilities.

(m) Carwash bays must be clearly marked and signed, even though this may also be utilised as a visitor space. Run-off from the car washing bay must not discharge into the stormwater drainage system. Stormwater quality treatment for the car park run-off must be considered as part of the treatment for the whole site.

(n) Bicycle storage racks must be provided on-site in accordance with AS/NZS 2890.3.

(o) Provision of lighting in off-street car parks is to comply with AS1158.

(2) Parking on-street

(a) Developers must undertake all works identified in the traffic impact assessment report required in SC6.4.3.5.2(1) Transport network impact.

(b) If a new driveway is to be constructed in a street where parallel parking exists and it is necessary to remove parking bays and install a driveway, the remaining parallel parking bays must be remarked such that at least 3 m is left clear from the edge of the driveway on the approach side of the driveway and at least 2 m is left clear on the other side of the driveway. Remarking of the remaining on street bays and any relocation/alteration to parking control signs must be undertaken as part of this works. A parking layout plan must be submitted for the approval of council.

(c) Where a loading zone, bus stop or a taxi zone is required as a result of a development, the infrastructure, line marking and signage must be provided by the developer. The design must be submitted to council for approval prior to works commencing on site.

Editor's note—a loss of parking may occur due to access requirements by Queensland Fire and Rescue at hydrant boosters.

SC6.4.3.5.6 Servicing

(1) The development must make adequate on-site provision for the access, loading, unloading and manoeuvring of service vehicles sufficient to cater for the demand generated by the development and the service vehicles

utilised. The design must ensure the safety of other vehicles, pedestrians and cyclists and that other users are not inconvenienced. The design must also consider any adverse effect on the amenity of the development and its surroundings including the effects of visual amenity, operating hours, the generation of noise odour and dust, and proximity to sensitive uses. The design of this layout must conform to AS 2890.2.

(2) The development must make adequate internal provision within the site to allow all vehicles servicing the development to enter and exit the site in a forward direction only. In demonstration of this requirement, council may request a turning path plan to show how the intended vehicle types that are expected to use the development can enter and exit the site in a forward gear.

(3) Entry of B-double or other multi-combination vehicles servicing a proposed development will be considered by council on a case-by-case basis. In making this assessment, council will:

(a) assess the status of the roadway fronting the development;

(b) consider the zoning of the adjoining properties;

(c) design particulars of the vehicle entry and exit layout – with particular attention to the footway/verge crossing details;

(d) the internal manoeuvring capacity of the development site; and

(e) safety implications to the public and other road users.

Editor's note—road manager consent is required for travel on the road network. Applications are coordinated by the National Heavy Vehicle Regulator.

(4) Provision for refuse collection must be in accordance with SC6.4.3.22 Waste management guidelines.

SC6.4.3.5 Attachment A: Information and guidelines for public transport

(1) Bus routes are preferred along the shortest route, or up to 120% of the shortest length, between destinations.

(2) Preferred bus routes are generally located along arterial, sub-arterial and collector roads. Passenger bus services will not service an estate with only one entry/exit; as existing passengers are taken on a tourist trip through the estate without getting closer to their destination.

(3) The main criteria in determining the location of a bus route is that no more than 10% of residents should have to walk more than 400m to catch a bus within the urban area. Council may request a public transport route plan as part of the development to demonstrate this requirement. Bus services operate to a published timetable, so routes with minimal delays at intersections are preferred; routes with multiple traffic signals can cause delays to timetable service.

(4) To minimise resident objection to the placement of bus stops in front of houses, any public open space (e.g. drainage or recreational reserve) should be considered to accommodate a bus stop. This is particularly pertinent if the public open space contains a pathway. Other options include high-density residential or commercial developments where off-street parking is a component of the development. It is most desirable to establish the location of future bus stops during the design process to ensure that future development proposals recognise the implications of this infrastructure and its location. A layout plan showing the proposed locations must be submitted for the approval of council.

(5) New bus stops will be one of four standards:

(a) Minimum boarding point - bus stop sign with timetable displays (TDC), platform with tactile ground surface indicators (TGSI); or

(b) regular stop - bus stop sign with TDC, platform with (TGSI) and seat (inbound definite, outbound optional); or

(c) intermediate stop - bus stop sign with TDC, platform with TGSI and shelter with seat (inbound definite, outbound optional) – site specific; or

(d) premium stop - generally limited to high route volume locations and stops at shopping centres. As per intermediate stop, with greater care to the infrastructure finish standards and capacity requirements.

(6) New regular and intermediate bus stops are to be designed and constructed in accordance with council's standard drawings (SC6.4.4.8 Standard drawings) and meeting disability compliance standards (DSAPT and Premises Standards) or set out under the Disability Discrimination Act 1992.

(7) Bus stops should be located where there is no conflict with the location of (drainage pits/surrounds, poles, items of street furniture), street trees or driveways to properties. Drainage pits must be located away from the bus platform (concrete slab) to avoid creating a safety hazard. They are generally located in residential areas at side boundaries of adjoining properties to avoid resident concerns about loss of amenity and view, by having a stop directly in front of their property. Bus stops are generally preferred to include a location near an intersection to pick up passenger from the side streets; however, it should not impact on intersection functionality or operation. Bus stops are preferred on the departure side of intersections and major driveways.

Bus stop facilities within private property must comply with the DSAPT and associated guidelines, the Premises Standards or under the DDA. The developer must provide documentation to demonstrate consultation with the Department of Transport and Main Roads and the all impacted bus operators about future passenger bus routes servicing the facility during the design phase. A layout plan showing the proposed location with details must be submitted for the approval of council.

(8) Pathways servicing bus stops must form an integral part of a pathway network servicing the entire estate, and not just be a short connection to the corner of the nearest street.

(9) The in-bound and out-bound bus stops along the same route should be in proximity to each other on opposite sides of the street, although the bus stops do not have to be directly opposite each other (especially at intersections).

(10) All new bus stops being constructed must comply with the requirements of the DSAPT and associated guidelines (including any bus stop relocations), the Premises Standards or under the DDA. It must also have a clear continuous accessible path of travel; that is be serviced by a smooth, level and impervious surface with a 1500mm minimum width. One aspect of compliance is that the preferred cross-fall on the bus stop platform slab is 2%, and absolute maximum of 2.5%. School bus stops (mostly in a rural environment) do not need to comply with this requirement at this time.

(11) A standard bus stop is 3 m wide by 12 m long, (see SC6.4.4.8 Standard Drawings) plus entry/exit tapers on roads with a posted speed limit of 60km/h or less. A bus bay (with associated parking restrictions) is approximately 42m long (allowing for a 15m in taper and 15m egress taper). These dimensions can vary and may severely impact on the required street width (especially where no indents are to be provided), driveway access to properties and the availability of visitor/customer parking.

(12) Consideration must be also given as to how elderly and young passengers (especially school children) will safely cross the street to access the bus service. This may require the installation of a nearby refuge crossing or traffic signals, or similar measures.

(13) Bus routes should avoid having vertical or horizontal deflection traffic calming measures along the route. Any vertical deflection devices that are to be used by a bus service intended to operate in high pedestrian environment must be flat-top road humps. Council may support a bus route where speed cushions are installed.

(14) Any roundabout along a bus route must be able to accommodate a turning bus without mounting the kerb and channel or encroaching onto any landscaping on the centre island, including during a right hand turn.

(15) The developer is to prepare a draft Master Plan for the proposed development together with a traffic impact

assessment in accordance with SC6.4.3.14 Traffic impact assessment guidelines.

(16) The Master Plan will identify (as a minimum):

(a) proposed residential development lot sizes and densities;

(b) any proposed commercial development, including approx. GFA;

(c) any proposed education facility or other significant bus passenger service attractor (e.g. retirement village, hospital etc.);

(d) location, type and hierarchy of open spaces areas;

(e) the proposed road hierarchy for the development, and how it connects to the existing road network;

(f) the location of proposed footpaths and shared paths and bicycle paths throughout the development, and how they connect to the existing, and future, networks; and

(g) the route of all existing passenger bus routes within 1 km of the proposed development and through the development; and

(h) The Master Plan must be submitted for the approval of council.

(17) As part of the information required in obtaining a development approval, the developer must provide evidence of feedback from consultation with all the following stakeholders on the feasibility of potential passenger bus service route/major bus corridor through the new development:

(a) Department of Transport and Main Roads (TransLink Division);

(b) Department of Transport and Main Roads (Northern Region);

(c) local contract bus operator (Sunbus Townsville) and if necessary school bus operator/s;

(d) local taxi operator (Townsville Taxis); and

(e) council's Infrastructure Services Division.

(18) The outcome from the engagement with the stakeholders will be:

(a) advice if the development is ever likely to be serviced by a passenger bus service or school bus service;

(b) agreement of the most likely route(s) through, or servicing, the proposed development;

(c) the need and likely location of bus stops necessary to service the development;

(d) general agreement on the location and route of footpaths and shared paths servicing any future bus service along the agreed bus routes;

(e) advice on the need for any bus stop to be constructed as part of any proposed commercial centre, and the likely required standard of the facility; and

(f) the need for the developer to provide any other additional facilities to ensure the operation of an efficient and effective public transport services, including taxis. This may include required intersection treatment, bus stop locations, the possibility of joint use bus stops and the like.

SC6.4.3.5 Attachment B: Guidelines - Authority consultation for public transport, taxis, buses and school buses

(1) Taxi operations
Contact the Department of Transport and Main Roads Northern Region and the local taxi operator about taxi service operations.

(2) Taxi infrastructure

(a) Contact Townsville City Council about existing and proposed taxi rank infrastructure in the area.

(b) Any existing or new infrastructure undergoing substantial refurbishment or alteration must comply with the *Disability Standards for Accessible Public Transport 2002* and associated guidelines, the Premises Standards or under the DDA, and be in accordance with SC6.4.4.8 Standard drawings at the time of the refurbishment or alteration. It must have clear continuous accessible path of travel; that is, be serviced by a smooth, level and impervious surface.

(3) Bus routes

(a) Contact the Department of Transport and Main Roads Northern Region and the local bus operator (Service Contract holder) about current and future passenger bus routes.

(b) The developer will need to be aware of, and make provision for, future bus routes as determined through the consultation process with DTMR, council and the local bus operators.

(4) Bus stop infrastructure

(a) Contact Townsville City Council in the first instance about existing and proposed bus stop infrastructure on the road reserve, then contact the Department of Transport and Main Roads about interchange-type infrastructure.

(b) Any existing or new infrastructure undergoing substantial refurbishment or alteration must comply with the DSAPT and guidelines, the Premises Standards or under the DDA, and be in accordance with SC6.4.4.8 Standard drawings at the time of the refurbishment or alteration.

(c) Townsville City Council has prepared standard drawings for bus stop infrastructure. Also, new or relocated bus stops must have the specified branding (J Pole/ Blade signing), an identifying name approved by council's Technical Services Unit and be in accordance with SC6.4.4.8 Standard drawings and the bus stop position identified by easting and northing.

(5) School buses services

Contact the Department of Transport and Main Roads Northern Region and the local bus operator about current and future school bus route operations.

(6) School bus stop infrastructure

Contact Townsville City Council about existing and proposed school bus stop infrastructure on the road reserve.

(7) Intercity buses (long distance)

Contact Townsville City Council about existing and proposed intercity bus stop infrastructure on the road reserve, but also contact the Department of Transport and Main Roads TransLink Division about bus stop infrastructure and bus stop operations.

SC6.4.3.6 Landscape policy

SC6.4.3.6.1 Introduction

(1) Purpose

The purpose of this sub-section is to:

(a) support the purpose of Part 9.3.3 Landscape code and other elements of the Townsville City Plan and Development manual planning scheme policy;

(b) identify the application of this sub-section to landscape and irrigation design across all types of open space; and

(c) provide detailed design and construction standards, advice and guidelines for landscaping on private and public land ensuring a high standard, strong contribution to the city image and local character that are suited to site and climatic conditions and will remain fit for purpose over the long-term.

(2) Scope

This sub-section provides direction on landscape and irrigation design within open space, both within the public and private realm.

The scope of this sub-section includes:

(a) overarching design, sustainability and management principles that should be applied to open space development including:

(i) general design principles, master plans and identified design outcomes;

(ii) principles of sustainability economic, environmental, and social; and

(iii) management frameworks for public open space Public Open Space (POS) Hierarchy, Public Open Space Management (POSM) Framework and Irrigation Profile Level (IPL) Framework;

(b) the types, functions and development objectives for open space:

(i) private open space;

(ii) streetscapes; and

(iii) public open space recreation parks, sporting parks and other public open space; and

(c) design and embellishment guidelines for application in open space development.

(3) Reference and source documents

(a) This sub-section should be read in conjunction with other sections of the Townsville City Plan and Development manual planning scheme policy including, but not limited to:

Part 4 – Priority infrastructure plan
Part 8.2.5 – Natural assets code
Part 9.3.3 – Landscape code
Part 9.3.4 – Reconfiguring a lot code
SC6.4.3.3 – Footpath treatment policy
SC6.4.3.4 – Outdoor dining design
SC6.4.4.1 – Geometric road design
SC6.4.4.7 – Bicycle, pedestrian and shared path design
SC6.4.3.20 – Public lighting and utility services
SC6.9 Natural assets planning scheme policy

(b) The following Australian Standards are also referenced and should be read in conjunction with this sub-section:

AS/NZS 1158.3.1	*Lighting for roads and public spaces*
AS 1170	*Structural design actions (set)*
AS 1428	*Design for access and mobility (set)*
AS 1926.1	*Swimming pool safety – safety barriers for swimming pools*
AS 2156	*Walking tracks*

AS 2890.3	*Parking facilities – Bicycle parking facilities*
AS 3996	*Access covers and grates*
AS 4373	*Pruning of amenity trees*
AS 4422.2016	*Playground surfacing – Specifications, requirements and test methods*
AS/NZS 4486.1	*Playgrounds and playground equipment – Development, installation, inspection, maintenance and operation*
AS 4685.1	*Playground equipment – General safety requirements and test methods (and Amendment 1 – 2006, and Amendment 2 – 2008)*
AS 4685.2	*Playground equipment – Particular safety requirements and test methods for swings (and Amendments 1- 2006 and 2 - 2008)*
AS 4685.3	*Playground equipment – Particular safety requirements and test methods for slides (and Amendment 1- 2006)*
AS 4685.4	*Playground equipment – Particular safety requirements and test methods for runways*
AS 4685.5	*Playground equipment – Particular safety requirements and test methods for carousels (and Amendment 1 – 2006)*
AS 4685.6	*Playground equipment – Particular safety requirements and test methods for rocking equipment (and Amendment 1 – 2008)*
AS 4685.11	*Playground equipment – Additional specific safety requirements and test methods for spatial network*
AS/NZS 4456.9	*Masonry units and segmental pavers and flags – Methods of test – Determining abrasion resistance*
AS/NZS 4586	*Slip resistance classification of new pedestrian surface materials*

(c) Other

SC6.4.3.6.2 Landscape design

(1) Introduction

Landscape and irrigation outcomes should demonstrate consideration and application of the overarching principles, as described within this sub-section, Part 9.3.3 Landscape Code and other parts of the Townsville City Plan.

Alignment with applicable principles should be expressed in the landscape and irrigation design outcomes and addressed in the “Landscape Statement of Intent”, as detailed in Section SC6.4.2 Development application guidelines.

(2) Master plans

For certain sites or localities, council may formally adopt Master Plans that identify specific strategies and plans to deliver key design and construction outcomes in the built environment.

At sites or locations where these Master Plans apply, any landscape design outcomes must be in accordance with the requirements for that site or area.

The following plans contain site specific outcomes that must be complied with:

(a) Thuringowa Riverway Master Plan (2003); and

(b) Riverway Sustainable Development Policy (2003).

Details of the above listed plans are contained in SC6.4.3.6 Attachment B – Adopted Master Plans

Editor's note—applicants should refer to all applicable sub-sections within the Development manual planning scheme policy which identify specific design principles and outcomes required across individual open space typologies as well as other infrastructure.

Editor's note—outcomes identified in an adopted master plan take precedence over all other design guidelines, unless approved otherwise. Where proposals deviate from the desired outcomes of the adopted master plan, applicants must justify this deviation for council's assessment and approval.

(3) Identifiable character and/or identified design outcomes
For key sites or localities where council has **not** formally adopted area specific plans and strategies but there is an identifiable character and/or desired design outcome, planning and design for new open space development in these areas should seek to be consistent or complementary to this established direction.

Identifiable character and/or design outcomes may include:

(a) an established colour or furniture palette;

(b) a dominant tree, plant species or planting style;

(c) heritage features or an identifiable character;

(d) significant natural features, materials, or environmental setting (e.g. natural bushland or coastal settings); and

(e) a consistent, hierarchical-based landscape design style (e.g. all "main roads" to be developed in "tropical boulevard" style).

Editor's note—statements pertaining to identifiable character or design outcomes for particular locations or land uses are contained within Townsville City Plan. Where applicable, landscape design outcomes are to comply with these statements and must be addressed within the "Landscape Statement of Intent". Where proposals will deviate from the desired outcomes, applicants must justify this deviation for further assessment and approval by council.

SC6.4.3.6.3 Economic sustainability

Landscape and irrigation outcomes should demonstrate consideration and application of economic sustainability principles, as described within this sub-section, Part 9.3.3 Landscape code and other areas of the Townsville City Plan.

Alignment with applicable principles should be expressed in the landscape and irrigation design outcomes and addressed in the "Landscape Statement of Intent", as detailed in Section SC6.4.2 Development application guidelines.

(1) General principles
Principles for consideration should include, but are not limited to:

(a) promoting opportunities for business and investments by:

(i) designing quality streetscapes that promote local business and attract patrons; and

(ii) creating opportunities for marketing initiatives such as festivals, events and community based activities (e.g. provision of event spaces within public open space areas);

(b) developing and implementing an integrated and strategic approach to the long term provision of open space infrastructure by:

(i) aligning new public open space development with council's Public Open Space Embellishment Framework and priority infrastructure plans; and

(ii) designing and developing new infrastructure and open space that improves the quality and value of the built environment within both the public and private realm (e.g. creating more liveable spaces that promote the city as an attractive place to live and invest); and

(c) establishing economically sustainable infrastructure outcomes by:

(i) identifying the lifecycle costs of open space infrastructure (e.g. the costs to plan, develop,

maintain, replace and demolish a recreational facility are established); and

(ii) identifying and developing new infrastructure with consideration of the ongoing operational requirements (e.g. identify and design a new open space development in line with defined maintenance resources).

(2) Lifecycle costing

Editor's note—currently, no framework or standard format for establishing lifecycle costs is developed. Applicants requested to submit lifecycle costing information should refer to best-practice examples until a formal framework is established.

(3) Ongoing operational requirements

(a) Where requested, applicants are required to identify the ongoing operational requirements in a maintenance plan, as detailed in Section SC6.4.2 Development application guidelines.

(b) For public open space, maintenance plans should be aligned with Public Open Space Management (POSM) Framework, as outlined in SC6.4.3.6.9(2)(b) POSM Framework and developed with consideration of the Public Open Space Embellishment Framework, as per Table SC6.4.3.6.1.

SC6.4.3.6.4 Environmental sustainability

Landscape and irrigation outcomes should demonstrate consideration and application of environmental sustainability principles, as described within this sub-section, Part 9.3.3 Landscape Code, other areas of the Townsville City Plan and council's Corporate Plan.

Alignment with applicable principles should be expressed in the landscape and irrigation design outcomes and addressed in the "Landscape Statement of Intent", as detailed in Section SC6.4.2 Development application guidelines.

Editor's note—currently, no framework has been developed for identifying and documenting outcomes against the environmental sustainability objectives listed. Until a formal framework or best-practice examples are identified, applications will be considered on a case by case basis. This includes recognition of independent certification under incentive-based branding and certification frameworks (e.g. EnviroDevelopment) designed to increased sustainability in developments.

(1) Principles for consideration should include, but are not limited to:

(a) conservation and substitution of non-renewable resources, by:

(i) responsible use of finite resources; and

(ii) implementation of efficiency mechanisms and strategies, (e.g. reduction of potable water use through water wise landscape and irrigation design);

(b) efficient and sustainable use of renewable resources, such as:

(i) prioritising and promoting innovative use of new, renewable materials or substitutes (e.g. plantation timber); and

(ii) transitioning to renewable energy sources and infrastructure where practicable (e.g. solar powered lighting);

(c) direct and indirect reduction in resource consumption and waste generation, by:

(i) implementing opportunities for waste reduction and reuse (e.g. concrete recycling for gabion walls);

(ii) prioritising and promoting use of recycled materials (e.g. recycled plastic composites);

(iii) promoting means for reducing carbon emissions and improving opportunities for carbon offsets and sequestration (e.g. reducing land clearing by promoting protection of existing trees and vegetation areas and incorporation of natural areas into public open space design); and

(iv) promoting environmentally sustainable design principles to directly and indirectly reduce resource consumption (e.g. increased street tree plantings to support passive cooling of streetscapes and buildings whilst improving amenity to promote pedestrian and cyclist activity); and

(d) protection, rehabilitation or enhancement of existing natural assets and systems through methods such as:

(i) responsive planting design and species selection;

(ii) protection of remnant vegetation, significant trees and habitat areas;

(iii) promotion of ecological design and responsible urban forestry management; and

(iv) implementation of integrated water cycle management practices.

(2) Responsive planting design principles and species selection
The following are provided as general guidelines for responsive planting design and species selection for all types of open space.

(a) Aesthetic requirements

(i) Planting design principles such as scale, proportion, repetition, balance, contrast, focal points and transition should be applied in the development of all planting designs.

(ii) The design qualities of the plant species including size, scale, form, line, texture and colour should be considered and maximised through the planting design process.

(iii) Plant selection and design should promote urban landscapes that reflect Townsville's climate, its natural environment, the existing local character, and any specific vegetation themes of a local area.

(b) Suitability and functional requirements

(i) Plant selection based on the biophysical attributes of the plant, the ideal growing conditions of the species and its appropriateness for the site conditions and the region's dry tropics climate.

(ii) The intended function and location of the plant species should be appropriate to its growing habit, size and other design qualities, in particular ensuring the expected size of the mature specimen can be support in the available planting space.

(iii) The quantity and density of planting proposed should consider the expected mature plant size, the density required to achieve the desired effect, account for expected die out during establishment, and avoid any foreseeable maintenance issues.

(iv) Planting location and/or species selection should not create any foreseeable, adverse impacts on access, circulation or critical sightlines.

(v) Plant habit and location should not have any foreseeable, adverse impact on adjacent properties, built assets, services, roads, drainage or other infrastructure.

(vi) The irrigation, maintenance and other resource inputs necessary to maintain the functionality and longevity of planting design outcomes and species should be sustainable, cost-effective and analogous with the available resources.

(c) Ecological requirements

(i) Plant selection and design should promote the use of local native and non-invasive introduced plant species.

(ii) Additional considerations and specifications applicable to plantings are detailed in sub-section SC6.4.6.26 Landscaping and other requirements of this sub-section.

(3) Retention of remnant vegetation and significant trees

(a) Site planning and landscape design should be used to protect and integrate significant vegetation or trees of the site including, but not limited to:

(i) large, existing mature trees;

(ii) vegetation in intact natural areas;

(iii) trees or vegetation protected by heritage listing;

(iv) trees or vegetation not formally protected by heritage listing but where the size and/or quantity present has a significant character impact;

(v) marine plants including mangroves;

(vi) vegetation in riparian zones or on slopes, especially where the vegetation is performing a stabilisation role; and

(vii) vegetation external to the development site but where activities within the site may impact its long-term sustainability.

(b) Where species/areas are identified as significant, all applicable tree and vegetation protection requirements are to be implemented, as per clause SC6.4.5.2(16) Work adjacent to trees and protection of environmentally significant vegetation.

(c) Additional detail on how the retained species will be protected and integrated into the proposed landscape works may need to be addressed in a vegetation protection plan, the "Landscape Statement of Intent" and included on the associated landscape plans.

Editor's note—refer Section SC6.4.2 Development application guidelines and clause SC6.4.5.2(14) Work adjacent to trees and protection of environmentally significant vegetation.

(4) Ecological buffers

(a) All buffer works to environmentally significant areas should be provided in accordance with Part 8.2.5 Natural assets code and SC6.9 Natural assets planning scheme policy.

(b) All buffers and ecological designs should be prepared in consultation with an appropriate specialist for the local region.

Editor's note—due to the variable nature of ecological design, no further guidelines or specifications are currently developed for the establishment of ecological buffers within open space. Proposals will be considered on a case-by-case basis in accordance with all necessary requirements defined by all applicable ecological, landscape and irrigation standards, legislation, and council's overarching design and management principles. Engagement and approval from other stakeholders/authorities may additionally be required as part of any development proposal of this nature.

(5) Integrated water cycle management and water efficiency

Editor's note—currently, no framework or standard principles for establishing integrated water cycle management and water efficiency objectives are developed specifically for open space. Applicants should refer to other requirements within the planning scheme, this sub-section and other sub-sections of the Development manual planning scheme policy.

SC6.4.3.6.5 Social sustainability

Landscape and irrigation outcomes should demonstrate consideration and application of social sustainability principles, as described within this sub-section, Part 9.3.3 Landscape Code and other areas of the Townsville City Plan.

Alignment with applicable principles should be expressed in the landscape and irrigation design outcomes and addressed in the "Landscape Statement of Intent", as detailed in Section SC6.4.2 Development application guidelines.

(1) General principles

Principles for consideration should include, but are not limited to:

(a) community development principles, such as:

(i) promoting social interaction and inclusion (e.g. well-designed civic spaces that promote social activities and community gatherings);

(ii) design for universal access where possible (e.g. applying universal design principles in the design and construction of recreation facilities to promote inclusion of users of different abilities);

(iii) equitable distribution of open space opportunities and resources (e.g. equitable distribution of different open space facilities throughout the city);

(iv) designing for community diversity (e.g. promoting open space design that responds to the varying needs of the community and creates a diversity of experiences suitable for different cultures and demographics); and

(v) engaging with the community on design proposals (e.g. working with the local community/groups in the design or development of facilities within open space); and

(b) public health and safety principles, such as:

(i) creating opportunities for community health and well-being activities (e.g. provision of outdoor activity elements that promote physical activity for all ages through structured or unstructured recreation);

(ii) applying principles for crime prevention through environmental design (CPTED), refer to SC6.4.3.6.6 Crime prevention through environmental design; and

(iii) complying with all standards and safety requirements to ensure safe open space for the community and maintenance personnel.

(2) Universal access

Unless not practicable or cost prohibitive, open space development, embellishment provision and location must cater for accessibility and mobility requirements in accordance with AS 1428 Design for access and mobility (Set of standards), and as required by Part 9.3.3 Landscape Code. This should include, but is not limited to:

(a) providing an appropriate number of certified accessible items at key activity areas/locations;

(b) providing appropriate surface treatments that enhance safety, mobility and accessibility, whilst also being aesthetically pleasing and promoting sensory stimulation where required;

(c) providing appropriately sized concrete slabs that are designed to facilitate wheelchair and pram access around open space furniture and other infrastructure items;

(d) providing all ancillary infrastructure such as ramps and pathways to ensure access and compliance with applicable standards; and

(e) incorporation of all other universal design principles, as applicable.

SC6.4.3.6.6 Crime prevention through environmental design

Crime Prevention Through Environmental Design (CPTED) provides a common-sense approach to designing environments (new or redevelopment) in ways that help to create safer spaces and reduce crime. CPTED may be applied to any built environment or facility. For example, parks, toilet blocks, public areas, shopping centres, car parks and even residential dwellings. Implementing CPTED principles will not always eliminate crime but it is one of many different techniques that Council employs in a holistic approach to reduce and prevent criminal activity.

The design and landscaping associated with development for, parks, gardens, streetscapes or other public open space areas, shall be considered against the key CPTED elements.

Editor's note—further guidance on implementing CPTED principles can be found in the following locations: Queensland Government, *Crime Prevention through Environmental Design, Guidelines for Queensland, Parts A and B*, 2007 and CPTED Association website.

SC6.4.3.6.7 Private open space

Private open space is considered to be a usable outdoor area within a private development. It may include back and front yards, courtyards, gardens, balconies, terraces, decks, and communal areas in multi-unit developments. These spaces provide important private places for residents and other users to play, entertain, relax or seek respite from urban living.

Landscaping and irrigation within private open spaces assists in creating a shaded and attractive setting that is comfortable and usable, whilst also improving residential amenity and character. The significant environmental benefits of private open space are also recognised, noting the potential positive contribution of the spaces to reducing runoff, increasing biodiversity, heat amelioration and passive cooling.

Private open space does not include fully enclosed spaces, vehicle parking areas and verges. Open space contribution from roof gardens and vertical gardens will assessed on a case-by-case basis and with consideration of other on-site open space and landscaping provision.

Editor's note—further details of design outcomes for private open space are contained with the relevant development codes of the

SC6.4.3.6.8 Streetscapes

Streetscapes refer to the street or road landscape including all public open space within the road reserve. The design and development of streetscapes will vary according to the road or street hierarchy, its associated function, as well as the surrounding land use and built environment.

Editor's note - Applicants should refer to SC6.4.4.1 Geometric road design for more information.

It is noted, however, that there is interdependency between elements within the private realm and the overall streetscape. Critically, elements with the private realm (e.g. residential or commercial frontages) contribute to the appearance and function of a streetscape. It is important, therefore, that any streetscape design proposal is integrated and responsive to the surrounding context.

SC6.4.3.6.9 Public open space

The landscape and character design outcomes associated with the development of public open space are required to demonstrate alignment with the standards set out in this sub-section and addressed in accordance with Section SC6.4.2 Development Application Guidelines.

(1) General

Public open space includes all areas of open space that are publically owned and/or accessible. Public open space includes parks and land that has been reserved for the purpose of sport and recreation, ecological function and natural environment protection, infrastructure corridors and stormwater management and the general provision of green space.

Public open space and the provision of dedicated parks contribute significantly to community well-being, urban place-making and the general amenity and liveability of a city. Parks and other open space typologies also perform dual or multifunctional roles. This includes supporting the provision and buffering of roadways, detention basins and other infrastructure networks such as bikeways, and utility services, particularly within corridor parks.

Public open space excludes open space not publically accessible, not for community use or within the road reserve. However there are some areas that are designated Special Use Parks or Facilities, these parks provide specialised recreation use. This includes where the nature of the recreation activity only allows controlled access and precludes free, unrestricted access to members of the public, or where the land and facility result in a single use activity.

(2) Public Open Space Frameworks

(a) Public Open Space (POS) Hierarchy

The public open space hierarchy refers to the size, form and function of public open space which will vary significantly across different park types and other public open space typologies. As such, public open space networks are usually defined by various open space typologies that are rationalised, planned and designed against a “Public Open Space Hierarchy”.

This approach ensures the distribution, development and management of public open space occurs in a strategic and structured manner that reflects the differing classifications and importance of the each open space typology

Group and individual typologies within the Public Open Space Hierarchy reflect the diversity of functions and uses between different open space typologies within the city. Council’s open space hierarchy has been divided into three functional groups:

(i) recreation parks;

(ii) sports parks; and

(iii) other public open space.

Importantly, it should be recognised that one area of public open space may contain more than open space typology function across the different functional groups.

For example, a park may contain two formalised sports fields (district sporting function), a local recreation node (local park function) and a drainage corridor (utility function). In instances such as this, the public open space may be:

- classified based on the most dominant function (e.g. classified a district sports park, with the presence of a local recreation node recognised but not separately designated), or
- split into different functional areas, where each area is separately recognised and designated.

Classification of public open space against the hierarchy is reached through a strategic audit and evaluation of the open space, its characteristics and the standards of embellishment. Profile, accessibility and usage catchments are also a key determinant in hierarchy classifications, with typologies generally being categorised on a local, district or regional basis.

The POSM classifications subsequently inform council's management, development and all future planning for the public open space and the wider open space network.

To support these classifications, council has developed a Public Open Space Embellishment Framework that defines what level of embellishment and infrastructure is "essential" to different public open space typologies. The purpose of this framework is to support equitable, cost-effective and sustainable development of public open space that is functional and meets the needs of the community.

The Public Open Space (POS) Embellishment Framework is further defined in Table SC6.4.3.6.1 Open space embellishments and the balance of this sub-section.

Editor's note—Open Spaces classified as being of District or Regional significance have been determined as priority trunk infrastructure. (Refer Part 4 Priority infrastructure plan of the Townsville City Plan).

The proposed landscape design and character outcomes associated with the development of public open space are required to demonstrate alignment with the standards set out in this sub-section and address this through landscape design outcomes and in the "Landscape Statement of Intent", as detailed in Section SC6.4.2 Development application guidelines.

(b) Public Open Space Management (POSM) Framework

A key objective of the Public open space management and associated levels of service is to ensure that the level of embellishment is consistent and sustainable with the available resources to maintain them.

Associated with the Public Open Space Hierarchy, council has developed a Public Open Space Management (POSM) Framework that specifies acceptable maintenance levels of service against different open space typologies. This POSM Framework and associated levels of service are also applied against the road hierarchy.

In order for council to properly assess future POSM requirements for each public open space development proposal, council may request the provision of a maintenance plan for maintenance activities not already detailed in the POSM Framework, as detailed in Section SC6.4.2 Development application guidelines. Where requested, this maintenance plan should seek to demonstrate alignment with the adopted POS Embellishment and POSM Frameworks.

Maintenance levels of service under the POSM Framework are defined by the public open space or road hierarchy classification and the frequency of maintenance services required. Associated with this, maintenance activities and frequencies are assigned, based on the public open space or road hierarchy classification and/or embellishments present.

A key objective of both the POS Embellishment and POSM Frameworks is to ensure that the level of embellishment is consistent and sustainable with the available resources to maintain them. As such, infrastructure must not be provided where the necessary maintenance required exceeds the allocated

maintenance level of service in order to ensure the public open space or items remain serviceable and safe for public use (e.g. dynamic fitness equipment that requires weekly safety inspections or electric barbeques that require daily cleaning to remain hygienic should not be installed in a park that has assigned fortnightly maintenance service). Further, the cost to establish, maintain and ultimately renew the infrastructure must be sustainable and cost effective for council and the community in the long-term.

In order for council to properly assess future POSM requirements for each public open space development proposal, council may request the provision of a maintenance plan, as detailed in Section SC6.4.2 Development application guidelines. Where requested, this maintenance plan should seek to demonstrate alignment with the adopted POS Embellishment and POSM Frameworks.

Editor's note—the POSM Framework is currently under review to align the maintenance frequency with the (POS) hierarchy review and further development. As such, detailed specifications relating to maintenance activities and frequency are not available at the present. Enquiries relating to this should be directed to Construction and Maintenance Operations.

(c) Irrigation Profile Level (IPL) Framework

As part of council's commitment to efficient, cost effective and responsible use of natural resources, council has developed an Irrigation Profile Level (IPL) Framework to categorise and define irrigation water usage within public open space.

The IPL Hierarchy identifies and defines a number of "profile levels" based on the level of irrigation applied, an indicative "functional application" based on open space typologies, and the performance indicators associated with each irrigation application rate. Refer to SC6.4.3.6 Attachment C for IPL Hierarchy.

Supporting this, the IPL Matrix identifies a number of criteria and "influences" used in the determination of an assigned IPL. Refer to SC6.4.3.6 Attachment D for the IPL Matrix.

Importantly, it must be recognised that the level of irrigation required is directly dependent upon the landscaping which it must support. As such, in the development of new public open space, the landscaping should be designed with consideration of the typical IPL classification for the public open space typology as well as the extent of landscaping and irrigation defined by the POS embellishment standards. Additional requirements are identified in SC6.4.3.6.34 Irrigation design and system requirements.

For existing public open space, the IPL classification must be based upon the required irrigation application rate necessary to support the health and longevity of the existing landscaping. Where a change to the IPL is proposed, this must include consideration of the open space typology, the intended use of the open space area and the impacts of reduced water application rate on existing plant specimens and include changes to the landscaping plantings where required.

Critically, an area of public open space may have more than one IPL (e.g. "high" IPL level around the activity node or within the minimum usable space, and then a "medium" or "low" profile for the balance of the open space). To achieve this in an efficient and effective manner, however, the associated landscaping and irrigation systems must be purpose-designed for this outcome (i.e. separate irrigation systems consistent with species selection and placement based on principles of hydro-zoning).

SC6.4.3.6.10 Recreation parks

Recreation parks includes the following:

(1) pocket parks: are small open space parklands that offer a limited range of recreational activities for local residents. Pocket parks are generally associated with specific urban design outcomes, e.g. to support small lot housing.

(2) local recreation parks: are moderately small open space parklands that offer local residents a communal open space to complement their own backyards. Local recreation parks are ideally located within 400m walking distance from residential properties and are generally accessed by non-motorised transport. These parks contain only basic infrastructure for recreational use, refer to the embellishment table for details.

(3) district recreation parks: are much bigger than local sized parks that can service several suburbs, or a whole community and or a community event. The parks provide for a variety of passive and active recreation and/or contain facilities to cater for a wider user group of all age and levels of ability. The parks are well known destinations for those people living within their catchment, enabling the park to become a significant social hub.

(4) regional recreation parks: are large open space parklands that offer a wide variety of both active and passive recreation opportunities to a broad section of the community.. The park area is capable of hosting large community events such as festivals, and unique functions. These parks have major embellishments features designed to attract visitation from a wider catchment area and encourage extended stay. It provides unique recreational experiences and is a major landmark and/or destination where people may spend (4+hours) in these parks.

(5) recreation corridors: are usually a linear open space that follows creeks, drainage channels, service corridors or green belts. Corridor parks traditionally have a dual functionality and may include opportunities for cycling, walking and other recreational activities. It can also provide an important ecological link for flora and fauna. Corridor parks are intended to provide a safe connection between two or more destination points.

Editor's note—currently, further definitions and intent statements are not developed for all individual recreation park typologies. Refer Part 4 Local government infrastructure plan of the Townsville City Plan for definitions, distribution and land areas relating to trunk recreation parks.

SC6.4.3.6.11 Sporting parks

Sporting parks includes the following:

(1) district sporting parks: are large sized open space parks that provide facilities that are suitable for the practicing and playing of structured or organised sports. These parks may not have the quality of playing surface or amenities of a regional sports park. The park generally contains a good level of embellishment provision. To service a wider user group the sporting areas are often lit, spectator facilities may include a club house, toilets, change rooms and off- street car parking. These parks may also include a limited range of informal recreation activities to cater for unstructured recreation.

(2) regional sporting parks: are large quality sports parklands that meet state regulations for the sport and can comfortably host either regional (or State competitions). Generally these sports parks cater to a large number of sporting organisation's and spectators who share the site. People may spend (4+hours) in these parks. The playing field may be lit to the required standard for the dedicated sport. Regional Sports parks also have a high level of player and spectator facilities, including clubhouse, canteen, toilets, change rooms, off-road car parking The park may also include a limited range of informal recreation activities for other park users such as playgrounds and BBQ areas.

(3) special use parks or facilities; are specialised recreational use and facility spaces where the nature of the activity precludes free, unrestricted access to members of the public, or where the land and facility result in a single use activity. These park spaces may be controlled by either Council or private organisation's (User Pays). Specialised use parks include (but are not limited to);Water parks/Privately Owned or Leased Swimming Pools, Equestrian, Archery/Bow hunting/Sport Shooting, Golf, Tennis, Lawn bowls, Model Planes and Motor Vehicle Sports.

Editor's note—Refer Part 4 Local government infrastructure plan of the Townsville City Plan for definitions, distribution and land areas relating to trunk sports parks.

SC6.4.3.6.12 Other public open space

Other public open space includes the following:

(1) amenity parks: are small landscaped areas with a strong focus on visual. Traditionally Amenity parks may include monuments, memorials or gateway treatments. The park area may also include opportunities for passive recreation such as seating areas. An example of an Amenity Park is Garbutt Park, Garbutt, which acts as an entrance statement welcoming visitors and residents to Townsville.

(2) civic parks and spaces: are relatively small areas generally associated with a high level of built infrastructure. While recreation use is minimal they provide landscape and amenity values for the general community. Civic parks provide an urban respite for social interaction and community gatherings. Often characterized by hard surface treatments associated with its setting and high activity use levels, these spaces may be used for social events such as community markets.

(3) natural and bushland areas: are set aside primarily for conservation purposes to protect and retain natural vegetation and habitat areas. Size may range from small to large areas that reflect the importance of the environmental value. These parks may also provide opportunities for outdoor recreation activities such as bushwalking, trail running, mountain biking, nature viewing and appreciation. Embellishment improvements are generally limited infrastructure associated with the above activities such as seating, lookouts and signage. Some of the park areas may also include cleared areas intended to be rehabilitated to improve habitat corridors.

(4) utility spaces: are areas that are often owned or maintained by council, for specific utility services such as electrical transmission, telecommunications, water and sewerage pump stations or other infrastructure purposes. These spaces may offer some dual functionality for recreation activities such as walking, cycling or civic amenity.

(5) unallocated open space: may be any reserve area of land and/or water reserve which has not been named or developed at present, but which has been deemed important enough to be set aside for future park development. The park area is usually substantially undeveloped with no built infrastructure and only minor improvements such as rural fencing.

(6) cemeteries: are an area under the control of council that is dedicated for the burial of the dead, or containing graves, tombs, funeral urns and interment of ashes.

Editor's note—currently definitions and intent statements are not developed for individual typologies within other public open space hierarchy categories.

SC6.4.3.6.13 Open space embellishments

(1) General requirements

A key objective of the POS Embellishment and POSM Framework is to ensure that the level of embellishment is consistent and sustainable.

As such, infrastructure must not be provided where the necessary maintenance required exceeds the allocated maintenance level of service. This is to ensure that the public open space or items remain serviceable and safe for public use (e.g. dynamic fitness equipment that requires weekly safety inspections or electric barbeques that require daily cleaning to remain hygienic should not be installed in a park that has assigned fortnightly maintenance service intervention). Further, the cost to establish, maintain and ultimately renew the infrastructure must be sustainable and cost effective for council and the community in the long-term.

(a) Open space embellishment levels should be consistent with the assigned public open space typology (refer Table SC6.4.3.6.1 public open space embellishment framework) and / or road hierarchy classification or the characteristics of the associated land use.

(b) Where private open space is associated with development, the private open space shall be considered on a case-by-case basis with consideration of the design points set out below.

(c) The quantity and amount of the embellishment level will be dependent on the available area of open space and the spatial requirements of the selected embellishment facility.

(d) The following key characteristics should be considered in the design process when selecting the level of embellishment:

(i) comply with any adopted master plan, environmental, heritage and character requirements;

(ii) consider the context, functionality and purpose for use (e.g. particular open space usage patterns for the site such as regular use for community events, or shared usage by multiple tenants in a large residential complex);

(iii) consider the setting, durability and aesthetic requirements for the intended area (e.g. specific materiality requirements for areas with a risk of vandalism, or more ornate detailing for intimate private courtyard space);

(iv) cater for the expected usage rates, demographic/s and their associated needs (e.g. reduced intervals between accessible bench seats along a pathway at a location with large senior user group);

(v) be located at appropriate locations or intervals, clustered near activity nodes and/or to

complement any distinguishing site features (e.g. seating situated to maximise a vista or allow surveillance of a play area by carers);

(vi) be climatically appropriate and consider localised conditions of the site (e.g. dynamic activity elements in coastal areas are not located in areas exposed to high onshore winds and salt spray);

(vii) ideally be located under natural or built shade to allow day long use through reduced exposure, glare and heat absorption, particularly on metal or dark coloured surfaces (e.g. metal playground slides to be shaded and/or swapped for plastic slides, or, communal gathering areas located under shelters in private unit complex);

(viii) complement natural materials or features and/or incorporate these where possible (e.g. grass mounding for seating; feature rock retaining walls consistent with local geology);

(ix) be vandal resistant;

(x) be installed on an appropriate surface material, on well drained ground and with an appropriate level of flood immunity (e.g. playgrounds not installed in an area surrounded by a retention basin); and

(xi) prioritise use of recycled, sustainable materials where practicable and available (e.g. decking to be constructed of recycled plastic and composite fibre supports).

(2) Public open space and streetscape embellishment standards

(a) Within public open space, embellishment selection must be in accordance with council's Public Open Space Embellishment Standards Framework, as detailed in Table SC6.4.3.6.1.

(b) For streetscapes, landscape treatments shall be provided per SC6.4.3.6.31 Streetscape design and landscape treatments.

(c) For public open space and streetscapes, embellishment standards must:

(i) be analogous to the Public Open Space Hierarchy, road hierarchy, or centre classification;

(ii) be consistent with any overarching design and embellishment strategy (e.g. adopted furniture suite against Public Open Space/Road Hierarchy);

Editor's note—other than landscape treatments as noted above, currently, detailed standards and specifications are not developed for other infrastructure items (e.g. shelters and seating) within streetscapes. Applications will therefore be assessed on a case-by-case basis and with consideration of the principles and standards outlined in this sub-section, and other sections of the Townsville City Plan. Refer to SC6.4.3.3 Footpath treatment policy and SC6.4.3.4 Outdoor dining design guidelines for requirements specific to these elements of a streetscape.

(iii) complement those facilities in nearby precincts or parks, ideally providing diversity in the facilities available to the community;

(iv) be consistent with any an existing style that is already established unless approved otherwise;

(v) only include high quality, fit for purpose, proprietary items for which replacement parts are readily available from an Australian distributor;

(vi) for district and regional level parks, custom suites or items may be permitted at particular sites, where the profile and location of the park warrants it. The decision will be made on a case by case basis at the discretion of council with consideration of the individual site characteristics and public open space classification

Editor's note—this decision will be made on a case-by-case basis, at the discretion of council and with consideration of the individual site characteristics and public open space classification

(vii) minimise the use of timber elements unless approved otherwise. Where timber is permitted for use, only hardwood timber or painted pine should be used and all furniture items should ideally be undercover, protected from direct exposure to the sunlight and other elements;

(viii) utilise high quality finishes that will reduced ongoing maintenance requirements and/or frequency (e.g. 2PAC epoxy paint in lieu of powder coating where items are not easily dissembled or repainted); and

(ix) for all foreshore locations and other locations subject to salt spray or prolonged wet conditions, embellishments must be constructed of marine grade materials, including 316L stainless steel fittings, to ensure improved asset longevity and lifecycle cost reduction.

Editor's note—the above are provide as guidelines to be considered in the course of public open space and streetscape development. Additional areas within this sub-section provide specifications for individual open space infrastructure types and for landscape treatments in streetscapes.

SC6.4.3.6.1 Public Open Space Embellishment Framework

		RECREATION PARKS					SPORTS PARKS			OTHER PUBLIC OPEN SPACE				
		POCKET	LOCAL	DISTRICT	REGIONAL	CORRIDOR	DISTRICT	REGIONAL	SPECIALISED	AMENITY	CIVIC SPACES	NATURAL /BUSHLAND	UTILITY	UNALLOCATED
CATEGORY	EMBELLISHMENT TYPE													
Activity elements	**Outdoor fitness equipment**			**Expected** (Max 6 Pieces)	**Expected** (Min 6 Pieces)	**Desirable** (Max 6 Pieces)			Embellishment standards not defined due to custom nature of specific sport activity and facility requirements - to be assessed on a case by case basis					
	Informal sports/courts (e.g. basketball half court; table tennis table)		**Desirable** (Max 1 informal sport facility)	**Expected** (Max 2 informal sports facilities)	**Expected** (Max 2 informal sports facilities)		**Desirable** (Max 2 informal sport facility)							
	Playground (all abilities)				**Desirable** (Max 1 play facility)									
	Playground (mixed ages)	**Desirable** (Max 1 Combination unit)	**Expected** (Max 1- 3 Pieces)	**Expected** (Min 3-5 Pieces)	**Expected** (Min 6-10 Pieces suitable for the catchment)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)								
	Skate facilities			**Desirable** (Max 1500 sqm, Suitable to meet the catchment zone, approved on a case by case basis	**Desirable** (Min 3000 sqm, Suitable to meet the catchment zone, approved on a case by case basis									
	Water-play				**Desirable** (Appropriate facility suitable to meet the needs of the catchment zone, approved on a case by case basis)									
Electrical	**3 phase power (events usage)**			**Desirable** (Max 1 unit)	**Expected** (Min 2 Units)		**Expected** (Max 1 Unit)	**Expected** (Min 2 Unit)			**Expected** (Min 1 Unit)			

	Activity node lighting		**Expected** (Max 1 Lighting node as required for the activity)	**Expected** (Min 2 Lighting nodes as required for the selected activity areas)	**Expected** (Multiple lighting nodes as required for selected activity areas)	**Desirable** (Min Lighting nodes as required for CEPTED along pathway links)	**Expected** (Min 2 Lighting nodes as required for the selected activity areas)	**Expected** (Multiple lighting nodes as required for selected activity areas)			**Expected** (Multiple lighting nodes as required for selected activity areas)				
	Pathway lighting (ex. designated bikeways/shared pathways)			**Desirable** (Multiple lighting nodes as per ASNZ 1158.3.14_2005 - Lighting for roads and public spaces)	**Expected** (Multiple lighting nodes as per ASNZ 1158.3.14_2005 - Lighting for roads and public spaces)	**Desirable** (Multiple lighting nodes as per ASNZ 1158.3.14_2005 - Lighting for roads and public spaces)	**Desirable** (Multiple lighting nodes as per ASNZ 1158.3.14_2005 - Lighting for roads and public spaces)	**Expected** (Multiple lighting nodes as per ASNZ 1158.3.14_2005 - Lighting for roads and public spaces)		**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Expected** (Multiple lighting nodes as per ASNZ 1158.3.14_2005 - Lighting for roads and public spaces)			
	Sports field/court lighting						**Expected** (Multiple lighting nodes as per AS2560 Sporting Facilities Manual - Part 1 Sports Lighting)	**Expected** (Multiple lighting nodes as per AS2560 Sporting Facilities Manual - Part 1 Sports Lighting)							
Fencing	**Fencing (inc. bollards; post and rail; panels)**	**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)		**Expected** (To adequately deter unauthorised vehicles from entering the Park Space)	**Essential** (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** Min RURAL FENCING TYPE (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** Min RURAL FENCING TYPE (To adequately deter unauthorised vehicles from entering the Park Space)	**Expected** Min RURAL FENCING TYPE (To adequately deter unauthorised vehicles from entering the Park Space)
	Maintenance access gate	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)		**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)	**Expected** (To provide adequate access for Maintenance requirements)
Furniture	**Bench seats**	**Desirable** (Max 1 Park bench seat)	**Expected** (Max 2 Park bench seat)	**Expected** (Min 4 Park bench seat)	**Expected** (Min 8 Park bench seat)	**Expected** (Min 2 park bench seats, or number as required spaced at approx. 400m intervals along pathway links)	**Expected** (Min 4 Park bench seat)	**Expected** (Min 8 Park bench seat)		**Expected** (Max 2 Park bench seat)	**Expected** (Min 8 Park bench seat)	**Expected** (Min 2 park bench seats, or number as required spaced at approx. 400m intervals along pathway links)		

	Barbeques (electric)			**Expected** (Max 2 Double Plate BBQ Units)	**Expected** (Min 4 Double Plate BBQ Units)									
	Bins	**Desirable** (Max 1 Bin unit)	**Expected** (Max 1 Bin unit)	**Expected** (Min 2 Bin units)	**Expected** (Min 4 Bins, or adequate number of Bins to meet anticipated demand - Including recycling bins)	**Desirable** (Min 2bins, or number as required spaced at approx. 800m intervals along pathway links)	**Expected** (Min 2 Bin units)	**Expected** (Min 4 Bins, or adequate number of Bins to meet anticipated demand - Including recycling bins)		**Desirable** (Max 1 Bin unit)	**Expected** (Min 2 Bins, or adequate number of Bins to meet anticipated demand - Including recycling bins)			
	End of trip facilities (e.g. bicycle racks)			**Expected** (Min 1 bike rack unit)	**Expected** (Max 2 bike rack units)		**Expected** (Min 1 bike rack unit)	**Expected** (Max 2 bike rack units)			**Expected** (Min 1 bike rack unit)			
	Picnic tables and seats	**Desirable** (Max 1 Picnic Table Set)	**Desirable** (Min 2 Picnic Table Sets)	**Expected** (Min 4 Picnic Table sets)	**Expected** (Min 6 Picnic Table sets, or number to meet anticipated demand)	**Desirable** (Min 2 picnic table sets, or number as required spaced at approx. 800m intervals along pathway links)	**Expected** (Min 2 Picnic Table sets)	**Expected** (Min 6 Picnic Table sets, or number to meet anticipated demand)		**Desirable** (Max 1 Picnic Table Set)	**Expected** (Min 6 Picnic Table sets, or number to meet anticipated demand)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)		
	Water bubbler/tap (inc. connection; drainage inlet; soakage well)	**Desirable** (Max 1 Drinking Fountain - must be disability compliant and include dog drinking outlet as well)	**Expected** (Max 1 Drinking Fountain - must be disability compliant and include dog drinking outlet as well)	**Expected** (Max 2 Drinking Fountain - must be disability compliant and include dog drinking outlet as well)	**Expected** (Min 2 Drinking Fountain - must be disability compliant and include dog drinking outlet as well)	**Desirable** (Max 1 Drinking Fountain along pathway link- must be disability compliant and include dog drinking outlet as well)	**Expected** (Max 2 Drinking Fountain - must be disability compliant and include dog drinking outlet as well)	**Expected** (Min 2 Drinking Fountain - must be disability compliant and include dog drinking outlet as well)			**Expected** (Min 2 Drinking Fountain - must be disability compliant and include dog drinking outlet as well)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)		
Irrigation	**Irrigation**	**Desirable** (May have natural areas that are not irrigated, provide adequate irrigation to cover key activity high use areas. To be considered on a case by case basis)	**Desirable** (May have natural areas that are not irrigated, provide adequate irrigation to cover key activity high use areas. To be considered on a case by case basis)	**Expected** (May have natural areas that are not irrigated, provide adequate irrigation to cover key activity high use areas. To be considered on a case by case basis)	**Expected** (May have natural areas that are not irrigated. Provision of required irrigation to ensure all key activity high use areas are covered. To be considered on a case by case basis)	**Desirable** (May have natural areas that are not irrigated, provide adequate irrigation to cover key activity high use areas. To be considered on a case by case basis)	**Expected** (Provision of appropriate irrigation to be considered on a case by case basis, to ensure adequate coverage of key sporting and high activity use areas. designated playing fields to be irrigated at 100 % of field coverage)	**Expected** (Provision of required irrigation to be considered on a case by case basis, to ensure adequate coverage of key sporting and high activity use areas. designated playing fields to be irrigated at 100 % of field coverage)		**Desirable** (Provide adequate irrigation to cover key activity high use areas. To be considered on a case by case basis)	**Expected** (May have natural areas that are not irrigated. Provision of required irrigation to ensure all key activity high use areas are covered. To be considered on a case by case basis)			

Landscaping and surfacing	**Earthworks (e.g. grassed mounds)**	**Desirable** (Min 1 Mound, suitable mounding for play space relief and considered on a case by case basis)	**Desirable** (Min 1 Mound, suitable mounding for play space relief and considered on a case by case basis)	**Desirable** (Min 1 Mound, suitable mounding for play space relief and considered on a case by case basis)	**Desirable** (Min 2 Mound, suitable mounding for play space relief and considered on a case by case basis)		**Expected** (Min 2 Mounds, suitable mounding for Spectator viewing and considered on a case by case basis)	**Expected** (Min 2 Mounds, suitable mounding for Spectator viewing and considered on a case by case basis)			**Desirable** (Min 2 Mound, suitable mounding for play space relief and considered on a case by case basis)			
	Garden beds (excluding natural vegetation areas)	**Desirable** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)	**Desirable** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)	**Expected** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)	**Expected** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)	**Desirable** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)	**Desirable** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)	**Expected** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)		**Desirable** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)	**Expected** (Min 5% gardens cover. Extent and levels will be dependent on the park typology and considered on a case by case basis)			
	Shade trees	**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 35% coverage. With the shade coverage focused around park activity nodes)	**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 35% coverage. With the shade coverage focused around park activity nodes)	**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 35% coverage. With the shade coverage focused around park activity nodes, where this cannot be achieved supplementary man-made shade cover must be considered)	**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 35% coverage. With the shade coverage focused around park activity nodes, where this cannot be achieved supplementary man-made shade cover must be considered)	**Expected** (The desirable natural shade coverage outcome for corridor parks shall be min 35% coverage along pathway linkage alignments)	**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 20% coverage. With the shade coverage focused around park activity nodes, where this cannot be achieved supplementary man-made shade cover must be considered)	**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 20% coverage. With the shade coverage focused around park activity nodes, where this cannot be achieved supplementary man-made shade cover must be considered)		**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 35% coverage. With the shade coverage focused around park activity nodes, where this cannot be achieved supplementary man-made shade cover must be considered)	**Expected** (The desirable natural shade coverage outcome for recreational parks shall be min 35% coverage. With the shade coverage focused around park activity nodes, where this cannot be achieved supplementary man-made shade cover must be considered)	**Desirable** (The desirable natural shade coverage will consist of the predominant existing natural vegetation cover)	**Desirable** (Shade Trees should not impact on operation of services or facility structure)	

	Turf areas (Inc. events/activity lawns)	**Desirable** (The desirable turf coverage outcome shall be min 60% coverage of park area, with adequate turf coverage to meet the intended usage and anticipated demand	**Expected** (The desirable turf coverage outcome shall be min 60% coverage of park area, with adequate turf coverage to meet the intended usage and anticipated demand	**Expected** (The desirable turf coverage outcome shall be min 60% coverage of park area, with adequate turf coverage to meet the intended usage and anticipated demand	**Expected** (The desirable turf coverage outcome shall be min 60% coverage of park area, with adequate turf coverage to meet the intended usage and anticipated demand	**Expected** (The desirable turf coverage outcome shall be min 60% coverage of park area, with adequate turf coverage to meet the intended usage and anticipated demand	**Expected** (The desirable turf coverage outcome shall be min 70% coverage of park area, including a 100% cover of the playing fields. The turf coverage shall be adequate to meet the intended usage and anticipated demand	**Expected** (The desirable turf coverage outcome shall be min 70% coverage of park area, including a 100% cover of the playing fields. The turf coverage shall be adequate to meet the intended usage and anticipated demand		**Desirable** (The desirable turf coverage outcome shall be min 60% coverage of park area, with adequate turf coverage to meet the intended usage and anticipated demand	**Expected** (The desirable turf coverage outcome shall be min 60% coverage of park area, with adequate turf coverage to meet the intended usage and anticipated demand			
Signage	**Park name sign**	**Expected** (1 Park Name Sign near the predominant park entry access)	**Expected** (1 Park Name Sign near the predominant park entry access)	**Expected** (1 Park Name Sign near the predominant park entry access, for larger parks with multiple entry access entry points - additional park name signs shall be considered on a case by case basis)	**Expected** (1 Park Name Sign near the predominant park entry access, for larger parks with multiple entry access entry points - additional park name signs shall be considered on a case by case basis)	**Expected** (1 Park Name Sign near the predominant park entry access, for larger parks with multiple entry access entry points - additional park name signs shall be considered on a case by case basis)	**Expected** (1 Park Name Sign near the predominant park entry access, for larger parks with multiple entry access entry points - additional park name signs shall be considered on a case by case basis)	**Expected** (1 Park Name Sign near the predominant park entry access, for larger parks with multiple entry access entry points - additional park name signs shall be considered on a case by case basis)		**Expected** (1 Park Name Sign near the predominant park entry access)	**Expected** (1 Park Name Sign near the predominant park entry access, for larger parks with multiple entry access entry points - additional park name signs shall be considered on a case by case basis)	**Expected** (1 Park Name Sign near the predominant park entry access)		
	Information signage (inc. regulatory, directional and interpretive signage)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Expected** (Fit for Purpose, as required - will be considered on a case by case basis)	**Expected** (Fit for Purpose, as required - will be considered on a case by case basis)	**Expected** (Fit for Purpose, as required - will be considered on a case by case basis)	**Expected** (Fit for Purpose, as required - will be considered on a case by case basis)	**Expected** (Fit for Purpose, as required - will be considered on a case by case basis)		**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Expected** (Fit for Purpose, as required - will be considered on a case by case basis)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)
Sporting	**Indoor sport and recreation facility**						**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)						
	Outdoor spectator facilities						**Expected** (Min 20 Spectator Seat Capacity)	**Expected** (Min 100 Spectator Seat Capacity)						

	Motorised sports facilities						**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)	**Desirable** (Fit for Purpose, as required - will be considered on a case by case basis)							
	Sports courts/fields (formal)						**Expected** (Min number of formal courts or fields required to undertake the sport, will be considered on a case by case Basis)	**Expected** (Min number of formal courts or fields required to undertake the sport, will be considered on a case by case Basis)							
Structures and buildings	**Picnic shelters/gazebos**		**Desirable** (Max 1 Picnic Shelter or gazebo)	**Desirable** (Max 2 Picnic Shelter or gazebo)	**Expected** (Min 2 Picnic Shelter or gazebo, or adequate number to meet anticipated demand)	**Desirable** (Max 1 Picnic Shelter or gazebo, generally kept to a minimum)	**Desirable** (Max 2 Picnic Shelter or gazebo)	**Expected** (Min 2 Picnic Shelter or gazebo, or adequate number to meet anticipated demand)		**Desirable** (Max 1 Picnic Shelter or gazebo, generally kept to a minimum)	**Expected** (Min 2 Picnic Shelter or gazebo, or adequate number to meet anticipated demand)				
	Clubhouse/change rooms/canteens						**Desirable** (Adequate developable land of a min 200 sq m. for approved clubs to develop their relevant facility requirements for their respective club)	**Desirable** (Adequate developable land of a min 200 sq m. for approved clubs to develop their relevant facility requirements for their respective club)							

	Community buildings			**Desirable** (Within the available park space adequate total developable land to a max 200 sq m. (includes space for toilets etc.) to develop relevant facility requirements for the park space)	**Desirable** (Within the available park space adequate total developable land to a max 400 sq m. (includes space for toilets etc.) to develop relevant facility requirements for the park space)		**Desirable** (within the available park space an allowance for total developable land to a maximum 400 sq m. (includes clubhouse/change room 200 sq m) of a minimum 200 sq m. for approved clubs to develop their relevant facility requirements for their respective club)	**Desirable** (within the available park space an allowance for total developable land to a maximum 800 sq m. (includes clubhouse/change room 400 sq m) of a minimum 400 sq m. for approved clubs to develop their relevant facility requirements for their respective club)			**Desirable** (Within the available park space adequate total developable land to a max 400 sq m. (includes space for toilets etc.) to develop relevant facility requirements for the park space)			
	Commercial facilities				**Desirable** (must fit within available Park space and not at the expense of available public open space, to be considered on a case by case basis)			**Desirable** (must fit within available Park space and not at the expense of available public open space, to be considered on a case by case basis)			**Desirable** (must fit within available Park space and not at the expense of available public open space, to be considered on a case by case basis)			
	Shade sails		**Desirable** (Shall only be considered for use where there is not enough natural shade cover over prescribed park facilities, particularly playgrounds)	**Desirable** (Shall only be considered for use where there is not enough natural shade cover over prescribed park facilities, particularly playgrounds)	**Expected** (Shall only be considered for use where there is not enough natural shade cover over prescribed park facilities, particularly playgrounds)		**Desirable** (Shall only be considered for use where there is not enough natural shade cover over prescribed park facilities, particularly playgrounds)	**Expected** (Shall only be considered for use where there is not enough natural shade cover over prescribed park facilities, particularly playgrounds)			**Desirable** (Shall only be considered for use where there is not enough natural shade cover over prescribed park facilities, particularly playgrounds)			

	Toilet block			**Desirable** (Max 1 toilet facility, to be considered on a case by case basis)	**Expected** (Max 2 toilet facility, to be considered on a case by case basis)		**Desirable** (Max 1 toilet facility, to be considered on a case by case basis)	**Expected** (Max 2 toilet facility, to be considered on a case by case basis)			**Expected** (Max 2 toilet facility, to be considered on a case by case basis)			
Transport and access infrastructure	**Car parking (off-street)**			**Expected** (Minimum 20 car parking bays, , or adequate number of car parking spaces to meet anticipated demand shall be considered on case by case basis)	**Expected** (Minimum 30 car parking bays, or adequate number of car parking spaces to meet anticipated demand shall be considered on case by case basis)		**Expected** (Minimum of 125 car parking bays – total on and off street. Minimum of 50% to be off-street parking bays. Parking may be angled or at 90 degree, including allowance for additional space for bus parking, turnaround and pull out zone)	**Expected** (Minimum of 300 car parking bays – total on and off street. Minimum of 50% to be off-street parking bays. Parking may be angled or at 90 degree, including allowance for additional space for bus parking, turnaround and pull out zone)			**Desirable** (Minimum 20 car parking bays. May be angled or 90 degrees, or adequate number of car parking spaces to meet anticipated demand shall be considered on case by case basis)			
	Car parking (on-street)	**Expected** (Minimum 5 car parking bays, kerbside external only. May be parallel or indented at 90 degrees)	**Expected** (Minimum 15 car parking bays, kerbside external only. May be parallel or indented at 90 degrees)	**Expected** (Minimum 20 car parking bays kerbside external only. May be parallel or indented at 90 degrees)	**Expected** (Minimum 50 car parking bays. May be parallel or indented at 90 degrees - including allowance for additional space for bus stop parking and pull out zones.)	**Expected** (Minimum 10 car parking bays, kerbside external only. May be parallel or indented at 90 degrees)	**Expected** (Maximum 75 parking bays. May be parallel or indented at 90 degrees - including allowance for additional space for bus stop parking and pull out zones.)	**Expected** (Maximum 150 parking bays. May be parallel or indented at 90 degrees - including allowance for additional space for bus stop parking and pull out zones.)		**Desirable** (Minimum 15 car parking bays, kerbside external only. May be parallel or indented at 90 degrees)	**Expected** (Minimum 20 car parking bays. May be angled or indented at 90 degree, or adequate number of car parking spaces to meet anticipated demand shall be considered on case by case basis. Including space for bus pull out zone where required)	**Desirable** (Minimum 5 car parking bays, kerbside external only. May be parallel or indented at 90 degrees)		

	Drainage and service connections	**Desirable** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Expected** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Expected** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Expected** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Expected** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)		**Desirable** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Expected** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (As required shall be considered on a case by case basis where there is a demonstrated need for such a facility)	
	Internal concrete pathways (min. 1.5m wide)	**Desirable** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)	**Desirable** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)	**Expected** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)	**Expected** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)	**Desirable** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)	**Expected** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)	**Expected** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)		**Desirable** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)	**Expected** (Min length Pathways should provide connection from the park entrance access point to the key park activity elements)			
	Internal roads/vehicle access pathways			**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Expected** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Expected** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)			**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	
	Walking tracks (dirt)				**Desirable** (Will only be considered on a case by case basis, where a demonstrated need for the facility has been identified)							**Desirable** (Will only be considered on a case by case basis, where a demonstrated need for the facility has been identified)		

	Dog off leash park (fenced)			**Desirable** (Shall only be developed in accordance with Councils adopted Dog off-leash strategy. (Refer to SC6.4.3.6.24 Dog Off-leash facilities).	**Desirable** (Shall only be developed in accordance with Councils adopted Dog off-leash strategy. (Refer to SC6.4.3.6.24 Dog Off-leash facilities).	**Desirable** (Shall only be developed in accordance with Councils adopted Dog off-leash strategy. (Refer to SC6.4.3.6.24 Dog Off-leash facilities).								
	Fishing platform/pontoons/ boat ramps and Jetty's			**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)								
Other Infrastructure	**Lookout platforms**			**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)	**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)							**Desirable** (Shall be considered on a case by case basis where there is a demonstrated need for such a facility)		
	Public art			**Desirable** (Will only be considered on a case by case basis, in accordance with the Public Art - policy and strategies)	**Expected** (Will only be considered on a case by case basis, in accordance with the Public Art - policy and strategies)			**Desirable** (Will only be considered on a case by case basis, in accordance with the Public Art - policy and strategies)		**Desirable** (Will only be considered on a case by case basis, in accordance with the Public Art - policy and strategies)	**Expected** (Will only be considered on a case by case basis, in accordance with the Public Art - policy and strategies)			
	Swimming pools						**Desirable** (Will only be considered on a case by case basis, where a demonstrated need for the service has been identified)	**Desirable** (Will only be considered on a case by case basis, where a demonstrated need for the service has been identified)						

	Water features				**Desirable** (To be kept to a minimum and considered on a case by case basis)						**Desirable** (To be kept to a minimum and considered on a case by case basis)			

Expected infrastructure – critical to the intended function of the open space classification.

Desirable infrastructure – not considered essential but may compliment the function of the park space and is dependent on location, need and adjacency to other infrastructure/services.

Indoor and aquatic sports facilities are not included in the Public Open Space Hierarchy, largely due to the enclosed, custom nature and high level of built form.

Editor's note—Table SC6.4.3.6.1 indicates items that are considered "essential" to the function of each open space typology and therefore should be provided with the development of that type of public open space. Importantly, the embellishment standard set for each typology is considered an "average" standard and therefore variation between locations with the same hierarchy classification may occur. However, whilst some locations may include less or additional infrastructure items, the overall level of embellishment cannot exceed the "average" to the point where the location would be delivering a standard equivalent to another typology. (e.g. a local park embellished to the standard of an district park). Items considered "desirable" and/or "conditional" are to be considered on a case-by-case basis, and provided as required, dependent on location, need, affordability and adjacency to other infrastructure/services. Where there is a co-location of open space typologies with the one open space area, embellishment infrastructure can be "shared" between the two functional areas.

SC6.4.3.6.14 Activity elements

(1) General requirements

(a) Activity elements may include, but are not limited to the following:

(i) outdoor fitness equipment;

(ii) play spaces and play equipment;

(iii) softfall surfacing;

(iv) skate and parkour elements and facilities; and

(v) informal sporting facilities.

(b) All activity elements must be of a high standard, being designed, constructed and installed in accordance with:

(i) the provisions within the planning scheme, planning scheme policies and this sub section of the Development manual planning scheme policy;

(ii) manufacturer specifications;

(iii) all applicable Australian Standards and legislation;

(iv) all applicable council local laws; and

(v) council's approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for activity elements.

(2) Outdoor fitness equipment

(a) Outdoor fitness equipment may include a combination of:

(i) static fitness equipment such as step ups, hurdles and sit up benches; and

(ii) dynamic fitness equipment such as bench presses, leg presses and pull downs.

(b) Within public open space, outdoor fitness equipment shall only be provided at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1.

Editor's note—currently no further guidelines and standards are developed for the provision of outdoor fitness equipment across the public open space network. Inclusion of fitness equipment within public open space will be considered on a case-by-case basis and with consideration of the Public Open Space Hierarchy and Embellishment Frameworks. Where council develops and adopts a strategic plan for the provision of outdoor fitness equipment, all development proposals will be assessed against the provisions within that plan.

(c) Fitness equipment selection

(i) All fitness equipment shall be designed, manufactured, installed, certified and maintained in accordance with all applicable Australian Standards, including:

(A) AS4685 – *Playground equipment – General safety requirements and test methods*;

(B) AS2555 – *Supervised adventure playground – Guide to establishment and administration*;

(C) AS4422 – *Playground Surfacing – Specification, requirements and test methods*; and

(D) AS4486.1 – *Playgrounds and playground equipment – Development, installation, inspection,*

maintenance and operation.

(ii) Equipment selection should take into account the existing demographics and cater for multiple age groups, subject to the population profile within the local area. Projected changes to the local demographic and/or aging of the original groups that will utilise the equipment should also be considered.

(iii) A diversity of exercise activities should be developed within the site.

(iv) Future inspection and maintenance requirements of the fitness equipment must be considered and the more onerous, dynamic equipment must be limited to district or regional level public open spaces only.

(v) Longevity of materials must be considered, particularly within the context of the local conditions (e.g. only include equipment of a high quality design and materials, particularly for moving parts and where intense usage is anticipated).

(d) Fitness equipment siting

(i) Fitness equipment should be located away from play spaces to reduce the temptation for children to play on the equipment.

(ii) Ideally, the equipment should be located along or in close proximity to a primary access path, with the fitness units to be offset from this for the comfort of users.

(iii) Individual units may be clustered together or spaced separately in a circuit along a pathway, dependent on the equipment, design and usage intent.

(iv) All fitness equipment is to have concrete slabs, all required shock pads, and wet-pour rubber surfacing in accordance with AS/NZS 4422 *Playground Surfacing – Specifications, requirements and test method*.

(3) Play spaces and play equipment

(a) Play spaces are to be provided in order to:

(i) provide a wide range of quality play opportunities that meet the needs of the local children and young people alike;

(ii) aid children's development by providing spaces and elements for physical coordination activities such as balancing, climbing, jumping, crawling and running;

(iii) assist in the development of social skills such as sharing and cooperation;

(iv) promote children's use of their imagination and development of problem solving skills; and

(v) provide a place for meeting and socialising amongst children, parents and other care givers.

(b) Play spaces shall include a combination of:

(i) active, equipment based play structures (e.g. swings);

(ii) active, non-structured play areas (e.g. kick-around areas or grass mounding);

(iii) imaginative and creative play areas (e.g. trees or natural "cubby" areas);

(iv) a parent or care-givers area (e.g. picnic settings or bench seats); and

(v) special features that cater for children and young people of all abilities (at select locations only).

(c) Within public open space, play spaces and play equipment shall only be provided at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1.

(d) Playground equipment selection

(i) All playground equipment shall designed, manufactured, installed, certified and maintained in accordance with all applicable Australian Standards, including:

(A) AS 4685 – *Playground equipment – General safety requirements and test methods, including AS 4685 parts 1- 6 and part 11*;

(B) AS 4486 – *Playgrounds and playground equipment – Development, installation, inspection, maintenance and operation*; and

(C) AS/NZS 4422 – *Playground surfacing –Specifications, requirements, and test method*.

(ii) Equipment selection should take into account the existing demographics and cater for multiple age groups, subject to the population profile within the local area and the likely park users. Projected changes to the local demographic and/or aging of the original groups that will utilise the equipment should also be considered.

(iii) Diversity of play experiences between sites within the local area should be provided where possible.

(iv) Future inspection and maintenance requirements of the play facilities must be considered and elaborate, more complicated equipment limited to locations with a higher maintenance level of service.

(v) Longevity of materials must be considered, particularly within the context of the local conditions (e.g. plastic coated chains are to be avoided due to accelerated deterioration in North Queensland sun).

(vi) Equipment selection and orientation should take into account the potential for vandalism. As such, equipment with significant amounts of hard, non-transparent panels should be avoided, except where this can be mediated through orientation and casual surveillance opportunities.

(e) Playground equipment siting

(i) Active and passive play areas should be integrated but physically separated to promote more cohesive use of the space and facilitate quiet areas for creative and imaginative play activities.

(ii) Play spaces, particularly toddler areas, should be sited within close proximity to the main activity node to maximise accessibility and casual surveillance from parents, carers and adjacent users.

(iii) Play spaces should ideally be located within close proximity to the main access path. Care should be taken, however, to not create a point of conflict by locating a busy activity area on a main thoroughfare of the open space, as per below.

(iv) Play spaces should be located away from potential safety hazards such as car parks or trafficable areas, watercourses or steep slopes.

(v) Play spaces should be located away from adjacent properties to limit potential nuisance from ongoing noise. A minimum buffer of 15 m from adjacent property boundaries should be applied.

(vi) Sun safety and protection opportunities including natural and built shade options should be addressed in accordance with SC6.4.3.6.19 Shelters and shading devices. Shading opportunities should consider sun orientation and ensure that shading of the equipment is maximised during the highest UV risk period of the day and over the highest need elements (e.g. metal slides).

(vii) Natural elements such as turf mounding, trees, shrubs and rocks should be safely integrated into the play space where possible.

(viii) Fencing of the play space is to be considered on a case-by-case basis and established as required, in accordance with SC6.4.3.6.16 Fencing.

(ix) At larger playgrounds of a district or regional level, consideration should be given to the location of public toilets within short walking distance of the play space.

Editor's note—public toilets should be installed at select locations only. Refer SC6.4.3.6.21(2) Public toilets for further details.

(x) Large, purpose built, "all-abilities" play areas are to be considered on a case by case basis and established as required.

(f) All playground equipment must be installed in accordance with the manufacturer's specifications. Certification of the equipment must also be provided.

(4) Softfall surfacing

(a) Softfall surfacing shall be provided in order to:

(i) create a safe, impact absorbing surface underneath activity elements; and

(ii) provide textual stimulation through different surfacing types (e.g. sand and rubber softfall).

(b) Softfall surfacing may include a combination of:

(i) wet-pour rubber softfall or approved rubber alternatives, including shock pads beneath;

(ii) astro turf, including shock pads beneath; and

(iii) certified softfall sand.

(c) Softfall surfacing shall be installed under all play spaces/equipment where a fall zone has been identified. Within public open space, the provision of equipment, and therefore softfall surfacing shall be at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1.

(d) Organic softfall surfacing such as woodchips is not considered an acceptable softfall outcome.

(e) Rubber softfall surfacing

(i) Rubber softfall must be installed in accordance with the equipment fall zone requirements, manufacturer's specifications and council approved standard drawings. Certification of the softfall installation must also be provided.

(ii) Shockpads shall be installed under all rubber softfall layers, as required by the applicable Australian Standards.

(iii) Rubber softfall colour selection shall minimise large areas of bright colours prone to fading in the sun. Rubber softfall mixes shall contain a minimum 70% EPDM rubber due to higher UV rating of this product.

(iv) Small, narrow and intricate designs (e.g. less than 300 mm in width) within the rubber softfall should be avoided due to ongoing deterioration of such designs.

(v) Rubber softfall shall be prioritised to areas requiring higher levels of accessibility or underneath high wear items.

Editor's note—currently, no standard drawings are formally adopted for rubber softfall surfacing.

(5) Informal sporting facilities
Informal sporting facilities may include but are not limited to:

(a) basketball half courts;

(b) outdoor table tennis tables; and

(c) handball courts or rebound walls.

Editor's note—currently no specific requirement relating to informal sporting facilities are developed.

(6) Skate facilities and parkour practice areas

Editor's note—currently no specific requirement relating to skate facilities and parkour practice areas are developed.

SC6.4.3.6.15 Electrical and lighting

(1) Lighting

(a) All lighting must be of a high standard, being designed, constructed and installed in accordance with:

(i) the provisions within the planning scheme, planning scheme policies and this sub-section of the Development manual planning scheme policy;

(ii) manufacturer specifications;

(iii) all applicable Australian Standards and legislation;

(iv) all applicable council local laws; and

(v) council's approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for lighting.

(b) Lighting requirements within public open space will be advised by council in accordance with the hierarchy classification of the public open space or pathways involved.

(c) Power supply options (mains or solar) will be considered on a case-by-case basis, subject to the nature of the proposal, the existing supply opportunities and the site context.

(d) All lighting works must be undertaken in accordance with SC6.4.3.20 Public lighting and utility services.

(e) Pathway lighting
Bicycle paths or pedestrian paths within public open space that require lighting shall be lit to the applicable pathway lighting category, as per AS 1158 Lighting for roads and public spaces and SC6.4.3.20.2(2)(c) Lighting for bicycle, pedestrian and shared paths.

(f) Activity node lighting
Pathways within public open space that require lighting shall be lit to the applicable pathway lighting category, as per AS 1158 Lighting for roads and public spaces and SC6.4.3.20.2 Public lighting (urban and rural).

Editor's note—currently, no further standards are set for lighting of activity nodes. Council will negotiate these requirements on a case-by case basis until formal standards are set.

(g) Sports field and court lighting in accordance with SC6.4.3.20.2(2)(e) Lighting for sports grounds and sports complexes .

Editor's note—currently, no further standards are set for lighting of sports fields and courts. Council will negotiate these requirements on a case-by case basis until formal standards are set. Guidance on the recommended levels of illumination for each sport can be found in external references such as the Western Australian Department of Sport and Recreation Sports Dimensions Guide for Playing Areas.

(2) Electrical
All electrical works must be undertaken in accordance with SC6.4.3.20 Public lighting and utility services, all applicable Australian Standards and legislative requirements.

SC6.4.3.6.16 Fencing

(1) General requirements

(a) Fencing may include, but is not limited to the following:

(i) fencing panels;

(ii) bollards;

(iii) post and rail systems;

(iv) rural type fencing; and

(v) other crash barriers.

(b) Fencing is to be provided in order to:

(i) provide a legible definition of the open space boundaries and limits;

(ii) provide enclosure of a space appropriate to its function (e.g. fenced playgrounds);

(iii) prevent encroachment into open space by adjacent private properties;

(iv) prevent unwanted vehicle access by the provision of barriers along the road frontage, including into drainage reserves, parks and other public open spaces; and

(v) restrict access to unsafe locations or private property.

(c) All fencing must be of a high standard, and designed, constructed and installed in accordance with:

(i) the provisions within the planning scheme, planning scheme policies and this sub-section of the Development manual planning scheme policy;

(ii) manufacturer specifications;

(iii) all applicable Australian Standards and legislation;

(iv) all applicable council local laws; and

(v) council's approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for fencing.

(d) Fencing materials, design and location

(i) Fencing materials, design and location should not unreasonably hinder pedestrian circulation through open space, with sufficient pedestrian access points to be provided.

(ii) Where vehicle access prevention is required along pathways or bikeways, bicycle deflections rails are the preferred method and removable bollards should be avoided. Refer to SD-066 - Miscellaneous traffic details – bicycle path terminal treatments deflection rail and intersection at side street.

(iii) For public open space or streetscapes, proposals should seek to be consistent with any existing fencing style that is already established unless approved otherwise.

(iv) Fencing materials, design and location should be considered in the context, functionality and purpose for fencing use (e.g. post and rail installed where prevention of vehicle access, including motorbikes, is required).

(v) Public playground area and pool fencing must be in accordance with AS1926.1 *Swimming pool safety – safety barriers for swimming pools*.

(vi) Where appropriate, use of plants to screen or soften the fencing is recommended, except where this will conflict with CPTED requirements.

(e) Within public open space and streetscapes, fencing alignment and type shall include consideration of ongoing maintenance requirements and ensure:

(i) access for maintenance and other authorised vehicles shall be provided through a lockable gate or removable bollard, including provision of a kerb ramp or crossover at a safe location acceptable for council;

(ii) where provided in turf, a minimum 2 m wide clearance to other infrastructure (including trees) shall be maintained on either side of the fencing alignment to allow efficient mowing activities;

(iii) where bollards are provided in concrete, construction joints shall be provided to minimise damage to concrete slabs due to collisions, and allow ease of removal and replacement to damaged bollards; and

(iv) fencing is to be located within the surveyed boundary of the open space allotment; or

(v) where open space borders private property, fencing is to be located within the surveyed boundary of the private allotment.

SC6.4.3.6.17 Furniture

(1) General requirements

(a) Furniture may include, but is not limited to the following:

(i) barbeques (gas, electric and wood-fired);

(ii) benches, seats and picnic settings;

(iii) refuse bins;

(iv) bicycle parking facilities;

(v) water bubblers and taps; and

(vi) tree grates and guards.

(b) All furniture must be of a high standard, being designed, constructed and installed in accordance with:

(i) the provisions within the planning scheme, planning scheme policies and this sub section of the Development manual planning scheme policy;

(ii) manufacturer specifications;

(iii) all applicable Australian Standards and legislation;

(iv) all applicable council local laws; and

(v) council's approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for furniture.

(2) Electrical and gas barbeques

(a) Within public open space, gas and electric barbeques are to only be provided at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1 Public Open Space Embellishment Framework.

Editor's note—Deviation from council's Public Open Space Embellishment Framework provisions for barbeques may only be considered where sufficient benefit to the wider community is demonstrated and supplementary conditions are satisfied. Proposed deviations must be discussed with council at preliminary approval stage and will only be approved where all community expectations have been considered; an extended maintenance period has been successfully negotiated and all other conditions are satisfied.

Editor's note—currently, no standard drawings are formally adopted for electrical and gas barbeques.

(b) Where permitted, gas and electric barbeques must be provided in accordance with council approved standard drawings.

(c) The following are the preferred specifications for outdoor gas and electric barbeques:

(i) cooktops to be all stainless steel construction, including high efficiency mono pressed stainless steel hotplate with laminated heat dispersion coating, high contact heating element and all stainless clamp plate;

(ii) timing, ignition and temperature control functions should feature on all hotplates to ensure optimum cooking temperature is constantly maintained and to maximise performance and efficiency. Visual and audible indication of operation and mode change should also be a key feature;

(iii) safety push button/stop systems are a mandatory requirement. These should ideally be located above the bench top, out of reach of children and fitted with a safety delay feature to ensure units cannot be inadvertently turned on;

(iv) hotplates are to be enclosed in a raised hob elevated and isolated above the bench top and with a minimum 100 mm protection zone. Benches should be designed without protrusions or ledges that may assist climbing;

(v) hotplates should be non-porous with no welds, creases or deep corners to trap food and bacteria. An automatic pre-heat mode should also feature and deliver minimum sterilising temperature;

(vi) enclosure frames are to consist of high strength, powder-coated aluminium extrusions. Cladding to be 18 mm compressed fibre cement backing panels with 0.55 mm stainless steel decorative fascia panels or approved similar. All doors to be stainless steel powder-coated or brushed stainless steel and fitted with a door lock matching council's preferred security key system;

(vii) barbeques are to be ideally located underneath a shelter, mounted on a concrete slab with minimum 450 mm clearance around the bench top on all sides;

(viii) units should be fitted with a fat collection tray and unobstructed access through fat tray access doors. Components should be designed to be easily unbolted and lifted out for maintenance and easy replacement;

(ix) electric components to be all fully sealed and power requirements are to be 240 volt A.C., 3.6 Kw, per plate or approved similar. All electrical works to be undertaken by a qualified electrician and in accordance with all relevant Australian Standards and legislation;

(x) gas barbeques may only be permitted by council where electricity power supply is restricted or

where connection to an electrical supply is cost prohibitive. Gas supply to be installed by a qualified plumber and in accordance with all relevant Australian Standards and legislation;

(xi) a water tap should be readily accessible to the barbeque cooking and eating area for ease of use during barbeque operation and cleaning; and

(xii) a minimum 2 year warranty must be provided with all barbeques installed within public open space.

(3) Wood fire barbeques and open fire areas

(a) Wood fire barbeques or open fire areas are NOT to be provided unless approved by council.

(b) "Natural settings" will be the only exception where wood fire barbeques or open fire areas may be permitted. Adequate environmental, fire and other safety measures must be included as part of any provision proposal to council.

(c) Where permitted, wood fire barbeques must be provided in accordance with council approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for wood fire barbeques and open fire areas.

(4) Benches, seats and picnic settings

(a) Where provided, benches, seats and picnic settings must be provided in accordance with council approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for benches, seats and picnic settings.

(b) All benches, seats and picnic settings are to be flange mounted on an appropriately sized concrete slab unless approved otherwise.

(c) Where within public open space or streetscapes, furniture should be consistent with any existing or adopted furniture suite for the public open space or streetscape, unless approved otherwise.

Editor's note—currently, no city-wide adopted furniture suite is developed. Some individual locations do, however, have formally adopted furniture suites and colour schemes. Others have informally established suites and colour schemes that have developed over the years. In both instances, new furniture selection should be consistent with these suites unless reasonable justification for deviating from the palette can be established.

(5) Refuse bins

(a) Where provided, refuse bins must be provided in accordance with council approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for refuse bins.

(b) For district and regional level parks, civic spaces and amenity parks, acceptable bin provision includes 240 L rubbish and recycling wheelie bins, with single or dual bin enclosures, mounted on a concrete slab. Cigarette Butt bins may be attached where deemed appropriate.

(c) For local recreation parks and all other public open space, acceptable bin provision is restricted to 240 L rubbish and recycling wheelie bins, mounted on a concrete slab with a metal security bin stand unless approved otherwise.

Editor's note—refuse bin style and design for streetscapes will be considered on a case by case basis until further standards and design guidelines are developed.

(d) For all public open space and streetscapes where bin enclosures are provided, these must be fitted with a door lock matching council's preferred security key system.

(e) For all public open space, variations to size and quantity standards may be approved, as required to

support the associated waste collection requirements, particularly at locations of high usage or where sporting and community clubs are co-located.

(f) All bins and enclosures are to be appropriately screened and located to ensure ease of accessibility for use and waste collection, without compromising the amenity of the public open space or adjacent land uses.

(g) All bins and enclosures are of a design, construction and location that minimises any likely impacts, or the risk of hazards due to vandalism or fire.

(6) Bicycle parking facilities
Bicycle parking facilities are to be provided in accordance with AS 2890.3 *Parking facilities – Bicycle parking facilities*.

Editor's note—refer also SC6.4.4.7 Bicycle, pedestrian and shared path design

(7) Water fountains and taps

(a) For all public open space, ready access to a potable water source is to be provided as part of any open space development, including at activity nodes and at reasonable intervals along corridor parks or recreational pathways.

(b) All water fountains and taps should be located near existing services and water supply points wherever possible, focused around activity nodes or areas of high use.

(c) Dog bowls should be included as part of water fountain provision where necessary. Separate stand-alone units may be required where anticipated usage will be very high (e.g. in dog off-leash area).

(d) All water fountains should be installed on a concrete slab, above a drainage well and with adequate surface drainage inlets to prevent water pooling on adjacent surfaces.

(e) For all public open space, water fountains and taps should be designed, constructed and installed as per council specifications detailed in SC6.4.6.27 Irrigation. Each water fountain/tap is to have a water meter connected.

SC6.4.3.6.18 Signage

Signage may include, but is not limited to the following:

(1) park name signs;

(2) information signs;

(3) directional signs;

(4) regulatory signs; and

(5) entry statements (private developments and public statements).

Editor's note—currently no specific requirements relating to signage are developed. For signage within public open space, consideration should be given to the Public Open Space Embellishment Framework and council's corporate branding requirements, as detailed in council's Graphic Standards Manual (GSM). Signs within streetscapes should be as per requirements detailed in sub-section SC6.4.6.24 Signposting.

SC6.4.3.6.19 Shelters and shading devices

(1) General requirements

(a) Shelters and shading devices may include, but is not limited to the following:

(i) awnings;

(ii) picnic shelters or gazebos; and

(iii) shade sails.

(b) All shelters and shading devices must be of a high standard, being designed, constructed and installed in accordance with:

(i) the provisions within the planning scheme, planning scheme policies and this sub-section of the Development manual planning scheme policy;

(ii) manufacturer specifications;

(iii) all applicable Australian Standards and legislation;

(iv) all applicable council local laws; and

(v) council's approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for shelters and shading devices.

(2) Awnings

Editor's note—due to the place-specific, custom nature of awnings, no standard specifications are currently developed. Proposals will be considered on a case-by-case basis in accordance with all applicable building and engineering requirements, Australian Standards and council's overarching design and management principles. Applicants should refer to SC6.4.3.4 Outdoor dining design for shading requirements applicable in this situation.

(3) Shade sails

(a) All shade sails are to be:

(i) designed, engineered, built and certified against Building Code of Australia, C2 wind rating requirements as per AS1170 *Structural design actions* and all other applicable standards;

(ii) located with consideration of shading requirements, sun orientation and natural shading opportunities on site. As such, provision must be considered on a case-by-case basis, and account for the existing versus desired extent and daily duration of shade cover (natural and built); and

(iii) provided in public car parking areas as a substitute to natural shading when there is insufficient available planting space or shade sails are deemed a more practicable and/or cost effective shading system.

Editor's note— Refer SC6.4.3.6.32 Car park plantings and shading for additional information

(b) All shade sails within public open space are to:

(i) be provided at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in SC6.4.3.6.13 Open space embellishments, unless approved otherwise;

Editor's note—currently no further guidelines and standards are developed for the provision of shade sails across the public open space network. Inclusion of shade sails will be considered on a case-by-case basis and with consideration of the Public Open Space Hierarchy and Embellishment Frameworks. Where council develops and adopts a strategic plan for the provision of shade sails, all development proposals will be assessed against the provisions within that plan.

(ii) be primarily provided over high use activity elements, where practicable and not cost prohibitive. Demand and need for shade sails is likely to be higher in greenfield sites or where there are minimal mature shade trees. In these instances, shade sail provision should be supplemented by ancillary shade tree plantings to ensure both natural and built shade are developed in the long term;

(iii) be located to minimise proximity to trees that may increase maintenance due to leaf drop or pose a risk to the sail structure from falling limbs during storm events;

(iv) have a 2.5 m minimum clearance between the highest accessible standing point of the shaded equipment/item and the lowest point of the shade sail. Access opportunities from adjacent structures should also be avoided, in order to reduce potential vandalism and damage to the structure or sail;

(v) within playground areas, all poles are to be located outside equipment fall zones and, where practicable, outside the softfall surfacing area provided this will not conflict with mowing activities or circulation;

(vi) be of premium quality shade fabric made of 100% monofilament yarns with a 10 year fabric warranty unless approved otherwise;

(vii) include hot-dipped galvanised and powder coated poles of a colour consistent with any existing colour palette or adjacent park infrastructure;

(viii) pole profile and diameter should inhibit climbing of the poles or anti climbing devices should be installed;

(ix) include marine grade fittings for all locations; and

(x) include quick release mechanisms on all sails for ease of removal during storm events and all necessary edge reinforcement and hardware to ensure longevity of the shade sail.

(4) Shelters and gazebos

(a) All shelter structures are to be designed, engineered, built and certified against Building Code of Australia, C2 wind rating requirements as per Australian Standard AS 1170.2 *Structural design actions – wind actions* and all other applicable standards.

(b) All shelter installations within public open space are to:

(i) be provided at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1 Public Open Space Embellishment Framework;

(ii) have a minimum 300 mm clearance from the edge of the roofline to the edge of the slab to reduce erosion around the structure;

(iii) be design and installed without roof gutting systems unless specified otherwise;

(iv) have a frame constructed of oiled hardwood timber, painted pine or marine grade metal materials;

(v) include marine grade fittings for all locations; and

(vi) where painted, be of a colour consistent with any existing colour palette or accompanying furniture suite.

SC6.4.3.6.20 Outdoor sporting facilities

Outdoor sporting facilities may include, but is not limited to the following:

(1) sports fields and courts;

(2) outdoor spectator facilities;

(3) specialised sports facilities;

(4) motorised sports facilities;

(5) aquatic facilities; and

(6) equestrian facilities.

Editor's note—currently no further guidelines and standards are developed for the provision of outdoor sporting facilities across the public open space network. Inclusion of outdoor sporting facilities will be considered on a case-by-case basis and with consideration of the Public Open Space Hierarchy and Embellishment Frameworks and all other applicable sections of the Townsville City Plan and sub-sections of the Development manual planning scheme policy. Where council develops and adopts a strategic plan for the provision of outdoor sporting facilities, all development proposals will be assessed against the provisions within that plan.

SC6.4.3.6.21 Structure and buildings

(1) General requirements

Structures and buildings may include, but are not limited to the following:

(a) public toilets;

(b) community facilities;

(c) commercial facilities;

(d) clubhouses, change rooms or canteens; and

(e) sheds and shipping containers.

Editor's note—currently no further guidelines and standards are developed for the provision of structures and buildings across the public open space network. Inclusion of structures and buildings will be considered on a case-by-case basis and with consideration of the Public Open Space Hierarchy and Embellishment Frameworks and all other applicable sections of the Townsville City Plan and sub-sections of the Development manual planning scheme policy. Where council develops and adopts a strategic plan for the provision of outdoor sporting facilities, all development proposals will be assessed against the provisions within that plan.

(2) Public toilets

Editor's note—currently no further guidelines and standards are developed for the provision of public toilets across the public open space network. Inclusion of public toilets will be considered on a case-by-case basis and with consideration of the Public Open Space Hierarchy and Embellishment Frameworks and all other applicable sections of the Townsville City Plan and sub-sections of the Development manual planning scheme policy. Where council develops and adopts a strategic plan or design guidelines for the provision of public toilets, all development proposals will be assessed against the provisions within these documents.

SC6.4.3.6.22 Surface treatments

Surface treatments within all open space are to be:

(1) of an appropriate extent and material that will be durable under the local climatic and site conditions;

(2) of an appropriate extent and material that will mitigate the effects of large areas of impervious surfaces on run-off infiltration;

(3) fit for the intended purpose of the surface, its location, and the anticipated type and level of usage;

(4) shaded wherever possible and not prone to excessive heat retention, reflectivity and glare;

(5) not conducive to water pooling or slippery when wet;

(6) designed and located with consideration of the need for softening of hard surfaces with plantings; and

(7) be practical to maintain.

Editor's note—currently no further requirements relating to surface treatments are developed. Compliance with relevant sections of the Development manual planning scheme policy is required.

SC6.4.3.6.23 Transport and access infrastructure

(1) General requirements

(a) Transport and access infrastructure within open space is considered to include:

(i) car parking, both on and off street, associated with the open space or facilities;

(ii) internal roadways;

(iii) pedestrian paths, bicycle paths, shared paths;

(iv) public transport facilities;

(v) end of trip facilities;

(vi) walking tracks; and

(vii) boat ramps.

(b) All transport and access infrastructure within public open space must be designed, constructed and installed in accordance with:

(i) the provisions within the Townsville City Plan, planning scheme policies, sub-section SC6.4.4.7 Bicycle, pedestrian and shared path design and this sub-section of the Development manual planning scheme policy;

(ii) all applicable Australian Standards and legislation;

(iii) all applicable council local laws; and

(iv) council's approved standard drawings.

Editor's note—refer to SC6.4.3.6.31 Streetscape design and landscape treatments for requirements relating to areas of a designated road reserve.

(c) Bicycle, pedestrian and shared paths within public open space are to connect to activity areas within the open space and to the on-street verge pathway network. Where a verge pathway network does not exist, consideration may be given towards the future design and establishment of such a network in order to establish the best outcome for connectivity.

Editor's note—refer to SC6.4.4.7 Bicycle, pedestrian and shared path design for design guidelines for consideration of the type of paths to be provided through/within public open space. Consideration should be given to connectivity of bicycle paths and pedestrian path networks.

(d) All landscaping and irrigation associated with transport and access infrastructure is to be in accordance with the provisions of this sub-section, and sub-sections SC6.4.6.26 Landscaping and SC6.4.6.27 Irrigation.

Editor's note—with the exception of the below, currently no further guidelines and standards are developed for the provision of transport and access infrastructure specifically within open space. Proposals will be assessed against the policies and standards contained in the Townsville City Plan other sub-sections of and the Development manual planning scheme policy. Where proposals are within public open space, consideration of the Public Open Space Hierarchy and Embellishment Frameworks will be given. Refer clause SC6.4.3.6.9 Public open space.

(2) Walking tracks
Walking track provision is to:

(a) be provided in accordance with infrastructure design requirements, track markers and signage, in accordance with AS 2156 *Walking tracks*;

(b) be at select locations only, where construction of the walking track/s will not create any foreseeable adverse impacts including unsustainable maintenance requirements, public safety and liability concerns, habitat destruction, land slip or slope destabilisation; and

(c) be provided in accordance with any council adopted walking track strategy.

Editor's note—currently no further guidelines and standards are developed for the provision of walking tracks within public open space. Inclusion of walking tracks will be considered on a case-by-case basis and with consideration of the Public Open Space Hierarchy and Embellishment Frameworks. Where council develops and adopts a strategic plan for the provision of walking tracks, all development proposals will be assessed against the provisions within that plan.

(3) Boat ramps
Boat ramp provision is to:

(a) be permitted in limited circumstances only, at specific locations, and where all relevant considerations are reasonably satisfied; and

(b) include engagement with, and approval from all relevant authorities and asset owner/s.

Editor's note—due to the place-specific, custom nature of boat ramps, no standard specifications are currently developed. Proposals will be considered on a case-by-case basis in accordance with all necessary requirements defined by all applicable engineering, water safety and transport standards, legislation, and council's overarching design and management principles.

SC6.4.3.6.24 Dog off-leash facilities

Dog off-leash facilities are designated spaces under council's local law where within an open space dogs can recreate with their owners. Dog off-leash areas provide a safe and fun environment for owners and their dogs to enjoy parks and open spaces.

Dog off-leash facilities are to be built to a high standard that meets community expectations. Facilities where proposed Dog off-leash areas are proposed to be established shall have due regard for;

(1) Site selection

(a) within public open space, dog off-leash facilities shall only be provided at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1;

(b) an appropriate sized large dog off-leash fenced facility should range between 2000 to 4000 m^2;

(c) an appropriate sized small dog off-leash fenced facility should range between 1000s m^2 to 1500 m^2. It should be noted that small dog off-leash fenced facilities will not be installed as stand-alone facilities by themselves;

(d) dog off-leash facilities should have adequate drainage and should have reasonable flood immunity;

(e) dog off-leash facilities should have cross fall drainage of at least 2%. This will ensure that water will not pond within the dog off-leash area;

Editor's note—the surface cover all dog off-leash facilities will primarily consist of turf. In most instances open turfed areas above 2000 m^2 should be considered as a minimum for dog off-leash areas. Turf cover shall consist of 25 mm depth of dense, well rooted, vigorous grass growth with a 25 mm depth of topsoil. The type of turf to be used will be selected from the SC.6.2.6.26 – Attachment A list of preferred plant species.

(f) the use of native groundcovers, shrubs and trees should be incorporated into the overall design of the dog off- leash areas. The usage of existing established trees can provide visual amenity to the park and will provide protection from the wind and sun;

(g) landscaping and plants add to the amenity of the park, but it is important to ensure that plants are non-toxic and non-irritating to dogs. Some plants may have seeds, stems, leaves, fruits or flowers that are irritating and/or toxic to dogs;

(h) all dog off-leash enclosures are required to be irrigated with pop up sprinklers; and

(i) all dog off-leash facilities must be of a high standard, being designed, constructed and installed in accordance with:

  (i) the provisions within the Townsville City Plan and this sub-section;

  (ii) manufacturer specifications;

  (iii) all applicable Australian Standards and legislation;

  (iv) all applicable council local laws; and

  (v) council's approved standard drawings.

Editor's note—Currently there are no approved standard drawings for dog off-leash areas.

(2) Siting of dog off-leash facilities

(a) dog off-leash facilities should be located away from play spaces to minimise the temptation for children to have unsupervised interaction with dogs;

(b) dog off-leash facilities should also be located away from other non-congruent recreation activities (e.g. barbeque areas and fitness equipment). As a general guide it is recommended that a spatial buffer of approximately 40 m is considered appropriate. However, other factors such a site gradient and vegetation coverage can be utilised to lessen the spatial buffer;

(c) dog off-leash areas should also be sited to minimise noise nuisance into residential areas. As a general guide it is recommended that a minimum spatial buffer of approximately 40 m is considered appropriate. However, other factors such a site gradient and vegetation coverage can be utilised to lessen the spatial buffer;

(d) a variety of open and shaded spaces should be created within a dog off-leash facility. There should be enough space to include active running areas as well as quieter environments where dogs can sniff, play and interact with their owners. As a guide it is recommended that a dog off-leash area have shade coverage (both natural and artificial) of approximately 35 per cent;

(e) effective dog off- leash areas disperse the dog and human traffic throughout the park, and spread the wear and tear on the underlying surface evenly across the facility;

(f) in all instances dog off-leash facilities should be supported by sufficient car parking spaces to

accommodate the amount of vehicle traffic likely to be generated by the particular use of the site. Refer to Table SC6.4.3.6.1 Public Open Space Embellishment Framework;

(g) to enhance site accessibility and convenience, locate dog off-leash areas in close proximity to the available car parking. Additionally, equitable access ramps and a connecting path from the car parking to the dog off-leash facility should also be installed; and

(h) The placement of Dog off-leash facilities and planting treatments, shall take into account the maintenance requirements for maintaining such a facility (e.g. allow minimum 2m between perimeter fence and facility item such as a seat).

(3) Design - entry way

(a) double-gated entry to prevent dog escapees is required at all access points. Consideration should be given to the installation of multiple access points, to minimise congestion.

(b) access points are high wear areas and appropriate sized concrete pads will be installed. These concrete pads should cover the entire entrance areas and extend out past the arc of the gate openings.

(c) gates should be fitted with self-closing child-proof locks to prevent dog escapees and unsupervised children from entering the facility.

(d) a separate entry for a maintenance gate (which should be 3-3.5m wide) will be installed within the perimeter fence line. This should be located away from all the other user access points.

(e) other physical structures to support amenity such as shelters, benches or drinking fountains should be located at a suitable distance away from the access points to discourage dogs and people from congregating.

(4) Design - fencing

(a) secure perimeter fencing will be installed that discourages canines from escaping under, over or through the fence;

(b) the fence alignment shall avoid acute angles that can result in entrapment issues for dogs and humans;

(c) fencing around all Dog Off-Leash Facilities will be approximately 1.2m – 1.5m in height; and

(d) fencing materials must provide good visibility so that park users can see activity inside and around the park. Standard powder coated fencing panels traditionally used in pool fencing should be utilised as fence panels.

Editor's note—Be aware that smaller dog breeds may be able to run through the gaps in the panels of traditional pool fencing.When designing small dog off-leash areas give consideration to the installation of alternatives or undertaking modifications to the fencing panels to ensure that the enclosure is fit for purpose.

(5) Design Amenities - Seating

(a) as a minimum, four bench seats should be installed within the large dog off-leash areas, and two bench seats within small-dog off-leash areas;

(b) seating should be placed in areas to maximise the benefit of any nearby shade;

(c) seating should be aligned and in close proximity to the fencing of the off-leash area. This ensures that the majority of the dog activity will occur in front of where the owner is sitting. A mowing strip of 2 m should be allowed between the fence and the seating. Finally seating should be located away from entry/exit gates to avoid congestion;

(d) the type of seating used within the dog off-leash will be consistent with any existing or adopted furniture suite within the nearby park open space;

(e) however, consideration should also be given to the space between the slat sizes utilised on the bench seat. Minimum gaps should be utilised to avoid dog paws entrapment points; and

(f) picnic tables should not be located inside dog off-leash areas as this encourages food to be brought into the facility.

(6) Design Amenities - Drink facilities

(a) as a minimum, two drink fountains should be installed within dog off-leash areas. These fountains should be accessible by dogs and people, but should be located away from the main entry gates to discourage

congregation in high traffic areas;

(b) dog water bowls should be fixed to the drink fountain and be hinged so that owners can tip water out of the bowl. Adequate drainage around the water bowl should be installed to ensure that water logging and muddy areas do no occur. All drinking fountains are required to be installed on a concrete slab, above a drainage well with adequate surface drainage inlets;

(c) drinking fountains should be aligned and in close proximity to the fencing of the off-leash area. This ensures that that drinking dogs are not impacting activity areas. A mowing strip of 2 m should be allowed between the fence and the drink fountains; and

(d) water fountains and taps should be designed, constructed and installed as per council's specification, Drink Fountain and Water Tap (SC.6.4.6.27 Irrigation).

(7) Design Amenities - Waste facilities

(a) as a minimum, two dog faeces bag dispensers should be installed within dog off-leash areas;

(b) dog faeces bag dispensers should have a locking device to prevent bags being pulled continuously and scattered in the park. Dog faeces bag dispensers should be located in close proximity to the access points (but should also not impede access). However, dog faeces bag dispensers should also be located in positions that ensure an ease of refill, which does not require council staff to enter the enclosure;

(c) two covered rubbish bins should be installed outside of the dog off leash area, in close proximity to the main gate access point (but should also not impede access).Bin position should also ensure easy collection: and

(d) generally, the acceptable bin provision will be a 240L rubbish wheelie bin, mounted on a concrete slab with a metal security bin stand. Variations to size and quantity standards may be approved, as required to support the associated waste collection requirements, particularly at locations of high usage.

(8) Design Amenities – Lighting

(a) most dog off-leash facilities do not require lighting. In many instances one security light may be installed to link the entrance of the dog off-leash area to the adjacent car parking will be sufficient;

(b) full lighting of dog off-leash facilities will be accepted where there is a demonstrated need and where the lighting will not have a negative impact on adjacent residential areas; and

(c) all lighting shall be carried out to the applicable lighting category, as per the Australian Standard AS11580 – Lighting for roads and public spaces.

(9) Design - Agility Equipment / Separate Small Dog Area / Specialised Play

(a) not all dog off-leash facilities require agility equipment or a dedicated small dog off-leash area. These facilities will only be supported where there is a demonstrated demand on a case-by-case basis;

(b) if agility equipment is considered appropriate it should be located away from access points and high running areas. Consultation with agility dog groups should be undertaken prior to assist in the design of appropriate agility facilities within dog off-leash areas;

(c) small dogs are considered to be dogs that weigh less than 8 kilograms or are less that 35cm in height when measured from the floor to the top of the dog's front shoulders;

(d) small dog off-leash areas will not contain agility equipment; and

(e) specialised canine recreation equipment will be considered on a case-by-case basis. Consideration of ongoing maintenance costs, asset replacement costs and any potential impacts on canine health will be the major considerations when determining the request to install specialised canine recreation equipment.

(10) Design - Signage

(a) council information signs on dog off-leash area rules are required to be installed in close proximity to all access points;

(b) council has standard information signs on dog off-leash and small dog off-leash areas for usage and behavioural requirements that shall be used at dog off-leash areas;

(c) park name signage should be installed in close proximity to the dog off-leash area so that people utilising the facility are able to readily recognise the name of the facility. Generally, dog off-leash areas will not have a separate specialised park name; and

(d) when dog off-leash facilities are not readily visible from the road frontage, directional signage from car parking facilities or areas of high visibility should be utilised.

Editor's note—For further information on the construction of dog off-leash facilities, refer to the detailed landscape specification standards as provided in SC6.4.6 Construction Standards, in particular SC6.4.6.26 Landscaping.

SC6.4.3.6.25 Drainage and service connections

Editor's note—currently no specific requirements relating to drainage within open space are developed. All drainage requirements should be determined in accordance with sub-section SC6.4.4.4 Stormwater drainage design along with the relevant construction specifications.

SC6.4.3.6.26 Landscape entry statements

(1) Landscape entry statements may be of the following types:

(a) sign/graphics on a wall or acoustic fence;

(b) a structure;

(c) public art; and

(d) landscaping plantings only.

(2) Landscape entry statements to public open space, residential or commercial estate developments are to meet the following requirements:

(a) landscape entry statements are to be suitably located to clearly identify the public open space, an individual neighbourhood or development, or area of distinctive character;

(b) landscape entry statements are to be of a high quality urban form that is easily maintained;

(c) landscape entry statements are to be of a scale appropriate for the hierarchy classification and surrounding landscape character;

Editor's note—refer to Table SC6.4.3.6.1 Public Open Space Embellishment Framework relating to entry statement and signage in public open space.

(d) where involving a wall entry statement, the wall is to be located within the private property on the property boundary, unless relating to public open space or designated park;

(e) any private properties containing wall/s or other landscape entry statements require a covenant protecting the wall or feature and outlining maintenance responsibilities, and a Property Note in council's rates system to ensure owners are aware of the existence of the wall or feature;

(f) other entry statements of an alternative nature or located within the road reserve will be considered on merit and must meet requirements for visibility and frangibility;

(g) landscape entry statements for residential or commercial estates are to be provided and maintained by the developer for the life of the development (i.e. off maintenance of the final stage); and

(h) landscape entry statements will not include water features.

(3) Landscape entry statements are be provided in accordance with the following hierarchy and requirements:

(a) "Suburb" level landscape entry statements:

(i) generally be located on public land and owned by council after completion of any applicable maintenance period; and

(ii) conform with corporate graphics standards;

Editor's note—refer to council's Graphics Standards Manual.

(b) Estate" level landscape entry statement:

(i) walls or acoustic fence located within private property; and

(ii) structures, public art or landscaping may be located on public land subject to operational works (landscaping) approval;

Editor's note—public art needs to be coordinated through the Manager Gallery Services in accordance with council's Public art policy.

(c) Neighbourhood/village" level landscape entry statement:

(i) generally a sign wall located on private property; and

(d) "Street" level landscape entry statement:

(i) generally not acceptable.

SC6.4.3.6.27 Lookout platforms and fishing pontoons

(1) Lookout platforms and fishing pontoons will only be permitted in limited circumstances, at specific locations, and where all relevant considerations are reasonably satisfied.

(2) Where the proposed lookout platforms or fishing pontoons are associated with public open space, council owned land or will involve potential future council assets, infrastructure may only be permitted at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1. Approval from the relevant council asset owner/s will also be required.

(3) In order to properly assess any such proposals, council may request the provision of a maintenance plan as part of the development application, as per Section SC6.4.2 Development application guidelines.

Editor's note—due to the place-specific, custom nature of lookout platforms and fishing pontoons, no further standard specifications are currently developed. Proposals will be considered on a case-by-case basis in accordance with necessary requirements defined by all applicable engineering and water safety standards, legislation, and council's overarching design and management principles. Engagement and approval from other stakeholders/authorities may additionally be required as part of any development proposal.

SC6.4.3.6.28 Public art

(1) Public art is considered to be "a concept or work created by an artist/s in any medium, permanent, temporary or ephemeral, which enables stimulation of one or more of the senses and is situated in a place of public access".

(2) Public art will only be permitted in limited circumstances, at specific locations, and where all relevant considerations are reasonably satisfied.

(3) All public art proposals must demonstrate alignment with any council adopted public art policy.

Editor's note—refer to council's Public art policy.

(4) Where the proposed public art is associated with public open space, streetscapes, council owned land, or will involve potential future council assets, the public art may only be permitted at approved locations and where the following overall requirements are also satisfied:

(a) the provision of the public art adds interest to the public open space or streetscape, reinforces the unique identity of Townsville, and contributes significantly to the sense of place;

(b) the public art is used as a medium to interpret the social and cultural values of the community, reflecting Townsville's diverse heritage and cultural identity, as well as the social context of the site;

(c) the public art responds to the environmental context of the site, and is integrated into the overall landscape or streetscape, being well-chosen and appropriately sited;

(d) the provision of public art within public open space is in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1, unless approved otherwise;

Editor's note—where a public art strategy has been formally approved by council for a precinct or development, this may take

precedence over the Public Open Space Embellishment Framework provisions.

(e) the provision of public art within streetscapes and at centres is aligned with the expected levels of embellishment and characteristics of the road or centre hierarchy classification;

(f) all public art should not create a public safety risk to the community or council maintenance staff;

(g) engagement and approval from the relevant council asset owner/s and other stakeholders is required;

(h) for all public art proposals, council may request the provision of a concept statement and details including, but not limited to the following:

  (i) concept images or models;

  (ii) detailed description of the artwork/theme/concept;

  (iii) materiality;

  (iv) scale;

  (v) structural detailing and footing designs;

  (vi) public safety considerations;

  (vii) ongoing maintenance requirements;

  (viii) project budget/costs; and

  (ix) previous works and references; and

(i) for all public art proposals, council may request the provision of a maintenance plan as part of the development application, as per Section SC6.4.2 Development application guidelines.

Editor's note—due to the place-specific, custom nature of public art, no further specifications are currently developed. Proposals will be considered on a case-by-case basis in accordance with all necessary requirements defined by all applicable engineering and electrical standards, legislation, and council's overarching design and management principles.

SC6.4.3.6.29 Screening

Screening may include, but is not limited to the following:

(1) acoustic screening;

(2) vegetated visual screening; and

(3) architectural visual screening.

Editor's note—currently no specific requirements relating to acoustic and visual screening has been developed. Reference should be made to Department of Transport and Main Roads' *Road landscape manual*. Per SC6.4.2 Development application guidelines, council may ask for a description of any ongoing maintenance requirements to ensure that the stated noise attenuation performance of the measure does not deteriorate with time.

SC6.4.3.6.30 Soft landscaping

(1) General requirements

Soft landscaping may include, but is not limited to the following:

  (a) plant species selection;

  (b) earthworks and mounding;

  (c) garden beds;

  (d) shade trees; and

  (e) turf areas.

(2) Plant species selection

  (a) Preferred plant species

    (i) Plant species used are to be those recommended in the Preferred plant species list in SC6.4.3.6 Attachment A – Plant species schedules.

Editor's note—the Preferred plant species list found in SC6.4.3.6 Attachment A has been prepared as an inclusive list that takes into account council's requirements and those of relevant service providers, and is acceptable for use in most circumstances. The species list does not account for frangibility requirements relating to street tree plantings in streets or roads. This, along with all other relevant considerations associated with the site context must be considered in the development of the landscape plan and species selection. Refer to sub-section SC6.4.6.26 Landscaping for further detail relating to planting construction specifications.

(ii) Plant species are to be selected by a suitably qualified and experienced horticulturist, landscape architect or designer to suit each of the site's hydro zones, so that direct rainfall supplies all or most of their water needs.

(b) Undesirable plant species
Plant species are not to include undesirable species listed in the undesirable plant species list.

Editor's note—currently, no undesirable plant species list has been developed.

(c) Declared weed species
Plant species used are not to include prohibited species listed in any declared weeds list.

Editor's note—refer to the Department of Agriculture, Fishers and Forestry for a declared weed species list. Currently, no design guidelines relating to other soft landscaping elements are developed.

SC6.4.3.6.31 Streetscape plantings

(1) General requirements

(a) Landscape treatments may include, but is not limited to the following:

(i) street trees;

(ii) planted and/or mulched garden areas;

(iii) turf areas;

(iv) irrigation;

(v) artificial turf;

(vi) stencil-crete;

(vii) concrete (plain or coloured); and

(viii) other associated hard landscape treatments.

Editor's note—refer to the streetscape requirements under SC 6.4.3.3 Footpath treatment policy.

(b) All streetscapes must be of a high standard, being designed, constructed and planted in accordance with:

(i) the provisions within the Townsville City Plan, planning scheme policies and this sub-section of the Development manual planning scheme policy;

(ii) all applicable Australian Standards and legislation;

(iii) all applicable council local laws; and

(iv) all council approved standard drawings.

Editor's note—currently, no standard drawings are formally adopted for landscape treatments.

Editor's note—where streetscape outcomes are within roads managed by the Department of Transport and Main Roads, applicants should refer to the Department of Transport and Main Roads' *Landscape Design Manual* (2013). Requirements of the Department of Transport and Main Roads' Landscape Design Manual will take precedence in these instances. Engagement and

approval from other stakeholders/authorities may additionally be required as part of any development proposal.

(c) All streetscape outcomes should be underpinned by and contribute to the following strategic objectives:

(i) safety – streetscapes do not introduce risk to road users, must contribute positively to a safe road environment and be safe to maintain and construct;

(ii) functionality – proposed outcomes are fit-for purpose and comply with landscape and road planning and design principles, appropriate to the road hierarchy and function;

(iii) environment - ecological and sustainable design principles are incorporated to mitigate the environmental impacts of the road and maintain or improve the intrinsic value of the streetscape;

(iv) aesthetics – streetscapes provide high visual amenity and are contextually sensitive to the character of the surrounding built and natural environment;

(v) community – proposed outcomes are responsive to the needs and concerns of stakeholders and maintain or improve the quality of life and liveability of communities; and

(vi) economic – streetscapes represent value for money and provide cost effective design outcomes that seek to minimise costs over whole of life cycle.

Editor's note—whilst the above strategic objectives are relating specifically to streetscape outcomes, these objectives are aligned with the overarching sustainability principles outlined at the beginning of this sub-section and within Part 9.3.3 Landscape code. Alignment with both the above strategic objectives and the overarching sustainability principles are to be expressed in the proposed streetscape design outcomes and detailed in the "Landscape statement of intent" per SC6.4.2 Development application guidelines.

(2) Safety

(a) Streetscapes shall create a safe road environment by ensuring:

(i) a safe system approach to road safety is used, as detailed by Austroads;

(ii) safe and efficient pedestrian, cyclist and vehicle movement is facilitated through the integration of all infrastructure and landscape elements within the road corridor;

(iii) hazards, safety or security risks are not introduced;

(iv) safe sight distances are applied and maintained as per Austroads Part 3 and Part 4. At intersections, use of Minimum Gap Sight Distance, and at roundabouts, criteria 1 and 2, are mandatory;

(v) clear zones and frangibility requirements are met in accordance with clear zone criteria as per Austroads Part 6;

(vi) setbacks and other clearances are met;

(vii) signage and other road furniture is not obscured;

(viii) safety and traffic management is enhanced through the functional use of landscape plantings;

(ix) surface treatments are slip-resistant and non-reflective;

(x) effects of glare and shadowing are minimised;

(xi) CPTED principles are incorporated into all streetscape designs; and

(xii) a safe work environment for maintenance personnel is achieved and requirements for traffic control are minimised.

(b) Associated with the above, the following definitions apply.

(i) "Frangible" vegetation - is plants (including trees) with a stem or trunk diameter equal to or less than 100 mm in diameter at maturity, measured from 300 mm above the finished ground level. Shrubs and ground covers are considered frangible except for shrubs that exceed 3.5 m in height.

(ii) "Non-frangible" vegetation - is plants (including trees) with a stem or trunk diameter greater than 100 mm in diameter at maturity, measured from 300 mm above the finished ground level. This includes shrubs greater than 3.5 m in height and most trees.

(iii) Setback - is the distance measured from the outer edge of the specified component to the centre

of the vegetation trunk.

(iv) Clearance - is the distance measured from the edge of the specified component to the perimeter of the second component or vegetation.

(v) Canopy clearance – is the vertical distance measured between the finished ground level and the underside of the tree canopy.

Editor's note—the above definitions are based on Austroads' *Guide to Road Design*, Part 6B: Roadside Environment (2009) and Department of Transport and Main Roads' *Landscape Design Manual* (2013) – Appendix 4.

(3) Functional

Streetscape outcomes must be fit-for-purpose and shall:

(a) be supported by all other ancillary infrastructure requirements that are essential to the overall functionality and longevity of the streetscape, including but not limited to irrigation, subsoil drainage and root barrier; and

Editor's note—refer to sub-sections SC6.4.6.20 Subsoil, foundation and pavement drains, SC6.4.6.21 Subsurface drainage, SC6.4.4.1 Geometric road design, SC6.4.6.26 Landscaping and SC6.4.6.27 irrigation.

(b) demonstrate sound application of design theories including legibility, form, function, connectivity, way-finding, accessibility and mobility, robustness, place-making and imaging.

Editor's note—where proposed streetscape outcomes deviate from the outlined requirements of this sub-section, the merit for this deviation must be detailed. Notes documenting how all safety, functional and operational requirements are satisfied by the design exception must be included for further consideration. Any variances will be assessed on a case by case basis relative to the situation. Approval will not be granted where the design exception opposes safety requirements or increases safety risk. All plans are required to be signed off by a RPEQ registered engineer.

(4) Environment

Ecological and sustainable design principles shall be incorporated by:

(a) applying an appropriate planting approach such as: structured, naturalistic, and water sensitive planting; grass seeding; or turfing;

(b) integrating street trees in the streetscape that will create shade for all users (including pedestrians and cyclists) and ameliorate the urban heat island effect;

(c) providing a buffer between the road and surrounding land uses;

(d) integrating the streetscape within natural areas through planting approaches with a natural appearance and naturalistic, informal distribution;

(e) improving the health and resilience of the urban forest by establishing green corridors along streets or roads and providing habitat corridors within the urban matrix;

(f) incorporating functional landscape components such as the use of vegetation to screen headlight glare;

(g) using varied vegetation treatments to highlight progression or transition to a different speed environment;

(h) designating feature areas or nodal points by creating a marker or landmark element at interchanges, intersections, major structures and entry gateways;

(i) using vegetation and other components to maintain or frame views;

(j) establishing economical ways to treat large areas;

(k) assisting with integrated stormwater management by establishing vegetation that will reduce erosion and large expanses of impervious surface; and

(l) incorporating vegetation and other treatments in ways that minimise maintenance in high risk areas, require reduced maintenance interventions and become self-sustaining over time.

(5) Aesthetics

Streetscapes shall be contextually sensitive and provide high visual amenity by:

(a) establishing streetscape characters themes that address, retain, reflect and where possible enhance the local context of the project area (architectural themes, colours, visual heritage values etc.);

(b) creating balance in term of scale and mass between new streetscape components and the existing natural features and urban building forms;

(c) integrating natural elements that recognise and promote the value of the urban forest in all streetscapes;

(d) establishing innovative approaches to providing functional, high amenity outcomes whilst maintaining and enhancing the safety and operational function of the road;

(e) responding to changes in road conditions and promoting legibility under varied road conditions or different design speeds;

(f) presenting a visually cohesive and unified suite of treatments that are simple, refined and without unnecessary, non-functional embellishment;

(g) creating treatments that are visually recessive except where intended to be highly visible feature elements;

(h) maintaining an uncluttered road environment with limited visual intrusion that will minimise risk of road user distraction and conflict with official traffic signs and signals; and

(i) devising colouration and surface treatment solutions that shall mitigate the visual impact of dirt, staining and adhesion of other pollutants.

(6) Community

Proposed streetscaping shall be responsive to stakeholder needs and concerns by:

(a) identifying and addressing community values and associated interests, perceptions and preferences as part of transport and road landscape planning and design process;

(b) promoting participation and contribution by implementing effective community engagement processes;

(c) enhancing public amenity for all users through improvements to user comfort, way finding and walkability;

(d) promoting the health and well-being of the community by improving the useability of pedestrian networks through provision of shade or boulevard treatments;

(e) improving accessibility, connectivity and security within the streetscape;

(f) establishing streetscapes that are functional and facilitate equitable access to a variety of multi-modal transport systems;

(g) seeking design outcomes that create a sense of community and reinforce local character, identity, and cultural heritage; and

(h) improving experiences both for users traveling within the transport infrastructure corridor itself and the community beyond.

(7) Economic

Streetscapes will represent value for money and minimise costs over whole of life cycle by:

(a) implementing appropriate designs that provide balanced outcomes across all strategic objectives;

(b) creating iconic gateway entry statements, in strategic locations only, which emphasise the urban or regional identity and enhance tourism, business potential and associated economic benefits;

(c) promoting increased usage and visitation to business and services through the provision of user friendly vehicular, pedestrian, cyclist and public transport networks which incorporate a high level of amenity and deliver a high quality experience;

(d) ensuring the ongoing cost and level of service for operational requirements associated with the streetscape is appropriate for the hierarchy and profile of the road;

(e) minimising the overall cost of operational activities through responsive design that reduces high cost, high risk, high frequency and high intensity activities;

(f) creating designs that will evolve into a self-sustaining streetscape and have a progressive reduction in the number of maintenance interventions over the operational life of the corridor; and

(g) promoting innovation in the development of alternative treatment types that achieve a balance between the desired aesthetic and reduce maintenance outcomes.

(8) Streetscape treatment provision

(a) Requirements relating to all safety objectives such as clear zones, sight distances and frangibility will take precedence and determine the placement and control of landscaping elements within the streetscape.

(b) All hard and soft landscape treatment construction must be in accordance with the specifications set out in sub-sections SC6.4.6.26 Landscaping and SC6.4.6.27 Irrigation.

(c) Kerb types will be as per SC6.4.4.8 Standard drawings (Typical Road Cross Sections SD-001, SD-002, SD-003, SD-004, SD-005, SD-006, SD-010), and SC6.4.4.1 Geometric road design.

(d) Where a zero object height is necessary, only hard landscape areas must be established, subject to meeting all other requirements within this sub-section and other sub-sections of the Development manual planning scheme policy.

(e) A minimum 1.2 m width of hard surface treatment (which may be inclusive of road pavement, kerb, concrete, mountable aprons etc.) must be provided between soft landscaping and the edge of the traffic lane, unless approved otherwise.

(f) In areas >70 km/hr, an increase to 3 m in width of hard surface treatment may be required between soft landscaping and the edge of the traffic lane, subject to assessment of the associated risks of the road environment.

Editor's note—the above widths are based on standard clearances between traffic lanes and work sites, as detailed in *Manual Uniform Traffic Control Devices* (MUTCD), Queensland. These clearance requirements may be subject to reduction or increase dependent on the road speed environment being assessed and subject to council approval. The intention for all standard clearances is to ensure a safe work environment, reduced inconvenience to road users and reduced the reliance on traffic control and the associated costs.

(g) Installation of decorative walls, entry signs, rocks or other fixed objects in the medians or central island of roundabouts will only be approved in select locations and where:

(i) the median or roundabout is larger than 10 m in width/diameter;

(ii) vehicles are not likely to run off the road;

(iii) placement of the fixed objects will not distract drivers;

(iv) maintenance or repairs to the fixed objects will not put maintenance personnel at risk;

(v) all requirements (including frangibility, clear zones, sight triangles etc.) per Austroads are satisfied; and

(vi) green walls or vine trellises shall only be provided in limited circumstances and where all design, construction, safety and maintenance conditions are satisfied.

Editor's note—due to the custom nature of green walls, vertical gardens and façade greening, no design and construction standards are provided. Each site will be assessed on a case-by-case basis. Generally the majority of these type of planting features are to be within private property and should be under the maintenance regime of the owner. All engineering and hydraulic certification must be provided with any structure proposed.

(h) For medians, specific requirements apply being:
Streetscape treatments shall be provided in accordance with Table SC6.4.3.6.7 Treatment application based on median width and other requirements of this policy.

Table SC6.4.3.6.7 Treatment application based on median width

Treatment	Appropriateness of treatment application by median widths (including width of kerbs)				
	< 2.5 m	**2.5 m – 3.5 m**	**3.5 m – 6.0 m**	**6.0 m – 10.0m**	**> 10.0m**
Hard landscape (Stencil-crete, artificial turf, concrete or similar) [1] where the width of hard landscape treatments may exceed 6.0m, a combination of hard and soft landscape treatments should be applied to avoid large expanses of hardscape, subject to satisfaction of all safety requirements	Yes	Yes	Yes	Yes[1]	Yes[1]
Turf (Zoysia spp. or approved alternative) [2] may be approved in select locations only, minimum clearances may still apply subject to road speed environment. Unless approved otherwise, turf areas must be a minimum width of 2.0m to support an irrigation system in a safe and efficient manner and facilitate efficient operational maintenance. Turf areas greater than 6.0m in width should be combined with other hard and soft landscaping treatments	No	No[2]	Yes	Yes	Yes
Garden areas (Shrubs/ground covers below 3.5m in height) *Frangible* [3] may be approved in select locations only, minimum garden area width and clearances may still apply subject to road speed environment, subject to satisfaction of all safety requirements	No	Yes[3]	Yes	Yes	Yes
Small trees/ large shrubs (Mature canopy between 5.0 – 10.0m in height or large shrubs greater than 3.5m in height) *Frangible or* *Non – frangible*	No	No	Yes	Yes	Yes
Medium trees (Mature canopy between 10.0 – 15.0m in height) *Non – frangible*	No	No	No	Yes	Yes
Large tree (Mature canopy greater than 15.0m in height) *Non – frangible*	No	No	No	No	Yes
Palms *Frangible or* *Non – frangible* [4] select locations only, minimum setbacks may also apply subject to species selection and mitigation of risks associated with frond drop	No	No	No	Yes[4]	Yes[4]

Editor's note—appropriateness of treatment application is based on clearance and setback requirements in a 60 km/h speed environment. Council approval of design outcomes that deviate from the above may be granted at select locations, dependent on the road speed

environment being assessed and that all safety and operational requirements are satisfied. This includes requirements outlined in MUTCD (Queensland) relating to work sites, with the intention being to design streetscapes to minimise reliance on traffic control during regular, routine maintenance operations.

(i) For the roundabouts, specific requirements apply being:

(i) streetscape treatments shall be provided in accordance with Table SC6.4.3.6.8 and other requirements of this sub-section;

(ii) splitter or blister islands should not accommodate any soft landscaping unless approved otherwise (generally, islands must be an average width of 6 m or greater and all safety and operational requirements must firstly be satisfied); and

(iii) where garden areas and trees are provided, plant species in the central islands of roundabouts should only consist of ground covers, low growing shrubs and/or mulched areas with clean trunked trees unless approved otherwise.

Table SC6.4.3.6.8 Treatment application based on roundabout diameter

Treatment	Treatments application by roundabout diameter (including width of kerbs and mountable apron)			
	< 7.0 m	**7.0 m – 10.0 m**	**10.0 m – 14.0m**	**> 14.0m**
Hardscape (Stencil-crete, artificial turf, concrete or similar) [1] where the width of hardscape treatments may exceed 10.0 metres, a combination of hard and soft landscaping treatments must be applied to avoid large expanses of hardscape	Yes	Yes	Yes[1]	Yes[1]
Turf (Zoysia spp. or approved alternative) [2] may be approved in select locations only, minimum clearances may still apply subject to road speed environment. Unless approved otherwise, turf areas must be a minimum width of 2.0m to support an irrigation system in a safe and efficient manner and facilitate efficient operational maintenance. Turf areas greater than 6.0m in width should be combined with other hard and soft landscaping treatments	No	No	Yes[2]	Yes[2]
Garden areas (Shrubs/ground covers below 3.5m in height) *Frangible* [3] may be approved in select locations only, minimum garden area width and clearances may still apply subject to road speed environment	No[3]	Yes	Yes	Yes
Small trees/ large shrubs (Mature canopy between 5.0 – 10.0m in height or large shrubs greater than 3.5m in height) *Frangible or* *Non – frangible*	No	Yes	Yes	Yes
Medium trees (Mature canopy between 10.0 – 15.0m in height) *Non – frangible*	No	No	Yes	Yes
Large tree (Mature canopy greater than 15.0m in height) *Non – frangible*	No	No	No	Yes
Palms *Frangible or* *Non – frangible* [4] select locations only, minimum setbacks may also apply subject to species selection	No	No	Yes[4]	Yes[4]

(9) Hard landscape treatment requirements

(a) Hard landscape treatments must:

(i) comply with all requirements relating to:

(A) appropriate abrasion resistance in accordance with test methods stipulated in AS/NZS 4456.9 - *Masonry units and segmental pavers and flags - Methods of test - Determining abrasion resistance*; and

(B) appropriate slip resistance capability as required by AS/NZS 4586 - *Slip resistance classification of new pedestrian surface materials*; and

(ii) be colour-fast, UV resistant and non-reflective.

(b) Where the width of hard landscape treatments may exceed 6 m, it is desirable that a combination of hard and soft landscape treatments is used to avoid large expanses of hard surface. This excludes roundabouts below 10 m in diameter.

(10) Turf area requirements

(a) Turf areas shall be in accordance with all applicable council approved standard drawings for turf areas.

Editor's note—currently, no standard drawings are formally adopted for streetscape treatments.

(b) Turf areas may form part of clear zones, provided all other requirements are satisfied.

(c) Turf areas must be a minimum 1.5 m **clear** width to allow for mowing access unless approved otherwise (noting minimum 2 m **total** widths are desirable for irrigation purposes).

(d) Where the width of the medians exceed 6 m, it is desirable that turf areas are combined with other hard and soft landscape treatments to provide balance against the median width.

(e) Turf species must be low maintenance and Empire Zoysia or an approved equivalent species.

(11) Garden area requirements

(a) Garden areas (planted or mulched only) shall be in accordance with all applicable council approved standard drawings for garden areas.

Editor's note—currently, no standard drawings are formally adopted for garden areas.

(b) All garden areas must be a minimum width of:

(i) 1 m where combined with other soft and hard landscaping treatment; and

(ii) 1.5 m where provided as full width planting.

(c) Where garden areas are **within** the sight triangle, plantings should only consist of ground covers and low shrubs with a maximum mature height of 600 mm or less in order to preserve sight lines.

(d) Where garden areas are **outside** the sight triangle, plantings expected to exceed 600 mm in mature height may be provided where all clear zone and frangibility requirements are satisfied and plantings are provided:

(i) as screen planting or buffers along fence lines or acoustic barriers;

(ii) for functional reasons such as a visual barrier for headlight glare, a windbreak or a physical barrier to human movement; and

(iii) where screening or accent planting is desired.

(e) Approval of full width planting may be provided:

(i) for strategic locations only;

(ii) where the garden area will be a minimum width of 1.5 m; and

(iii) where garden areas will be located behind road safety barrier system; or

(iv) where the road speed and required clearances between the edge of the traffic lane and the garden area complies with MUTCD (Queensland) requirements for work sites (Short-term Low Impact - Built Areas or Static Work Areas) and will not require the use of traffic control.

Editor's note—approval for full width planting will only be for select locations, subject to the satisfaction of all safety and operational maintenance requirements. Approved locations will generally be associated with central median screening or buffering plantings, key entry gateways or high profile roads, and/or associated with centres or commercial precincts. Where the road speed is 40 km/h or less, full width plantings may be provided in medians between 2.5-3.5 m, subject to achieving the

minimum garden area width and council approval.

(f) Where full width plantings are approved, plants must setback (from back of kerb) at least half the mature plant diameter, in order to mitigate potential encroachment into the roadway, reduce obstructions that compromise safety and increased maintenance requirements.

(g) All species selection should have regard to aesthetic, suitability, functional and ecological selection criteria and include consideration of:

(i) appropriateness for the planting approach (e.g. structured or naturalistic);

(ii) mature spread dimension and required density, noting encroachment into road shoulder must be avoided;

(iii) mature height and compliance with sight triangle requirements, noting reliance on frequent maintenance to maintain sight lines must be avoided;

(iv) frangibility requirements;

(v) drought resistance/water requirements;

(vi) suitability for prevailing soil type;

(vii) lifespan, noting long-lived species are desired and annuals are not to be used unless approved otherwise;

(viii) salt tolerance;

(ix) pollution resistance;

(x) environmental and habitat value of particular species;

(xi) ongoing care and maintenance requirements; and

(xii) the intended purpose of the planting and the species' suitability for this, including uses such as:

(A) headlight screen planting;

(B) buffer screening;

(C) visual screening;

(D) visual guidance planting;

(E) user perceptions of speed;

(F) shade and sunlight control;

(G) windbreak;

(H) physical barrier;

(I) erosion control;

(J) safety; and

(K) noise attenuation.

(h) Garden areas (mulched only) shall:

(i) be provided where shrubs and groundcovers are not desired or cannot be planted without impacting sight lines; and

(ii) where tree planting is incorporated in the mulched garden area.

(12) Street tree requirements

(a) Street trees should be provided at the following rate:

(i) a minimum of one tree per standard building lot or spaced at approximately 20 m intervals; and

(ii) a maximum of four trees per standard building lot or spaced at approximately 7 m intervals.

(b) The above rates may be altered where:

(i) there is insufficient available space based on safety and setback requirements; or

(ii) existing street trees will be retained; and

(iii) subject to council approval of the reduced rate.

Editor's note—in locations where lot sizes are below the standard lot width, street tree provision rates will need to be assessed on a case by case basis. In these instances, a balance between provision rates, reduced setback requirements and appropriate mitigation measures to reduce potential damage to adjacent infrastructure must be sought.

(c) Street trees shall be planted in accordance with:

(i) all applicable council approved standard drawings for tree planting; and

Editor's note—currently, no standard drawings are formally adopted for landscape treatments.

(ii) all setback requirements, being:

(A) a minimum 5 m from an electricity pole or pillar box;

(B) a minimum 7 m from a street light pole;

(C) a minimum 2 m from side entry stormwater pits;

(D) a minimum 2.5 m from either side of a driveway;

(E) a minimum 1.05 m from back of kerb; and

(F) a minimum 0.5 m from a footpath.

Editor's note—the above requirements are based on cross sections outlined on SD-015 Verge Service Corridors and other longitudinal setbacks intended to mitigate risk of conflict between street trees and other infrastructure. Setbacks from all utility services should be confirmed with the relevant asset owner/service provider. For setbacks on the approach and departure sides of bus stops, refer to SC6.4.4.8 Standard drawings (SD-515 Standard bus stop urban location layout details Type 1 and 2). For setbacks from intersections, refer to Austroads minimum gap acceptance and sight distance criteria. For setbacks on the approach and departure sides of pedestrian crossings and other designated crossing points, refer to crossing sight distance (CSD) requirements in *Traffic and Road Use Management Manual – Pedestrian Cross Facility Guidelines* and *Prioritisation System User Guide*.

(d) In addition to the above, the following apply:

(i) When street trees are to be planted in medians or roundabouts, extended planting setbacks (from back of kerb or adjacent hard surface treatments) apply, being:

(A) for small trees or large shrubs (mature canopy between 5 – 10 m in height or large shrubs greater than 3.5 m in height), setback at a distance of 2 m or half the mature canopy diameter, whichever is greater;

(B) for medium trees (mature canopy between 10 – 15 m in height), setback at a distance of 4 m or half the mature canopy diameter, whichever is greater; and

(C) for large trees (mature canopy greater than 15 m in height), setback at a distance of 6 m or half the mature canopy diameter, whichever is greater.

(ii) Where setbacks cannot be achieved, appropriate mitigation measures such as root barrier must be included.

(iii) Where species proposed have a known invasive root system, increased setbacks are required and mitigation measures such as root barrier are to be provided as per arborist advice.

(iv) Street tress will not be planted in clear zones, except where:

(A) Tree species are considered frangible and the mature trunk diameter will not exceed 100 mm; or

(B) where non-frangible tree species will be located behind road safety barriers.

(v) When planted in the CBD, commercial zones, or where the planting area is completely surrounded by impervious surfaces, a minimum root development zone of 4 m^3 must be provided for each street tree. This may be achieved through the use of structural soils, root cell products, pervious pavements or a combination of these treatments.

(e) Street tree species selection should:

(i) be selected with consideration of suitability criteria, including:

(A) whether there is an existing dominant species in the street or suburb that contributes to the streetscape or suburb character;

(B) size of the available planting space as some tree species are better able to survive in restricted growing areas;

(C) location of the new tree, the species growing habit and branch structure;

(D) whether the new tree will be planted under power lines as only a limited number of species are suitable in this situation;

(E) tree species water requirements and drought resistance;

(F) suitability for prevailing soil type;

(G) pollution resistance;

(H) species with minimal fruit, leaf and limb drop;

(I) species with high shade potential;

(J) species with higher resilience to cyclone damage; and

(K) environmental and habitat value of particular species;

(ii) be appropriate for the available planting space, accounting for all setback, offset and clearance requirements (overhead, longitudinally and horizontally across the road cross section);

(iii) only consist of trees that will achieve canopy clearance heights applicable to the streetscape situations outlined in Table SC6.4.3.6.9 Canopy clearance heights and exhibit a 1.2 m clear trunk at the time of planting;

Table SC6.4.3.6.9 Canopy clearance heights

Streetscape situation	Minimum vertical clearance height (at maturity)
Standard pedestrian and car park environment	2.4m
Cyclist environment	2.7m
Main and arterial roads	5.4m
Other roads	4.6m
High clearance routes	5.9m
Very high clearance routes (with no alternative)	6.5m

Editor's note—above clearances are based on minimum vertical clearances detailed in Austroads *Guide to Road Design*, Part 3: Geometric Design.

(iv) in established areas, the street trees species are to be nominated by council;

(v) in new development areas, the street trees species are to be nominated by the developer and approved by council; and

(vi) include palms in select locations only where:

(A) palm species are self-cleaning; or

(B) sufficient area beneath the palms are provided to mitigate risks from falling palms fronds; and

(C) the plantings will not impose an unsustainable maintenance requirement.

(f) Selection of the street tree stock size for planting should consider:

(i) the planting location such as whether it is in a median, roundabout or on the footpath (e.g. more mature stock may be required in roundabout plantings where sight lines will be impeded by the foliage of a young tree);

(ii) the optimal size to achieve best establishment (e.g. smaller stock typically establish better, larger stock may be required to meet visibility requirements at time of planting); and

(iii) the size of the original tree where replacing a removed tree (e.g. in instances were a large,

significant tree is removed, a larger sized and/or increased quantity of replacement stock may be considered).

(13) Tree guards

(a) Tree guards may be used in order to temporarily, semi-permanently or permanently protect trees during establishment and ongoing growth.

(b) Trees guards should consist of proprietary available products and be installed as per manufacturer specifications.

(c) Where new trees are to be planted within known areas of high vandalism, more durable, vandal resistant, temporary tree guards may need to be selected and installed to reduce potential loss of new plantings during establishment.

(d) Where tree guards are to be provided semi-permanently or permanently and/or in conjunction with tree grates, tree guards are to be designed, constructed and installed as an integrated component of the tree grate system. In these instances, all requirements for tree grates detailed below should be considered, where applicable.

(14) Tree grates and surrounds

(a) Tree grates and tree surrounds are to be provided in accordance with the following;

(i) tree grates are to be designed, constructed and installed in accordance with AS 3996 – Access covers and grates;

(ii) tree grates and alternative tree surrounds are to be provided in order to increase the usable walking space, protect tree and root systems and provide a cost effective solution to reduce maintenance requirements;

(iii) installation of tree grates and tree surrounds is to be limited to high trafficable areas of streetscapes (as detailed in SC6.4.3.3 Footpath treatment policy), regional level parks and civic spaces, unless approved otherwise;

(iv) the tree grates or surrounds should be of an appropriate material, size and colour suitable for the location, tree type and available space. Tree grate or surround design must allow for the penetration of air and water to the soil, whilst minimising potential trip and slip hazards and rubbish trapping. Consideration should be given to the growing habit of the selected trees, trunk shape, "off centre" trunks and expected changes to trunk and root diameter, allowing for variation or future modification with tree growth;

(v) tree grates or surrounds must be installed flush with adjacent surfaces, with grate metal support frames and appropriate fixings to be installed at the time of construction, as required to meet the specified loading capacity;

(vi) tree plantings with grates or other surrounds must be supported by all other necessary elements including but not limited to, structural root cell, root barrier, drainage gravel, and perforated pipe;

(vii) permeable paving is considered to be a suitable tree surround option, particularly for installation around existing, mature trees;

(viii) where the sub-section SC6.4.3.3 Footpath treatment policy applies, permeable paving is considered to be an alternative option for tree grates. In these instances, the specified colours must be used, in accordance with the pavement treatment hierarchy as per SC6.4.3.3 Footpath treatment policy. Table SC6.4.3.6.2, Table SC6.4.3.6.3, Table SC6.4.3.6.4, Table SC6.4.3.6.5, Table SC6.4.3.6.6 identify the corresponding permeable paving colours against the Footpath treatment policy pavement hierarchy; or

(ix) where SC6.4.3.3 Footpath treatment policy does not apply, alternative colours may be proposed.

(15) Operational requirements

(a) Streetscape designs must seek to minimise the ongoing costs and operational maintenance requirements by:

(i) ensuring treatments are durable, weatherproof, UV resistant and of robust construction and finish to reduce repair or replacement frequency;

(ii) minimising the potential to create litter traps;

(iii) promoting resistance to damage, vandalism, unauthorised use and removal;

(iv) promoting easy cleaning and are fully accessible and responsive to maintenance activities including mechanical cleaning procedures;

(v) incorporating erosion and sediment control measures to reduce clearing out of drains;

(vi) minimising the need for herbicide applications and brush cutting around furniture such as guard rail posts or signs;

(vii) ensuring effective access for maintenance and to critical road infrastructure is integrated into the streetscape design to support easy, time efficient operations;

(viii) ensuring all turf areas are of the minimum specified width to facilitate safe and efficient operation of mowing vehicles and reduce the requirement for "on foot" maintenance;

(ix) complying with all clearance and setback requirements to ensure maintenance can be safely undertaken without a reliance on traffic control;

(x) considering the plant maintenance regimes needed to maintain all safety requirements. Ongoing pruning requirements and frequency to maintain all clearances (particularly within clear zones and sight triangle) should be minimised through appropriate planting and species selection. All costs associated with these maintenance regimes should be built into the whole of life design cost;

(xi) using planting design to progressively reduce the number of maintenance interventions required over time for planted areas. This should include reducing weed and vegetation management activities through improved plant layout and layering, densities and species selection that establish quickly to choke out competing weeds and require no pruning or shaping;

(xii) identifying any traffic control requirements associated with ongoing maintenance operations in early design stages. This should include any lane or road closures, detours, and the ongoing cost to implement any such requirements. All options to reduce identified traffic control requirements should be explored in order to reduce ongoing operational costs; and

(xiii) mitigating any potential for streetscape elements to cause significant damage to other road infrastructure such as driveways, kerb and channel, road pavement and utility services.

(b) In order to properly assess maintenance requirements associated with streetscape proposals, council may request the provision of a maintenance plan and approved traffic management plan as part of the development application, as per Section SC6.4.2 Development application guidelines.

SC6.4.3.6.32 Car parking plantings and shading

(1) Landscaping is to be provided to on-street and off-street car parking areas so as to improve the aesthetic and climatic properties associated with these sites. The prevailing climatic conditions in Townsville demand that shade is provided to car parking areas to improve the comfort and reduce the urban heat island effect from large areas of hard surface.

(2) Planting and shading options
Dependent on site and safety considerations, shading of car parks can be in the following manner:

(a) in single sided, angle or parallel bays – 1 tree per 3 car parks;

(b) in double sided – 1 tree per 6 car parks; and

(c) shade structures may be used in conjunction with low shrubs and low groundcovers internal to the parking area; and trees, low shrubs and ground covers on the periphery of the car park.

(3) Tree planting in car parks

(a) Trees planted within off-street car parking areas are provided with:

(i) a minimum surface planting area of 1.2 m^2, or are incorporated into continuous garden beds; and

(ii) planting pits for trees in car parks surrounded by hardstand are to provide a minimum of 4 m^3 for root zone development, at no greater depth than 1 m. The use of structural soils or root cell type products is highly recommended to achieve acceptable growth and form in shade trees.

(b) Trees planted within road reserve angle car parking areas are provided with garden bed areas between parking bays, which are to be kerbed and no less than 1.2 m wide internally.

(c) Trees must be planted in accordance with any approved standard drawings.

(d) Trees must be allowed to mature naturally and only pruned in accordance with AS4373.

Editor's note—currently, no standard drawings are formally adopted for tree planting. Refer also to SC.6.4.3.3 Footpath treatment policy.

(4) Landscape design and species selection

All car parking plantings must satisfy the following landscape design and species selection requirements:

(a) ground cover and shrubs should have a maximum height of 600 mm to preserve sight lines;

(b) tree canopies should achieve a minimum clearance above ground of 2.4 m above pedestrian and parking zones, or 4.6 m over vehicle movement zones;

(c) in public parking areas, trees are to be a species as nominated by council;

(d) in private parking areas, trees species are to be nominated by the developer and approved by council;

(e) trees and garden beds within car parking areas are protected by raised kerbs, wheel stops or bollards;

(f) all plantings in streetscapes and car parks are to comply with the specific design and construction requirements as detailed in sub-section SC6.4.6.26 Landscaping.

SC6.4.3.6.33 Green roofs, wall and vertical gardens

(1) Green roofs

Editor's note—due to the custom nature of green roofs, no design and construction standards are provided. Each site will be assessed on a case-by-case basis.

(2) Green walls, vertical gardens and façade greening

Editor's note—due to the custom nature of green walls, vertical gardens and façade greening, no design and construction standards are provided. Each site will be assessed on a case-by-case basis. Generally, planting features these types are to be within private property and should be under the maintenance regime of the owner. All engineering and hydraulic certification must be provided with any structure proposed.

SC6.4.3.6.34 Irrigation design and system requirements

(1) Introduction

Intent: Irrigation systems solely exist for the purpose of providing water to maintain the soil moisture content above the horticultural assets permanent wilting point and below the maximum field capacity. These conditions are required to maintain the health and growth of the horticultural assets.

(a) These guidelines, supported by SC6.4.6.27 Irrigation, set out the scope of work, workmanship standards and the responsibilities for the supply and installation of irrigation systems within private open space and public open space and streetscapes that will become a council asset on handover.

(b) In addition to this requirement council seeks to minimise water usage within all open space and reduce maintenance and operational costs associated with the council owned irrigation systems.

(c) Product and brand names for components in this sub-section and SC6.4.6.27 Irrigation are used to define a standard and quality acceptable to council, with particular emphasis on long term maintenance requirements. Components other than those specified may only be used if the components are of equal or better standard and quality of those specified and an authorised change has been approved by council.

(d) Where the developer/applicant has installed an unauthorized irrigation system not approved by Council, the developer/applicant will be required to remove such irrigation systems and rectify at their expense.

(e) Developer/applicants must aquaint themselves with Townsville's water restrictions of the time, and where required obtain written permission from Council to implement landscape treatments that require establishment water treatment. Such water treatment permissions shall be in line with Townsville's water restriction policy requirements for the establishment period.

(2) Irrigation design objectives:

(a) to ensure that irrigation systems are designed to the highest industry standards with the goal of maximising the efficient usage of water;

(b) to ensure that irrigation systems and components are installed in accordance with the relevant industry standards and tradesman like workmanship; and

(c) to ensure that the irrigation systems and components installed are of a quality and standard acceptable to council, with regard to the life of the system, the ongoing ease of maintenance and operational costs of the system and its components.

(3) General requirements

(a) All irrigation must be of a high standard, being designed, constructed and installed in accordance with:

(i) the provisions within the planning scheme, planning scheme policies and this sub section of the Development manual planning scheme policy;

(ii) manufacturer specifications;

(iii) all applicable Australian Standards and legislation;

(iv) all applicable council local laws; and

(v) council's approved standard drawings.

(b) All irrigation systems are to be:

(i) designed to achieve an even and efficient supply of water to the nominated Hydro-Zone areas;

(ii) designed with consideration of local conditions such as topography, prevailing winds, micro-climate, rainfall volumes and seasonal dry and wet periods;

(iii) constructed using quality materials and components;

(iv) automated to allow for efficient water usage;

(v) programmed to operate in accordance with any council water restrictions;

(vi) designed to operate efficiently and effectively based on the water supply pressure and flow volume available to the system;

(vii) The minimum industry accepted standard by TCC for turf sprinkler uniform cover is a Distribution Uniformity (DU) of 75% cover; and

(viii) The minimum industry accepted standard by TCC for sportsfield turf sprinkler uniform cover is a Distribution Uniformity (DU) of 100% cover for all of the sport playing surface with a 85% cover of the surrounding safety zone of the playing field surface.

(c) All irrigation in private open space that is to be:

(i) installed and operated by a **private entity**, is **not** required to comply with the specific design and construction standards, however such systems that are connected to the reticulated water network is required to comply with Townsville's water restrictions of the time.

(ii) installed and/or operated by council, is to be designed and constructed as per requirements detailed in this sub section and SC6.4.6.27 Irrigation.

(d) All irrigation systems in public open space and road landscaping are to:

(i) be designed by qualified professionals, being a certified irrigation agronomist or a certified irrigation designer;

(ii) constructed using quality materials and components to ensure a robust, reliable, and long asset life;

(iii) be designed to minimise life cycle costs through reduced operational and maintenance requirements;

(iv) be designed and apply volume that should not cause foreseeable damage to the road structure or surface; and

(v) be designed and constructed as per requirements detailed in this sub–section and SC6.4.6.27 Irrigation.

(e) All irrigation systems in streetscapes and car parking areas are to:

(i) in a "main street" or "special character" situation where council owns and operates an irrigation system or has agreed to accept irrigation assets, the irrigation is to be provided in accordance

with SC6.4.6.27 Irrigation, and will be subject to the acceptance of works procedure as per Section SC6.4.7 Acceptance of completed works; and

(ii) in all other locations where irrigated turf or plantings are required as a condition of development, the irrigation system is to be connected to the adjacent private development.

(f) Irrigation systems in public open space and streetscapes should be designed in conjunction with all landscape elements to ensure that:

(i) landscape design and plant selection ensures the required level of irrigation to maintain the function and longevity of landscape is analogous with the assigned irrigation profile, as detailed in SC6.4.3.6 Attachment C Irrigation Profile Level Hierarchy and SC6.4.3.6 Attachment D Irrigation Profile Level Matrix;

(ii) landscape design and plant selection facilitates hydro-zoning;

(iii) landscape features are designed to maximise water infiltration through use of appropriate landforms, soil types and mulches;

(iv) landscape features are designed and constructed to ensure ease of irrigation coverage in the short and long term; and

(v) landscape features are designed to contribute to an integrated water management system.

(4) Irrigation types requirements

(a) All turf areas shall be irrigated with pop-up sprinklers or subsurface drip irrigation with the following specific requirements:

(i) all turf areas in roundabouts and median strips that border roadways shall be irrigated by drip irrigation;

(ii) all turf areas within 5 m of a roadway and within 50 m of the centre of an intersection shall be drip irrigated; and

(iii) where a site specific risk analysis recommending either method has been provided and accepted by council.

(b) All garden areas shall to be irrigated with subsurface drip irrigation, except for areas containing plants or trees with vigorous root systems such as palms or lilies which shall be irrigated by pop-up sprinklers.

(5) Agronomic requirements

For all irrigation systems the approved hours of operation shall be between 10.00pm and 5.00am, the operation of such irrigation systems shall also comply with Townsville's water restrictions of the time.

(a) For pop-up sprinklers the total time taken to deliver 7 mm of equivalent precipitation when each station is operated individually and consecutively shall not exceed a 7 hour period for all stations on a given system. Variations to this requirement may apply for stations operated simultaneously.

(b) For drip irrigation the total time taken to deliver 7 mm of equivalent precipitation when each station is operated individually and consecutively shall not exceed a 7 hour period for all stations on a given system. Variations to this requirement may apply for stations operated simultaneously.

(c) The irrigation application rate shall not exceed the infiltration rate of the soil.

(d) The operation of irrigation systems must avoid operating in strong winds, excessive or poor irrigation mains pressure, poor irrigation design or lack of maintenance, which all contribute to system delivery inefficiency.

(e) All irrigation systems that are to become Council assets to maintain must be fully commissioned and operating efficiently in accordance with the approved irrigation design plans for a minimum of 3 months prior to acceptance "Off Maintenance".

(6) Environmental requirements

The system shall not have excessive runoff which causes erosion or pollution of surrounding native areas and/or storm water drains.

(7) Automation requirements

(a) The irrigation controller shall be chosen from the units outlined in Table SC6.4.3.6.10.

Table SC6.4.3.6.10 Controller Selection list

Controller Name	Power Type / Source	Valve Capacity
AC Irrinet M Slave 12 - 24	AC / 240V Mains	12 to 24
AC Irrinet M Slave 36 - 48	AC / 240V Mains	36 to 48
AC Irrinet M 12 - 24	AC / 240V Mains	12 to 24
AC Irrinet M 36 - 48	AC / 240V Mains	36 to 48
AC Irrinet ACE 24 - 48	AC / 240V Mains	24 to 48
XR 1 - 4	DC / 6V Solar	1 to 4

(b) A maximum of three stations may be operated simultaneously (by programming only) given the follow conditions:

(i) irrigation type and precipitation rate of the stations to be operated simultaneously shall be the same;

(ii) the soil type, vegetation and topography of the stations to be operated simultaneously shall be the same; and

(iii) all stations to be operated simultaneously shall be able to supply the manufacturer's recommended pressure.

(c) Only one valve per controller output is acceptable.

(8) Separation of irrigation zones

(a) Irrigation zones shall be classified in the following vegetation types:

(i) turf grass;

(ii) garden bed; and

(iii) native vegetation or revegetation plantings.

(b) A single irrigation valve shall water no more than one irrigation zone.

(9) Safety requirements

The system shall not have runoff onto roadways, footpaths or other pedestrian areas to such an extent that it may result in a hazard to traffic and/or pedestrians.

(10) Temporary irrigation design

Temporary irrigation is exempt from the technical design and installation conditions outlined in this document provided it meets all other legislated requirements.

(a) All temporary irrigation installed in the public realm must be removed and terminated in accordance with council specifications prior to the area being accepted "off maintenance". All terminations and disconnections of temporary irrigation must be inspected by a council officer prior to backfilling.

(11) Existing Council Irrigation Assets

(a) Council's Irrigation Operations Unit must be notified of any disruptions to council owned irrigation assets prior to works commencing on these assets;

(b) Works in areas containing existing council irrigation assets are required to have plans for the deconstruction and isolation of the existing irrigation to ensure the system is not unnecessarily damaged and account for the ongoing watering requirements of the soft landscaping serviced by that irrigation;

(c) All existing council irrigation affected by development works must be reinstated to standards current at the time of the works;

(d) Any extensions to existing mainline require the installation of an isolation valve;

(e) Council shall charge costs for water usage based on agreement with the developer. Options include the installation of a sub-metering device or use of Irrinet flow data.

(f) Upon activation of any additions to council owned irrigation, revised flow data must be provided to council's Irrigation Operations Unit.

Editor's note—For further information on the construction of all irrigation systems, refer to the detailed landscape specification standards as provided in SC6.4.6 Construction Standards – in particular SC6.4.6 26 Landscape Construction and SC6.4.6.27 Irrigation

SC6.4.3.6.35 Water features and water play areas

(1) Water features and water play areas will only be permitted in limited circumstances, at specific locations, and where all relevant considerations are reasonably satisfied, and will be considered on a case-by-case basis.

(2) Where the proposed water features and water play areas are associated with public open space, council owned land, or will involve potential future council assets, the infrastructure may only be permitted at approved locations and in accordance with council's Public Open Space Embellishment Framework, as detailed in Table SC6.4.3.6.1. Approval from the relevant council asset owner/s will also be required.

(3) In order to properly assess any such proposals, council may request the provision of a maintenance plan and a life-cycle costing as part of the development application, as per SC6.4.2 Development application guidelines.

(4) Where water features are proposed as a development entry statement, applications may only be approved where the water feature will be within private property and the developer will remain, for the life of the asset, solely responsible for all aspects relating to the water feature (including ongoing maintenance and water costs).

(5) All water features and water play areas must be designed and installed to comply with all relevant Australian Standards.

Editor's note—due to the place-specific, custom nature of water features and water play areas, no further specifications are currently developed. Proposals will be considered on a case-by-case basis in accordance with necessary requirements defined by all applicable engineering, electrical, drainage, swimming pool and water safety standards, legislation, local laws and council's overarching design and management principles. Engagement and approval from other stakeholders/authorities may additionally be required as part of any development proposal.

SC6.4.3.6 Attachment A: Preferred plant species list

CATEGORY	BOTANICAL NAME1	COMMON NAME	STREET TREES 3m wide desirable planting width (1m min)2	STREET TREES- 3-6 m desirable planting with (2m min)2	STREET TREES for ≥ 6m desirable palnting width (5m min)2	STREET TREES Suitable for planting under powerlines2	STREET TREES Suitable for avenue plantings2	TREES Suitable as features or specimen trees in parks & open space3	Suitable for COASTAL FOREHSORE AREAS	Suitable in and near NATURAL AREAS4	Suitable for Council PARKS AND OPEN SPACE (greater than 5m of space required for trees)3	Suitable for COMMERCIAL AND DOMESTIC PREMISES where space permits5
	Blank = does not fit criteria or	N.A.• = fits criteria.	TREES (BY LOCATION SUITABILITY)						ALL VEGETATION (BY 'SETTING' SUITABILITY)			
Large Trees over 10m (Native)												
	Acacia auriculiformis	Black Wattle		•	•			•		•	•	•
	Acacia crassicarpa	Beach Wattle							•	•	•	•
	Acacia mangium	Hickory Wattle						•		•	•	
	Acacia melanoxylon	Blackwood			•			•		•	•	•
	Adenanthera pavonina	Red Bead Tree		•	•			•		•	•	•
	Agathis robusta	Kauri Pine			•			•		•	•	•
	Aidia racemosa	Archer Cherry								•	•	•
	Albizia procera	Forest Siris			•					•	•	•
	Allocasuarina torulosa	Forest Oak						•		•	•	
	Alstonia actinophylla	Cape Milkwood						•		•	•	
	Alstonia scholaris	Milky Pine			•			•		•	•	
	Araucaria bidwillii	Bunya Pine			•			•		•	•	
	Araucaria cunninghamii	Hoop Pine			•		•	•		•	•	•

Bombax ceiba	Native Kapok Tree			•		•	•			•	
Brachychiton acerifolius	Flame Tree	•	•			•	•		•	•	•
Calophyllum inophyllum	Beauty Leaf			•			•	•	•	•	
Cananga odorata	Ylang Ylang Tree						•		•	•	
Canarium australasicum	Mango Bark		•	•			•	•	•	•	
Canarium australianum	Melville Island White Beech		•	•			•	•	•	•	•
Castanospermum australe	Black Bean			•			•		•	•	•
Casuarina cunninghamiana	River she-oak						•		•	•	
Corymbia citriodora (syn. Eucalyptus citriodora)	Lemon-scented Gum			•			•		•	•	
Corymbia clarksoniana (syn.Eucalyptus clarksoniana)	Clarkson's Bloodwood						•		•	•	
Corymbia erythrophloia (syn. Eucalyptus erythrophloia)	Red-barked Bloodwood						•		•		
Corymbia ptychocarpa (syn. Eucalyptus ptychocarpa)	Swamp Bloodwood						•			•	
Corymbia setosa (syn. Eucalyptus setosa)	Rough Leaf Bloodwood						•		•	•	
Corymbia tessellaris (syn. Eucalyptus tessellaris)	Moreton Bay Ash			•			•	•	•	•	•
Eleocarpus angusitfolius (syn E. grandis)	Blue Quandong			•			•	•	•	•	
Eucalyptus camaldulensis	River Red Gum						•			•	
Eucalyptus crebra	Narrow leafed Ironbark						•		•	•	
Eucalyptus drepanophylla	QLD Grey Ironbark						•		•	•	
Eucalyptus miniata	Darwin Woollybutt		•	•			•			•	•
Eucalyptus pellita	Red Mahogany		•	•			•		•	•	
Eucalyptus platyphylla	Poplar Gum						•		•	•	
Eucalyptus raveretiana	Black Ironbox						•		•	•	
Eucalyptus similis	Inland Yellow Jacket		•	•			•		•	•	
Eucalyptus tereticornis	Blue Gum						•		•	•	
Euroschinus falcatus	Ribbon Wood		•	•					•	•	
Ficus benjamina	Weeping Fig			•			•			•	
Ficus microcarpa var hillii	Hills Weeping Fig			•			•		•	•	
Ficus racemosa	Cluster Fig						•		•	•	
Flindersia brayleyana	Queensland Maple		•	•			•			•	
Ganophyllum falcatum	Scaly Bark Ash		•	•			•	•	•	•	
Gossia bidwillii (syn. Austromyrtus bidwillii)	Python Tree		•	•						•	•
Grevillea hilliana	White Silky Oak		•	•			•		•	•	
Lophostemon confertus	Brush box			•			•		•	•	
Lophostemon grandiflorus	Northern Swamp Mahogany		•	•			•		•	•	•
Melaleuca dealbata	Cloudy or Silver-leaved Paperbark		•	•			•		•	•	•
Melaleuca fluviatilis	Weeping Paperbark		•	•		•	•		•	•	
Melaleuca leucadendra (fine leaf form included)	Paperbark		•	•			•		•	•	•
Melaleuca quinquenervia	Broad leaved paperbark		•	•			•		•	•	•

	Nauclea orientalis	Leichhardt Tree			•			•		•	•	•
	Peltophorum pterocarpum (Nth Aust. Form)	Yellow Flame Tree			•			•			•	•
	Pittosporum ferrugineum	Rusty Pittosporum			•			•	•	•	•	•
	Pleiogynium timorense	Burdekin 87vPlum			•		•	•	•	•	•	•
	Rapanea variabillis	Muttonwood		•	•		•	•			•	•
	Syzygium forte	White Apple		•	•			•			•	•
	Syzygium fortes subsp. Potamophilum	Flaky Barked Satinash		•	•		•	•			•	•
	Syzygium francisii	Francis's Water Gum		•	•			•			•	
	Syzygium hemilamprum (Syn. Acmena hemilampra)	Broad-leaved Lillpilly	•	•				•		•	•	•
	Sygyzium luehmannii	Small leaved Lillypilly		•	•			•		•	•	•
	Syzygium tierneyanum	River Cherry			•			•		•	•	•
	Terminalia arenicola	Damson Plum			•			•		•	•	•
	Terminalia catappa	Sea Almond			•			•	•	•	•	
	Terminalia complanata	Cape York Terminalia			•			•			•	
	Terminalia melanocarpa	Sea Almond			•			•		•	•	
	Terminalia porphyrocarpa	Sea Almond		•	•			•		•	•	
	Terminalia sericocarpa = T. microcarpa	Damson Plum			•			•		•	•	
	Timonius timon	Tim Tam Tree		•	•			•		•	•	•
	Toona ciliata (syn. T. australis)	Red Cedar						•			•	
	Xanthostemon chrysanthus	Golden Penda	•	•	•			•		•	•	•
Large Trees over 10m (Exotic)												
	Caesalpinia ferrea	Leopard Tree		•	•			•			•	•
	Cassia javanica	Pink Cassia		•	•		•	•			•	
	Ficus benghalensis	Banyan Fig						•			•	
	Khaya senegalensis	African Mahogany						•			•	
	Mangifera indica	Mango		•	•			•			•	•
	Mesua ferrea	Ceylon Ironwood		•	•		•	•			•	•
	Pterocarpus indicus	Rosewood			•			•			•	
	Pterocarpus indicus 'Pendula'	Weeping Rosewood		•	•			•			•	•
	Handroanthus impetiginosus (syn.Tabebuia palmerii)	Pink Trumpet Tree		•	•			•			•	•
	Samanea saman (syn. Albizia saman)	Rain Tree						•			•	
	Swietenia mahoganii	Mahogany						•			•	•
	Tamarindus indica	Tamarind		•	•			•			•	•
	Tectona grandis	Teak						•			•	
Trees 5-10 m (Native)												
	Acacia flavescens	Yellow Wattle, Toothed Wattle							•	•	•	•
	Acmena smithii = Syzygium smithii	Lillypilly		•	•						•	•
	Alphitonia excelsa	Red Ash		•	•				•	•	•	•
	Antidesma bunius	Herbert River Cherry		•	•					•	•	•
	Arytera divaricata	Rose Tamarind	•	•	•		•			•	•	•
	Atalaya hemiglauca	Whitewood		•						•	•	•
	Atractocarpus fitzalanii (Syn. Randia fitzalanii)	Brown Gardenia		•						•	•	•
	Backhousia citriodora	Lemon Scented Myrtle			•					•	•	•
	Barringtonia acutangula	Freshwater Mangrove	•	•	•			•	•	•	•	•
	Barringtonia asiatica	Fish Killer Tree		•	•			•	•	•	•	•

Barringtonia calyptrata	Cassowary Pine	•	•	•		•	•	•	•	•	•
Barringtonia racemosa	Fish Poison Tree	•	•	•			•	•		•	•
Brachychiton australis	Broad-leaved Bottle Tree		•	•			•		•	•	•
Brachychiton discolor	White Kurrajong	•	•	•			•			•	•
Brachychiton rupestris	Bottle Tree		•	•		•	•			•	•
Buchanania arborescens	Little Gooseberry Tree					•	•			•	•
Buckinghamia celsissima (NQ Form)	Ivory Curl Tree	•	•	•		•	•		•	•	•
Bursaria spinosa	Prickly Box, Native Blackthorn		•	•	•			•	•	•	•
Carallia brachiata	Corkwood	•	•	•			•	•	•	•	•
Cassia brewsteri	Brewster's Cassia	•	•	•			•		•	•	•
Cassia queenslandica	Queensland Cassia	•	•	•			•			•	•
Cassia sp. (Paluma Range)	Paluma Range Cassia	•	•	•			•		•	•	•
Casuarina equisetifolia	Horsetail She-oak, Beach Casuarina			•				•	•	•	
Chionanthus ramiflorus	Native Olive	•	•	•					•	•	•
Cochlospermum gillivraei	Native Kapok							•	•	•	•
Cordia dichotoma	Glue Berry			•				•			
Cordia subcordata	Sea Trumpet	•	•	•			•	•		•	•
Corymbia peltata (syn. Eucalyptus peltata)	Rusty Jacket		•	•				•	•	•	•
Cupaniopsis anacardioides	Tuckeroo	•	•	•	•	•	•	•	•	•	•
Davidsonia pruriens	Davidson's Plum			•				•	•	•	•
Deplanchea tetraphylla	Golden Bouquet Tree		•	•			•		•	•	
Dillenia alata	Red Beech		•	•			•	•	•	•	•
Elaeocarpus eumundi	Eumundi Quandong	•	•	•			•		•	•	•
Eleocarpus reticulatus	Blueberry Ash		•	•			•			•	
Erythrina vespertilio	Bat Wing Coral Tree						•	•	•	•	
Eucalyptus phoenicea	Scarlet Gum		•	•						•	•
Eucalyptus pruinosa	Silver Box		•	•			•		•	•	•
Eucalyptus shirleyi	Shirley's Silver Leaved Ironbark			•					•	•	•
Ficus platypoda	Rock-cracker Fig			•					•	•	•
Geijera salicifolia	Scrub Wilga		•				•		•	•	•
Glochidion philippicum	Daintree Cheese Tree							•	•	•	•
Grevillea baileyana	Findlay's Silky Oak	•	•			•			•	•	•
Grevillea parallela	Beefwood								•	•	•
Grevillea pteridifolia	Golden Grevillea								•	•	•
Grevillea striata	Beefwood								•	•	•
Harpullia hillii	Tulipwood		•	•					•	•	•
Harpullia pendula (NQ Form)	Tulipwood/ Tulip Lancewood	•	•	•		•	•		•	•	•
Hibiscus tiliaceus	Cottonwood							•	•	•	•
Hymenosporum flavum	Native Frangipani	•	•	•					•	•	•
Lysiphyllum hookeri = Bauhinia hookeri	Native Bauhinia	•	•		•	•	•		•	•	•
Macaranga tanarius	Heart Leaf								•	•	•
Mallotus phillipensis	Red Kamala		•	•					•	•	•
Maniltoa browneoides	Handkerchief Tree		•	•			•			•	•
Maniltoa lenticellata	Silk Handkerchief Tree		•	•			•			•	•

	Melaleuca bracteata	Black Tea-tree	•	•		•	•			•	•	•
	Melaleuca linariifolia	Narrow-leaved Paperwork	•	•		•	•				•	•
	Melaleuca nervosa	Paperbark								•	•	•
	Melaleuca 'Revolution Green' & M. 'Revolution Gold'	Revolution Green & Revolution Gold	•			•						
	Melaleuca viminalis & cultivars (syn. Callistemon viminalis)	Bottlebrush	•	•		•				•	•	
	Melaleuca viridiflora	Broad-leaved Paperbark				•				•	•	•
	Melicope elleryana	Corkwood		•	•						•	•
	Melicope rubra (syn. Evodiella muelleri)	Little Evodia	•	•						•	•	•
	Micromelum minutum	Lime Berry								•	•	•
	Millettia pinnata (syn. Pongamia pinnata)	Pongamia or Indian Beech		•	•			•		•	•	•
	Mimusops elengi	Red Coondoo	•	•	•	•	•	•	•	•	•	•
	Mimusops elengi 'Street Elegance'	Variegated Mimusops	•	•	•		•				•	•
	Morinda citrifolia	Cheese Fruit							•	•	•	•
	Pararchidendron pruinosum	Snow Wood	•	•	•					•	•	•
	Petalostigma pubescens	Quinine Bush								•	•	•
	Pipturus argenteus	Native White Mulberry								•	•	•
	Planchonia careya	Cocky Apple							•	•	•	•
	Premna serratifolia	Creek Premna							•	•	•	•
	Scolopia braunii	Brown Birch	•	•	•	•	•	•		•	•	•
	Sterculia quadrifida	Peanut Tree	•	•	•		•			•	•	•
	Syzygium angophoroides	Yarrabah Satinash		•	•					•	•	•
	Syzygium australe & cultivars	Lillypilly	•	•						•	•	•
	Syzygium cormiflorum	Bumpy Satinash			•			•		•	•	•
	Syzygium johnsonii	Rose Satinash		•	•					•	•	•
	Syzygium oleosum	Blue Lillypilly		•	•					•	•	•
	Terminalia muelleri	Mueller's Damson			•			•		•	•	•
	Waterhousea floribunda = Syzygium floribundum	Weeping Lillypilly	•	•	•			•			•	•
	Waterhousea unipunctata = Syztgium unipunctatum	Roly Poly Satinash	•	•	•					•	•	•
	Vachellia bidwillii (syn. Acacia bidwillii)	Corkwood								•	•	•
Trees 5-10m (Exotic)												
	Cassia 'Rainbow Shower'	Rainbow Shower Cassia		•	•			•			•	•
	Delonix regia	Poinciana, Flamboyant Tree		•	•			•			•	•
	Fraxinus griffithii	Flowering Ash	•	•	•	•	•				•	•
	Kigelia pinnata	Sausage Tree						•			•	•
	Lagerstroemia speciosa	Queens Crepe Myrtle, Pride of India		•	•		•	•				
	Magnolia champaca (syn. Michelia champaca)	Michelia	•	•	•	•	•	•			•	•
	Plumeria obtusa and cultivars	Evergreen Frangipani	•	•	•	•	•	•			•	•
	Plumeria rubra and cultivars	Frangipani	•	•	•	•	•	•			•	•
	Polyalthia longifolia "Pendula'	Indian Mast Tree	•	•	•		•	•			•	•
	Schotia brachypetala	Drunken Parrot Tree	•	•	•		•	•			•	•

	Tabebuia aurea syn. T. argentea	Silver Trumpet Tree	•	•	•	•	•	•			•	
	Tabebuia heterophylla (syn. T. pallida [in part))	Pale Pink Trumpet Tree	•	•	•		•	•			•	•
	Tabebuia pallida	White Trumpet Tree	•	•	•		•	•			•	•
	Various tropical fruit, nut and spice trees	tropical fruit, nut and spice trees										•
Small Trees & Shrubs to 5m (Native)												
	Acacia leptostachya	Townsville Wattle								•	•	•
	Acacia jackesiana	Jackes Wattle								•	•	•
	Acacia podalyriifolia	Mt Morgan Wattle								•	•	•
	Acacia simsii	Sims Wattle								•	•	•
	Acmena smithii var. minor = Syzygium smithii	Lillypilly	•			•	•				•	•
	Acmena smithii 'Hot Flush'	Lillypilly - Hot Flush	•			•	•				•	•
	Antidesma parvifolium	Currant Bush								•	•	•
	Babingtonia spp. = Baeckea spp.	Baeckea									•	•
	Babingtonia virgata (Complex) syn. Baeckea virgata & cultivars	Twiggy Baeckea									•	•
	Banksia robur	Swamp Banskia								•	•	•
	Brachychiton bidwillii	Little Kurrajong	•	•		•	•				•	•
	Breynia oblongifolia (& 'Iron Range')	Coffee Bush (& Bronze Coffee Bush)								•	(•)	(•)
	Bursaria incana	Prickly Pine								•	•	•
	Bursaria tenuifolia	Native Mock Orange	•	•	•	•				•	•	•
	Clerodendrum floribundum	Lolly Bush	•			•		•	•	•	•	•
	Clerodendrum inerme	Scrambling Clerodendrum							•	•		
	Cleistanthus apodus	Weeping Cleistanthus	•	•	•						•	•
	Cleistanthus hylandii	Bernie's Cleistanthus		•		•	•				•	•
	Dodonaea lanceolata	Hop Bush								•	•	•
	Dodonaea viscosa	Sticky Hop Bush								•	•	•
	Gossia floribunda (syn. Austromyrtus floribunda)	Cape Ironwood	•			•					•	•
	Graptophyllum excelsum	Scarlet Fuchsia								•	•	
	Graptophyllum ilicifolium	Holly Leaved Fuchsia								•	•	
	Hibiscus divaricatus	Pink Native Hibiscus								•		•
	Hibiscus tiliaceus 'Rubra'	Bronze Cottonwood									•	•
	Jasminum simplicifolium subsp. australiense	Stiff Jasmine							•	•		•
	Larsenaikia ochreata	Native Gardenia								•	•	•
	Leptospermum madidum ssp. madidum syn. L. longifolium (in part)	Northern Weeping Tea Tree			•						•	•
	Leptospermum parvifolium syn. L. longifolium (in part)	Weeping Tea Tree		•	•						•	•
	Leptospermum petersonii	Lemon-scented Tea Tree									•	•
	Leptospermum polygalifolium syn. L. flavescens and cultivars	Yellow Tea Tree								•	•	•
	Leptospermum Cultivars	Tea Tree									•	•
	Leea indica	Bandicoot Berry								•	•	•

	Melaleuca linariifolia cultivars 'Purpurea', 'Claret Tops' and similar	Claret Tops									•	•
	Melaleuca sp. (Mount Stuart) (syn. Callistemon sp. (Mount Stuart))	Mount Stuart Bottlebrush								•	•	•
	Melaleuca thymifolia & cultivars	Thyme Honey Myrtle									•	•
	Melaleuca viminalis (Cultivars to 5m) (syn. Callistemon viminalis)	Bottlebrush	•	•	•	•	•			•	•	•
	Melastoma affine	Blue Tongue								•		•
	Melicope rubra	Little Evodia								•	•	•
	Murraya ovatifoliolata	Native Murraya	•			•				•	•	•
	Neofabrica myrtifolia	Yellow Tea Tree	•	•		•				•	•	•
	Phyllanthus cuscutiflorus & cultivars	Pink Phyllanthus	•	•		•		•			•	•
	Phyllanthus lamprophyllus	Phyllanthus								•	•	•
	Scaevola taccada	Cardwell Cabbage						•	•	•		•
	Sophora tomentosa	Silverbush						•	•	•		•
	Syzygium australe 'Aussie Southern'	Lillypilly	•	•		•	•				•	•
	Syzygium 'Elite'	Lillypilly	•	•		•	•				•	•
	Syzygium australe (Cultivars to 5m)	Lillypilly	•	•		•	•				•	•
	Thespesia populneoides	Beach Hibiscus						•	•			
	Xanthostemon 'Daintree Gem'	Varigated Penda	•	•	•	•	•	•			•	•
	Xanthostemon verticulatus	Cream Dancer									•	•
	Vitex trifolia	Native Lavender						•	•	•	•	•
Shrubs to 5m (Exotic)												
	Abelia spp.	Abelia									•	•
	Acalypha spp. and cultivars	Acalypha									•	•
	Barleria obtusa and cultivars	Purple Dazzler and Purple Gem									•	•
	Brunfelsia australis (syn. B. latifolia & B. bonodorata)	Yesterday, Today and Tomorrow									•	•
	Calliandra spp and cultivars	Pom pom Bush									•	•
	Codiaeum variegatum	Croton									•	•
	Duranta repens and cultivars	Duranta										•
	Eugenia uniflora	Surinam Cherry									•	•
	Euphorbia leucocephala	Snow Flake									•	•
	Euphorbia pulcherrima	Poinsettia									•	•
	Gardenia spp. and cultivars	Gardenia									•	•
	Graptophyllum pictum and cultivars	Caricature Plant									•	•
	Hibiscus spp and cultivars	Hibiscus									•	•
	Ixora spp. and cultivars	Ixora									•	•
	Mussaenda spp. & cultivars	Bangkok Rose									•	•
	Polyscias spp and cultivars	Ming Aralias									•	•
	Raphiolepis 'Apple Blossum' and similar	Indian Hawthorn									•	•
	Russelia equisetiformis and cultivars	Coral Plant									•	•
	Various tropical fruit, nut, spice, condiments and herbs	Tropical fruit, nut, spice,condiment & herbs										•

Palms, palm like and tropical foliage (Native)												
	Archontophoenix alexandrae	Alexandra Palm								•	•	•
	Archontophoenix cunninghamiana	Bangalow Palm									•	•
	Asplenium australasicum	Birds Nest Fern								•	•	•
	Asplenium nidus	Birds Nest Fern								•	•	•
	Alpinia caerulea	Native Ginger								•	•	•
	Alpinia modesta	Narrow-leaf Ginger								•	•	•
	Bowenia serrulata	Byfield Fern									•	•
	Bowenia spectabilis	Zamia Fern								•	•	•
	Carpentaria acuminata	Carpentaria Palm							•		•	•
	Cordyline cannifolia	Palm Lillies									•	•
	Curcuma australasica	Native Turmeric, Cape York Lily									•	•
	Cyathea cooperi	Tree Fern								•	•	•
	Cyathea rebeccae	Rebecca's Tree Fern								•	•	•
	Cycas media subsp. media	Australian Nut Palm								•	•	•
	Cycas spp	Cycad									•	•
	Lepidozamia hopei	Hopes Lepidozamia									•	•
	Lepidozamia peroffskyana	Peroffskys' Lepidozamia									•	•
	Licuala ramsayi	Australian Fan Palm								•	•	•
	Livistona australis	Cabbage Palm								•	•	•
	Livistona decora [syn. L. decipiens]	Weeping Cabbage Palm						•	•	•	•	•
	Livistona drudei	Fan Palm						•	•	•	•	•
	Livistona lanuginosa	Cape River Fan Palm						•		•	•	•
	Livistonia muelleri	Dwarf Fan Palm									•	•
	Macrozamia spp	Cycad									•	•
	Pandanus cookii [syn. P. whitei]	Screw Pine						•	•	•	•	•
	Pandanus spp	Pandanus							•		•	•
	Ptychosperma elegans	Solitare Palm								•	•	•
	Ptychosperma macarthurii	Macarthur Palm									•	•
	Wodyetia bifurcata	Foxtail Palm						•			•	•
	Xanthorrhoea johnsonii	Grass Tree								•	•	•
	Xanthorrhoea glauca	Grey Grass Tree									•	•
Palms, palm like and tropical foliage (Exotic)												
	Alpinia spp. and cultivars	Shell Ginger									•	•
	Alpinia galangal	Galangal									•	•
	Ananas comosus 'Variegatus'	Variegated Pineapple									•	•
	Beaucarnea recurvata	Ponytail Palm									•	•
	Bismarckia nobilis	Bismarckia Palm									•	•
	Calathea spp and cultivars	Calathea									•	•
	Chamaedorea spp	Bamboo Palms									•	•
	Codiaeum variegatum cultivars and forms	Garden Croton									•	•
	Cordyline fruticosa and cultivars	Ti-Plant									•	•
	Crinum spp. & cultivars	Crinum Lily									•	•
	Ctenanthe spp and cultivars										•	•
	Curcuma spp and cultivars	Ornamental Tumeric									•	•
	Cyathea spp and cultivars	Tree Ferns									•	•
	Cyrtostachys lakka	Lipstick Palm, Sealing Wax Palm						•			•	•
	Cycas revoluta	Cycad									•	•
	Dictyosperma album	Princess Palm						•	•		•	•
	Dypsis lutescens	Golden Cane Palm									•	•

	Dypsis spp	Palms									•	•
	Dracaena spp and cultivars	Dragon Tree						•			•	•
	Furcraea foetida and cultivars	Mauritius Hemp									•	•
	Heliconia spp and cultivars	Crab Flowers									•	•
	Hippeastrum spp and cultivars	Amaryllis									•	•
	Hyophorbe lagenicaulis	Bottle Palm									•	•
	Hyophorbe verschaffelti	Spindle Palm									•	•
	Licuala grandis	Ruffled Fan Palm									•	•
	Maranta spp and cultivars	Prayer Plants									•	•
	Neodypsis decaryii	Triangle Palm									•	•
	Pandanus spp	Screw Pines						•	•		•	•
	Philodendron spp and cultivars	Philodendron									•	•
	Phoenix roebelenii	Dwarf Date Palm									•	•
	Pitcairnia spp and cultivars	Stappy-leaved Bromeliads									•	•
	Pleomeles spp and cultivars	Lance Dracaena						•			•	•
	Pritchardia pacifica	Fijian Fan Palm							•		•	•
	Roystonea regia	Royal Palm									•	•
	Rhapsis excelsa and cultivars	Lady Palm									•	•
	Spathiphyllum spp and cultivars	Peace Lilly									•	•
	Strelitzia spp and cultivars	Bird of Paradise									•	•
	Veitchia merrelii	Christmas Palm									•	•
	Yucca spp. and cultivars	Yucca						•			•	•
	Verscaffeltia splendida	Stilt Palm									•	•
	Zamia furfuracea	Cardboard Plant							•		•	•
	Zamiaoculcas zamifolia	Zanzibar Gem or ZeeZee Plant									•	•
	Zingiber spp.	Ginger									•	•
Groundcover, border and tufted plants (Native)												
	Abelmoschus moschatus ssp.tuberosus	Native Rosella								•	•	•
	Acmena smithii 'Hedgemaster' , 'Allyn Magic','Mini Magic' and similar	Dwarf Acmena									•	•
	Bothriochloa bladhii subsp. bladhii	Local Native Grass								•	•	•
	Bothriochloa decipiens	Local Native Grass								•	•	•
	Bothriochloa ewartiana	Local Native Grass								•	•	•
	Bothriochloa spp. (other)	Native Grass									•	•
	Canavalia maritima	Beach Bean							•	•	•	•
	Casuarina glauca 'Cousin It'	'Cousin It'							•	•	•	•
	Crinum pedunculatum	Swamp Lily							•		•	•
	Crinum uniflorum	Small Swamp Lily							•		•	•
	Cajanus reticulatus	Rusty Rattlepod								•	•	•
	Canavalia rosea	Beach Bean							•	•		•
	Cymbopogon ambiguus	Australian Lemon-scented Grass								•	•	•
	Cymbopogon bombycinus	Silky Oil Grass								•	•	•
	Cymbopogon queenslandicus	Queenland Lemon-scented Grass							•	•		•
	Cymbopogon refractus	Barbed Wire Grass							•	•		
	Dianella atraxis	Flax Lily								•	•	•
	Dianella caerulea	Blue Flax Lily								•	•	•

	Dianella caerulea 'Little Jess'	Dwarf Flax Lily									•	•
	Eleocharis atropurpurea	Purple Spikerush								•	•	•
	Eleocharis dulcis	Water Chestnut								•	•	•
	Eleocharis geniculata	Spike Sedge								•	•	•
	Enchylaena tomentosa	Ruby Salt Bush							•	•	•	•

Click here to view PDF of SC6.4.3.6 Attachment A: Preferred plant species list

Note—

1. Nomenclature generally based on Census of the Queensland Flora 2013, edited by Peter D. Bostock and Ailsa E. Holland found on the Queensland Government data website = indicates where plant name differs from Australian Plant Name Index at http://www.anbg.gov.au/cgi-bin/apclist
   Synonyms included where superseded name is still in common use in trade.
2. Refer streetscape design and treatments section for location and setback requirements. Case by case assessment of species suitability will be required dependent on location (verge, central median etc.)
3. Refer public open space section for requirements in these locations.
4. Species with a natural distribution within North Kennedy Pastoral District. Distribution checked against Census of the Queensland Flora 2010.
5. Refer to development codes for offset distances from property boundaries.

SC6.4.3.6 Attachment B: Adopted Master plans

Thuringowa Riverway Master Plan
Stage 1: Pioneer Park and Loam Island
February 2003

Riverway Sustainable Development Policy
City of Thuringowa Planning Scheme Policy 2003

SC6.4.3.6 Attachment C: Irrigation Profile Level (IPL) Hierarchy definition

The TCC Irrigation Profile Level (IPL) Hierarchy includes the following types: High, Medium, Low, Non.

IPL	Function Description	Performance Requirements	Typical Image of Turf Area

High	• Provides irrigation to Townsville City Councils landscaped areas including:
	  • Public open spaces,
	  • Facilities and utility assets,
	  • Local road reserves and street scaping
	
	• Provides irrigation to State Government main road - road reserves.
	
	• Formal gardens irrigated to (IPL) levels High and Medium only.
		• Provide irrigation in a uniform application to supply landscaping plants with soil moisture to **Promote**:
		  • **Vigorous plant growth,**
		  • **Best plant health,**
		  • **Best presentation.**
		
		Visual Indicators - **turf**:
		  • **Lush thick turf,**
		  • **Rich even green appearance.**
		
		• Yearly application range (assumed clay to clay loam soil types and subject to site conditions)
		  • **Turf 28 - 38mm/week.**
		  • **Garden 18 – 28mm/week.**	

IPL	Function Description	Performance Requirements	Typical Image of Turf Area

Medium	• Provides irrigation to Townsville City Councils landscaped areas including:
	  • Public open spaces,
	  • Facilities and utility assets,
	  • Local road reserves and street scaping
	
	• Provides irrigation to State Government main road - road reserves.
	
	• Formal gardens irrigated to (IPL) levels High and Medium only.
		• Provide irrigation in a uniform application to supply landscaping plants with soil moisture to **Promote**:
		  • **Good plant growth,**
		  • **Good plant health,**
		  • **Good presentation.**
		
		• Visual Indicators - **turf**:
		  • **Mostly medium thickness turf,**
		  • **Mostly green appearance, with some patches of green/brown.**
		
		• Yearly application range (assumed clay to clay loam soil types and subject to site conditions)
		  • **Turf 18 - 28mm/week,**
		  • **Garden 15 – 25mm/week.**	

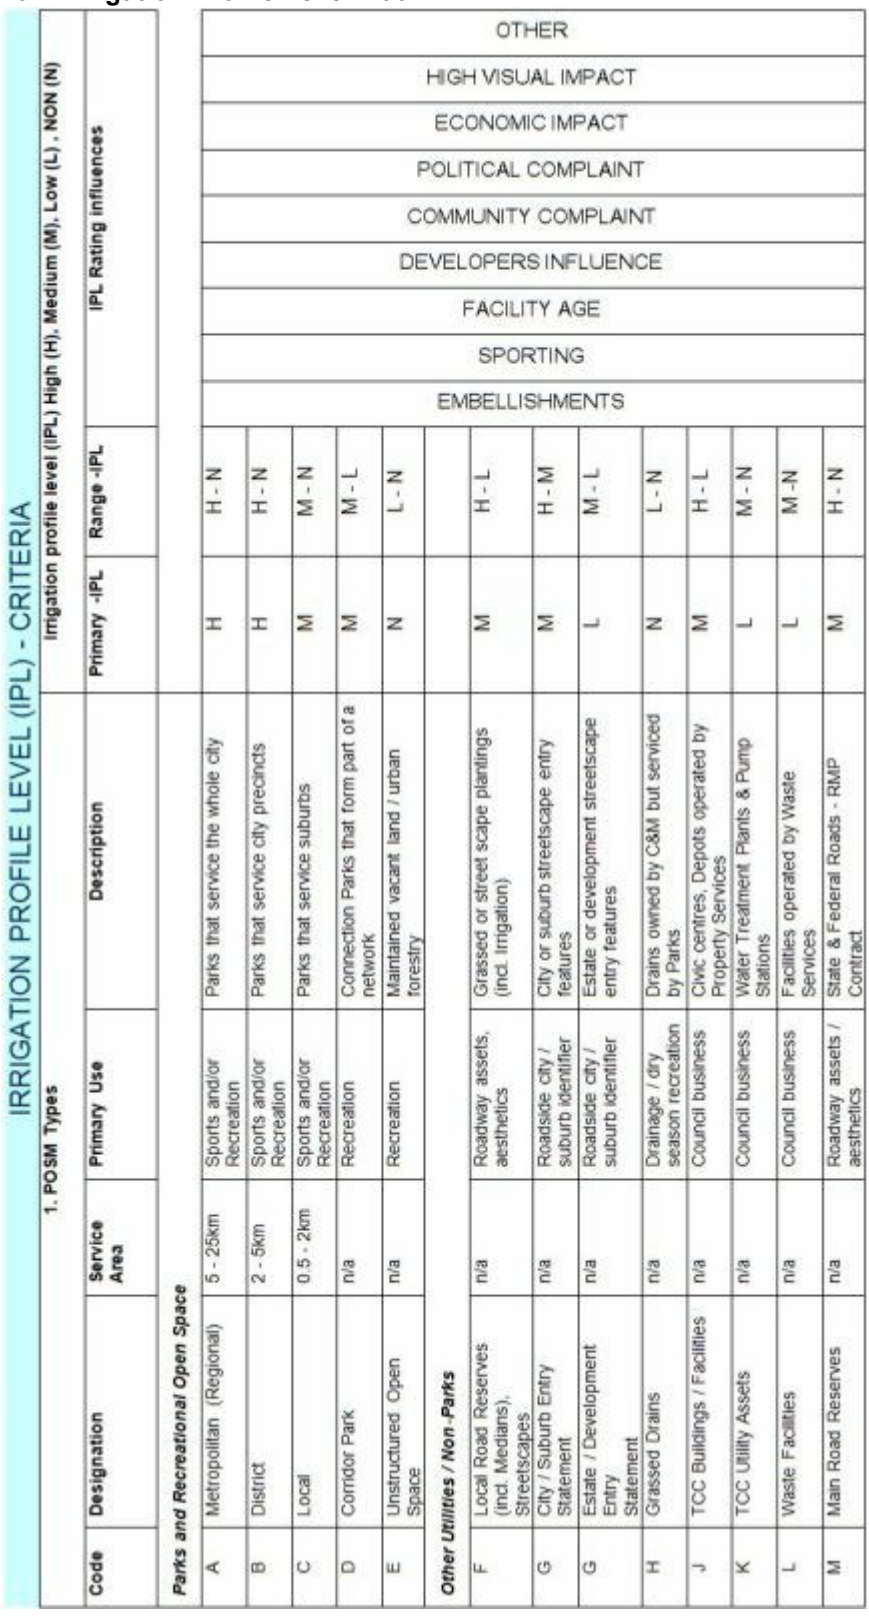
IPL	Function Description	Performance Requirements	Typical Image of Turf Area

Low	• Provides irrigation to Townsville City Council's landscaped areas including:
	  • Public open spaces,
	  • Facilities and utility assets
	  • Local road reserves and street scaping
	
	• Provides irrigation to State Government main road - road reserves.
	
	• **Formal gardens irrigated to (IPL) levels High and Medium only**.
		• Provide irrigation in a uniform application to supply landscaping plants with soil moisture to **Sustain**:
		  • **Minimal plant growth,**
		  • **Minimal plant health,**
		  • **Minimal plant presentation.**
		
		• **Significant seasonal influences on landscaping**.
		
		• Visual Indicators – **turf**:
		  • **Thin coverage of turf,**
		  • **Mostly brown with green tinge appearance, some patches of brown.**
		
		• Yearly application range (assumed clay to clay loam soil types and subject to site conditions)
		  • **Turf 12 - 20mm/week.**	

IPL	Function Description	Performance Requirements	Typical Image of Turf Area

Non	• Areas where no irrigation is required:
	  • Natural areas
	  • Naturally landscaped areas such as native plantings,
	  • Open grass areas such as drainage swales,
	  • Other areas deemed not requiring irrigation.
		• Areas depend solely on rain and naturally occurring moisture. **Seasonal plant growth, health and presentation**.	

SC6.4.3.6 Attachment D: Irrigation Profile Level Matrix



IRRIGATION PROFILE LEVEL (IPL) - CRITERIA

1. POSM Types					Irrigation profile level (IPL) High (H), Medium (M), Low (L) , NON (N)		IPL Rating influences									
Code	Designation	Service Area	Primary Use	Description	Primary -IPL	Range -IPL	EMBELLISHMENTS	SPORTING	FACILITY AGE	DEVELOPERS INFLUENCE	COMMUNITY COMPLAINT	POLITICAL COMPLAINT	ECONOMIC IMPACT	HIGH VISUAL IMPACT	OTHER

SC6.4.3.7 Steep land development design guidelines

SC6.4.3.7.1 Introduction

(1) Background

(a) Development on steep land requires additional considerations for design, in particular, geotechnical considerations, as well as safety, servicing, environmental and economic considerations for the provision of development and associated infrastructure services.

(b) The stability of land which is steep, erosion prone, prone to slip and other geotechnical problems can be adversely affected by the following actions or development:

(i) earthworks (filling and excavation);

(ii) vegetation clearing;

(iii) construction of buildings and other structures (retaining walls);

(iv) construction of roads and driveways;

(v) on-site disposal of waste water; and

(vi) changes to the existing flow of surface or groundwater.

Inappropriate development on land subject to landslide hazard can result in significant risk to people and property on the subject site, on surrounding land and land down slope of the site. To ensure that these matters are appropriately considered when making decisions, geotechnical investigations are required and appropriate design solutions implemented. In some circumstances development may be avoided.

(c) This sub-section provides guidelines and advice for undertaking development on steep lands and the application of suitable design practices and design considerations.

Editor's note—this policy sub-section should also be read in conjunction with the AGS (2007e), *The Australian GeoGuides for slope management and maintenance*, Australian Geomechanics Society, *Australian Geomechanics*, Vol 42, No 1 and the planning scheme policy sub-section SC6.4.3.18 Geotechnical investigations.

(d) Wherever practical to do so, best practice techniques for construction and development techniques are expected to be demonstrated.

(e) In a broad sense, development should seek to achieve the following objectives:

(i) avoid unstable or hazardous sites and protect lives and property from hazardous conditions such as rock falls, excess stormwater run-off, erosion etc.;

(ii) minimise infrastructure maintenance requirements and costs to the community and residents;

(iii) provide practical and safe access for residents, visitors and service providers;

(iv) complement the scenic hillside character of the surrounding area by integrating unique or special natural features such as landforms, rock outcroppings, existing trees and vegetation, water features, hilltops and ridgelines and avoid further expansion onto scenic features, particularly ridgelines;

(v) minimise the footprint of development during and after construction;

(vi) protect wildlife habitat, corridors and environmentally sensitive areas; and

(vii) be compatible with existing adjacent development.

The creation of good amenity, when viewing the development from streetscapes and surrounding areas, should be a key consideration in all designs to avoid development on steep slopes that is visually dominant.

SC6.4.3.7.2 Development on steep land

As a general and overall consideration, the design of development on steep land should consider the following.

(1) Safety

(a) Major considerations in relation to safety are:

(i) landslide risk; and

(ii) debris flow.

(b) The location and/or form of development and infrastructure should not increase the extent or severity of any landslide hazard or present any unacceptable risk to life, property, the community, or the environment. Risks may arise internally or externally to the site, or affect the subject site or adjacent sites.

(c) Safety of the development should be addressed though appropriate investigations and design.

Editor's note—the preparation of a site specific geotechnical investigation is to be undertaken in accordance with SC6.4.3.18 Geotechnical investigations.

(d) The findings, recommendations and specific works of the geotechnical investigation report must be implemented and complied with to ensure that the risk level for the development will be no more than "low" in accordance with SC6.4.3.18 Geotechnical investigations. If the engineer's assessment report finds that the site will be "low risk" after development without the need for specific works to achieve this, certification need not be required.

Editor's note—risk level "low" in accordance with "Landslide Risk Management", Australian Geomechanics Volume 42 No 1 March 2007.

(e) Any recommendations contained in the geotechnical investigation report must be adopted in the final approved design.

(2) Servicing

(a) Development should provide for the safe and efficient servicing of the site by appropriate infrastructure and minimise ongoing costs to the final user and community. Specific designs for earthworks, roads, drainage, water and sewerage, water quality treatment, and site access may need to be demonstrated at an earlier stage than comparable developments on flatter land.

(b) Stormwater, in particular, should be controlled and conveyed in a manner that mitigates potential problems and emulates the area's natural water cycle, rather than shifting increased flows and issues downstream. Post development flows must not exceed pre-development flows. Particular attention should be paid to designing practical and robust inter-allotment drainage systems. Groundwater flows should also be a key consideration in relation to drainage systems and the potential for landslide risk.

(c) Any public infrastructure developed should not result in unsustainable increases in infrastructure operation and maintenance costs relative to the number of rateable units created (e.g. high level water systems, high maintenance drainage systems). Retaining walls in road or drainage reserves are discouraged and will only be accepted in exceptional circumstances where there is demonstrated benefit for the protection of public infrastructure. All retaining structures must be certified by an RPEQ and constructed of material that ensures public safety and minimised maintenance costs for the design life and should be designed to achieve good streetscape amenity.

(d) Road geometry should be designed in accordance with SC6.4.4.1 Geometric road design and Austroads with particular attention to grades, property accesses, design speeds and sight distances to ensure the safety of all road users. Where variations are sought to council's standards strong justification must be given to support the application. Long distances of steep roads or sharp curves without adequate sight distances or turning paths will not be approved. Road aesthetics are valued as a significant contributor to the character and quality of development and should be a key consideration.

(e) Access to all properties must be safe and functional. The design of the accesses must be shown in the overall development design to ensure the safety, practicality and impact on the public and private

domains. Lot levels should reflect the requirement of accesses to meet minimum grade requirements and allow for additional near level on-site parking for visitors, service vehicles and other parking needs. Access designs should be in accordance with the SC6.4.3.17 Driveways. Where lot accesses may be problematic to construct later, they should be constructed with the roads.

(f) Pedestrian, cyclist and public transport infrastructure design should also be considered at the overall development design as these means of movement are often restricted on steep lands. Alternate facilities to standard road routes and footpaths (e.g. pedestrian connections stairs) may require special design considerations due to grade and safety needs. Residential streets are designed to create low speed environments and to facilitate and encourage pedestrian and cyclist use.

(3) Sustainability

(a) Hillside development can add its own positive character to the particular region however it can also have negative effects on the natural and built environment. Development should seek to enhance positive site characteristics and should enhance the natural qualities of hillsides (e.g. skylines, vistas, landscape form, vegetation, rock outcrops and other topographic features) whilst negative effects (e.g. scarring and a lack of respect for natural terrain and aesthetics) should be contained and avoided. Scenic natural features should be incorporated into the subdivision design as natural open space or through the use of larger allotments that can contain the features.

(b) The layout of a development should be sympathetic to the area's natural terrain and hazardous conditions. It should endeavour to maintain sensitive natural areas and protect and preserve the scenic characteristics of hillsides. Where possible the clustering of development should be used to restrict the impact on the natural state, improve the financial efficiency of the development and assist in creating a variety of the housing forms.

(c) The effect of slope on built form should be identified in the initial stages of the development's design and appropriate types of construction should be encouraged through suitable lot sizes, site and access works, building envelopes, and covenants. This will help ensure the development can be built as proposed and reduce the likelihood of conflict or compromise at a later date.

(d) The extent of earthworks (cut and fill) is a major consideration in the design of developments on steep slopes, not just for reasons of site stability but in terms of cost and efficient use of land as well as visual impact. Constructed slopes should be stable and capable of re-vegetation and effective maintenance. They should also not be so high as to be obtrusive to the streetscape or scenic quality of the development. Heights between the streets and site levels should not be so great as to provide a disconnect between housing and the street or prove impractical for regular movement. Long stretches of high cuts or fill adjacent to road edges will not be approved. Site grading and retaining walls respect existing terrain; that is, large cuts/fills are not used to create “build-able lots” or flat yards. Final lot grades should wherever practical mimic the natural slope.

(e) Where disturbance from future site development is likely to be problematic then earthworks to individual sites should occur at the subdivision stage. For subdivision, this may include providing level building pads to accommodate a future dwellings, associated filling and the construction of private retaining walls. This may occur where there are large cuts and fills, repeated or close accesses, or where future blasting may be required.

(f) Retaining walls should be minimised and should not be of heights that detract from the amenity and human scale of the development. Generally, walls should not exceed one metre in height adjacent to roadways on property boundaries. High walls should be articulated, be constructed with appealing materials or finishes (complementing natural materials where possible), and have sufficient landscaping to screen the wall and should be set back from the road boundary to permit landscape treatment. Where possible a series of smaller stepped walls should be utilised and designed to permit landscaping of the terraces. Retaining walls can be used to reduce slope disturbance, rather than modify natural terrain – lot sizes should increase as the natural slope increases. Constructed slopes can be placed behind buildings if needed, however, consideration should be given to the principle of reduced earthworks in the first instance.

(4) Economic

(a) The volume of cut and fill over the development should be minimised and a cut and fill balance over the

site as a whole should be achieved where possible.

(b) It is expected that with any new public infrastructure the cost of ongoing maintenance should generally be no more for steep sites than for flat sites on a per lot basis. Where there may be a special requirement for non-standard or higher maintenance infrastructure it is expected that a full life cycle cost comparison would be provided (e.g. high level pumps or reservoirs, drainage structures, access to landscaped areas, etc.).

SC6.4.3.7.3 Development applications advice

Particular steep land issues that must be addressed at various application stages are indicated below.

(1) Council encourages applicants to discuss development proposals with council during initial design phases.

(2) It is important that the design reflect all the recommendations of the geotechnical report and that sufficient design detail is provided to demonstrate that the proposed road and lot layouts will work in practice and result in infrastructure and built form outcomes that comply with these guidelines. In particular, there should be enough certainty provided to be sure that the layout will not require significant change due to technical design constraints, i.e. it should not be left to the operational works stage to prove the development will work. Sufficient drawings and design data (including multiple sites and building sections) should be provided to determine this.

(3) The technical design of all earthworks and infrastructure should reflect the recommendations of the geotechnical report and all relevant design guidelines and standards. Where the initial MCU/ROL geotechnical report outlined further detailed investigation prior to design as necessary then this must be carried out. The operational works design should be certified by a geotechnical engineer as complying with the recommendations of the geotechnical report.

SC6.4.3.8 Stormwater management plans for development

SC6.4.3.8.1 Introduction

The development of effective site based stormwater management plans is imperative to the understanding of stormwater quality and quantity during the land development phase to minimise the risk of causing environmental harm to receiving waters, damage to council infrastructure, and unnecessary financial burdens to council and the community.

Where a development is required to demonstrate how proposed stormwater management is protecting water quality and quantity, an applicant will be requested to undertake and prepare a conceptual site based stormwater management plan (CSBMP) or a site based stormwater management plan (SBMP) which addresses the likely impacts of the proposed development and suggests measures to avoid or mitigate against unacceptable risk and other impacts.

(1) Objectives

(a) Ensure that land-use activities potentially discharging contaminated run-off or wastes to waterways during land development, construction and operation phases are sited and managed to minimise such discharges and to protect the quality and quantity of water entering natural and constructed waterways, natural and constructed wetlands, as well as groundwater resources.

(b) To assist planning and decision making on development that may result in stormwater erosion of disturbed soil and sediment transport to land and waters, potentially having an impact on receiving waters environmental values under the *Environmental Protection (Water) Policy 2009* (the EPP Water).

The environmental values established under the EPP Water need to be protected, in part, by:

(i) providing natural water infiltration and flows;

(ii) using water sensitive urban design (WSUD) principles and effective erosion and sediment control; and

(iii) using best practice urban stormwater quality and quantity management.

(2) Terminology

In addition to the definitions presented in Part 1.3.1 of the Townsville City Plan, the following terminology is referenced in support of this policy sub-section.

Site based stormwater management	land development controls identified by a site assessment report. Examples of land development controls include: • erosion source control; • sediment traps; • wetlands for nutrient control; • stabilised temporary drainage lines; • riparian management; and • site rehabilitation.
Wetland	area of permanent or periodic/intermittent inundation, whether natural or artificial, with water that is static or flowing, fresh, brackish or salt, including areas of marine water the depth of which a low tide does not exceed 6 m. AS/NZS 1547:2000 Onsite domestic waste water management.

(3) References and source documents

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:

SC6.4.3.9 Water sensitive urban design guidelines

SC6.4.4.4 Stormwater drainage design

SC6.4.6.1 Water sensitive urban design construction and establishment guidelines

(b) Queensland guidelines
Queensland Government (1999) *Strategy for the conservation and Management of Queensland Wetlands*
Queensland Government (2010) *Urban Stormwater Quality Planning Guidelines*
SEQ Healthy Waterways Partnership, *Construction and Establishment Guidelines*: Swales, Bioretention Systems and Wetlands

(c) Other guidelines
Water by Design, *Construction and establishment guidelines*; Swales, Bioretention Systems and Wetlands
International Erosion Control Association (2008), *Best practice erosion and sediment control*.
Water by Design, *MUSIC modelling guidelines*, June 2012 (as amended)

Note—where local guidelines exist and these include modifications to the Queensland or other guidelines based on local knowledge or investigation, these shall take precedence over Queensland or other guidelines.

SC6.4.3.8.2 Planning and concept design guidelines

(1) Pre-lodgement development guidelines

(a) Prior to the lodgement of a development application it is recommended that the applicant meet with council to confirm acceptable stormwater management practices (for example, wetland, sediment basin and bioretention system designs) and discuss how stormwater treatment may influence overall development design.

(b) In order to make pre-lodgement more beneficial, it is recommended that applicants undertake a preliminary site assessment and provide a range of baseline information to council to assist and inform the pre-lodgement discussions.

(c) This baseline information ideally will include accurate survey plans which demonstrate information on pre-development site conditions including:

(d)

topography	a suitable ground survey of the site is required to allow an assessment of existing grades and flow pathways;
drainage characteristics	drainage infrastructure and flowpaths upstream, within, and downstream of the development must be surveyed for size, location and level;
proposed discharge points and invert levels	define likely flow paths and the level of the receiving drainage system or waterway. Critically, levels must be collected for inverts of drainage systems that will accept treated water from the stormwater treatment systems. If water is ponding in these drainage systems, the water level must also be surveyed;
wetlands	if the site contains wetlands identified through council wetland mapping (refer to Part 8 Overlays and SC2.5 Overlay maps), they should be identified on preliminary plans;
soils	a soil evaluation undertaken in accordance with AS/NZS 1547:2000. Clause 4.1.3 will assist in selecting and locating treatment devices. The soil evaluation should identify soil types, hydraulic conductivity, presence of potential acid sulphate, sodic or saline soils, presence of rock, and general groundwater details; and
site disturbance	an indication of the current extent of disturbance across the site during the previous 12 months.

(e) This baseline information is critical to facilitate designs which suitably respond to site constraints and opportunities. Consideration of constraints and opportunities early in the design process minimises redesigns and expedites the assessment process. The recommended approach allows the information request stage to then be used to clarify minor issues in the report (should this practically be required).

(2) General guidelines

(a) It is recommended that the above information is included with the lodgement of an application to manage stormwater quality and quantity. This will ensure that stormwater treatment matters are suitably addressed prior to a decision notice being issued and do not contribute to extended assessment timeframes.

(b) The design and location of stormwater treatment measures has the potential to greatly influence a

number of things, including lot configuration and as a result, needs to be resolved prior to the presentation to council for approval of any site development plans. Designers should be aware that the design of stormwater treatment measures will not only influence site design due to the footprint but also potentially due to their specific drainage requirements. Ensuring that treatment systems can freely drain becomes an increasingly important issue on sites with flat topography and must be resolved on every site prior to plan approval.

(c) A conceptual site based stormwater quality management plan (CSBMP) should be submitted for material change of use (MCU) and reconfiguring a lot (ROL) applications to demonstrate that there are feasible measures available to adequately manage the impacts of development as they are understood and relevant to those stages and to the degree required to protect the environmental values. See Table SC6.4.3.8.1 for a checklist of items to be included in a CSBMP.

(d) Table SC6.4.3.8.1 has been provided as a check list to outline the minimum standards for creation and preparation of a SBMP. Further, SC6.4.3.8.5and SC6.4.3.8.6 provide additional information to that provided in Table SC6.4.3.8.1 and should be read in conjunction when preparing a SBMP.

(e) This also informs the developer of the economic consequences of impact management at the outset of the development process. As site constraints increase, the cost-effectiveness of best practice control measures decrease. Where the conceptual plan cannot substantiate that best practice control measures are feasible and still achieve the environmental performance objectives, the proposed nature, layout and intensity of development should be reconsidered, for example—by fitting the development more to the terrain, rather than fitting the terrain to the development, to reduce the need for clearing and earthworks.

(f) The designer is to consider the site characteristics, constraints and opportunities relating to stormwater management at the initial planning phases of the development. This is to ensure that sufficient area is allocated within the development site for appropriate stormwater management infrastructure during land development, construction and operational stages.

SC6.4.3.8.3 Development Applications

(1) Development applications may require a CSBMP or site based stormwater management plan (SBMP) to be submitted with the development application to council for all developments requiring assessment against the Part 9.4.2 Healthy waters code. This will assist in assessing the impact of the development on the site.

(2) SC6.4.3.8.5 SBMP document information outlines the overall framework required for SBMPs.
The following information should also be considered:

(a) the overall potential impacts of both the construction and permanent phases, and the feasibility and cost-effectiveness of control measures on each site (given, for example, site constraints, and nature and scale of the development) need to be considered first when a change in land use is proposed, and subsequently as the development unfolds; and

(b) potentially serious land capability constraints affecting the cost-effectiveness and hence the feasibility of a development include:

flood prone areas	sediment basins are often located at the low point of a development and they may not be stable or able to be properly installed or operated if subject to flooding;
acid sulphate soils	larger treatment devices such as sediment basins, wetlands and bioretention systems are often located in low lying areas that are susceptible to the disturbance of acid sulphate soils;
steep terrain	high erosion risk, difficulty in preventing erosion, and in installing a stable and adequately sized sediment basin; and
flat terrain with high groundwater levels	difficulty in collecting and directing surface flows, coupled with difficulty of installing a sediment basin in the presence of high groundwater, which is sometimes geochemically contaminated.

Editor's note—this will include a brief description of erosion and sediment control (ESC) for these two stages of the development approval process.

(4) Operational works guidelines

(a) Operational works applications may require the submission of a preliminary erosion and sediment control plan (ESCP) as supportive information which complies with council requirements as a minimum technical standard.

(b) The preliminary ESCP will be confirmed on site during the pre-start meeting. At this stage, council can check the appropriateness of the preliminary design on site to ensure that the contractor(s) will implement what is on the design plan and will not be responsible in making any changes to suit the site condition during the construction phase.

(c) The preliminary ESCP should take into consideration change to surface levels that are reflected in the bulk earthworks plan(s) of the siteworks plan(s) accepted as part of the operational works approval. The primary ESCP submitted as part of the CSBMP may later be followed by a series of secondary ESCPs for the various stages of the project.

(d) Subsequent installation, operation, maintenance and monitoring of structural controls and their works programming and coordination requires ongoing adaptive management, and this must be carried out in compliance with the general environmental duty under the Environmental Protection Act, that is, taking all reasonable and practicable measures to protect the environmental values of receiving waters from environmental harm. Refer to information in Table SC6.4.3.8.1. Operational works applications should be accompanied by a series of detailed stormwater management drawings. The plans (ESCP) should include notes on the drawings which require contractors to follow the preferred construction and establishment methodology outlined in an approved SBMP and in accordance with the *SEQ Healthy Waterways Partnership Construction and Establishment Guidelines*: Swales, Bioretention Systems and Wetlands.

(e) Drawings should be in accordance with SC6.4.2 Development application guidelines.

(f) The extent of unnecessary soil disturbance, including disturbances outside the designated work area, must be minimised at all times.

(g) Land clearing must be limited to the current stage of works unless otherwise approved in writing possible standard condition by the assessment manager.

(h) It is recommended that land clearing is undertaken, as a minimum, necessary to provide either of the following:

(i) up to 8 weeks of site activity during those months when the expected rainfall erosivity is less than 100, 6 weeks if between 100 and 285, 4 weeks if between 285 and 1500, and 2 weeks if greater than 1500; or

(ii) up to 8 weeks of site activity during those months when the actual or average rainfall is less than 45 mm, 6 weeks if between 45 and 100 mm, 4 weeks if between 100 and 225 mm, and 2 weeks if greater than 22 mm; or

(iii) utilising local sediment export data to assess the risks of land exposure during different months of the year.

Editor's note—minimise works during the "wet season" months of 1 December to 31 March. The month of December is also critical to allow establishment of 70% groundcover prior to the expected high rainfall in the months of January and February.

These impacts need to be considered separately from the post-development or permanent settlement phase as the issues and impact assessment methodology are different.

(i) The critical impact factors are site erosion hazard (including the timing of development with respect to wet seasons) and the duration and areal extent of exposed soil until final site stabilisation after the end of major house-building activities.

Editor's note—definitions of site erosion hazard and major house-building activities to come.

(j) Avoiding exposure of disturbed areas during peak rainfall periods will significantly reduce the potential for erosion and stream hydro-modification to occur. While it is generally recommended that larger sites are

cleared and developed in manageable smaller stages, this may sometimes conflict with the need to quickly complete and stabilise a large development prior to the wet season.

Editor's note—minimise works during the "wet season" months of 01 December to 31 March. The month of December is also critical to allow establishment of 70% groundcover prior to the expected high rainfall in the months of January and February.

(k) Where larger sites are not staged, however, there should be a progressive revegetation (or other effective stabilisation measure) program implemented following commencement of clearing (not at the end) so that no part of the site is left exposed and unstable for extended periods in the high rainfall coastal regions. Refer to SC6.4.3.8 Attachment A: Background information - Sediment load from unprotected soils during construction.

Editor's note—even temporary grass vegetation or synthetic covers can reduce erosion levels to less than 1 per cent of the level expected if the site is left with soils exposed.

(5) Water quality objectives

(a) Environmental values (EVs) and water quality objectives (WQOs) need to be identified to ensure that the quality of affected receiving waters are maintained or enhanced. WQOs includes all measurable water quality goals that have been derived to protect corresponding environmental values.

(b) The EPP (Water) establishes the EVs in receiving waters.

(c) The associated WQOs form the basis for defining the required water quality of urban stormwater entering and mixing in local waterways.

(d) There are three ways to estimate the level of stormwater quality improvement necessary for a site to ensure WQOs are taken into account to help protect council infrastructure and the EVs for waterways.

For the site scale these are:

(i) monitoring – actual stormwater quality can be compared with receiving water quality to establish the level of treatment necessary to protect EVs, where sufficient monitoring data are available from the same development type in similar landscape conditions;

(ii) modelling – stormwater quality and its potential impact on receiving waters can be mathematically modelled to determine treatment requirements (design objectives). Some monitoring data are usually required to validate such models. e.g. SC6.4.3.8.6 MUSIC modelling; and

(iii) best management practices – best available data on the performance efficacy of current best practice treatment technologies can be used to establish minimum standards of performance (typically expressed as minimum average annual pollutant load reductions, or minimum average percentage reductions in pollutant loads, e.g. measures in SC6.4.3.9 Water sensitive urban design guidelines).

(e) In rapidly urbanising catchments, the wet-weather impacts of the construction phase of the land development phase need to be considered as well as the post-development (or permanent settlement phase), as the issues and impact assessment methodology are different. Critical impact factors include soil erosion hazard of the landscapes being developed, and increased rainfall run-off coefficients which occur when land is cleared and topsoil removed.

(f) The preferred method for determining the required level of treatment is described in SC6.4.3.9 Water sensitive urban design guidelines.

(g) Modelling provides an ability to predict likely changes in water quality associated with proposed urban developments. Such water quality models can be used to establish performance outcomes for stormwater systems. These are limited by the availability of local water quality data and the understanding of the biological and physical processes that influence water quality and the receiving water environment. There are often significant limits on the confidence with which predictions can be made using water quality models at the site scale. Despite the uncertainty of modelling, adopting predictive modelling techniques to quantify estimates of stormwater pollutant concentrations and loads from urban land surfaces and the pollutant removal efficacy of current best practice stormwater treatment infrastructure is an accepted method for establishing best practice stormwater management "treatment

train" design for regions where limited or no monitoring data exists.

(6) Stormwater quality risk classification
Developments are classified as either having a “low risk” or a “high risk”.

Note—a development (or development proposal) may be classified as “high risk” if it falls within one of the following categories:

(a) any development (or development proposal) within or adjoining areas of identified ecological status as indicated on council planning scheme maps; or

(b) material change of use for urban purposes that involves:

(i) greater than 2,500m2 of land; or

(ii) 6 or more additional dwellings; or

(c) reconfiguring a lot for urban purposes that:

(i) would result in 6 or more residential allotments or that provides for 6 or more dwellings; or

(ii) involves greater than 2,500m2 of land and results in an increased number of lots; or

(iii) is associated with operational work disturbing greater than 2,500m2 of land; or

(d) operational work for urban purposes that involves:

(i) disturbing greater than 2,500m2 of land.

“Low risk” is a development (or development proposal) that is not “high risk”.

Small, “low risk” developments in Townsville do not have to identify EVs and WQOs for receiving waters. Proposals for these developments need to demonstrate achievement of best management practices for the type of pollutants that are likely to be generated.

(a) Developments in Townsville considered as “high risk” in relation to impacts on stormwater quality require the identification of EVs and WQOs for receiving waters within and/or downstream of the development. Proposals for these developments need to demonstrate that stormwater draining from the site will not threaten the relevant environmental values and their corresponding water quality objectives, in affected receiving waters through the use of appropriate SBMPs.

(7) Water sensitive urban design considerations.

Note—refer to information in Table SC6.4.3.8.1.

(a) WSUD approaches to water management during development and its construction aim to minimise impacts on the natural water cycle, avoid or minimise off-site pollutant discharge, limit changes to the volume, rate, duration and frequency of stormwater discharge, and protect council infrastructure and the EVs of receiving waters.

(b) WSUD applied to the construction phase of land development is primarily concerned with surface drainage and erosion and sediment control.

(c) WSUD at the construction stage needs to take account of the final layout of permanent stormwater controls that will be constructed.

(d) Temporary erosion and sediment controls need to be incorporated into SBMPs to protect permanent stormwater controls such as wetlands, swales, and bio-retention systems proposed to be constructed.

(e) Poor erosion and sediment control planning and implementation can severely compromise the success of biological assets utilised as part of operational stormwater quality controls and increase weed infestations, decrease drainage and filtering capacities, smother landscaping and greatly reduce system reset times.

(f) WSUD principles must be incorporated into construction phase, planning and design.

(8) Detailed design

(a) A SBMP shall be submitted to council as part of the detailed engineering design documentation following

approval of the concepts from council.

(b) The documents are to be site specific and not a generalisation of erosion and sediment control or stormwater quality. The documents may also form part of the contract specifications for a contractor to comply with during construction.

(c) Where available, examples of proposed developments detailing locations of water quality structures, sediment and erosion control methodology may be obtained from council and used as a guide when preparing SBMPs.

(9) Construction

(a) No site works shall commence prior to council's approval of the detailed design documents.

(b) All works are to be undertaken in accordance with the development conditions, accepted drawings, the approved SBMP, local laws and environmental regulations.

(c) Implementation of the approved works during construction must be supervised by the nominated professional.

(d) The developer (or representative) shall constantly monitor, review and modify soil and water management practices to correct any deficiencies.

(e) Random audits may be performed by council throughout the construction phase of the project to review compliance with approved documentation.

Editor's note—where inconsistencies are noted, written advice will be sent to the developer (or representative) requiring appropriate action within 24 hours.

(f) A key reference document, *Best Practice Erosion and Sediment Control*, should be consulted for information on the main concepts for reducing pollution from construction sites.

(g) Construction activity can be divided into two phases—the land development stage and the building construction stage.

Editor's note—both of these phases are known to result in serious stormwater pollution unless appropriately managed.

(i) Land development stage
Land development involves making undeveloped vacant land suitable for urban uses through vegetation clearing, land forming and provision of services such as roads, drainage, water supply, sewers, electricity, gas and other services.

Land development usually involves major earthworks resulting in significant potential for contamination of stormwater by eroding soils.

(ii) Building stage
Building construction can result in significant soil disturbance as well as the contamination of stormwater with building wastes. Pollutants can include litter, rubble, concrete-mixer waste, paints, plaster, brick sand, cleaning products and imported soils, etc. It should be noted that conventional allotment sediment control practices for a building site are largely ineffective at turbidity control. Therefore, for greenfield developments, subdivision-scale controls may be needed.

(iii) Effective source control measures employed during construction can greatly minimise the impact of both phases of construction activity on stormwater quality. SBMPs (these may sometimes be referred to as erosion and sediment control plans or include such provisions) are an effective means of planning and implementing measures to minimise the generation of pollutants from construction activities.

(10) Maintenance plan requirements

(a) Maintenance plans are to be provided for stormwater quality improvement devices (SQIDs) that are to be handed over to council.

(b) SC6.4.3.9 Water sensitive urban design guidelines should be consulted when preparing a maintenance plan.

(c) The responsibilities for maintenance of SQIDs are to be detailed in the SBMP.

(d) The maintenance plans are to be written for use by council's maintenance and asset personnel.

Editor's note—examples of SQIDs that require maintenance plans include trash racks, constructed wetlands and ponds.

Note—trash racks, Gross Pollutants Traps and similar are not preferred.

(e) The maintenance plans are to include as a minimum:

(i) design details;

(ii) manufacturer and supplier contact details (where relevant);

(iii) inspection frequency;

(iv) maintenance frequency;

(v) data collection requirements;

(vi) clean-out procedures that address, at a minimum, public safety, maintenance techniques, wet waste disposal, equipment requirements, environmental management considerations and occupational health and safety and disposal requirements; and

(vii) permeability testing requirements and guidelines for the filter media.

(f) An on-site hand-over meeting and completion of handover documentation must occur between the developer (or representative), responsible maintenance personnel and appropriate representatives from council.

(g) In the event that the SQID is not complying with approved conditions, council is under no obligation to accept responsibility of the asset.

SC6.4.3.8.4 Lodgement of site based stormwater management plans

(1) A site based stormwater management plan (SBMP) identifies stormwater management strategies and actions to broadly address:

(a) water quality;

(b) water quantity;

(c) waterway corridor issues; and

(d) The contents of the SBMP are dependent on the stage of development (concept or detailed design) and the level of risk for the proposed development ("low" or "high").

(2) The SBMP should contain sufficient detail to determine whether the stormwater controls are acceptable to address water quality, water quantity and waterway corridor issues. All SBMP should consider if a development is staged, including the anticipated timeframes for the staged works.

(3) Where an SBMPs is required, it should be prepared in accordance with this sub-section and Table SC6.4.3.8.1 as a minimum standard.

(4) Tables SC6.4.3.8.1, SC6.4.3.8.2 and SC6.4.3.8.3 Checklist for preparation of a site based stormwater management plan has been provided as a detailed check list to outline the minimum standards for creation and preparation of an SBMP that has been requested by council, to be submitted as part of an application or as part of a development condition.

SC6.4.3.8.1 Rapid risk assessment for conceptual site based management plans

Rapid risk assessment for cSBMP	Value
Land size:	
≤5,000m²	0
>5,000m² ≤10,000m²	1
>10,000m²	2
Estimated impervious area of site (road, roofs, parking, etc)	
≤25% of developable area	0
>25% ≤75% of developable area	1
>75% of developable area	2
Lot distance from areas identified within Natural assets environmental importance overlay map OM-08 as of 'very high environmental importance'	
>100m from the proposed development	0
Within 100m of the proposed development	1
Within 50m of the proposed development	2
Within the proposed development	3
Total value – 3 scores combined	
Conceptual site based management plan required at MCU and ROL stages for scores >6	

Table SC6.4.3.8.2 Checklist for preparation of a site based stormwater management plan

Site Based Management Plan Requirements
Introduction and Site Characteristics - Both Operational and Construction Phases
Description and location of the proposed development including existing and proposed land uses
Identification and description of any waterways or wetlands on or adjacent to the site including relevant background water quality data
Related studies and or plans such as catchment management plans, waterway management plans, stormwater management plans
Description of site flora and fauna including any areas of ecological significance
Summary of hydrologic and hydraulic information
Map indicating the proposed size and location for all major stormwater treatment devices such as sediment basins, constructed wetlands and bioretention systems
Parkland contributions (if required)
Completed site risk assessment
Summary of the SBMP study team
Construction Phase Elements (ESCP)
General Plan Requirements
Plan sign off including contact details for the nominated 'Suitably Qualified Person' and 'Responsible Person'
A summary statement describing the scope and intent of the work to be performed
Proposed limits of disturbance during construction activities including fencing, non-disturbance areas, retained groundcover and vegetation
Description of the proposed works including commencement and duration
Description of site preparation and initial land clearing strategies, including ESC controls to be installed prior to disturbance
Map indicating any areas of high erosion risk and/or critical environmental values
Map indicating the existing and proposed topography and drainage (including clearly depicted overland flows)
Descriptions of stabilised construction access points
Plan indicating the locations of the site office, car park(s), sediment stockpiles and associated drainage and sediment controls
Soils
General soil description as identified from published soil maps used in the soil investigation for the site
If required by State Planning Policy 2/02 - an acid sulphate soil investigation
Testing and description of local soil types, identifying the limitations of both topsoils and subsoils determined through soil testing and in particular the 'Cation Exchange Capacity' values
Description of the proposed remedial actions required to treat problem soils: steep slopes, saline soils, dispersive soils, extremely acidic or alkaline soils and acid sulphate soils

Drainage, Erosion and Sediment Control Measures
Map indicating how off site water is diverted around or through the site and how stormwater is diverted away from site entry and exit points
Plan/s submitted for each stage of works that utilise standard ESC symbols and clearly indicate the proposed controls and control locations
Design and construction details for any specified ESC measures, including calculation sheets for the sizing and layout of sediment basins
Specification of the flocculent type, methodology and application rate for any and each sediment basin proposed
Description of how any soil stockpiles are to be protected
Hydraulic analysis demonstrating flow velocities and capacities on site
Implementation schedule providing specific timeframes and sequences for works to be carried out
Specifications of stabilising measures for surfaces exposed for more than 14 days
Technical notes demonstrating best practice site management including dust, chemical, oil, fuel, litter and debris control
Site Revegetation, Rehabilitation, Maintenance and Monitoring
Capital cost of proposed strategy
Description of revegetation, hydroseeding, hydromulching or mulching methods
Site maintenance plan indicating performance standards for ESC structures, establishment of ground cover and monitoring frequencies
An Inspection Test Plan (ITP) for monitoring site performance is provided clearly indicating witness points, hold points and end points
Nominated Total Suspended Solid (TSS) concentration targets for water leaving site
Weekly site inspection checklist for ESC controls in place
Completion of the Townsville City Council Erosion and Sediment Control Plan Checklist
Nomination of 'Responsible Person' accountable for maintenance of structural controls
Total Suspended Solids monitoring program identifying methodology and locations for water quality monitoring
Operational Phase Elements (WSUD)
General Plan Requirements
Plan sign off and contact details for the nominated 'Suitably Qualified Person' and 'Responsible Person'
Clear indication of proposed works including expected commencement and duration
Map indicating the existing and proposed topography and drainage (including clearly depicted flowpaths for various AEP’s)
General soil description as identified from published soil maps used in the soil investigation for the site
Testing and description of local soil types, identifying the limitations of both topsoils and subsoils determined through soil testing and in particular the Cation Exchange Capacities values
Proposed remedial actions required to treat problem soils: steep slopes, saline soils, dispersive soils, extremely acidic or alkaline soils and acid sulphate soils
Electronic copy of MUSIC (or similar pollution reduction modelling program) outputs for the proposed works
Description of any existing stormwater infrastructure
Stormwater Quantity (Hydrology and Hydraulics)
Description of proposed methodology
Details of model analysis
Comparison of existing and proposed hydrology and hydraulics eg. catchments, flows and flood levels for various AEP’s
Selection and assessment of controls
Description of proposed mitigation measures
Designs drawings for proposed controls
Stormwater Quality (Pollution Reduction)
Identification of environmental values, pollutions of concern and water quality objectives
Description of proposed methodology
Details of model analysis
Selection and assessment of controls
Description of proposed mitigation measures
Design drawings for proposed controls

Water quality monitoring program identifying methodology and locations for water quality monitoring
Maintenance and Asset Handover
Capital cost of proposed strategy
Map and details of maintenance access points and dewatering areas
Annual maintenance strategy including asset access, maintenance and resetting methodologies
Details of asset reset times and life cycle costings including ongoing maintenance costs
Nomination of 'Responsible Person' accountable for maintenance of structural controls
Description and timing for asset handover to council

SC6.4.3.8.3 Checklist preparation of a conceptual site based stormwater management plan

Site Based Management Plan Requirements

Introduction and Site Characteristics Both Operational and Construction Phases

Description and location of the proposed development including existing and proposed land uses

Identification and description of any waterways or wetlands on or adjacent to the site including relevant background water quality data

Description of site flora and fauna including any areas of ecological significance

Map indicating the proposed size and location for all major stormwater treatment devices such as sediment basins, constructed wetlands and bioretention systems

Parkland contributions (if required)

Completed site risk assessment

Construction Phase Elements (ESCP)

General Plan Requirements

Description of the proposed works including commencement and duration

Map indicating the existing and proposed topography and drainage (including clearly depicted overland flows)

Soils

General soil description as identified from published soil maps used in the soil investigation for the site

Testing and description of local soil types, identifying the limitations of both topsoils and subsoils determined through soil testing and in particular the 'Cation Exchange Capacity' values

Drainage, Erosion and Sediment Control Measures

Site Revegetation, Rehabilitation, Maintenance and Monitoring

Nominated Total Suspended Solid (TSS) concentration targets for water leaving site

Operational Phase Elements (WSUD)

General Plan Requirements

Clear indication of proposed works including expected commencement and duration

Map indicating the existing and proposed topography and drainage (including clearly depicted flowpaths for various AEP’s)

Description of any existing stormwater infrastructure

Stormwater Quality (Pollution Reduction)

Description of proposed mitigation measures

SC6.4.3.8.5 SBMP document information

The SBMP should outline information relevant to the authorship of the SBMP (ideally provided in tabular form), including document title, reference number, document ownership (including names of personnel that have issued and checked the SBMP) and name of client (and client representative, if appropriate).

The lodgement of development information should be accompanied by information including topographic, drainage, vegetation and soils details as well as the proposed development plan in addition to the following items (1) to (12) and clause SC6.4.3.8.6.

(1) Executive summary

A concise summary of the study methodology and findings should be presented along with a table outlining how the proposed methodology and findings and response to any previous information requests from council.

(2) Table of contents

The table of contents should include a table of the body of the report, a table of appendixes and a table of figures and diagrams.

(3) Introduction

The introduction should include a general description of the proposed development/ works, existing site, scope of the SBMP and the following information:

(a) submission date;

(b) developer's name;

(c) consultant's name;

(d) current and proposed land use of development site;

(e) description of site location (including street directory reference); and

(f) reference to associated documents.

(4) Locality plan

The report should include a locality plan which shows the site location in relation to major topographic features and landmarks such as waterways and major infrastructure such as roads as well as applying the principles of good mapping and drafting.

(5) Site characteristics

(a) An accurate site plan, including survey, should be presented at a smaller scale than the locality plan to show appropriate development site details; and

(b) The plan should include the baseline information used to determine the layout including existing topography catchment/drainage information and vegetation.

(c) If the development is to be constructed in stages these should also be shown on the site plan.

(d) Depending on the extent of information available and scale, it may be more appropriate to present a range of plans which show the different site characteristics. These plans can be presented in the appendixes but for ease of assessment the report should not simply refer to separate reports.

(e) Supporting text should include detailed description of the site characteristics and discussion of how proposed clearing/earthworks will influence existing drainage.

(f) A description of the opportunities and constraints (for example, steep topography preventing the application of devices like swales) should also be discussed.

(6) Proposed land uses

As well as presenting information in plan format, land uses should also be presented in tabular form as follows:

Table SC6.4.3.8.4 Proposed land-uses in tabular format

Land type	Area (ha)	Assumed impervious area
Open space/parkland		
Low density residential		
Medium density residential		
High density residential		
Industrial		
Commercial		
Other		
Total/Overall		

(7) Location conditions

The rainfall and soil category will influence treatment location, design and construction and should also be presented.

(8) Design objectives

The report is to identify the stormwater quality management objectives for both the construction phase and post-construction phase (operational-construction phase) of the proposed development.

(9) Strategy description and plan

(a) The proposed treatment strategy should be presented in plan format (with scale bar) showing sub-catchment boundaries (including any untreated areas) and flow paths.

(b) Other aspects critical in explaining the proposed strategy include:

(i) treatment area locations and indicative footprints including allowance for all relevant design;

(ii) requirements, for example, batters, maintenance access and fore bays;

(iii) description of how run-off will be conveyed to treatment systems; and

(iv) confirmation that treatment system can drain (that is, outlet can freely drain).

(c) Sub-catchments should also be presented in tabular form as follows:

Table SC6.4.3.8.5 Sub-catchment in tabular format

Sub-catchment code	Sub-catchment land use category	Treatment ID	Sub-catchment area (ha (% imp))
A			
B			
Total			

The designer should ensure that sub-catchment names (for example, sub-catchment A) and sub-catchment areas noted on the plan also match those presented in the table. Similarly the designer should ensure that the areas match the sub-catchment names and areas modelled. Confirmation that these cross checks have occurred should be noted in the report.

(10) Modelling approach
Reporting the modelling approach should be undertaken in accordance with council's music modelling requirements.

(11) Treatment plans and sections

(a) The tables should be supported by a full layout plan and sections (longitudinal and cross sections) for each stormwater treatment measure showing integration with the existing or proposed drainage system, benching levels (and, if appropriate, standing water, extended detention and peak water levels), bunding and other conceptual features such as, but not limited to, maintenance access, monitoring access (if proposed) and safety precautions (for example, fencing and/ or dense vegetation restricting public access).

(b) For sites with multiple small treatment devices, a full layout plan and a section drawing of a selected representative sample of devices must be provided.

(c) Layout plans should consider the integration of the stormwater treatment measures into the surrounding topography.

(d) These designs must be prepared as preliminary design drawings suitable for the subsequent preparation of detailed civil design drawings for construction.

(e) The design of treatment devices should be in accordance with SC6.4.3.9 Water sensitive urban design guidelines.

(12) Professional preparation of site based stormwater management plans

(a) It is a requirement that all site based stormwater management plans are prepared by suitably qualified and experienced professionals.

(b) A suitably qualified and experienced professional is defined as a person with the following attributes:

(i) Site Based Stormwater Management Plans (SBMP): relevant tertiary qualifications or equivalent, including being a registered professional Engineer of Queensland (RPEQ).

SC6.4.3.8.6 MUSIC modelling requirements

(1) MUSIC modelling is the standard accepted for modelling for stormwater management for development in Townsville.

(2) The modelling, reporting and assessment methodology presented in the MUSIC Modelling Guidelines is to be applied using local data.

(3) Rainfall, evaporation and pollutant data are to be used from the following sources to ensure that parameter values within the Townsville Local Government Area are regionally relevant to the Townsville environment.

(a) Data for rainfall is to be based on Townsville records for a significant period of time (10 – 20 years) with a range of significant wet and dry periods.

(b) Parameter values for pollutant loads are to be sourced from SC6.4.3.9 Water sensitive urban design guidelines.

(4) Reporting is to specifically outline all parameters used (for example, meteorological data, time step, percentage effective impervious areas, base and stormflow concentration parameters, pollutant reduction efficiencies, treatment node dimensions), either in the body of the report or as an appendix.

(5) The report should record the version of urban stormwater model used.

(6) A digital file containing all relevant modelling files must be provided with the report to enable checking of all modelling calculations by Townsville City Council. The files should include a 'readme' text file, containing a description of the contents and details of any naming conventions used for model files. The checking will also ensure integrity of data to ensure that no parameters have been altered.

(7) Models provided should include:

(a) pre-development condition;

(b) developed site without any stormwater treatment measures; and

(c) developed site with proposed stormwater treatment strategy.

(8) The design of treatment devices should be in accordance with the SC6.4.3.9 Water sensitive urban design guidelines.

(9) Parameters used in the modelling will therefore need to be checked for consistency during design as well as assessment.

(10) A description of the selected stormwater management options should be presented.

(11) This section should include modelling results and dimensions of stormwater treatment measures.

SC6.4.3.8.7 Erosion and sediment control plans

(1) Erosion and sediment control plans (ESCPs) shall contain the following.

(a) Adequate local site data, including soil data, must be obtained to allow the preparation of an appropriate ESCP, and allow the selection, design and specification of required Erosion and sediment control (ESC) measures.

(b) Prior to development of the ESCP, the site must be assessed from a hydrological, hydro-geological, hydraulic, vegetation, soils and geological perspective to determine relevant site constraints that may affect the focus or detail of the plan.

(c) The plan(s) must include all aspects of proposed site disturbance, temporary drainage works, erosion and sediment control measures, installation sequence, and site rehabilitation for the duration of the project, including (where appropriate) the nominated maintenance period.

(d) Generally, an ESCP must address the following issues:

(i) identify the likely need for the construction of sediment basins on the site;

(ii) identify that adequate space has been made available for the construction and operation of major sediment traps and essential flow diversion systems;

(iii) demonstrate that there is a feasible means of constructing the project while still protecting key environmental values;

(iv) identify problem soil areas including, dispersive soils, acid sulfate soils, areas of potential mass movement; and

(v) identify key environmental features on the site such as protected vegetation.

(e) The level of detail supplied in the ESCP must be commensurate with the complexity of the proposal and the assessed environmental risk.

(f) Where appropriate, ESCPs (including supporting documentation) should include, but not be limited to:

(i) north point and plan scale;

(ii) site and easement boundaries and adjoining roadways;

(iii) construction access points;

(iv) site office, car park and location of material stockpiles;

(v) limits of disturbance;

(vi) retained vegetation including protected trees;

(vii) general soil information and location of problematic soils;

(viii) groundwater, and flood-affected areas (50% AEP);

(ix) location of critical environmental values (where appropriate);

(x) existing site contours (unless the provision of these contours adversely impacts the clarity of the ESCP);

(xi) final site contours including locations of cut and fill;

(xii) construction drainage plans for each stage of earthworks, including land contours for that stage of construction, sub-catchment boundaries and location of watercourses;

(xiii) existing and final overland flow drainage paths;

(xiv) location of vegetated buffer strips;

(xv) stabilised entry/exit point (rumble pad);

(xvi) location of soil and sand stockpiles;

(xvii) location of all proposed temporary drainage control measures;

(xviii) location of all proposed erosion control measures (alternatively, use notes to describe locations);

(xix) installation sequence and maintenance requirements;

(xx) permanent site stabilisation measures;

(xxi) a statement of who is responsible for establishing and maintaining all erosion and sediment control measures;

(xxii) general layout and staging of proposed works;

(xxiii) location of all drainage, erosion and sediment control measures;

(xxiv) full design and construction details (such as, cross-sections, minimum channel grades, channel linings) for all drainage and sediment control devices, including diversion channels and sediment basins;

(xxv) site revegetation requirements (if not contained on a separate plan submitted to the assessing authority);

(xxvi) site monitoring and maintenance program, including the location of proposed water quality monitoring stations (if required);

(xxvii) technical notes relating to:

(A) site preparation and land clearing;

(B) extent, timing and application of erosion control measures;

(C) temporary ESC measures installed at end of working day;

(D) temporary ESC measure in case of impending storms, or emergency situations;

(E) installation sequence for ESC measures;

(F) site revegetation and rehabilitation requirements;

(G) application rates (or at least the minimum application rates) for mulching and revegetation measures;

(H) legend of standard symbols used within the plans; and

(I) sediment basin operation and flocculent dosing.

(xxviii) calculation sheets for the sizing of ESC measures;

(xxix) completed ESCP checklist; and

(xxx) any other relevant information council may require to properly assess the ESCP.

(g) If the timing of the proposed construction activities are not known during development of the ESCP, and if rainfall erosivity varies significantly throughout the year, then the erosion control specifications placed on the ESCP must specify appropriate erosion control measures for each level of rainfall erosivity. Refer to SC6.4.3.8 Attachment A: Background information - Sediment load from unprotected soils during construction.

(h) The timing of works and the installation of control measures has a major influence on the management of stormwater. As such, the installation sequence must be considered generally as outlined below.

(i) establish a single stabilised entry/exit point (rumble pad);

(ii) install sediment fence(s) along the low side of the site;

(iii) divert up-slope water around or through the work site and appropriately stabilise any drainage channels;

(iv) clear only those areas necessary for building or construction work to occur;

(v) stockpile topsoil within the sediment-control zone;

(vi) stabilise exposed earth banks e.g. vegetation, erosion control blankets;

(vii) install on-site waste receptacles e.g. mini-skips, bins, reo cages. These should be covered to prevent waste being moved by wind;

(viii) commence building activities;

(ix) install roof downpipes as soon as practicable after the roof is laid;

(x) maintain all control measures in good working order; and

(xi) revegetate or otherwise stabilise the site.

(i) An ESCP is required to be approved by council prior to the commencement of any work or activity, including land clearing (except as allowed under for the purposes of ground survey, geotechnical investigation, or other recognised essential purposes), provided the work is:

(i) consistent with state and council vegetation protection and/or preservation requirements and/or policies; and

(ii) undertaken so that the ground surface is not disturbed and at least 150mm stubble remains on the surface (where such a stubble exists prior to clearing); or

(iii) to provide site access via the minimum practicable number of site access corridors.

(j) Erosion and sediment control management plans (ESCMP) shall be scaled drawings (no larger than 1:1000) with detailed specifications/diagrams which can be readily understood and applied on site by supervisory staff.

(k) All drawings/plans shall be prepared in accordance with SC6.4.2 Development application guidelines and good drafting principles.

(2) Professional ESCP sign-off

(a) The ESCP must clearly state that no land-disturbing activities on the site shall occur until all perimeter ESC measures, sediment basins, and associated temporary drainage controls, have been constructed in accordance with best practice erosion and sediment control.

(b) It is a requirement that all ESCPs are signed by suitably qualified and experienced professional. A suitably qualified and experienced professional is defined as a person with the following attributes:

(i) design phase (ESCP) - relevant tertiary qualification or satisfies at least one of the following 3 criteria:

(A) Statement of Attainment from a Townsville City Council 5 or 6 Day Course (Erosion and Sediment Control Planning for North Queensland); or

(B) Certified Professional in Erosion and Sediment Control (CPESC); or

(C) holds a qualification which is equivalent to either of the above and is accepted by council.

(ii) construction phase (ESCP): relevant tertiary qualifications or satisfies at least one of the following criteria:

(A) holds a Statement of Attainment from a Townsville City Council 2 Day Course (Erosion and Sediment Control for Site Supervisors); or

(B) holds a qualification which is equivalent to the above and is accepted by council; or

(iii) operational phase (WSUD):

(A) relevant tertiary qualifications or a Statement of Attainment from a Townsville City Council 2 day course (Water sensitive urban design for Site Supervisors).

(B) holds a qualification which is accepted by council.

Editor's note—Statement of Attainment from a Townsville City Council 2 Day Course (Water sensitive urban design for Site Supervisors) is a course currently being developed by TCC.

(c) When signing-off on an ESCP, the signatory is deemed to be making the following statements:

(i) the ESCP satisfies the intent and design/performance standards established by all relevant local, state and federal policies relating to erosion and sediment control;

(ii) the ESCP has been reviewed and approved by personnel suitably trained and experienced (to a degree appropriate for the given type and size of the land disturbance) in each of the following categories: construction, soil science, hydrology/hydraulics, and site revegetation/rehabilitation;

(iii) the ESCP is both reasonable and practicable; and

(iv) the ESCP contains sufficient information to allow the appropriate implementation of the plans.

(d) ESCPs that incorporate a sediment basin with a constructed earth embankment with a height greater than 1m, must be signed-off by a geotechnical specialist.

(e) The approved ESCP must be available on-site for inspection by council officers while work activities are occurring.

(3) Should the development be commenced and not completed within 12 months of approval of the ESCP, a revised ESCP must be prepared, with further revisions thereafter at half-yearly intervals. For master planned developments this requirement applies for the ESCPs for each stage.

(4) Additional erosion and sediment control measures are implemented, and a revised ESCP is submitted for approval (within five business days of any such amendments) in the event that:

(a) there is a high probability that serious or material environmental harm may occur as a result of sediment leaving the site; or

(b) the implemented works fail to achieve the local government ESC standard/code, or state environmental protection requirements; or

(c) site conditions significantly change; or

(d) site inspections indicate that the implemented works are failing to achieve the "objective" of the ESCP.

(5) In circumstances where it is considered necessary to prepare an amended ESCP, and the preparation of the amended ESCP is not imminent, then all necessary new or modified erosion and sediment control measures

must be implemented in accordance with current best practice:

(a) in circumstances where there is significant risk of environmental harm, then upon receipt of the amended ESCP, all works must be implemented in accordance with the revised plan;

(b) otherwise, only upon approval of the amended ESCP by the assessing authority shall works be implemented in accordance with the amended plan; and

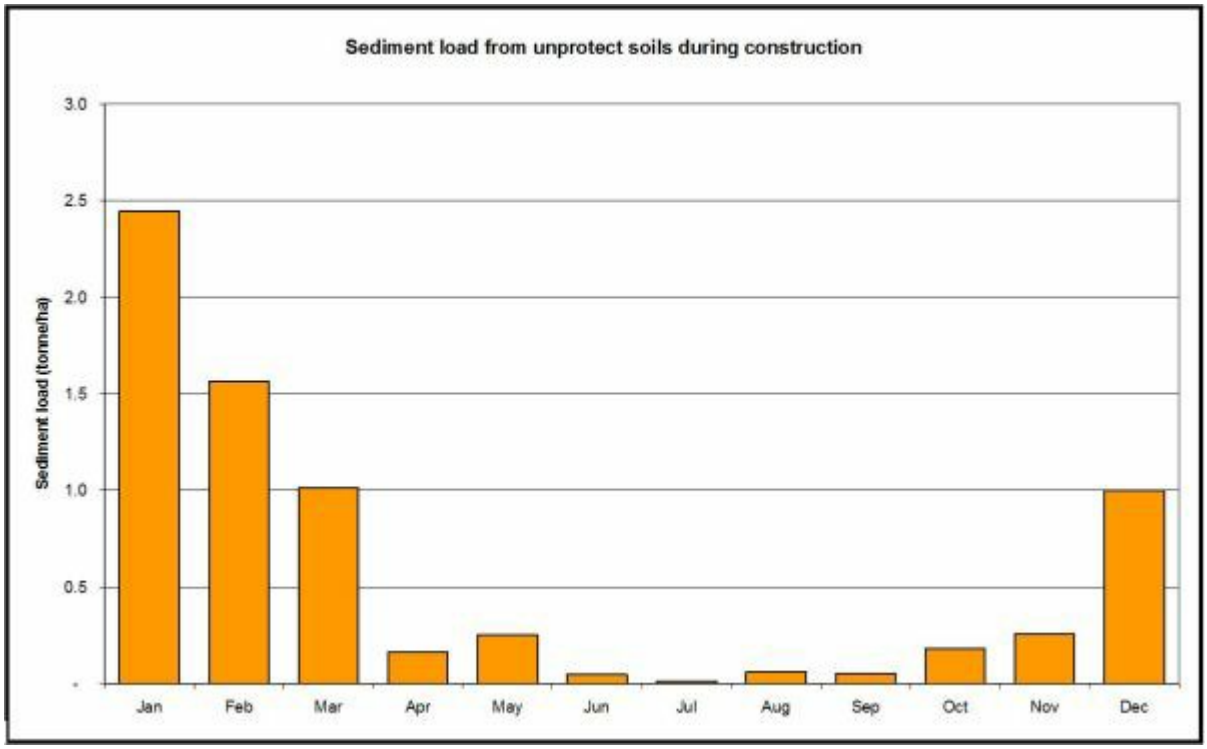
(c) a copy of the amended ESCP must be forwarded to council within 5 business days of any such amendments.

(6) The design standard of erosion and sediment control must be commensurate with the degree of environmental risk associated to the proposed works.

(7) All erosion and sediment control measures, including temporary drainage control measures, must be designed in accordance with the design standards in SC6.4.4.4 Stormwater drainage design.

(8) The ESCP must incorporate “hold points” (where appropriate) detailing critical performance indicators of the various elements of the ESCP. The development must not be allowed to proceed without adherence to designated hold points at specified times.

SC6.4.3.8 Attachment A: Background information - Sediment load from unprotected soils during construction



Month	Sediment (Tonnes/hectare)	% yearly load

SC6.4.3.9 Water sensitive urban design guidelines

SC6.4.3.9.1 Introduction

(1) Water By Design's *Water Sensitive Urban Design Technical Design Guidelines for South East Queensland*, Version 1, 2006 (or as amended), are adopted, with the following exclusions:

(a) Chapter 1 Introduction

(b) Chapter 6 Constructed Stormwater Wetlands.

Note—Chapter 3 Bioretention Swales, Chapter 5 Bioretention Basins, and Appendix A Plant Selection for WSUD Systems, which formed part of the original version of the Technical Design Guidelines, have been superseded by Healthy Waters' *Bioretention Technical Design Guidelines (Version 1, October 2012)*. The *Bioretention Technical Design Guidelines* are **not** being adopted.

(2) The following sections – Introducing water sensitive urban design, Bioretention swales, Bioretention basins, Constructed stormwater wetlands, and Appendix A Plant selection for water sensitive urban design systems - have been developed specifically for the coastal dry tropic conditions found in the Townsville area, and replace those equivalent sections in the *Water Sensitive Urban Design Technical Design Guidelines for South East Queensland* (and the superseded parts that form the *Bioretention Technical Design Guidelines*).

(3) References to chapters and sections in this sub-section refer to the chapters and sections in the *Water Sensitive Urban Design Guidelines for South East Queensland*.

SC6.4.3.9.2 Introducing water sensitive urban design

(1) Water sensitive urban design (WSUD) is an internationally recognised concept that offers an alternative to traditional development practices. WSUD is a holistic approach to the planning and design of urban development that aims to minimise negative impacts on the natural water cycle and protect the health of aquatic ecosystems. It promotes the integration of stormwater, water supply and sewage management at the development scale.

The key principles of WSUD are to:

(a) protect existing natural features and ecological processes;

(b) maintain the natural hydrologic behaviour of catchments;

(c) protect water quality of surface and ground waters;

(d) minimise demand on the reticulated water supply system;

(e) minimise sewage discharges to the natural environment; and

(f) integrate water into the landscape to enhance visual, social, cultural and ecological values.

These guidelines are not intended to limit innovation in design or construction of WSUD elements by restricting alternative approaches to those presented here. Alternative designs should be considered where potential improvements in performance, constructability or maintenance requirements can be demonstrated. However, the design procedures and recommendations given in these guidelines are based on contemporary best practice, incorporating lessons from local experience, and are regarded as appropriate for the coastal dry tropics region.

(2) Design objectives for stormwater management
The adopted design objectives for the coastal dry tropics in mean annual pollutant load leaving a development site, compared to traditional urban design where stormwater is not treated:

(a) >= 80% reduction in total suspended solids load

(b) >= 65% reduction in total phosphorus load

(c) >= 40% reduction on total nitrogen load

(d) >= 90% reduction in gross pollutant load.

Editor's note—this sub-section contains illustrations and photographs of stormwater treatment devices. These are intended as examples only and should not be regarded as acceptable solutions. Unless specifically indicated, all drawings are not to scale.

(3) Selection of appropriate stormwater management measures

(a) Not all of the stormwater management measures presented in this sub-section are suitable for any given site. Appropriate measures should be selected by matching device characteristics to target pollutants and the physical constraints of the site.

(b) These guidelines are not intended to provide detailed advice on selection of stormwater treatment devices. However, the following tables provide an indication of:

(i) the scale at which various treatment measures are typically applied (Table SC6.4.3.9.1);

Table SC6.4.3.9.1 Scale of WSUD application in urban catchments

WSUD Measure	Allotment Scale	Street Scale	Precinct or Regional Scale
Swales and buffer strips		✓	
Bioretention Swales		✓	✓
Sedimentation basins			✓
Bioretention basins	✓	✓	✓
Constructed wetlands		✓	✓
Infiltration measures	✓	✓	
Sand filters	✓	✓	
Aquifer storage and recovery			✓

(ii) the effectiveness of these treatment measures in removing pollutants, attenuating peak flow rates and reducing runoff volume (Table SC6.4.3.9.2); and

Table SC6.4.3.9.2 Effectiveness of WSUD measures for runoff quality and quantity management

WSUD Measure Water	Quality Treatment			Peak Flow Attenuation*	Reduction in Runoff Volume*
	TSS	TP	TN		
Swales and buffer strips	H	M	L	L	L
Bioretention Swales	H	H	H	M	L
Sedimentation basins	H	M	L	M	L
Bioretention basins	H	H	H	M	L
Constructed wetlands	H	H	H	H	L
Infiltration measures**	-	-	-	H	H
Sand filters	H	M	L	L	L
Aquifer storage and recovery**	-	-	-	H	H

H – High; M – Medium; L – Low * Frequent events only ** Water quality treatment is not a primary function of these devices

(iii) site conditions that may affect the suitability of different treatment measures (Table SC6.4.3.9.3).

Table SC6.4.3.9.3 Site constraints for WSUD measures

WSUD Measure	Steep site (>5%)	Shallow bedrock	Acid Sulfate Soils	Low permeability soil (eg. Clay)	High permeability soil (eg. sand)	High water table	High sediment input	Land availability
Swales and buffer strips	C	D	D	✓	✓	D	D	D
Bioretention Swales	C	C	C	✓	✓	C	D	D
Sedimentation basins	C	✓	✓	✓	✓	D	✓	D
Bioretention basins	D	D	D	✓	✓	C	C	D
Constructed wetlands	C	D	C	✓	D	D	D	D
Infiltration measures	C	C	C	C	✓	C	C	D
Sand filters	D	✓	✓	✓	✓	D	C	✓
Aquifer storage and recovery	C	C	C	C	✓	C	C	D

C – Constraint may preclude use; D – Constraint may be overcome through appropriate design; ✓ – Generally not a constraint

(4) Safety and risk management

(a) WSUD aims to protect the environmental assets of a site and enhance liveability through greater integration of built and natural features. This approach may introduce some risks to the urban environment that are greater than or different to those encountered in traditional land development practice. The more obvious of these risks relate to the presence of open water bodies and the introduction of street-scape elements that may alter lines of sight or other aspects of traffic safety.

(b) Whilst this sub-section makes occasional comment on various aspects of safety, they are not intended to provide comprehensive advice on appropriate risk management strategies. Designers are responsible for providing an appropriate level of public safety in their designs and for ensuring that risk management procedures, in accordance with relevant standards and guidelines, are followed. Further information on risk management for water-related urban infrastructure is provided in the *Queensland Urban Drainage Manual*.

SC6.4.3.9.3 Bioretention swales

(1) Bioretention swales act to disconnect impervious areas from downstream waterways and provide protection to natural receiving waterways from frequent storm events by reducing flow velocities compared with piped systems. The bioretention component is typically located at the downstream end of the overlying swale “cell” (i.e. immediately upstream of the swale overflow pit(s) as shown in Figure SC6.4.3.9.1.

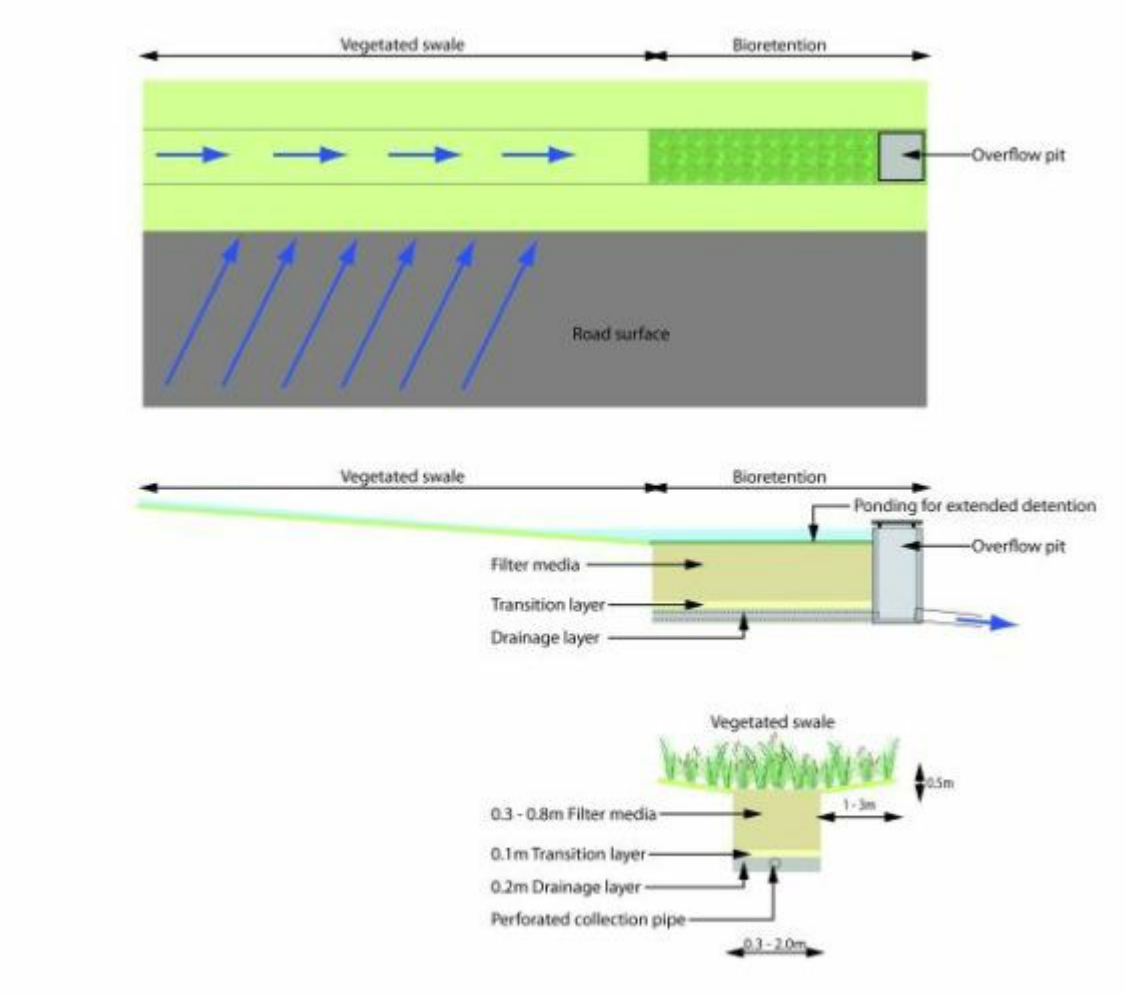

Figure SC6.4.3.9.1 Bioretention swale conceptual layout

The choice of bioretention location within the overlying swale will depend on a number of factors, including area available for the bioretention filter media and the maximum batter slopes for the overlying swale. Typically, when used as a continuous trench along the full length of a swale, the desirable maximum longitudinal grade of the swale is 4%. For other applications, the desirable grade of the bioretention zone is either horizontal or as close as possible to encourage uniform distribution of stormwater flows over the full surface area of bioretention filter media and allowing temporary storage of flows for treatment before bypass occurs.

(2) Design considerations for bioretention swales

(a) This section outlines some of the key design considerations for bioretention swales that the detailed designer should be familiar with before applying the design procedure presented later in this chapter. Standard design considerations for the swale component of bioretention swales are discussed in detail in Chapter 2 (Swales) and are not reproduced here. However, other swale design considerations that relate specifically to the interactions between the swale and bioretention components are presented in the following sections together with design considerations relating specifically to the bioretention component.

(i) Landscape design

Bioretention swales may be located within parkland areas, easements, car parks or along roadway corridors within footpaths (i.e. road verges) or centre medians. Landscape design of bioretention swales along the road edge can assist in defining the boundary of road or street corridors as well as providing landscape character and amenity. It is therefore important that the landscape design of bioretention swales addresses stormwater quality objectives whilst also being sensitive to these other important landscape functions. It is also necessary to adequately address potential aesthetics issues such as weeds and sustaining perennial plants during the dry season.

(i) Hydraulic design

A key hydraulic design consideration for bioretention swales is the delivery of stormwater runoff from the swale onto the surface of a bioretention filter media. Flow must not scour the bioretention surface and needs to be uniformly distributed over the full surface area of the filter media. In steeper areas, check dams may be required along the swale to reduce flow velocities discharged onto the bioretention filter media.

It is important to ensure that velocities in the bioretention swale from both minor (2-10 year ARI) and major (50-100 year ARI) runoff events are kept sufficiently low (preferably below 0.5 m/s and not more than 2.0 m/s for major flood) to avoid scouring. This can be achieved by ensuring the slope and hydraulic roughness of the overlying swale reduce flow velocities by creating shallow temporary ponding (i.e. extended detention) over the surface of the bioretention filter media via the use of a check dam and raised field inlet pits. This may also increase the overall volume of stormwater runoff that can be treated by the bioretention filter media.

(iii) Ex-filtration to in-situ soils

Bioretention swales can be designed to either preclude or promote ex-filtration of treated stormwater to the surrounding in-situ soils depending on the overall stormwater management objectives established for the given project.

Where the concept design specifically aims to preclude ex-filtration of treated stormwater runoff it is necessary to consider if the bioretention swale needs to be provided with an impermeable liner. The amount of water lost from bioretention trenches to surrounding in-situ soils is largely dependent on the characteristics of the local soils and the saturated hydraulic conductivity of the bioretention filter media (see SC6.4.3.9.3(2)(a)(iii)).

If the selected saturated hydraulic conductivity of the bioretention filter media is less than 10 times that of the native surrounding soils, it may be necessary to provide an impermeable liner. Flexible membranes or a concrete casting are commonly used to prevent excessive ex-filtration. This is particularly applicable for surrounding soils that are very sensitive to any ex-filtration (e.g. sodic soils and reactive clays in close proximity to significant structures such as roads).

The greatest pathway of ex-filtration is through the base of a bioretention trench, as gravity and the difference in hydraulic conductivity between the filter media and the surrounding native soil would typically act to minimise ex-filtration through the walls of the trench. If lining is required, it is likely that only the base and the sides of the drainage layer (refer to SC6.4.3.9.3(2)(a)(iii)) will need to be lined.

Where ex-filtration of treated stormwater to the surrounding in-situ soils is promoted by the bioretention swale concept design, it is necessary to ensure the saturated hydraulic conductivity of the in-situ soils is at least equivalent to that of the bioretention filter media, thus ensuring no impedance of the desired rate of flow through the bioretention filter media. Depending on the saturated hydraulic conductivity of the in-situ soils it may be necessary to provide an impermeable liner to the sides of the bioretention filter media to prevent horizontal ex-filtration and subsequent short-circuiting of the treatment provided by the filter media. Bioretention trenches promoting ex-filtration do not require perforated under-drains at the base of the filter media or a drainage layer.

A subsurface pipe is often used to prevent water intrusion into a road sub-base. This practice is to continue as a precautionary measure to collect any water seepage from bioretention swales located along roadways.

(iv) Vegetation types

Bioretention swales can use a variety of vegetation types including turf (swale component only), sedges and tufted grasses. Vegetation is required to cover the whole width of the swale and bioretention filter media surface, be capable of withstanding design flows and be of sufficient density to prevent preferred flow paths and scour of deposited sediments.

Grassed (turf) bioretention swales can be used in residential areas where a continuous bioretention

trench approach is used. The preferred vegetation for the bioretention component of bioretention swales is therefore sedges and tufted grasses (with potential occasional tree plantings) that do not require mowing.

The denser and taller the vegetation planted in the bioretention filter media, the better the treatment provided, especially during extended detention. Taller vegetation has better interaction with temporarily stored stormwater during ponding, which results in enhanced sedimentation of suspended sediments and associated pollutants. The vegetation that grows in the bioretention filter media also acts to continuously break up the surface of the media through plant root growth and wind induced agitation, which prevents surface clogging. Vegetation also provides a substrate for biofilm growth in the upper layer of the filter media which facilitates biological transformation of pollutants (particularly nitrogen).

To maintain aesthetics in highly visible areas supplemental irrigation may be required to sustain vegetation. The incorporation of saturated zones beneath the bioretention filter media can help to sustain soil moisture and is beneficial for nitrogen removal from stormwater. The ability to sustain dense perennial vegetation is important for long term weed management.

SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics provides more specific guidance on the selection of appropriate vegetation for bioretention swales.

(v) Bioretention filter media

Selection of an appropriate bioretention filter media is a key design step involving consideration of three inter-related factors:

(A) saturated hydraulic conductivity required to optimise the treatment performance of the bioretention component given site constraints on available filter media area;

(B) depth of extended detention provided above the filter media; and

(C) suitability as a growing media to support vegetation growth (i.e. retaining sufficient soil moisture and organic content).

The area available for bioretention swales in an urban layout is often constrained by factors such as the available area within the footpaths of standard road reserves. Selecting bioretention filter media for bioretention swale applications in the coastal dry tropics will often require careful consideration of saturated hydraulic conductivity and extended detention depth to ensure the desired minimum volume of stormwater runoff receives treatment. This must also be balanced with the requirement to also ensure the saturated hydraulic conductivity does not become too high such that it can no longer sustain healthy vegetation growth. The maximum saturated hydraulic conductivity should not exceed 500 mm/hr (and preferably be between 50 - 200 mm/hr) in order to sustain vegetation growth.

The concept design stage will have established the optimal combination of filter media saturated hydraulic conductivity and extended detention depth using a continuous simulation modelling approach (such as MUSIC). Any adjustment of either of these two design parameters during the detailed design stage will require the continuous simulation modelling to be re-run to assess the impact on the overall treatment performance of the bioretention system.

As shown in Figure SC6.4.3.9.2 below, bioretention media can consist of three or four layers. In addition to the filter media required for stormwater treatment, a saturated zone can also be added to enhance nitrogen removal and to provide a source of water for vegetation over the dry season. A drainage layer is also required to convey treated water from the base of the filter media or saturated zone into the perforated under-drains. The drainage layer surrounds the perforated under-drains and can be either coarse sand (1 mm) or fine gravel (2-5 mm). If fine gravel is used, a transition layer of sand must also be installed to prevent migration of the filter or saturated zone media into the drainage layer and subsequently into the perforated under-drains.

(vi) Saturated zone

The saturated zone design involves a relatively simple modification to a conventional bioretention system. An additional layer located below the filter media is designed to retain stormwater providing a saturated zone at the base of the bioretention system. A saturated zone can be formed by using a riser pipe with the outlet level higher than the drainage layer or by incorporating a weir within the outlet pit. The saturated zone holds water and therefore provides a source of water to maintain soil moisture for plant uptake during dry periods.

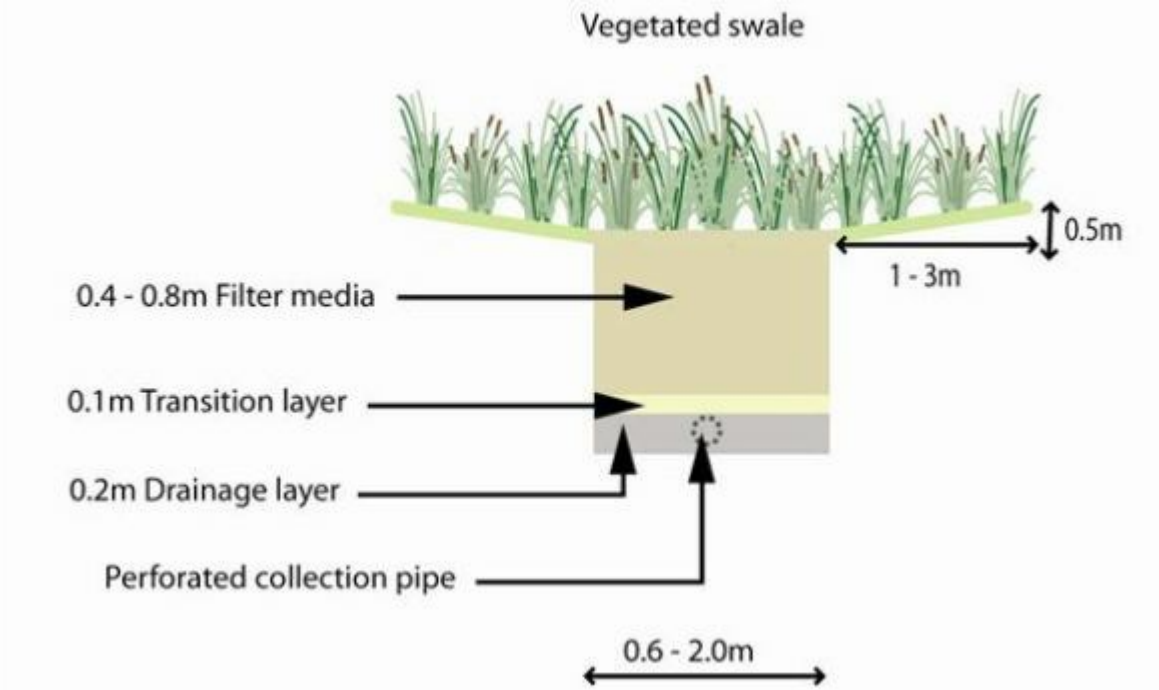

Figure SC6.4.3.9.2 Typical section of a bioretention swale

(vii) Traffic controls

Another design consideration is keeping traffic and building material deliveries off swales, particularly during the building phase of a development.

A staged construction and establishment method (SC6.4.3.9.3(5) Construction and establishment - bioretention swales) affords protection to the sub-surface elements of a bioretention swale from heavily sediment laden runoff during the subdivision construction and allotment building phases. However, to prevent vehicles driving on bioretention swales and inadvertent placement of building materials, it is necessary to consider appropriate traffic control solutions as part of the system design. These can include temporary fencing of the swale during the subdivision construction and allotment building phases with signage erected to alert builders and contractors of the purpose and function of the swales. Kerb and channel should be used at all corners, intersections, cul-de-sac heads and at traffic calming devices to ensure correct driving path is taken. For all of these applications, the kerb and channel is to extend 5 m beyond tangent points.

(viii) Roof water discharge

Roof runoff can contain a range of stormwater pollutants including nitrogen washed from the atmosphere during rainfall events. Roof water should be discharged onto the surface of the swale for subsequent conveyance and treatment by the swale (and downstream treatment measures) before being discharged to receiving aquatic environments. Depending on the depth of the roof water drainage system and the finished levels of the bioretention swale, this may require the use of a small surcharge pit located within the invert of the swale to allow the roof water to surcharge to the swale. Any residual water left in the surcharge pit can be discharged to the underlying subsoil drainage by providing perforations in the base and sides of the surcharge pit. If a surcharge pit is used then an inspection chamber along the roof water drainage line is to be provided within the property boundary. Surcharge pits are discussed further in SC6.4.3.9.3(3)(d)(ii) Concentrated inflow.

(ix) Services

Bioretention swales located within footpaths (i.e. road verges) must consider the standard location for services within the verge and ensure access for maintenance of services. Typically it is acceptable to have water and sewer services located beneath the batters of the swale with any sewers located beneath bioretention swales to be fully welded polyethylene pipes with rodding points.

(3) Bioretention swale design process

(a) Step 1: Confirm treatment performance of concept design

This design process assumes a conceptual design has been undertaken. Before commencing detailed design, the designer should first undertake a preliminary check to confirm the bioretention swale treatment area from the concept design is adequate to deliver the required level of stormwater quality improvement. This assessment should be undertaken by a WSUD specialist and can be achieved by modelling expected treatment performance in an appropriate quantitative modelling program. This modelling must be based on local rainfall data, the proposed configuration of the system, and based on local stormwater treatment performance data.

(b) Step 2: Determine design flows for the swale component

(i) Design flows

Two design flows are required for the design of a swale:

(A) minor flood flow (2 year ARI) to allow minor floods to be safely conveyed. For commercial and industrial areas the design flow requirement for minor flows is a 5 year ARI event.

(B) major flood flow (100 year ARI) to check flow velocities, velocity depth criteria, conveyance within road reserve, and freeboard to adjoining property.

(ii) Design flow estimation

A range of hydrologic methods can be applied to estimate design flows. As the typical catchment area should be relatively small (<50 ha) the Rational Method design procedure is considered to be a suitable method for estimating design peak flows.

(c) Step 3: Dimension the swale component with consideration to site constraints

Factors to consider are:

(i) allowable width given the proposed road reserve and/ or urban layout;

(ii) how flows are delivered into a swale (e.g. cover requirements for pipes or kerb details);

(iii) vegetation height;

(iv) longitudinal slope;

(v) maximum side slopes and base width;

(vi) provision of crossings (elevated or at grade); and

(vii) requirements of QUDM and Townsville City Plan.

Depending on which of the above factors are fixed, the other variables can be adjusted to derive the optimal swale dimensions for the given site conditions. The following sections outline some considerations in relation to dimensioning a swale.

(i) Swale width and side slopes

Where the swale width is not constrained by an urban layout (e.g. when located within a large parkland area) then the width of the swale can be selected based on consideration of landscape objectives, maximum side slopes for ease of maintenance and public safety, hydraulic capacity required to convey the desired design flow, and treatment performance requirements. The maximum swale width needs to be identified early in the design process as it dictates the remaining steps in the swale design process. Selection of appropriate sideslopes for swales in parks, easements or median strips is heavily dependent on site constraints, and swale side slopes are typically between 1 in 10 and 1 in 4.

For swales located adjacent to roads, the types of driveway crossing used will typically dictate batter slopes. Where there are no driveway crossings, the maximum swale side slopes will be established for ease of maintenance and public safety considerations. Generally “at-grade”

crossings, are preferred which require the swale to have 1:9 side slopes with a nominal 0.5 m flat base to provide sufficient transitions to allow for traffic movement across the crossing. Flatter swale side slopes can be adopted but this will reduce the depth of the swale and its conveyance capacity. Where “elevated” crossings are used, swale side slopes would typically be between 1 in 6 and 1 in 4. “Elevated” crossings will require provision for drainage under the crossings with a culvert or similar.

(ii) Maximum length of a swale

The maximum length of a swale located within parkland areas and easements is calculated as the distance along the swale to the point where the flow in the swale from the contributing catchment (for the specific design flood frequency) exceeds the bank full capacity of the swale. For example, if the swale is to convey the minor flood flow (1-5 year ARI) without overflowing, then the maximum swale length would be determined as the distance along the swale to the point where the 1-5 year ARI flow from the contributing catchment is equivalent to the bank full flow capacity of the swale (bank full flow capacity is determined using Manning’s equation as discussed in SC6.4.3.9.3(3)(c) (iii) Swale capacity).

(iii) Swale capacity – Manning’s Equation and selection of Manning’s *n*

To calculate the flow capacity of a swale, use Manning’s equation. This allows the flow rate and flood levels to be determined for variations in swale dimensions, vegetation type and longitudinal grade.

$$Q = \frac{A \cdot R^{2/3} \cdot S^{1/2}}{n}$$

Where A = cross section area of swale (m^2)
R = hydraulic radius (m)
S = channel slope (m/m)
N = roughness factor (Manning’s *n*)

Figure SC6.4.3.9.3 shows a plot of Manning’s *n* versus flow depth for a grass swale with longitudinal grade of 5 %. It is reasonable to expect the shape of the Manning’s n relation with flow depth to be consistent with other swale configurations, with the vegetation height at the boundary between low flows and intermediate flows (Figure SC6.4.3.9.3) on the top axis of the diagram. The bottom axis of the plot has been modified from Barling and Moore (1993) to express flow depth as a percentage of vegetation height.

Further discussion on selecting an appropriate Manning’s n for a swale is provided in Appendix E of the MUSIC User Guide (CRCCH 2005).

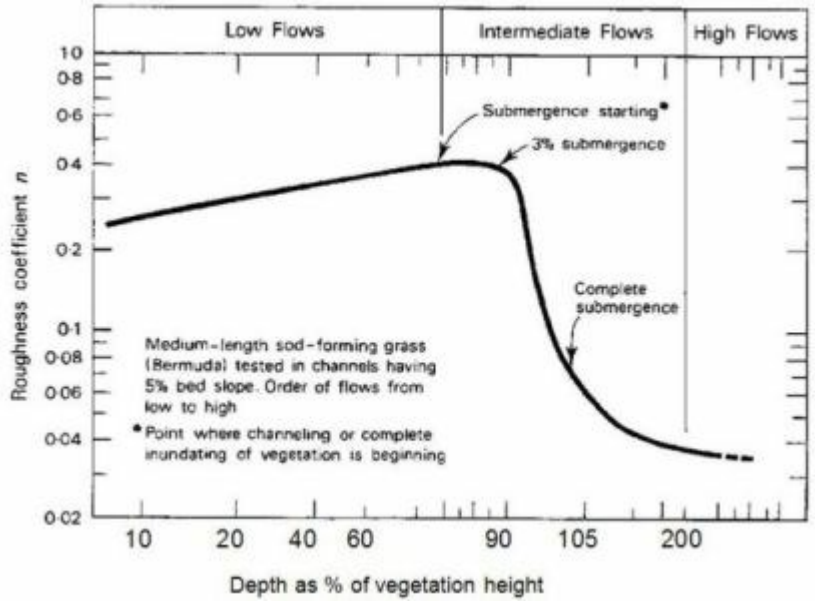

Figure SC6.4.3.9.3 Impact of flow depth on hydraulic roughness (adapted from Barling and Moore (1993))

(d) Step 4: Design inflow systems to swale and bioretention components

Inflows to bioretention swales can be via distributed runoff (e.g. from flush kerbs on a road) or point outlets such as pipe outfalls. Combinations of these inflow pathways can also be used.

(i) Distributed inflow

An advantage of flows entering a bioretention swale system in a distributed manner (i.e. entering perpendicular to the direction of the swale) is that flow depths are kept as shallow sheet flow, which maximises contact with the swale and bioretention vegetation, particularly on the batter receiving the distributed inflows. This swale and bioretention batter is often referred to as a buffer (see Figure SC6.4.3.9.4). The requirement of the buffer is to ensure there is dense vegetation growth, flow depths are shallow (below the vegetation height) and erosion is avoided. The buffer provides good pre-treatment (i.e. significant coarse sediment removal) prior to flows being conveyed along the swale.

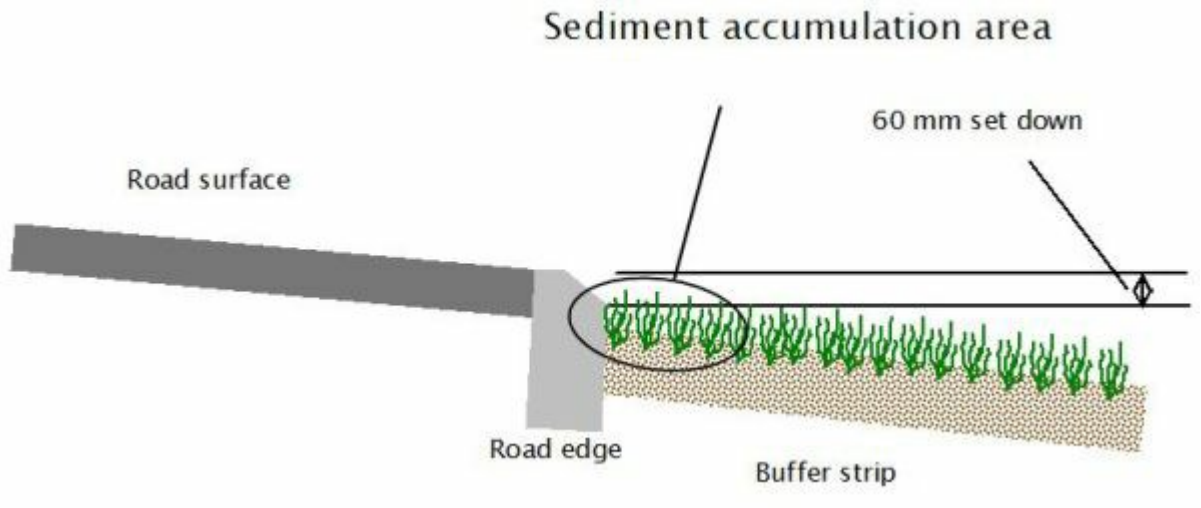

Figure SC6.4.3.9.4 Flush kerb with 60 mm setdown to allow sediment to flow into vegetated area

Distributed inflows can be achieved either by having a flush kerb or by using kerbs with regular breaks in them to allow for even flows across the buffer surface (Figure SC6.4.3.9.5).

Figure SC6.4.3.9.5 Kerb arrangements with breaks and flush kerbs to distribute inflows on to bioretention swales and prevent vehicle access

Key design parameters of buffer systems are:

(A) providing distributed flows into a buffer (potentially spreading stormwater flows to achieve this);

(B) avoiding rilling or channelised flows;

(C) maintaining flow heights lower than vegetation heights (this may require flow spreaders, or check dams); and

(D) minimising the slope of buffer, best if slopes can be kept below 5%.

Maintenance of buffers is required to remove accumulated sediment and debris therefore access is important. It is important to ensure coarse sediments accumulate off the road surface at the start

of the buffer. Figure SC6.4.3.9.6 shows sediment accumulating on a street surface where the vegetation is the same level as the road. To avoid this accumulation, a tapered flush kerb must be used that sets the top of the vegetation 60 mm which requires the top of the ground surface (before turf is placed) to be approximately 100 mm below the road surface. This allows sediments to accumulate off any trafficable surface.

Figure SC6.4.3.9.6 Flush kerb without setdown, showing sediment accumulation on road

(ii) Concentrated inflow

Concentrated inflows to a bioretention swale can be in the form of a concentrated overland flow or a discharge from a piped drainage system (e.g. allotment drainage line). For all concentrated inflows, energy dissipation at the inflow location is required to minimise any erosion potential. This can usually be achieved with rock benching and/ or dense vegetation.

The most common constraint on pipe systems discharging to bioretention swales is bringing the pipe flows to the surface of a swale. In situations where the swale geometry does not allow the pipe to achieve “free” discharge to the surface of the swale, a “surcharge” pit may be used but should be avoided where possible.

Surcharge pit systems are most frequently used when allotment runoff is required to cross a road into a swale on the opposite side of the road or for allotment runoff discharging into shallow profile swales. Where allotment runoff needs to cross under a road to discharge to a swale, it is preferable to combine the runoff from more than one allotment to reduce the number of crossings required under the road pavement. Figure SC6.4.3.9.7 illustrates a typical surcharge pit discharging into a swale.

Another important form of concentrated inflow in a bioretention swale is the discharge from the swale component into the bioretention component, particularly where the bioretention component is located at the downstream end of the overlying swale and receives flows concentrated within the swale. Depending on the grade, its top width and batter slopes, the resultant flow velocities at the transition from the swale to the bioretention filter media may require the use of energy dissipation to prevent scour of the filter media (if flow velocities > 0.5 m/sec). For most cases, this can be achieved by placing several large rocks in the flow path to reduce velocities and spread flows. Energy dissipaters located within footpaths must be designed to ensure pedestrian safety.

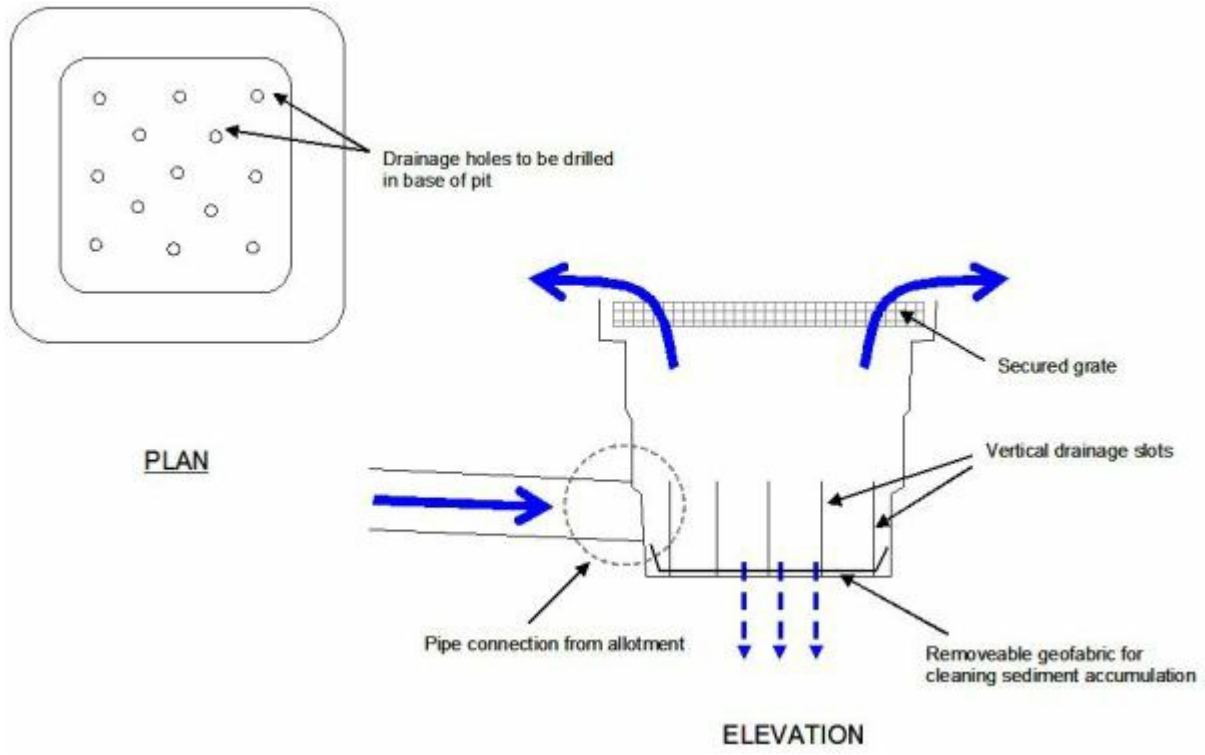

Figure SC6.4.3.9.7 Example of surcharge pit for discharging allotment runoff into a swale

(e) Step 5: Design bioretention component

(i) Select filter media saturated hydraulic conductivity and extended detention

Where design Steps 2 and 3 (SC6.4.3.9.3(3)(b) and SC6.4.3.9.3(3)(c)) reveal that the swale geometry derived during the concept design stage does not comply with the relevant local road drainage design standards and/or the standards established in QUDM for minor flood and major flood flows on adjoining road pavements and minimum freeboard requirements to adjoining properties, it is necessary to revise the swale geometry. As such, an alternative dimension for the surface area of the bioretention component may result and this may require further quantitative modelling to determine the “new” optimal combination of filter media saturated hydraulic conductivity and extended detention depth to maximise the water quality treatment function of the bioretention component.

(ii) Specify the bioretention filter media characteristics

Three to four types of media can be required in the bioretention component of bioretention swales (refer Figure SC6.4.3.9.2).

Filter media

The filter media layer provides the majority of the pollutant treatment function, through fine filtration and also by supporting vegetation. The vegetation enhances filtration, keeps the filter media porous, provides substrate for biofilm formation and provides some uptake of nutrients and other stormwater pollutants. As a minimum, the filter media is required to have sufficient depth to support vegetation. Typical depths are between 600-1000 mm with a minimum depth of 300 mm accepted in depth constrained situations. It is important to note that if deep rooted plants such as trees are to be planted in bioretention swales, the filter media must have a minimum depth of 800 mm to avoid roots interfering with the perforated under-drain system.

The saturated hydraulic conductivity of the filter media is established by optimising the treatment performance of the bioretention system given site constraints of the particular site (using a continuous simulation model). Saturated hydraulic conductivity should remain between 50-200 mm/hr (saturated hydraulic conductivity of greater than 500 mm/hr would not be accepted by most councils). Once the saturated hydraulic conductivity of the filter media has been determined for a particular bioretention swale, the following process can then be applied to derive a suitable filter media soil to match the design saturated hydraulic conductivity:

(A) identify available sources of a suitable base soil (i.e. topsoil) capable of supporting vegetation growth such as a sandy loam or sandy clay loam. In-situ topsoil should be considered first before importing a suitable base soil. Any base soil found to contain high levels of salt (see last bullet point), extremely low levels of organic carbon (< 5%), or other extremes considered retardant to plant growth and denitrification should be rejected. The base soil must also be structurally sound and not prone to structural collapse as this can result in a significant reduction in saturated hydraulic conductivity. The risk of structural collapse can be reduced by ensuring the soil has a well graded particle size distribution with a combined clay and silt fraction of < 12%;

(B) using laboratory analysis, determine the saturated hydraulic conductivity of the base soil using standard testing procedures (AS 4419-2003 Appendix H Soil Permeability). A minimum of five samples of the base soil should be tested. Any occurrence of structural collapse during laboratory testing must be noted and an alternative base soil sourced;

(C) the required content of sand or clay (by weight) to be mixed to the base soil will need to be established in the laboratory by incrementally increasing the content of sand or clay until the desired saturated hydraulic conductivity is achieved. The sand or clay content (by weight) that achieves the desired saturated hydraulic conductivity should then be adopted on-site. A minimum of five samples of the selected base soil and sand (or clay) content mix must be tested in the laboratory to ensure saturated hydraulic conductivity is consistent across all samples. If the average saturated hydraulic conductivity of the final filter media mix is within ± 20% of the design saturated hydraulic conductivity then the filter media can be adopted and installed in the bioretention system. Otherwise, further amendment of the filter media must occur through the addition of sand (or clay) and retested until the design saturated hydraulic conductivity is achieved;

(D) the base soil must have sufficient organic content to establish vegetation on the surface of the bioretention system. If the proportion of base soil in the final mix is less than 50%, it may be necessary to add organic material. This should not result in more than 10% organic content (measured in accordance with AS 1289.4.1.1-1997) and should not alter the saturated hydraulic conductivity of the final filter media mix;

(E) the pH of the final filter media is to be amended (if required) to between 6 and 7. If the filter media mix is being prepared off-site, this amendment should be undertaken before delivery to the site; and

(F) the salt content of the final filter media (as measured by EC1:5) must be less than 0.63dS/m for low clay content soils like sandy loam. (EC1:5 is the electrical conductivity of a 1:5 soil/ water suspension).

Transition layer (if required)

The purpose of the transition layer is to prevent the filter media from migrating down into the drainage layer (or saturated layer). It also acts as a buffer between the permanently saturated zone and the filter media. This buffer is necessary to ensure the filter media is not saturated for prolonged periods during rainfall events due to increases in water levels in the saturated zone. To achieve this, the transition layer depth must be greater than the head created by flows over the saturated zone outlet weir.

It is required if the particle size difference between the filter media and the drainage layer (or saturated layer) is more than one order of magnitude. If a transition layer is required then the material must be a clean, well-graded sand/coarse sand material containing little or no fines.

The transition layer is recommended to be 100 mm thick and have a minimum saturated hydraulic conductivity of 1000 mm/hr.

A recent particle size distribution for the transition layer sand will need to be obtained to ensure that it meets the required grading/"bridging" criteria outlined below. The "bridging" criteria is based on the engineering principles that rely on the largest 15% of the filter media particles "bridging" with the smallest 15% of the sand particles. This results in smaller voids, which prevent the migration of the filter media particles into the sand particles. The following equation is taken from the United

States Golf Association's recommendations for golf course construction:

Bridging Factor: **D15 (transitional layer sand) ≤ 8 x D85 (filter media)**

The addition of a transition layer increases the overall depth of the bioretention system and may be an important consideration for some sites where total depth of the bioretention system may be constrained. In such cases, the use of a sand drainage layer and/ or perforated pipes with smaller slot sizes may need to be considered (SC6.4.3.9.4(2)(e) Step 5: Design under-drain and undertake capacity checks (if required)).

Saturated layer (if required)

The saturated layer should be about 400 mm deep (but may deeper depending on the specific application) and composed of clean (i.e. free from fines) medium-coarse washed sand, gravel or small rock (50 mm diameter maximum) together with a long term carbon source. Hardwood wood chips, 5 mm to 40 mm in size, are recommended as the carbon source because they breakdown slowly to provide a long term carbon source yet have a decomposition rate that should not limit the denitrification process.

The total mass of carbon/electron donor that is required for denitrification must be calculated based on the expected stormwater influent TN mass over the desired life span of the system (e.g. 25 years). The calculation is based on the stoichiometry of the denitrification reaction (shown below).

Denitrification reaction:

$NO_3^- + 1.25\ (CH_2O) + H^+\ (10^7 M) \rightarrow 0.5N_2\ (g) + 1.75H_2O + 1.25CO_2\ (g)$

Based on a 400 mm deep saturated zone and the modelled annual TN runoff mass (for Townsville) for a bioretention system that is 2% of the contributing 1ha catchment, the saturated zone media would have the following composition:

- 76.7 m^3 washed coarse sand, gravel or small rock; and
- 3.3 m^3 hardwood wood chips, well graded 5 mm-40 mm.

This is equivalent to an organic carbon content of approximately 4-5% by volume. If the saturated zone depth changed, or the bioretention system to catchment area ratio changed, the hardwood proportion would need to be recalculated using the denitrification stoichiometry.

Calculating Carbon Source for Saturated Zone with safety factor (x2)	
Catchment Area	1 ha
Treatment Area Required	2%
Bioretention Surface Area	200 m^2
Saturated Zone Depth	400 mm
Total volume of Saturated Zone	80 m^3
TN load 1 year	12.5 kg/yr
TN load 25 years	312.5 kg/25yrs
Stoichiometry:	
N:C ratio = 1:1.25 (mol), which equates to 14:15(g) [Mw: N = 14g/mol, C = 12g/mol]	
Average total carbon content of hardwood woodchips is 50%, therefore	
N:C (woodchip) = 14:30 (g)	
N:C (woodchip) = 1:2.1	
Woodchips (312.5 x 2.1)	656 kg/carbon
Safety Factor (x 2)	1313kg/carbon
Density of wood chips	400 kg/m^3 (approx.)
Hardwood Wood Chips	**3.3 m^3**
Clean Coarse Sand	**76.7 m^3**

The saturated media must have a hydraulic conductivity of >1000 mm/hr (the ASTM F1815-06 test method is to be used to measure hydraulic conductivity).

The saturated zone should be lightly compacted (e.g. with one pass of a smooth drum lawn roller) during installation to stabilise the structure. Under no circumstances should heavy compaction or multiple-passes be made.

Drainage layer (if required)

The drainage layer is used to convey treated flows from the base of the filter media layer (or saturated zone) into the perforated under-drainage system. The composition of the drainage layer is to be considered in conjunction with the selection and design of the perforated under-drainage system (refer to SC6.4.3.9.3(e)(iii)) as the slot sizes in the perforated pipes may determine the minimum drainage layer particle size to avoid washout of the drainage layer into the perforated pipe system. Coarser material (e.g. fine gravel) is to be used for the drainage layer if the slot sizes in the perforated pipes are too large for use of a sand based drainage layer. Otherwise, sand is the preferred drainage layer media as it is likely to avoid having to provide a transition layer between the filter media and the drainage layer (if there is no saturated zone). The drainage layer is to be a minimum of 200 mm thick.

Bridging Factor:

D15 (drainage gravel/sand) ≤ 8 x D85 (filter media/saturated zone/transition layer)

Ensure drainage media is washed prior to placement in bioretention system to remove any fines.

(iii) Under-drain design and capacity checks

The maximum spacing of the perforated pipes in wide bioretention trenches is 1.5 m (centre to centre) so that the distance water needs to travel (horizontally) through the drainage layer does not hinder drainage of the filtration media.

By installing parallel pipes, the capacity of the perforated pipe under-drain system can be increased. The recommended maximum size for the perforated pipes 100 mm to minimise the required thickness of the drainage layer. Either flexible perforated pipe (e.g. ag pipe) or slotted

PVC pipes can be used, however care needs to be taken to ensure that the slots in the pipes are not so large that sediment would freely flow into the pipes from the drainage layer. This is also a consideration when specifying the drainage layer media.

To ensure the slotted pipes are of adequate size, several checks are required:

- ensure perforations are adequate to pass the maximum infiltration rate;
- ensure the pipe itself has capacity to convey the design flow/ infiltration rate; and
- ensure that the material in the drainage layer will not be washed into the perforated pipes (consider a transition layer).

The maximum infiltration rate represents the maximum rate of flow through the bioretention filter media and is calculated by applying Darcy's equation (Equation 3.2) as follows:

$$Q_{max} = K_{sat} \cdot L \cdot W_{base} \cdot \frac{h_{max} + d}{d}$$

Where Q_{max} = maximum infiltration rate (m^3/s)
K_{sat} = hydraulic conductivity of the soil filter (m/s)
W_{base} = base width of the ponded cross section above the soil filter (m)
L = length of the bioretention zone (m)
h_{max} = depth of pondage above the soil filter (m)
d = depth of filter media (m)

The capacity of the perforated under-drains need to be greater than the maximum infiltration rate to ensure the filter media drains freely and the pipe(s) do not become the hydraulic "control" in the bioretention system (i.e. to ensure the filter media sets the travel time for flows percolating through the bioretention system rather than the perforated under-drainage system).

To ensure the perforated under-drainage system has sufficient capacity to collect and convey the maximum infiltration rate, it is necessary to determine the capacity for flows to enter the under-drainage system via perforations in the pipes. To do this, orifice flow can be assumed and the sharp edged orifice equation can be used. Firstly, the number and size of perforations needs to be determined (typically from manufacturer's specifications) and used to estimate the flow rate into the pipes using the maximum driving head (being the depth of the filtration media if no extended detention is provided or if extended detention is provided in the design then to the top of extended detention). It is conservative but reasonable to use a blockage factor to account for partial blockage of the perforations by the drainage layer media. A 50% blockage of the perforation is recommended.

$$Q_{perf} = B \cdot C_d \cdot A\sqrt{2 \cdot g \cdot h}$$

Where Q_{perf} = flow through perforations (m^3/s)
B = blockage factor (0.5)
C_d = orifice discharge coefficient (assume 0.61 for sharp edge orifice)
A = total area of the orifice (m^2)
g = gravity (9.79 m/s^2)
h = head above the perforated pipe (m)

If the capacity of the drainage system is unable to collect the maximum infiltration rate then additional under- drains will be required.

After confirming the capacity of the under-drainage system to collect the maximum infiltration rate is it then necessary to confirm the conveyance capacity of the underdrainage system is sufficient to convey the collected runoff. To do this, Manning's equation (Equation 3.1) can be used (which assumes pipe full flow (in place of channel flow) but not under pressure). The Manning's roughness used will be dependent on the type of pipe used. When a saturated zone is incorporated into the design, the underdrainage pipes are laid flat however the conveyance capacity can be calculated using the Manning's equation with an assumed friction slope of 0.5%.

The under-drains should be extended vertically to the surface of the bioretention system to allow inspection and maintenance when required. The vertical section of the under-drain should be unperforated and capped to avoid short circuiting of flows directly to the drain.

In bioretention systems with a saturated zone, the capacity of the weir or up-turned pipe (maintaining the water level within the saturated zone) must also be checked to ensure it does not become the hydraulic "control" in the bioretention system (i.e. to ensure the filter media sets the travel time for flows percolating through the bioretention system). A broad crested weir equation can be used to determine the length of weir required (assuming free flowing conditions) to convey the maximum flow/filtration rate. The maximum depth of flow over the weir is to be 100 mm. This is important to limit increase in the saturated zone depth and avoid prolonged saturation of the filter media.

(iv) Check requirement for impermeable lining

The saturated hydraulic conductivity of the natural soil profile surrounding the bioretention system should be tested together with depth to groundwater, chemical composition and proximity to structures and other infrastructure. This is to establish if an impermeable liner is required at the base (only for systems designed to preclude ex-filtration to in-situ soils) and/or sides of the bioretention system (refer also to discussion in SC6.4.3.9.3(2)(a)(iii) Ex-filtration to in-situ soils). If the saturated hydraulic conductivity of the filter media in the bioretention system is more than one order of magnitude (10 times) greater than that of the surrounding in-situ soil profile, no impermeable lining is required.

(f) Step 6: Verify design

(i) Vegetation scour velocity check

Potential scour velocities are checked by applying Manning's equation (Equation 3.1) to the bioretention swale design to ensure the following criteria are met:

(A) less than 0.5 m/s for minor flood (2-10 year ARI) discharge; and

(B) less than 2.0 m/s for major flood (50-100 year ARI) discharge.

(ii) Velocity and depth check – safety

As bioretention swales are generally accessible by the public, it is important to check that depth x velocity within the bioretention swale, at any crossings and adjacent pedestrian and bicycle pathways, satisfies the following public safety criteria:

(A) depth x velocity < 0.6 m^2/s for low risk locations and 0.4 m^2/s for high risk locations as defined in QUDM; and

(B) maximum depth of flow over crossing = 0.3 m.

(iii) Confirm treatment performance

If the previous two checks are satisfactory then the bioretention swale design is satisfactory from a conveyance function perspective and it is now necessary to confirm the treatment performance of the bioretention swale by reference to the performance information presented in SC6.4.3.9.3(3)(a)).

(g) Step 7: Size overflow pit (field inlet pits)

In a bioretention swale system, an overflow pit can be provided flush with the invert of the swale and/ or bioretention system filter media (i.e. when no extended detention is provided in the design) or it can be provided with the pit crest raised above the level of the bioretention filter media to establish the design extended detention depth (if extended detention is provided for in the design).

Grated pits are typically used and the allowable head for discharges into the pits is the difference in level between the pit crest and the maximum permissible water level to satisfy the local council's minimum freeboard requirements. Depending on the location of the bioretention swale, the design flow to be used to size the overflow pit could be the maximum capacity of the swale, the minor flood flow (2-5 year ARI) or the major flood flow (50 year ARI). There should be a minimum of 100 mm head over the overflow pit crest to facilitate discharge of the design flow into the overflow pit.

To size an overflow pit, two checks should be made to test for either drowned or free flowing conditions. A broad crested weir equation can be used to determine the length of weir required (assuming free overflowing conditions) and an orifice equation used to estimate the area between openings required in the grate cover (assuming drowned outlet conditions). The larger of the two pit configurations should be adopted (as per Section 7.05 QUDM). In addition, a blockage factor is to be used, that assumes the grate is 50% blocked.

For free overfall conditions (weir equation):

$$Q_{weir} = B \cdot C_w \cdot L \cdot h^{3/2}$$

Where	Q_{weir}	=	Flow into pit (weir) under free overfall conditions (m^3/s)
	B	=	Blockage factor (= 0.5)
	C_w	=	Weir coefficient (= 1.66)
	L	=	Length of weir (perimeter of pit) (m)
	h	=	Flow depth above the weir (pit) (m)

Once the length of weir is calculated, a standard sized pit can be selected with a perimeter at least the same length of the required weir length.

For drowned outlet conditions (orifice equation):

$$Q_{orifice} = B \cdot C_d \cdot A\sqrt{2 \cdot g \cdot h}$$

Where B, g and h have the same meaning as in Equation 3.4

$Q_{orifice}$	=	flow rate into pit under drowned conditions (m^3/s)
C_d	=	discharge coefficient (drowned conditions = 0.6)
A	=	area of orifice (perforations in inlet grate) (m^2)

When designing grated field inlet pits, reference is also to be made to the procedure described in QUDM Section 7.05.4 (DNRW, IPWEA and BCC, 1998).

When a saturated zone is included in the design of a bioretention system, additional components must be incorporated into the outlet design. A saturated zone can be formed at the base of a bioretention system by using a riser pipe with the outlet level set at the top of the desired saturation depth (i.e. top of the saturated zone) or by incorporating a weir/overflow structure within the outlet pit (see Figure SC6.4.3.9.22). The saturated zone would hold water rather than draining freely, and would therefore provide a source of water to the plants during dry periods.

(h) Step 8: Make allowances to preclude traffic on swales

Refer to SC6.4.3.9.3(a)(vii) for discussion on traffic control options.

(i) Step 9: Specify plant species and planting densities

Refer to SC6.4.3.9.3(4) Landscape design notes - bioretention swales and SC6.4.3.6 Landscape policy for advice on selecting suitable plant species for bioretention swales in the coastal dry tropics. Consultation with landscape architects is recommended when selecting vegetation to ensure the treatment system compliments the landscape design of the area.

(j) Step 10: Consider maintenance requirements

Consider how maintenance is to be performed on the bioretention swale (e.g. how and where is access available, where is litter likely to collect etc.). A specific maintenance plan and schedule should be developed for the bioretention swale in accordance with SC6.4.3.9.3(6) Maintenance requirements - bioretention swales.

(k) Design calculation summary

The following design calculation table (Table SC6.4.3.9.4) can be used to summarise the design data and calculation results from the design process.

Click here to view **Table SC6.4.3.9.4 Bioretention swales design calculation summary**

(l) Typical design parameters

Table SC6.4.3.9.5 shows typical values for a number of key bioretention swale design parameters.

Table SC6.4.3.9.5 Typical design parameters for bioretention swales

Design Parameter	Typical Values
Swale longitudinal slope	1% to 4%
Swale side slope for trafficability (with “at grade” crossover)	Maximum 1 in 9
Swale side slope (with elevated driveway crossover)	1 in 4 to 1 in 10
Manning’s *n* (with flow depth lower than vegetation height)	0.15 to 0.3
Manning’s *n* (with flow depth greater than vegetation height)	0.03 to 0.05
Maximum velocity for scour in minor event (e.g. 2-10yr ARI)	0.5 m/s
Maximum velocity for 50-100yr ARI	2.0 m/s
Perforated pipe size	100 mm (maximum)
Drainage layer average material diameter (typically fine gravel or coarse sand)	1-5 mm diameter
Transition layer average material diameter typically sand to coarse sand	0.7 – 1.0 mm diameter

(4) Landscape design notes - bioretention swales

Bioretention swales are a combined solution that involves integrating a swale with the filtration function of a bioretention basin/trench. These can involve an extended detention treatment and some biological uptake through the planted bioretention component. The landscaping for both the swale and bioretention parts are essentially similar to the treatments for the stand alone components however consideration of the interface landscape between the vegetated swale and bioretention is important.

(a) Objectives

Landscape design for bioretention swales has four key objectives:

(i) ensure surface treatments and planting designs address stormwater quality objectives by incorporating appropriate plant species for stormwater treatment (biologically active root zone) whilst enhancing the overall natural landscape. This includes requirements for maintaining dense perennial vegetation throughout the dry season to maintain aesthetics and to minimise weed growth;

(ii) integrated planning and design of bioretention swales within the built and landscape environments;

(iii) incorporating crime prevention through environmental design (CPTED) principles and road, driveway and footpath visibility safety standards; and

(iv) create landscape amenity opportunities that enhance community and environmental needs, such as visual aesthetics, shade, screening, view framing, and way finding.

(b) Streetscape bioretention systems

When using bioretention swales in road reserves it is important to understand how the swale landscape can be used to define the visual road space. Creative landscape treatments may be possible given that the bioretention swale element will typically be a minimum of 4 m in width. Design responses may range from informal “natural” planting layouts to regimented avenues of trees along each external and internal edge of the bioretention swale element. Bioretention swales can be incorporated into a typical streetscape landscape using either a central splitter median or using one side of the road reserve.

Bioretention swale surface treatments are generally a vegetated swale that integrates into a densely planted bioretention component. The use of turf for the bioretention parts of the system is discouraged as mowing and public use of these areas will compact the upper filter media and limit the amount of filtration.

Vegetated bioretention swales can provide a relatively maintenance free finish if the planting and invert treatment are designed well. Key considerations when detailing are density and types of plantings, locations of trees and shrubs, type of garden (mowing) edges to turf areas that allows unimpeded movement of stormwater flow and overall alignment of swale invert within the streetscape.

(i) Centre median

Generally, the central median swale will provide a greater landscaped amenity, allowing planting and shade trees to enhance the streetscape more effectively, whilst verges remain constraint free. This swale configuration is however confined to roads requiring larger corridors for increased traffic.

This can be seen in Figure SC6.4.3.9.8 and Figure SC6.4.3.9.9.

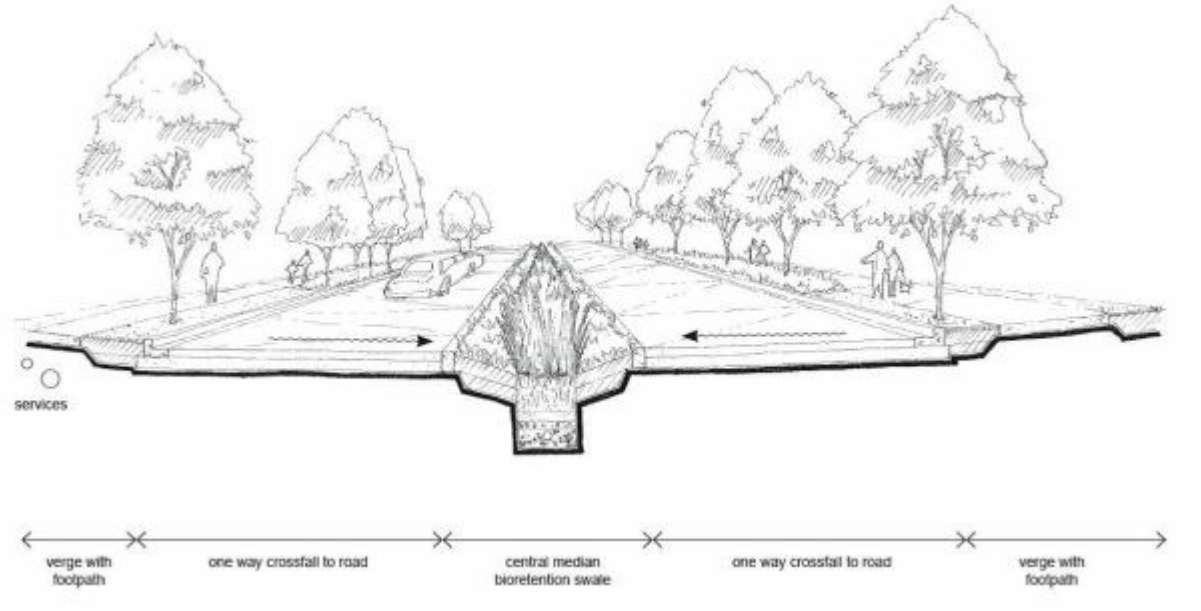

Figure SC6.4.3.9.8 Bioretention swale in centre median

Figure SC6.4.3.9.9 Median strip bioretention applications

(ii) Side of road

In smaller minor roads, one side of the road can have a swale landscape to capture stormwater runoff from road pavements and house lots. To enhance the visual road space, creative landscape treatments to driveway cross-overs, general planting and invert treatments should be used. It is important in this swale arrangement that services and footpaths that are standard for road verges have been planned and located to avoid clashes of function. This can be seen in Figure SC6.4.3.9.10.

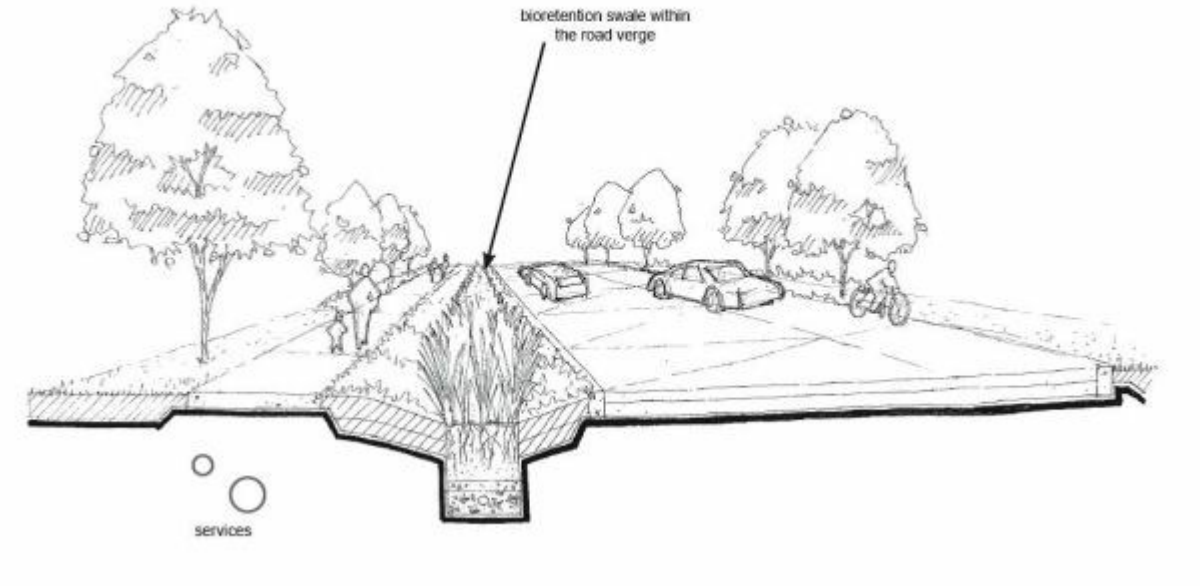

Figure SC6.4.3.9.10 Bioretention swale within road verge

(c) Civic and urban spaces

With increasing population growth in the coastal dry tropics, gentrification of urban areas is required to create more robust spaces that meet current environmental and social needs. Often constrained by existing infrastructure, landscape treatments of swales can have a dual role of providing functional stormwater quality objectives whilst creating landscapes that enhance the communities' perception of water sensitive design.

By creating hard useable edges to swales and using complimentary planting strategies, civic spaces can provide an aesthetic landscape that meets recreational uses and promotes water sensitive design to the community. Refer to Figure SC6.4.3.9.11 for an illustrative example.

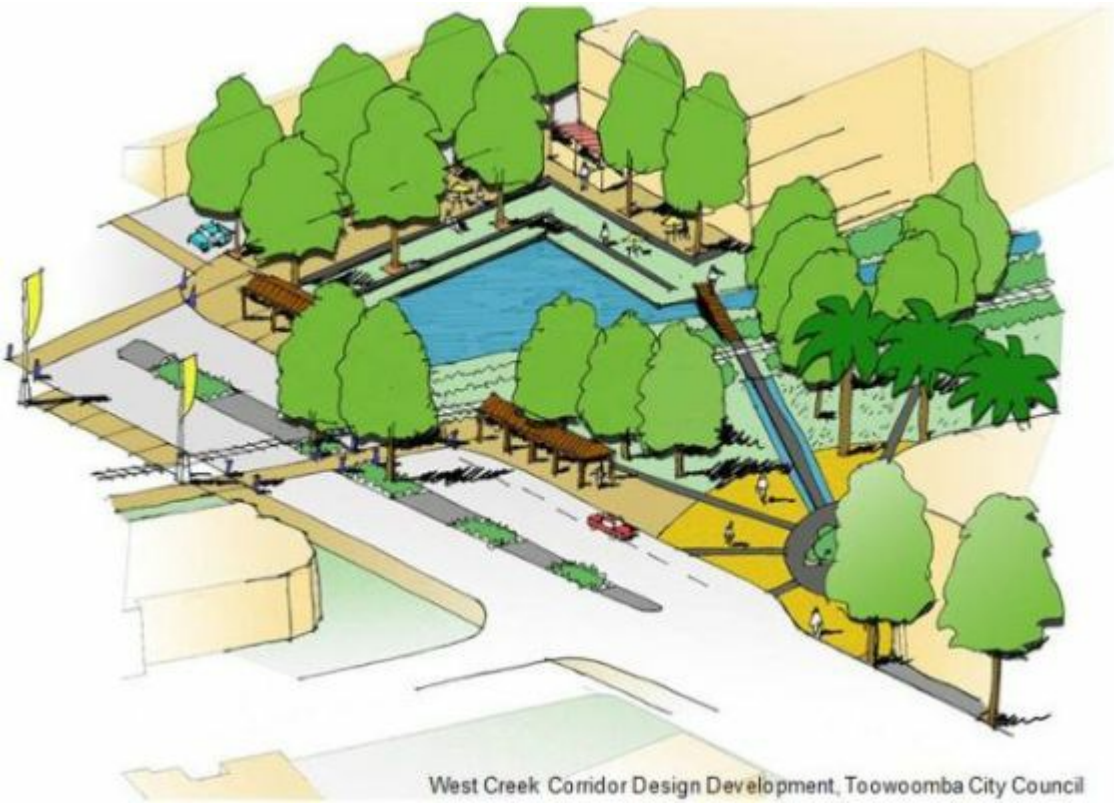

Figure SC6.4.3.9.11 Swale treatment in civic space

(d) Appropriate plant species

Planting for bioretention swale elements may consist of up to four vegetation types:

(i) groundcovers for stormwater treatment and erosion protection (required element);

(ii) shrubbery for screening, glare reduction, character, and other values;

(iii) street trees for shading, character and other landscape values; and

(iv) existing vegetation.

It is important to note that deep rooted plants such as trees are to be planted towards the top of the swale bank rather than near the bioretention trench, to avoid roots interfering with the underdrain system.

Where the landscape design includes canopy layers, more shade tolerant species should be selected for the groundcover layer. Trees and shrubbery should be managed so that the groundcover layer is not out-competed. If this does occur, replacement planting and possible thinning of the upper vegetation layers may be required.

(v) Groundcovers, shrubs and street trees

Refer to SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics for guidance on selecting suitable plant (including turf) species and cultivars that meet the functional requirements of bioretention swales to deliver the desired stormwater quality objectives.

(vi) Existing vegetation

Existing vegetation, such as remnant native trees, within the bioretention swale alignment may be nominated for retention. In this case, the swale will need to be diverted or piped to avoid the vegetation's critical root zone (equivalent to 0.5 m beyond the vegetation's drip line).

(e) Safety issues

Bioretention swales within streetscapes and parks need to be generally consistent with public safety requirements for new developments. These include reasonable batter profiles for edges, providing adequate barriers to median swales for vehicle/pedestrian safety and safe vertical heights from driveways to intersecting swale inverts.

(i) Crime prevention through environmental design (CPTED)

Landscape design of bioretention swales need to accommodate the standard principles of informal surveillance, exclusion of places of concealment and open visible areas. Regular clear sightlines should be provided between the roadway and footpaths/ property. Where planting may create places of concealment or hinder informal surveillance, groundcovers and shrubs should not generally exceed 1 m in height.

(ii) Traffic sightlines

The standard rules of sightline geometry apply – planting designs should allow for visibility at pedestrian crossings, intersections, rest areas, medians, driveways and roundabouts. Refer to the *Road Landscape Manual* (DMR 1997) for further guidance.

(5) Construction and establishment - bioretention swales

This section provides general advice for the construction and establishment of bioretention swales and key issues to be considered to ensure their successful establishment and operation.

(a) Staged construction and establishment method

(i) Construction and establishment challenges

There exist a number of challenges that must be appropriately considered to ensure successful construction and establishment of bioretention swales. These challenges are best described in the context of the typical phases in the development of a greenfield or infill development, namely the subdivision construction phase and the building phase (see Figure SC6.4.3.9.13).

(A) Subdivision construction - the risks to successful construction and establishment of the WSUD systems during this phase of work have generally related to the following:

- construction activities which can generate large sediment loads in runoff which can smother vegetation and clog bioretention filter media; and

- construction traffic and other works can result in damage to the bioretention swales. Importantly, all works undertaken during Subdivision Construction are normally “controlled” through the principle contractor and site manager. This means the risks described above can be readily managed through appropriate guidance and supervision.

(B) Building phase - the allotment building phase (see Figure SC6.4.3.9.12) represents the greatest risk to the successful establishment of bioretention swales.

Figure SC6.4.3.9.12 Example of building phase

(ii) Staged construction and establishment method

To overcome the challenges associated within delivering bioretention swales a staged construction and establishment method should be adopted (see Figure SC6.4.3.9.13).

(A) Stage 1: Functional installation - construction of the functional elements of the bioretention system at the end of subdivision construction (i.e. during landscape works) and the installation of temporary protective measures.

(B) Stage 2: Sediment and erosion control – during the building phase the temporary protective measures preserve the functional infrastructure of the bioretention swales against damage whilst also providing a temporary erosion and sediment control facility throughout the building phase to protect downstream aquatic ecosystems.

(C) Stage 3: Operational establishment - at the completion of the building phase, the temporary measures protecting the functional elements of the bioretention swales can be removed along with all accumulated sediment and the system planted in accordance with the design planting schedule.

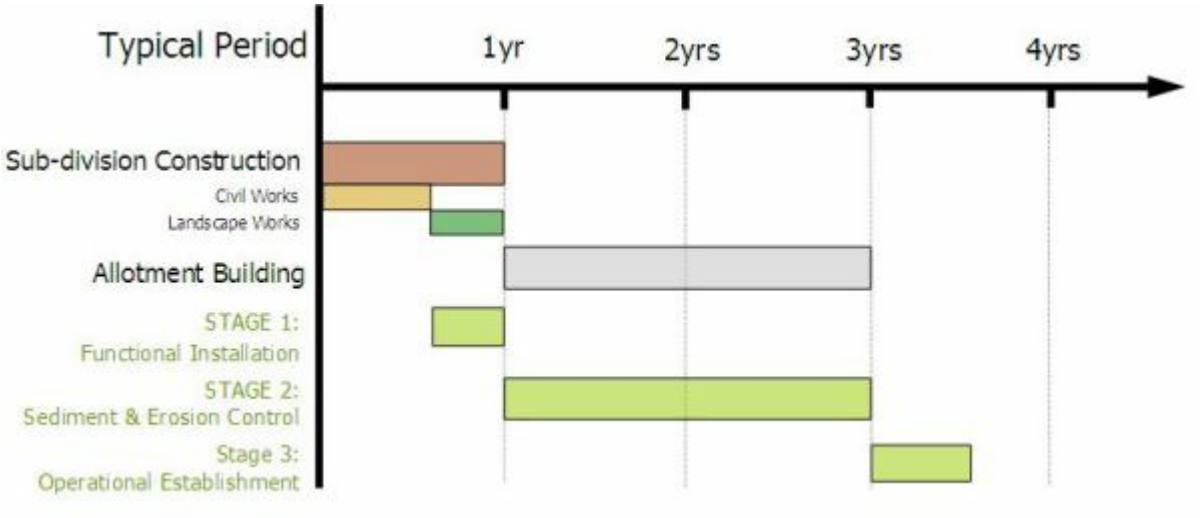

Figure SC6.4.3.9.13 Staged construction and establishment method

(iii) Functional installation

Functional installation of bioretention swales (see Figure SC6.4.3.9.14) occurs at the end of subdivision construction as part of landscape works and involves:

(A) bulking out and trimming;

(B) installation of the outlet structures;

(C) placement of liner and installation of drainage layer (i.e. under-drains and drainage layer);

(D) placement of filter media;

(E) placement of a temporary protective layer - covering the surface of filtration media with geofabric and placement of 25 mm topsoil and turf over geofabric. This temporary geofabric and turf layer will protect the bioretention system during construction (subdivision and building phases) ensuring sediment/litter laden waters do not enter the filter media causing clogging; and

(F) place silt fences around the boundary of the bioretention swale to exclude silt and restrict access.

Figure SC6.4.3.9.14 Bioretention swale functional installation

(iv) Sediment and erosion control

The temporary protective layers are left in place through the allotment building phase to ensure sediment laden waters do not clog the filtration media and allotment building traffic does not enter the bioretention swale (see Figure SC6.4.3.9.15). Importantly the configuration of the bioretention swale and the turf vegetation allow the system to function effectively as a shallow sedimentation

basin reducing the load of coarse sediment discharging to the receiving environment. Using this approach, WSUD systems can operate effectively to protect downstream ecosystems immediately after construction.

Figure SC6.4.3.9.15 Bioretention swale sediment and erosion control

(v) Operational establishment

At the completion of the allotment building phase the temporary measures are removed with all accumulated sediment and the bioretention swale re-profiled and planted in accordance with the proposed landscape design. Establishment of the vegetation to design condition can require more than two growing seasons, depending on the vegetation types, during which regular watering and removal of weeds will be required.

(b) Sourcing bioretention vegetation

The minimum recommended lead time for ordering is 3-6 months. This usually allows enough time for plants to be grown to the required size. The following pot sizes are recommended as the minimum:

(i) viro tubes 50 mm wide x 85 mm deep;

(ii) 50 mm tubes 50 mm wide x 75 mm deep; and

(iii) native tubes 50 mm wide x 125 mm deep.

(c) Vegetation establishment

The following weed control measures and watering schedule are recommended to ensure successful plant establishment. Regular general maintenance as outlined in SC6.4.3.9.3(6) Maintenance requirements - bioretention swales will also be required.

(i) Weed control

Conventional surface mulching of bioretention swales with organic material like tanbark, should not be undertaken. Most organic mulch floats and runoff typically causes this material to be washed away with the risk of blockage of drains occurring. Weed management will need to be done manually until such time that the design vegetation is established with sufficient density to effectively prevent weed propagation.

(ii) Watering

Regular watering of bioretention swale vegetation is essential for successful establishment and healthy growth and weed reduction. The frequency of watering to achieve successful plant establishment is dependent upon rainfall, maturity of planting stock and the water holding capacity of the soil. The following watering program is generally adequate but should be adjusted (increased) to suit the site conditions:

(A) Week 1-2 3 visits/ week;

(B) Week 3-6 2 visits/ week; and

(C) Week 7-12 1 visit/ week.

After this initial three month period, temporary, supplementary irrigation will be required in bioretention swales without submerged zones and may be required in bioretention swales with submerged zones (particularly during the 2 year plant establishment period). Watering requirements to sustain healthy vegetation should be determined during ongoing maintenance site visits.

(6) Maintenance requirements - bioretention swales

Bioretention swales have a flood conveyance role that needs to be maintained to ensure adequate flood protection for local properties. Vegetation plays a key role in maintaining the porosity of the soil media of the bioretention system and a strong healthy growth of vegetation is critical to its performance.

(a) Typical maintenance of bioretention swale elements will involve:

(i) routine inspection of the swale profile to identify any areas of obvious increased sediment deposition, scouring of the swale invert from storm flows, rill erosion of the swale batters from lateral inflows, damage to the swale profile from vehicles and clogging of the bioretention trench (evident by a “boggy” swale invert);

(ii) routine inspection of inlet points (if the swale does not have distributed inflows), surcharge pits and field inlet pits to identify any areas of scour, litter build up and blockages;

(iii) removal of sediment where it is impeding the conveyance of the swale and/ or smothering the swale vegetation, and if necessary, reprofiling of the swale and revegetating to original design specification;

(iv) repairing any damage to the swale profile resulting from scour, rill erosion or vehicle damage;

(v) tilling of the bioretention trench surface if there is evidence of clogging;

(vi) clearing of blockages to inlet or outlets;

(vii) regular watering/ irrigation of vegetation until plants are established and actively growing (see SC6.4.3.9.3(5)(c) Vegetation establishment);

(viii) mowing of turf or slashing of vegetation (if required) to preserve the optimal design height for the vegetation;

(ix) removal and management of invasive weeds;

(x) removal of plants that have died and replacement with plants of equivalent size and species as detailed in the plant schedule;

(xi) pruning to remove dead or diseased vegetation material and to stimulate new growth;

(xii) litter and debris removal; and

(xiii) vegetation pest monitoring and control.

(b) Additional maintenance required if a saturated zone is included in the design:

(i) check weir/up-turned pipe is clear of debris; and

(ii) check water level in the saturated zone is at the design level.

(c) Resetting (i.e. complete reconstruction) of bioretention elements will be required if the available flow area of the overlying swale is reduced by 25% (due to accumulation of sediment) or if the bioretention trench fails to drain adequately after tilling of the surface. Inspections are also recommended following large storm events to check for scour.

(d) All maintenance activities must be specified in a maintenance plan (and associated maintenance inspection forms) to be developed as part of the design procedure. Maintenance personnel and asset managers will use this plan to ensure the bioretention swales continue to function as designed. The maintenance plans and forms must address the following:

(i) inspection frequency;

(ii) maintenance frequency;

(iii) data collection/ storage requirements (i.e. during inspections);

(iv) detailed cleanout procedures (main element of the plans) including:

(A) equipment needs;

(B) maintenance techniques;

(C) occupational health and safety;

(D) public safety;

(E) environmental management considerations;

(F) disposal requirements (of material removed);

(G) access issues;

(H) stakeholder notification requirements; and

(I) data collection requirements (if any); and

(v) design details.
An example operation and maintenance inspection form is included in the checking tools provided in SC6.4.3.9.3(7).

(7) Checking tools - bioretention swales

A number of checking aids have been developed for designers and council development assessment officers. In addition, advice on construction techniques and lessons learnt from building bioretention swale systems are provided.

(a) Design assessment

The checklist at Table SC6.4.3.9.6 presents the key design features to be reviewed when assessing design of a bioretention swale. These considerations include configuration, safety, maintenance and operational issues that need to be addressed during the design phase. Where an item results in an “N” when reviewing the design, referral is to be made back to the design procedure to determine the impact of the omission or error.

In addition to the checklist, a proposed design is to have all necessary permits for its installations. Council development assessment officers need to ensure that all relevant permits are in place. These can include permits to clear vegetation, to dredge, create a waterbody, divert flows or disturb fish or platypus habitat.

Click here to view Table SC6.4.3.9.6 Bioretention swale design assessment checklist

(b) Construction (during and post)

The checklist at Table SC6.4.3.9.7 presents the key items to be reviewed when inspecting the bioretention swale during and at the completion of construction. The checklist is to be used by construction site supervisors and compliance inspectors to ensure all the elements of the bioretention system have been constructed in accordance with the design. If an item receives an “N” in Satisfactory criteria then appropriate actions must be specified and delivered to rectify the construction issue before final inspection sign-off is given.

Click here to view Table SC6.4.3.9.7 Bioretention swale construction inspection checklist

(c) Operation and maintenance inspection

The form at Table SC6.4.3.9.8 is to be used whenever an inspection is conducted and kept as a record on the asset condition and quantity of removed pollutants over time.

Click here to view Table SC6.4.3.9.8 Bioretention swale maintenance checklist

(d) Asset transfer (following defects period)

Land ownership and asset ownership are key considerations prior to construction of a stormwater

treatment device. A proposed design is to clearly identify the ultimate asset owner and who is responsible for its maintenance. Local authorities will use the asset transfer checklist at Table SC6.4.3.9.9 when the asset is to be transferred to the local authority.

Click here to view Table SC6.4.3.9.9 Bioretention swale asset transfer checklist

(8) Engineering drawings - bioretention swales

The relevant local authority should be consulted to source standard drawings applicable to bioretention swales. These drawings may provide example dimensions for a number of different road reserve configurations. Standard drawings are not intended to be prescriptive drawings which must be adhered to, rather they are intended to provide detailed examples of swales which can be incorporated into commonly used urban subdivision layouts. Designers are encouraged to develop alternative bioretention swale designs to suit site specific conditions.

In the absence of locally specific guidelines, Brisbane City Council (BCC) standard drawings applicable to swales and bioretention systems are UMS 151-158. These may also be used as reference standards for swale design. BCC Standard drawings are available online.

SC6.4.3.9.4 Bioretention basins

(1) Bioretention basins are vegetated areas where runoff is filtered through a filter media layer (e.g. sandy loam) as it percolates downwards. It is then collected via perforated under-drains and flows to downstream waterways or to storages for reuse. Bioretention basins often use temporary ponding above the filter media surface to increase the volume of runoff treated through the filter media. They treat stormwater in the same way as bioretention swales; however, "above design" flows are conveyed through overflow pits or bypass paths rather than over the filter media. This has the advantage of protecting the filter media surface from high velocities that can dislodge collected pollutants or scour vegetation.

Bioretention basins are generally not intended to be "infiltration" systems that discharge from the filter media to surrounding in-situ soils. Rather, the typical design intent is to recover stormwater at the base of the filter media in perforated under-drains and discharge to receiving waterways or to storages for potential reuse.

Figure SC6.4.3.9.16 shows examples of a basin integrated into a local streetscape and into a car park. Figure SC6.4.3.9.16 also illustrates the key elements of bioretention basins, namely surface vegetation, extended detention, filter media, drainage layer and overflow pit.

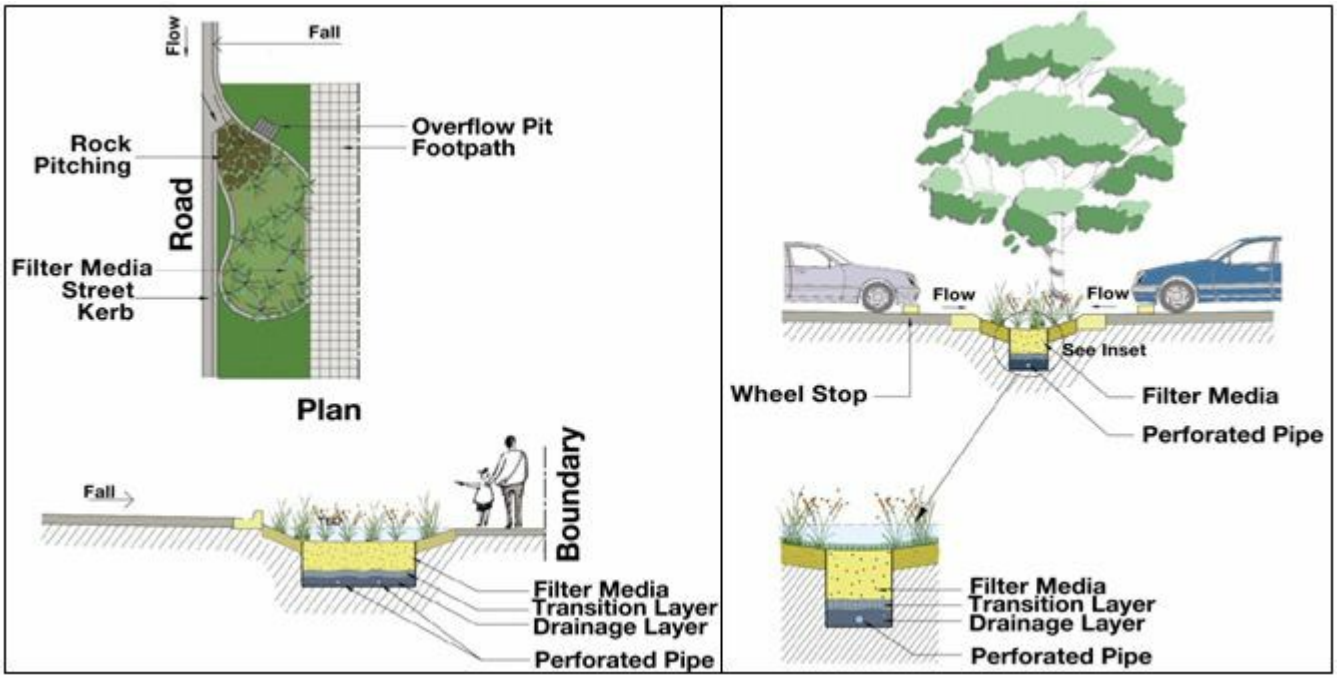

Figure SC6.4.3.9.16 Bioretention basin integrated into a local streetscape (left) and a car park (right).

(2) Design considerations – bioretention basins

This section outlines some of the key design considerations for bioretention basins that the detailed designer should be familiar with before applying the design procedure presented later in this chapter.

Rain patterns in the dry tropics mean that bioretention systems will receive large volumes of consistent rainfall during the wet season and are likely to remain dry for extended periods during the dry season. Therefore, bioretention basin design will need to be adapted to incorporate the following elements:

- controls to ensure the bioretention basin is not compromised by sediment smothering;
- a saturated zone beneath the filter media to increase soil moisture and help sustain vegetation during dry periods; or
- supplemental temporary irrigation to sustain vegetation and maintain aesthetics in highly visible areas (e.g. bioretention pods within road verges).

(a) Landscape design

Bioretention basins are predominantly located within public areas, such as open space or within streets, which provide a primary setting for people to experience their local community and environment. It is therefore necessary for bioretention basins to be given an appropriate level of landscape design consideration to compliment the surrounding landscape character and to adequately address potential aesthetics issues such as weeds and sustaining perennial plants during the dry season. The landscape design of bioretention basins must address stormwater quality objectives whilst also being sensitive to other important landscape objectives such as road visibility, public safety and community character and habitat. To achieve this, the design process requires close collaboration between landscape architects, urban designers, ecologists and WSUD engineers (see example at Figure SC6.4.3.9.17).

Figure SC6.4.3.9.17 Bioretention basin within roundabout at Kalynda Chase Development, Bohle Plains

(b) Hydraulic design

The correct hydraulic design of bioretention basins is essential to ensure effective stormwater treatment performance, minimise damage by storm flows, and to protect the hydraulic integrity and function of associated minor and major drainage systems. The following aspects are of key importance:

(i) the finished surface of the bioretention filter media must be horizontal (i.e. flat) to ensure even flow dispersion across the filter media surface (i.e. full engagement of the filter media by stormwater flows) and to prevent concentration of stormwater flows within depressions and ruts resulting in potential scour and damage to the filter media;

(ii) temporary ponding (i.e. extended detention) of up to 0.3 m depth over the surface of the bioretention filter media created through the use of raised field inlet pits (overflow pits) can assist in managing flow velocities over the surface of the filter media as well as increase the overall volume of stormwater runoff that can be treated by the bioretention filter media;

(iii) where possible, the overflow pit or bypass channel should be located near the inflow zone (refer to Figure SC6.4.3.9.16 (left)) to prevent high flows passing over the surface of the filter media. If this is not possible, then velocities during the minor (2-10 year ARI) and major (50-100 year ARI) floods should be maintained sufficiently low (preferably below values of 0.5 m/s and not more than 1.5 m/s for major flood) to avoid scouring of the filter media and vegetation;

(iv) where the field inlets in a bioretention system is required to convey the minor storm flow (i.e. is part of the minor drainage system), the inlet must be designed to avoid blockage, flow conveyance and public safety issues; and

(v) for streetscape applications, the design of the inflow to the bioretention basin must ensure the kerb and channel flow requirements are preserved as specified in the Queensland Urban Drainage Manual (QUDM) (DNRW, IPWEA and BCC 1998).

(c) Ex-filtration to in-situ soils

Bioretention basins can be designed to either preclude or promote ex-filtration of treated stormwater to the surrounding in-situ soils depending on the overall stormwater management objectives established for the given project. When considering ex-filtration to surrounding soils, the designer must consider site

terrain, hydraulic conductivity of the in-situ soil, groundwater and building setback. Where the concept design specifically aims to preclude ex-filtration of treated stormwater runoff it is necessary to consider if the bioretention basin needs to be provided with an impermeable liner. If the selected saturated hydraulic conductivity of the bioretention filter media is less than 10 times that of the native surrounding soils, it may be necessary to provide an impermeable liner. Flexible membranes or a concrete casting are commonly used to prevent excessive ex-filtration. This is particularly applicable for surrounding soils that are very sensitive to any ex-filtration (e.g. shallow groundwater or close proximity to significant structures).

Bioretention systems constructed in sodic soils without an impermeable lining are not at risk of exporting salt from in-situ soil into local streams or groundwater. Even after six months of intensive flushing under controlled, laboratory conditions, bioretention systems (constructed in sodic soils) did not leach salt from the surrounding soils (Deletic and Mudd, 2006).

The greatest pathway of ex-filtration is through the base of a bioretention basin, as gravity and the difference in hydraulic conductivity between the filter media and the surrounding native soil would typically act to minimise ex-filtration through the walls of the trench. If lining is required, it is likely that only the base and the sides of the drainage layer will need to be lined.

(d) Vegetation types

Vegetation is required to cover the whole bioretention filter media surface, be capable of withstanding minor and major design flows, and be of sufficient density to prevent preferred flow paths, scour and re-suspension of deposited sediments. Additionally, vegetation that grows in the bioretention filter media functions to continuously break up the surface of the filter media through root growth and wind induced agitation, which prevents surface clogging. The vegetation also provides a substrate for biofilm growth within the upper layer of the filter media, which facilitates biological transformation of pollutants (particularly nitrogen).

Ground cover vegetation (e.g. sedges and tufted grasses) is an essential component of bioretention basin function. Generally, the greater the density and height of vegetation planted in bioretention filter media, the better the treatment provided especially when extended detention is provided for in the design. Contact between stormwater and vegetation results in enhanced sedimentation of suspended sediments and adsorption of associated pollutants.

Plant species selected for bioretention systems must be able to tolerate free draining sandy soils and be capable of withstanding long dry periods as well as periods of inundation. To maintain aesthetics in highly visible areas (e.g. bioretention pods within road verges) temporary supplemental irrigation may be required to sustain vegetation. The incorporation of saturated zones beneath the filter media can help to sustain soil moisture and is beneficial for nitrogen removal from stormwater. The ability to sustain dense perennial vegetation is important for long term weed management.

SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics provides more specific guidance on the selection of appropriate vegetation for bioretention basins. It should be noted that turf is not considered to be suitable vegetation for bioretention basins. The stem and root structure of turf is not suitably robust and rapid growing to ensure the surface of the bioretention filter media is continuously broken up to prevent clogging.

(e) Bioretention filter media

Selection of an appropriate bioretention filter media is a key design step that involves consideration of the following four inter-related factors:

(i) saturated hydraulic conductivity required to optimise the treatment performance of the bioretention basin given site constraints and available filter media area;

(ii) depth of extended detention provided above the filter media;

(iii) surface area of the filter media; and

(iv) suitability as a growing media to support vegetation (i.e. retains sufficient soil moisture and organic content).

The concept design stage will have established the optimal combination of filter media saturated

hydraulic conductivity and extended detention depth using a continuous simulation modelling approach (i.e. MUSIC). Any adjustment of either of these two design parameters during the detailed design stage will require the continuous simulation modelling to be re-run to assess the impact on the overall treatment performance of the bioretention basin.

As shown in Figure SC6.4.3.9.18 below, bioretention media can consist of three or four layers. In addition to the filter media required for stormwater treatment, a saturated zone can also be added to enhance nitrogen removal and to provide a source of water for vegetation over the dry season. A drainage layer is also required to convey treated water from the base of the filter media or saturated zone into the perforated under-drains. The drainage layer surrounds the perforated under-drains and can be either coarse sand (1 mm) or fine gravel (2-5 mm). If fine gravel is used, a transition layer of sand must also be installed to prevent migration of the filter or saturated zone media into the drainage layer and subsequently into the perforated under-drains.

(f) Saturated zone

The incorporation of a saturated zone into bioretention design has evolved from research demonstrating improved nitrate removal through denitrification processes (Kim et al. 2003 and Zinger et al. 2007b).

The saturated zone design involves a relatively simple modification to a conventional bioretention system. An additional layer located below the filter media is designed to retain stormwater providing a saturated zone at the base of the bioretention system. A saturated zone can be formed by using a riser pipe with the outlet level higher than the drainage layer or by incorporating a weir within the outlet pit (see Figure SC6.4.3.9.18 below). The saturated zone holds water and therefore provides a source of water to maintain soil moisture for plant uptake during dry periods.

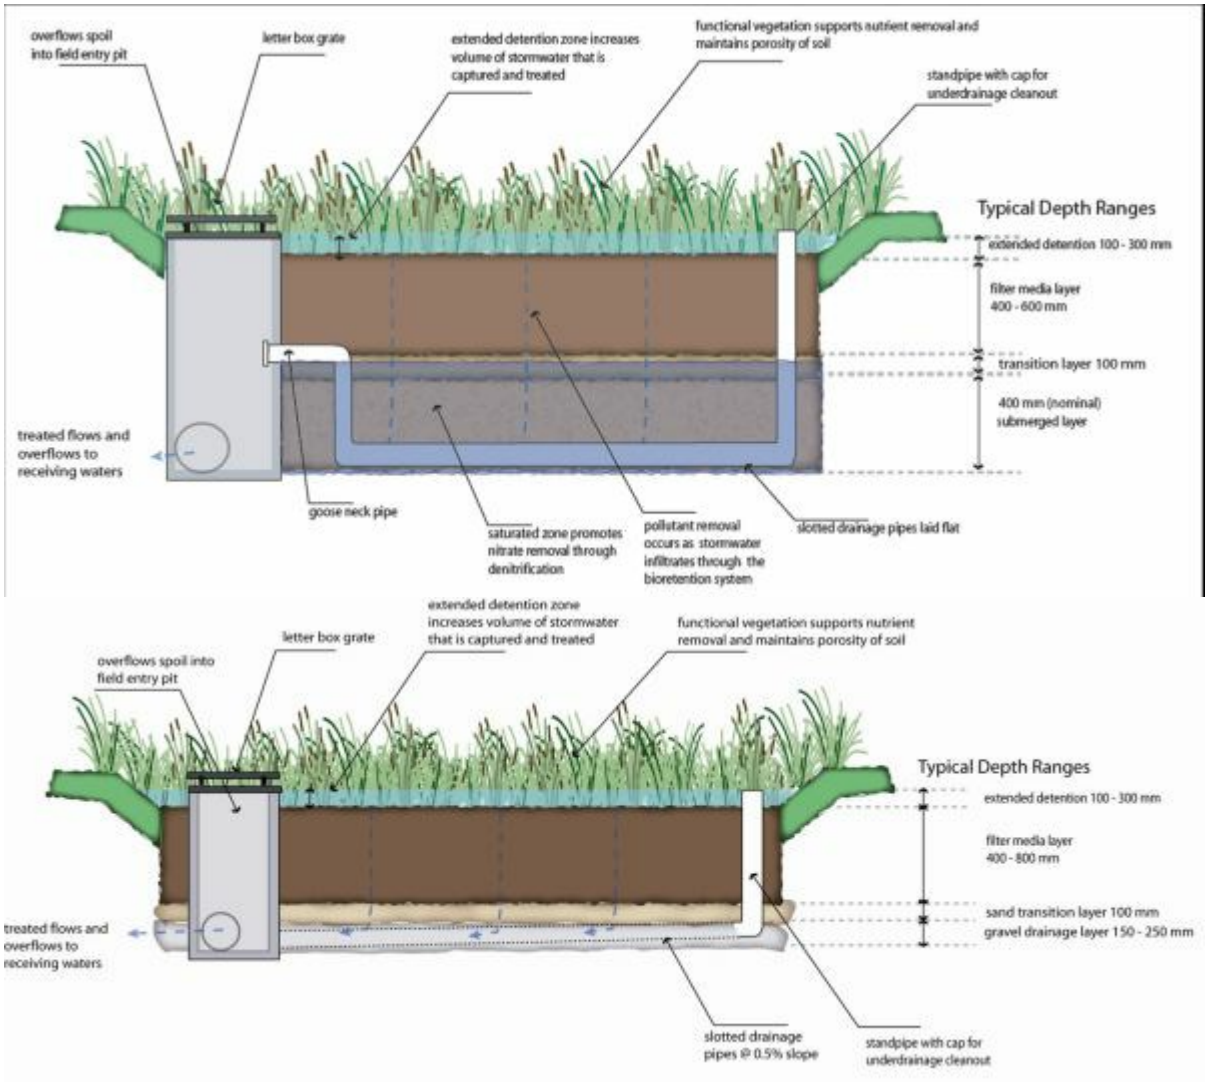

Figure SC6.4.3.9.18 Cross section of bioretention basins (top- with a saturated zone; below- without a saturated zone)

(g) Traffic controls

Another design consideration is keeping traffic and building material deliveries off bioretention basins (particularly during the construction phase of a development). If bioretention basins are driven over or used for parking, the filter media will become compacted and the vegetation damaged.

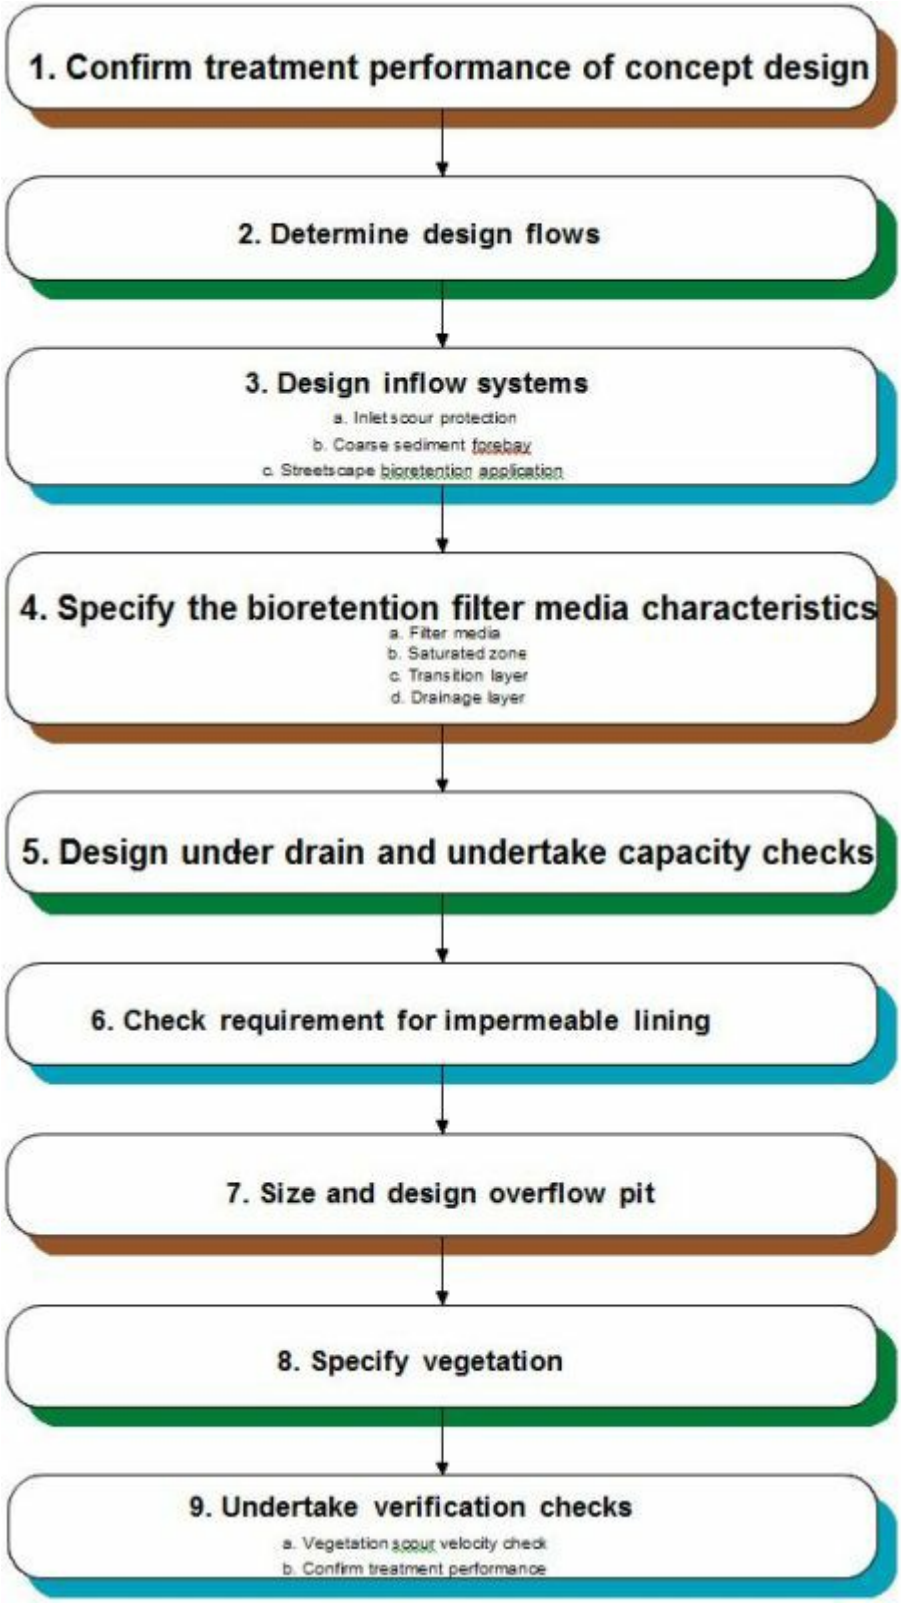
Streetscape bioretention systems must be designed to satisfy local authority requirements with respect to traffic calming devices within particular street or road reserve widths. Where bioretention is incorporated into traffic calming or control devices, or directly adjacent to mountable kerbs, consideration should be given to protection of the area immediately behind the kerb where vehicles are likely to mount the kerb.

(h) Services

Bioretention basins or cells located within road verges or within footpaths must consider the standard location for services within the verge and ensure access for maintenance of services without regular disruption or damage to the bioretention system.

(3) Design process – bioretention basins

The following sections detail the design steps required for bioretention basins. Key design steps are:



(a) Step 1: Check treatment performance of concept design

Before commencing detailed design, the designer should first undertake a preliminary check to confirm the bioretention basin treatment area (i.e. the surface area of the filter media) from the concept design is adequate to deliver the required level of stormwater quality improvement. This design process assumes a conceptual design has been undertaken.

This assessment should be undertaken by a WSUD specialist and can be achieved by modelling expected treatment performance in an appropriate quantitative modelling program. Where possible, this modelling should be based on local rainfall data, the proposed configuration of the system, and based on local stormwater treatment performance data.

(b) Step 2: Determine design flows

(i) Design flows

The hydraulic design of the bioretention basin should be based on the following design flows:

(A) minor flood flow (2 year ARI) to allow minor floods to be safely conveyed. For commercial and industrial areas the design flow requirement for minor flows is a 5 year ARI event; and

(B) major flood flow (100 year ARI) to check flow velocities, velocity depth criteria, conveyance within road reserve, and freeboard to adjoining property.

(ii) Design flow estimation

A range of hydrologic methods can be applied to estimate design flows. If the typical catchment areas are relatively small, the Rational Method design procedure is considered to be a suitable method for estimating design flows. However, if the bioretention system is to form part of a retention basin or if the catchment area to the bioretention system is large, then a full flood routing computation method needs to be used to estimate design flows.

(c) Step 3: Design inflow systems

(i) The design of the inflow systems to bioretention basins needs to consider a number of functions:

(A) scour protection – In most bioretention applications stormwater flows will enter the bioretention basin as concentrated flow (piped, channel or open channel) and as such is it important to slow and spread flows using appropriate scour (rock) protection;

(B) coarse sediment forebay – Where stormwater runoff from the catchment is delivered directly to the bioretention basin without any coarse sediment management (through vegetated swale or buffer treatment) a coarse sediment forebay is to be included in the design. The forebay is to remove coarse sediment (1 mm +) from stormwater to minimise the risk of vegetation in the bioretention basin being smothered;

(C) constant low base flows have to be taken into account and dealt with as they can blind the filter material and promote weed growth within permanently saturated areas; and

(D) street hydraulics (streetscape applications only) – In streetscape applications, where stormwater is delivered directly from the kerb and channel to the bioretention basin, it is important to ensure the location and width of the kerb opening is designed such that flows enter the bioretention basin without adversely affecting trafficability of the road (QUDM, Table 7.04.1).

(ii) Each of these functions and the appropriate design responses are described in the following sections.

(iii) Inlet scour protection

Erosion protection should be provided for concentrated inflows to a bioretention basin. Typically, flows will enter the bioretention basin from either a surface flow system (i.e. roadside kerb, open channel) or a piped drainage system. Rock beaching is a simple method for dissipating the energy of concentrated inflow, as depicted in Figure SC6.4.3.9.19 (with the “D” representing the pipe diameter dimension). The rocks can form part of the landscape design of the bioretention component.

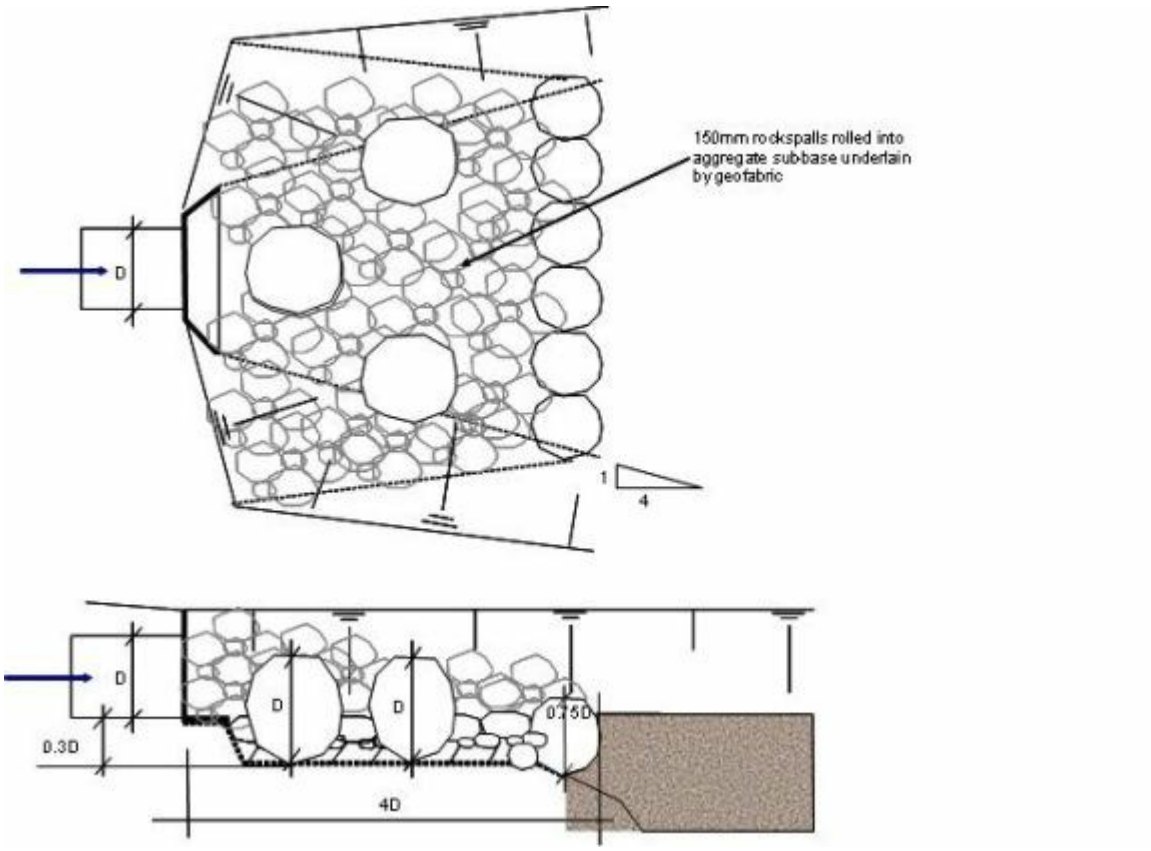


Figure SC6.4.3.9.19 Typical inlet scour protection detail for bioretention basins receiving piped flows

(iv) Coarse sediment control

Where stormwater runoff from the catchment is delivered directly to the bioretention basin without pre-treatment (through vegetated swale or buffer treatment), coarse sediment may accumulate near the basin inflow. This sediment may smother vegetation and reduce infiltration to the filter media. To mitigate these effects, either a sedimentation basin (see Chapter 4) is to be located upstream or the bioretention basin inflow system is to incorporate a coarse sediment forebay. The forebay should be designed to:

(A) remove particles that are 1 mm or greater in diameter from the 3 month ARI storm event; and

(B) provide appropriate storage for coarse sediment to ensure desilting is required no more than once per year.

The size of the sediment forebay is established using the following equation:

$$V_s = A_c \cdot R \cdot L_o \cdot F_c$$

Where
- V_s = volume of forebay sediment storage required (m^3)
- A_c = contributing catchment area (ha)
- R = capture efficiency (assume 80%)
- L_o = sediment loading rate (m^3/ha/year)
- F_c = desired cleanout frequency (years)

A catchment loading rate (L_o) of 1.6 m^3/ha/year for developed catchments can be used to estimate the sediment loads entering the basin. The area of the forebay is established by dividing the volume by the depth. The depth of the forebay should not be greater than 0.3 m below the surface of the filter media.

$$A_s = \frac{V_s}{D_s}$$

Where D = depth of sediment forebay (max 0.3 m below filter media surface).
The sediment forebay area should be checked to ensure it captures the 1 mm and greater particles using the following expression (modified version of Fair and Geyer (1954).

$$R = 1 - \left[1 + \frac{1}{n} \cdot \frac{v_s}{Q/A}\right]^{-n}$$

Where:

R	=	fraction of target sediment removed (80%)
v_s	=	settling velocity of target sediment (100 mm/s or 0.1 m/s for 1 mm particle)
Q/A	=	applied flow rate divided by forebay surface area ($m^3/s/m^2$)
n	=	turbulence or short-circuiting parameter (adopt 0.5)

The coarse sediment forebays will contain large rocks for energy dissipation and be underlain by filter material to promote drainage following storm events.

(v) Kerb opening configuration (streetscape applications)

In streetscape applications where stormwater is delivered directly from a kerb and channel to a bioretention basin, the following design issues must be considered:

(A) the location of the kerb opening must be designed to ensure flows in the channel do not exceed the maximum allowance widths as defined by QUDM Table 7.04.1 (DNRW, IPWEA & BCC 1998); and

(B) the width of the kerb opening is designed to allow the design flow to enter the bioretention basin.

Channel flow width at kerb opening

The width of channel flow at the kerb opening during a minor storm event (2 10 year ARI) needs to be checked to ensure it does not exceed the maximum allowable channel flow widths defined by QUDM Table 7.04.1 (DNRW, IPWEA & BCC 1998) and the local authority requirements. This check can be undertaken by applying Manning's equation or Izzard's equation and ensuring the flow depth does not exceed either the crest of the road or the top of kerb (whichever is lowest).

Design kerb opening width (where kerb and channel is used)

To determine the width of the opening in the kerb to allow flows to enter the bioretention basin, Manning's equation or Izzard's equation (QUDM Section 7.04.2) can be used with the kerb, channel and road profile to estimate the flow depth in the kerb and channel at the entry point. Once the flow depth for the minor storm (e.g. 2-10 year ARI) is known, this can then be used to calculate the required width of the opening in the kerb by applying a broad crested weir equation. The opening width is estimated by applying the flow depth in the channel (as h) and solving for L (opening width).

$$Q = C_w \cdot L \cdot h^{3/2}$$

Where

Q	=	flow (m^3/s)
Cw	=	weir coefficient (= 1.66)
L	=	length of opening (m)
h	=	depth of flow (m)

This method ensures the kerb opening does not result in an increase in the upstream channel flow depth, which in turn ensures the bioretention basin does not impact on the trafficability of the adjoining road pavement as required by the QUDM. To ensure the kerb opening width is adequate, additional width factors may be required to account for slope of the kerb and channel, and the angle at which flow meets the kerb opening. This will depend on the location and position of the bioretention system in relation to the kerb and channel. Design of the inflow system within the kerb and channel will need to consider maximising flow into the bioretention system. The kerb opening

can be made more effective by lowering the kerb opening below the channel, increasing the cross fall at the kerb opening or by providing deflectors at the kerb opening.

(d) Step 4: Specify the bioretention filter media characteristics

Up to four types of media are required in bioretention basins (refer Figure SC6.4.3.9.18 Cross section of bioretention basins (top—with a saturated zone; below—without a saturated zone)).

(i) Filter media

As a minimum, the filter media is required to have sufficient depth to support vegetation, typically between 400-600 mm (or as specified in the engineering design). It is important to note that if deep rooted plants such as trees are to be planted in bioretention basins, the filter media must have a minimum depth of 800 mm to avoid roots interfering with the perforated under-drain system.

In general, the media should be a loamy sand with an appropriately high permeability under compaction and should be free of rubbish, deleterious material, weed seeds, toxicants, and should not be hydrophobic. The filter media should contain some organic matter for increased water holding capacity but be low in nutrient content. To ensure a proposed soil is suitable as filter media, a testing regime is required. The *Guidelines for Soil Filter Media in Bioretention Systems*: Version 2.01 (FAWB, March 2008) (refer to http://www.monash.edu.au/fawb/products/index.html) provides best practice guidance on filter media selection and testing. It is recommended that soils used for bioretention filter media fulfil the requirements outlined in the FAWB Guideline. In summary, these requirements include:

(A) organic carbon levels < 5%;

(B) pH between 5.5 and 7.5;

(C) electrical conductivity < 1.2 dS/m;

(D) saturated hydraulic conductivity between 100-500 mm/hr. The saturated hydraulic conductivity of the filter media is established by optimising the treatment performance of the bioretention system given site constraints of the particular site (using a continuous simulation model such as MUSIC); and

(E) the filter media must also be structurally sound and not prone to structural collapse as this can result in a significant reduction in saturated hydraulic conductivity. The risk of structural collapse can be reduced by ensuring the soil has a well graded particle size distribution with a combined clay and silt fraction of < 3%.

(ii) Transition layer (if required)

The purpose of the transition layer is to prevent the filter media from migrating down into the drainage layer (or the saturated zone). It also acts as a buffer between the permanently saturated zone (if required) and the filter media. This buffer is necessary to ensure the filter media is not saturated for prolonged periods during rainfall events due to increases in water levels in the saturated zone. To achieve this, the transition layer depth must be greater than the head created by flows over the saturated zone outlet weir.

It is required if the particle size difference between the filter media and the drainage layer (or the saturated zone) is more than one order of magnitude. If a transition layer is required then the material must be a clean, well-graded sand/coarse sand material containing little or no fines.

The transition layer is recommended to be 100 mm thick and have a minimum saturated hydraulic conductivity of 1000 mm/hr.

A recent particle size distribution for the transition layer sand will need to be obtained to ensure that it meets the required grading/"bridging" criteria outlined below. The "bridging" criteria is based on the engineering principles that rely on the largest 15% of the filter media particles (or saturated zone particles) "bridging" with the smallest 15% of the sand particles. This results in smaller voids, which prevent the migration of the filter media particles into the sand particles. The following equation is taken from the United States Golf Association's recommendations for golf course construction:

Bridging Factor: **D15 (transitional layer sand) ≤ 8 x D85 (filter media)**

The addition of a transition layer increases the overall depth of the bioretention system and may be an important consideration for some sites where total depth of the bioretention system may be constrained. In such cases, the use of a sand drainage layer and/ or perforated pipes with smaller slot sizes may need to be considered.

(iii) Saturated layer (if required)

The saturated layer should be about 400 mm deep (but may deeper depending on the specific application) and composed of clean (i.e. free from fines) medium-coarse washed sand, gravel or small rock (50 mm diameter maximum) together with a long term carbon source. Hardwood wood chips, 5 mm to 40 mm in size, are recommended as the carbon source because they breakdown slowly to provide a long term carbon source yet have a decomposition rate that should not limit the denitrification process.

The total mass of carbon/electron donor that is required for denitrification must be calculated based on the expected stormwater influent TN mass over the desired life span of the system (e.g. 25 years). The calculation is based on the stoichiometry of the denitrification reaction (shown below).

Denitrification reaction:

$NO_3^- + 1.25\ (CH_2O) + H^+\ (10^{-7}\ M) \rightarrow 0.5N_2\ (g) + 1.75H_2O + 1.25CO_2\ (g)$

Based on a 400 mm deep saturated zone and the modelled annual TN runoff mass (for Townsville) for a bioretention system that is 2% of the contributing 1 ha catchment, the saturated zone media would have the following composition:

(A) 76.7 m^3 washed coarse sand, gravel or small rock; and

(B) 3.3 m^3 hardwood wood chips, well graded 5 mm-40 mm.

This is equivalent to an organic carbon content of approximately 4-5% by volume. If the saturated zone depth changed, or the bioretention system to catchment area ratio changed, the hardwood proportion would need to be recalculated using the denitrification stoichiometry.

Calculating carbon source for saturated zone with safety factor (x2)	
Catchment Area	1 ha
Treatment Area Required	2%
Bioretention Surface Area	200 m^2
Saturated Zone Depth	400 mm
Total volume of Saturated Zone	80 m^3
TN load 1 year	12.5 kg/yr
TN load 25 years	312.5 kg/25 yrs
Stoichiometry:	
N:C ratio = 1:1.25 (mol), which equates to 14:15 (g) [Mw: N = 14g/mol, C = 12g/mol]	
Average total carbon content of hardwood woodchips is 50%, therefore	
N:C (woodchip) = 14:30 (g)	
N:C (woodchip) = 1:2.1	
Woodchips (312.5 x 2.1)	656kg/carbon
Safety Factor (x 2)	1313kg/carbon
Density of wood chips	400kg/m^3 (approx.)
Hardwood Wood Chips	**3.3 m^3**
Clean Coarse Sand	**76.7 m^3**

The saturated media must have a hydraulic conductivity of >1000mm/hr (the ASTM F1815-06 test method is to be used to measure hydraulic conductivity).

The saturated zone should be lightly compacted (e.g. with one pass of a smooth drum lawn roller) during installation to stabilise the structure. Under no circumstances should heavy compaction or multiple-passes be made.

(iv) Drainage layer (if required)

The drainage layer is used to convey treated flows from the base of the filter media layer (or the saturated zone) into the perforated under-drainage system. The composition of the drainage layer is to be considered in conjunction with the selection and design of the perforated under-drainage pipes as the slot sizes in the perforated pipes may determine the minimum drainage layer particle size to avoid washout of the drainage layer into the perforated pipe system. Coarser material (e.g. fine gravel aggregate) is to be used for the drainage layer if the slot sizes in the perforated pipes are too large for use of a sand based drainage layer. The drainage layer is to provide a minimum of 50 mm cover above the perforated under-drainage pipes and have a minimum saturated hydraulic conductivity of 1000 mm/hr.

A particle size distribution for the gravel will need to be obtained to ensure that it meets the "bridging" criteria outlined below:

Bridging Factor:
D15 (drainage gravel/sand) ≤ 8 x D85 (filter media/saturated zone/transition layer)

Ensure drainage media is washed prior to placement in bioretention system to remove any fines.

(e) Step 5: Design under-drain and undertake capacity checks (if required)

The maximum spacing of the perforated under-drains in bioretention basins located in streetscape zones and small public zones (i.e. bioretention < 100 m^2) is 1.5 m (centre to centre). This ensures that the distance water needs to travel horizontally toward the perforated pipes through the drainage layer does not hinder drainage of the filter media. The maximum spacing of the perforated pipes in bioretention basins located in local parks and large open space areas (i.e. bioretention > 100 m^2) can be increased to 2.5 – 3 m.

In bioretention systems without saturated zones, perforated pipes are to grade at a minimum of 0.5% towards the overflow pit to ensure effective drainage. In bioretention systems with saturated zones, perforated pipes should be laid flat (i.e. at 0% grade) to avoid preferential flow paths forming vertically through the filter media closer to the outlet.

Perforated pipes should not use a geofabric wrapping, as this is a potential location for blockage and would require a complete resetting of the bioretention system. Where perforated pipes are supplied with geofabric wrapping, it is to be removed before installation.

Installing parallel pipes is a means to increase the capacity of the perforated pipe system. 100 mm diameter is recommended as the maximum size for the perforated pipes to minimise the thickness of the drainage layer. Either slotted PVC pipes or flexible perforated pipes (e.g. Ag pipe) can be used; however, care needs to be taken when selecting the type of pipe to consider the following:

(i) ensure the slots in the pipes are not so large that sediment will freely flow into the pipes from the drainage layer. This is also a consideration when specifying drainage layer media; and

(ii) minimise the potential for tree roots to enter the pipes in search of water. Generally, this is only a concern when the filter media has a low water holding capacity, or trees are planted in filter media whose depth is too shallow. In general, trees are not recommended if the filter media depth is less than 800 mm. Flexible "ribbed" pipes are more likely, than PVC pipes, to retain "beads" of moisture due to the small corrugations on the inside of the pipe. Therefore, a smooth surface perforated/slotted pipe system is recommended for use in bioretention basins exhibiting any of these characteristics.

(iii) To ensure slotted pipes are of adequate size, several checks are required:

(A) ensure the perforations are adequate to pass the maximum filtration rate;

(B) ensure the pipe itself has sufficient capacity; and

(C) ensure that the material in the drainage layer will not be washed into the perforated pipes (consider a transition layer).

The maximum filtration rate represents the maximum rate of flow through the bioretention filter media and is calculated by applying Darcy's equation as follows:

$$V_s = A_c \cdot R \cdot L_o \cdot F_c$$

Where V_s = volume of forebay sediment storage required (m^3)

A_c = contributing catchment area (ha)

R = capture efficiency (assume 80%)

L_o = sediment loading rate (m^3/ha/year)

F_c = desired cleanout frequency (years)

To ensure the perforated under-drainage system has sufficient capacity to collect and convey the maximum filtration rate, it is necessary to determine the capacity for flows to enter the under-drainage system via the perforations in the pipes. To do this, orifice flow can be assumed and the sharp edged orifice equation used. It is conservative, but reasonable to use a blockage factor to account for partial blockage of the perforations by the drainage layer media. A 50% blockage of the perforations should be used.

The flow capacity of the perforations is thus:

$$A_s = \frac{V_s}{D_s}$$

If the capacity of the drainage system is unable to collect the maximum filtration rate additional under-drains will be required.

The Manning's roughness used will be dependent on the type of pipe used (refer to QUDM Table 7.16.3 (DNRW, IPWEA & BCC 1998)). When a saturated zone is incorporated into the design, the underdrainage pipes are laid flat however the conveyance capacity can be calculated using the Manning's equation with an assumed friction slope of 0.5%.

Under-drains should be extended vertically to the surface of the bioretention system to allow inspection and maintenance when required. The vertical section of the under-drain should be unperforated and capped to avoid short-circuiting of flows directly to the drain. Reference is made to the drawings following the worked example (Section SC6.4.3.9.4(3)(i) Step 9: Undertake verification checks) for further guidance.

In bioretention basins with a saturated zone, the capacity of the weir or up-turned pipe (maintaining the water level within the saturated zone) must also be checked to ensure it does not become the hydraulic "control" in the bioretention system (i.e. to ensure the filter media sets the travel time for flows percolating through the bioretention system). A broad crested weir equation can be used to determine the length of weir required (assuming free flowing conditions) to convey the maximum flow/filtration rate. The maximum depth of flow over the weir is to be 100 mm. This is important to limit increase in the saturated zone depth and avoid prolonged saturation of the filter media.

(f) Step 6: Check requirement for impermeable lining

The saturated hydraulic conductivity of the natural soil profile surrounding the bioretention system should be tested together with depth to groundwater, chemical composition and proximity to structures and other infrastructure. This is to establish if an impermeable liner is required at the base (only for systems designed to preclude ex-filtration to in-situ soils) and/or sides of the bioretention basin (refer also to discussion in SC6.4.3.9.4(2)(c) Ex-filtration to in-situ soils). If the saturated hydraulic conductivity of the filter media in the bioretention system is more than one order of magnitude (10 times) greater than that of the surrounding in-situ soil profile, no impermeable lining is required.

(g) Step 7: Size overflow pit

There should be a minimum of 50 mm head over the overflow pit crest to facilitate discharge of the design flow into the overflow pit.

In streetscape bioretention applications, a level of conservatism is built into the design of grated overflow pits by placing their inverts at least 50 mm below the invert of the street channel (and therefore setting the maximum ponding depth). The head over the overflow pit crest is the sum of the 50 mm and the maximum ponding in the street channel under the minor storm (see SC6.4.3.9.4(3)(c)(v) Kerb opening configuration). To size an overflow pit, two checks must be made to test for either drowned or free flowing conditions. A broad crested weir equation can be used to determine the length of weir required (assuming free flowing conditions) and an orifice equation used to estimate the area between openings required in the grate cover (assuming drowned outlet conditions). The larger of the two pit configurations should be adopted (as per Section 7.05 QUDM (DNRW, IPWEA & BCC 1998)). In addition, a blockage factor that assumes the grate is 50% blocked is to be used.

For free overfall conditions (weir equation):

$$R = 1 - \left[1 + \frac{1}{n} \cdot \frac{v_s}{Q/A}\right]^{-n}$$

Where:

R	=	fraction of target sediment removed (80%)
v_s	=	settling velocity of target sediment (100 mm/s or 0.1 m/s for 1 mm particle)
Q/A	=	applied flow rate divided by forebay surface area ($m^3/s/m^2$)
n	=	turbulence or short-circuiting parameter (adopt 0.5)

Once the length of weir is calculated, a standard sized pit can be selected with a perimeter at least the same length of the required weir length.

For drowned outlet conditions (orifice equation):

$$Q = C_w \cdot L \cdot h^{3/2}$$

Where

Q	=	flow (m^3/s)
Cw	=	weir coefficient (= 1.66)
L	=	length of opening (m)
h	=	depth of flow (m)

When designing grated field inlet pits, reference is also to be made to the procedure described in QUDM Section 7.05.4.

In terms of the actual grate, letter box or dome type grates must be used in bioretention basins.

When a saturated zone is included in the design of a bioretention system, additional components must be incorporated into the outlet design. A saturated zone can be formed at the base of a bioretention system by using a riser pipe with the outlet level set at the top of the desired saturation depth (i.e. top of the saturated zone) or by incorporating a weir/overflow structure within the outlet pit (see Figure SC6.4.3.9.18). The saturated zone would hold water rather than draining freely, and would therefore provide a source of water to the plants during dry periods.

(h) Step 8: Specify vegetation

Refer to SC6.4.3.9.4(4) Landscape design notes and SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics for advice on selecting vegetation for bioretention basins in the coastal dry tropics.

Editor's note—applicants will also need to address 9.4.3 Landscape Code and sub-section SC6.4.3.6 Landscape policy.

(i) Step 9: Undertake verification checks

Once the detailed design is complete, a final check should be undertaken to confirm that vegetation will be protected from scour during flood events and that the final design will achieve the required treatment performance.

(i) Vegetation scour velocity check

Velocities should be kept below:

(A) 0.5 m/s for minor flood (2-5 year ARI) discharges; and

(B) 2.0 m/s for major flood (50 year ARI) discharges.

If the inlet to the bioretention basin "controls" the maximum inflow to the basin then it is appropriate to use this maximum inflow to check velocities. In this case, velocities should be maintained below 0.5 m/s.

(ii) Confirm treatment performance

If, during the course of undertaking detailed design of the bioretention basin, the basic design parameters established by the conceptual design phase have changed (e.g. area, filter media depth, etc.) then the designer should verify that the current design meets the required water quality improvement performance. This can be done by re-modelling expected treatment performance determined in the conceptual design based on the revised configuration of the system.

(j) Design calculation summary

A calculation summary sheet for the key design elements of a bioretention basin is provided in Table SC6.4.3.9.10.

Click here to obtain a copy of **Table SC6.4.3.9.10**

(4) Landscape design notes – bioretention basins

(a) Objectives

Landscape design for bioretention basins has four key objectives:

(i) addressing stormwater quality objectives by incorporating appropriate groundcover plant species for sediment removal, erosion protection, stormwater treatment (biologically active root zone) and preventing filter media blockages;

(ii) ensuring that the overall landscape design for the bioretention basin integrates with its surrounding environment. This includes requirements for maintaining dense perennial vegetation throughout the dry season to maintain aesthetics and to minimise weed growth;

(iii) incorporating crime prevention through environmental design (CPTED) principles and traffic visibility safety standards for roadside systems. This objective also needs to incorporate public safety; and

(iv) providing other landscape values such as shade, amenity, character, buffers, glare reduction, place making and habitat.

For further guidance refer to the *South East Queensland WSUD Conceptual Design Guidelines* (Healthy Waterways Partnership, 2008)

(b) Bioretention basin vegetation

Planting for bioretention basin elements may consist of up to three vegetation types:

(i) groundcovers for stormwater treatment and erosion protection;

(ii) shrubbery for screening, glare reduction and character; and

(iii) trees for shading, character, breaking up filter material and other landscape values.

The plant species listed in SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics tolerate free draining sandy soils and are capable of withstanding long dry periods as well as periods of inundation. However, because the dry periods in the coastal dry tropics can be severe, bioretention systems must have supplemental temporary irrigation or include a saturated zone. These measures ensure dense perennial vegetation can be sustained to maintain aesthetics, stormwater treatment capacity and to minimise weed growth.

(c) Parkland bioretention basins

Once the general location has been determined, it will be necessary to investigate how the elements of the bioretention system will be arranged within the open space including:

(i) opportunities and constraints presented by various siting options;

(ii) if the device is to be visually prominent (perhaps for educational value) or merged with the surrounding parkland space using a consistent planting layout in the basin, embankment and parkland; and

(iii) a formal or informal style dependent on the setting and surrounding open space and urban design.

(d) Safety issues

The standard principles of informal surveillance, exclusion of places of concealment and open visible areas apply to the landscape design of bioretention basins. Regular clear sightlines should be provided between the roadway and footpaths/ property. Safety measures in accordance with the requirements of the relevant local authority should also be installed around structural components of bioretention basins where safety hazards exist.

(i) Crime prevention through environmental design (CPTED)

Where planting may create places of concealment or hinder informal surveillance, groundcovers and shrubs should not generally exceed 1 m in height.

(ii) Traffic sightlines

The standard rules of sightline geometry apply. Planting designs should allow for visibility at pedestrian crossings, intersections, rest areas, medians and roundabouts.

(5) Construction and establishment – bioretention basins

This section provides general advice for the construction and establishment of bioretention basins and key issues to be considered to ensure their successful establishment and operation (see Figure SC6.4.3.9.20).

Figure SC6.4.3.9.20 Bioretention basin functional installation

(a) Staged construction and establishment method

(i) Sediment and erosion control

Many soils within the coastal dry tropics region are dispersive, highlighting the critical importance of appropriate sediment and erosion control. All development and land disturbance activities must employ best practice sediment and erosion control practices to minimise the impact on receiving environments (refer to the Development manual planning scheme policy SC6.4.3.8 Stormwater management plans for development).

In relation to bioretention systems, temporary protective layers must be installed and left in place throughout the allotment building phase to ensure sediment laden waters do not clog the filtration media and allotment building traffic does not enter the bioretention system (see Figure SC6.4.3.9.21). Importantly the configuration of the bioretention basin and the turf vegetation allow the system to function effectively as a shallow sedimentation basin reducing the load of sediment discharging to the receiving environment. Using this approach, WSUD systems can operate effectively to protect downstream ecosystems immediately after construction.

Figure SC6.4.3.9.21 Bioretention basin sediment and erosion control

(ii) Operational establishment

At the completion of the allotment building phase the temporary measures (i.e. geofabric and turf) are removed with all accumulated sediment and the bioretention system re-profiled and planted in accordance with the proposed landscape design. Establishment of the vegetation to design condition can require more than two growing seasons, depending on the vegetation types, during which regular watering and removal of weeds will be required.

(iii) Quality control during construction

The primary responsibility for supervision of the construction of WSUD elements lies with the site superintendent. Key milestones requiring inspection and sign off by either the superintendent or

the design team are detailed in the suggested construction sequence below.

Meetings between the design team and contractors should also take place at the commencement of each phase of works, i.e.:

- prior to commencement of civil works;
- prior to commencement of landscape works; and
- at the completion of works.

Regular site inspections by a member of the design team are also recommended to ensure the bioretention basins are constructed as per the design intent and to provide ongoing construction and establishment advice to the contractors.

The suggested construction sequence for the bioretention basins are as follows:

(A) survey bioretention basin location;

(B) undertake bulking out, including construction of bunds surrounding basin. Construct outflow headwall(s) and install section(s) of stormwater reinforced concrete pipes (RCP) that runs underneath bund. Terminate pipe at interface of bund and bioretention basin;

(C) excavate surrounding landform to design subsoil level (achieving surrounding level at this stage reduces the need for earthworks adjacent to the basins after they have been constructed);

(D) install overflow pit(s) and ensure pit crest(s) is at design level. The pit crest(s) will then be used as a datum from which other levels within the basin will be measured. The pit requires holes for pipe connections and these should be drilled at this stage;

(E) detailed excavation, trimming and profiling of sides and base of basin, ensuring base has minimum 0.5% grade (0% slope when saturated zones are included in the designs) towards pit. Ensure base of basins are free from debris. As constructed survey is required at this time and should include the base and bunds of the system and all hard structures (i.e. overflow pit, overflow weir and pipe connection punch-out holes);

(F) install silt fences around basin to prevent sediment entering system and to keep construction vehicles off the basin;

SUPERINTENDENT INSPECTION AND SIGN OFF REQUIRED BEFORE PROCEEDING

(G) line basin with geofabric, ensuring geofabric extends beyond top of bioretention basin side walls, up to the sediment control fence. This ensures that exposed earth on the bunds won't wash into basins during construction;

(H) install remaining RCP stormwater pipe connecting overflow pit(s) to existing RCP stormwater pipe installed as part of Step 2;

(I) install slotted PVC under-drainage pipes and PVC collector pipes in specified layout. Ensure all pipes are laid at min 0.5% slope (0% slope when saturated zones are included in the designs) with no localized depressions verified using level or string line. Arrange slots so that they are not directly on top of the pipe (to minimise fine particles blocking the slots). Seal junctions and connections (i.e. slotted PVC pipes to PVC collector pipes; slotted PVC pipes/PVC collector pipes to overflow pits) using sealant to prevent sand/gravel/soil passing into drainage network. Connect clean out points ensuring top of clean out points will ultimately sit 200 mm below overflow pit crest;

SUPERINTENDENT INSPECTION AND SIGN OFF REQUIRED BEFORE PROCEEDING

(J) install drainage, transition and saturated zones as required and as detailed in the design drawings;

(K) place prescribed bioretention filter media to design surface level of bioretention basin. Spread material using excavator bucket, hand tools, or a small "pozitrack" bobcat. Do not drive over filter media with any vehicle other than a "pozitrack" bobcat and only if agreed to by civil superintendent. In order to remove air pockets within the filter media, apply light and even compaction by making a single pass with a "pozitrack" bobcat (or similar). If required, apply additional filter media to ensure final surface level is correct. Use a spreader bar to flatten the surface of the filter media. Ultimately, the surface of the filter media must be level

(horizontal) and free from local depressions and set at 300 mm below pit crest;

(L) construct coarse sediment forebay utilising large, flat rocks to form base of forebay and interface between forebay and bioretention area;

(M) install temporary protective covering over bioretention surface. This involves covering the surface of filtration media with geofabric and placement of 50 mm topsoil and turf over the geofabric. This geofabric/turf layer is a temporary measure to protect the filter media from being clogged with construction sediment while allotment building is being undertaken. Once a majority of the allotment building is complete and the construction sediment load is minimal, this protective layer will be removed, and the system will be planted out with the vegetation as per designs;

(N) place landscaping topsoil on top of geofabric covering the bunds and around basin as per designs;

(O) flush under-drainage pipes to remove any initial ingress of material; and

(P) undertake as constructed survey of the basin surface and surrounding bunds, picking up at least one spot level per 100m² on the basin surface and at least one spot level every 10m along the top of the bunds.

FINAL SUPERINTENDENT INSPECTION AND SIGN OFF

(b) Construction tolerances

It is important to emphasise the significance of tolerances in the construction of bioretention basins (e.g. profiling of trench base and surface grades). Ensuring the surface of the bioretention filter media is free from localised depressions is particularly important to achieve even distribution of stormwater flows across the surface. In bioretention systems without saturated zones, the base of the trench should be sloped towards the outlet pit (min 0.5% longitudinal grade) to enable the perforated sub-surface drainage pipes to drain freely. Generally an earthworks tolerance of plus or minus 50 mm is considered acceptable.

(c) Sourcing bioretention vegetation

Notifying nurseries early for contract growing is essential to ensure the specified species are available in the required numbers and of adequate maturity in time for bioretention basin planting. When this is not done and the planting specification is compromised, poor vegetation establishment and increased initial maintenance costs may occur. The species listed in SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics are generally available commercially from local native plant nurseries. Availability is, however, dependent upon many factors including demand, season and seed availability. To ensure planting specification can be accommodated, the minimum recommended lead time for ordering is 3-6 months. This usually allows enough time for plants to be grown to the required size. The following pot sizes are recommended as the minimum:

(i) viro tubes - 50 mm wide x 85 mm deep;

(ii) 50 mm tubes - 50 mm wide x 75 mm deep; and

(iii) native tubes - 50 mm wide x 125 mm deep.

(d) Vegetation establishment

The following weed control measures and watering schedule are recommended to ensure successful plant establishment. Regular general maintenance as outlined in SC6.4.3.9.4(5) will also be required.

(i) Weed control

Conventional surface mulching of bioretention basins with organic material like tanbark, should not be undertaken. Most organic mulch floats and runoff typically causes this material to be washed away with a risk of blocking drains. Adopting high planting densities (e.g. 8-10 plants per square metre) and if necessary, applying a suitable biodegradable erosion control matting to the basin batters will help to combat weed invasion and reduce labour intensive maintenance requirements for weed removal. A heavy application of seedless hydro-mulch or hydro-mulch seeded with a sterile annual grass (e.g. Sterile Rye Grass) to create an anchored mulch can also provide short term erosion and weed control prior to planting with nursery stock. No matting or hydro-mulch is to be applied to the surface of the bioretention basin following the construction phase (i.e. in its final design form, vegetated as per planting schedule), as this will hinder filtration of stormwater through

the filter media.

(ii) Watering

Regular watering of bioretention basin vegetation is essential for successful establishment and healthy growth. The frequency of watering to achieve successful plant establishment is dependent upon rainfall, maturity of planting stock and the water holding capacity of the soil. The following watering program is generally adequate but should be adjusted (increased) to suit the site conditions:

(A) week 1-2 3 visits/ week;

(B) week 3-6 2 visits/ week; and

(C) week 7-12 1 visit/ week.

After this initial 3 month period, supplementary irrigation will be required in bioretention basins without submerged zones and may be required in bioretention basins with saturated zones (particularly during the 2 year plant establishment period (see Figure SC6.4.3.9.22)). Watering requirements to sustain healthy vegetation should be determined during ongoing maintenance site visits.

Figure SC6.4.3.9.22 Plant establishment period in bioretention basin

(6) Maintenance requirements – bioretention basins

Vegetation plays a key role in maintaining the porosity of the filter media of a bioretention basin and a strong healthy growth of vegetation is critical to its performance. Therefore the most intensive period of maintenance is during the plant establishment period (first 2 years) when weed removal and replanting may be required.

Inflow systems and overflow pits require careful monitoring, as these can be prone to scour and litter build up. Debris can block inlets or outlets and can be unsightly, particularly in high visibility areas. Inspection and removal of debris should be done regularly, and debris should be removed whenever it is observed on a site. Where sediment forebays are adopted, regular inspection of the forebay is required (3 monthly) with removal of accumulated sediment undertaken as required.

For larger bioretention basins, a maintenance access track for maintenance vehicles (e.g. 4WD ute) should be provided to the full perimeter of the system for maintenance efficiency and ease.

(7) Checking tools – bioretention basins

A number of checking aids have been developed for designers and council development assessment officers. In addition, SC6.4.3.9.4(5) Construction and establishment - bioretention basins provides general advice for the construction and establishment of bioretention basins and key issues to be considered to ensure their successful establishment and operation based on observations from construction projects around Australia.

(a) Design assessment

The checklist at Table SC6.4.3.9.11 presents the key design features that are to be reviewed when assessing the design of a bioretention basin. These considerations include configuration, safety, maintenance and operational issues that need to be addressed during the design phase. If an item receives an “N” when reviewing the design, referral is made back to the design procedure to determine the impact of the omission or error. A copy of the completed design calculation summary from Table SC6.4.3.9.10 should be provided as part of the application to assist in the design assessment. In addition to the checklist, a proposed design is to have all necessary permits for its installation. Council development assessment officers will require all relevant permits to be in place prior to accepting a design.

Click here to view **Table SC6.4.3.9.11 Bioretention basin design assessment checklist**

(b) Construction (during and post)

The checklist at Table SC6.4.3.9.12 presents the key items to be reviewed when inspecting the bioretention basin during and at the completion of construction. The checklist is to be used by Construction Site Supervisors and local authority Compliance Inspectors to ensure all the elements of the bioretention basin have been constructed in accordance with the design. If an item receives an “N” in Satisfactory criteria then appropriate actions must be specified and delivered to rectify the construction issue before final inspection sign-off is given.

Click here to view **Table SC6.4.3.9.12 Bioretention basin construction inspection checklist**

(c) Operation and maintenance inspection

The example form at Table SC6.4.3.9.13 should be developed and used whenever an inspection is conducted and kept as a record on the asset condition and quantity of removed pollutants over time. Inspections should occur every 1 - 6 months depending on the size and complexity of the system. More detailed site specific maintenance schedules should be developed for major bioretention basins and include a brief overview of the operation of the system and key aspects to be checked during each inspection.

Click here to view **Table SC6.4.3.9.13 Bioretention basin maintenance checklist**

(d) Asset transfer (following on maintenance period)

Land ownership and asset ownership are key considerations prior to construction of a stormwater treatment device. A proposed design should clearly identify the asset owner and who is responsible for its maintenance. The proposed owner should be responsible for performing the asset transfer checklist. For details on asset transfer to specific to each council, contact the relevant local authority. Table SC6.4.3.9.14 provides an indicative asset transfer checklist.

Click here to view **Table SC6.4.3.9.14 Bioretention basin asset transfer checklist**

(8) Example engineering drawings – bioretention basins

Where council has standard drawings appropriate to a bioretention basin application, these should be used to guide the design and construction of a bioretention basin. In the absence of local standards, Brisbane City Council have developed a set of Standard Drawings (UMS 155, 156 and 337) that can be readily applied to bioretention basin applications in the coastal dry tropics. These drawings relate specifically to inlet pits and sub-surface drains for bioretention swales but may be used to guide design for bioretention basins.

Editor’s note—these are not intended to be prescriptive drawings which must be adhered too; rather they are intended to provide detailed examples of bioretention system configurations.

SC6.4.3.9.5 Constructed stormwater wetlands

Editor's note—due to the different climatic conditions, the design of constructed wetlands in the coastal dry topics differs from the design of wetlands in south east Queensland and southern states. The following design considerations and criteria outlined below are specific to the coastal dry topics and are intended to address key requirements such as maintaining perennial wetland vegetation during the dry season; managing the potential for weed ingress and providing natural means of managing mosquito populations.

(1) Constructed wetland systems are densely vegetated water bodies that use enhanced sedimentation, fine filtration and biological uptake processes to remove pollutants from stormwater. Water levels rise during rainfall

events and outlets are configured to slowly release flows, typically over two to three days, back to dry weather water levels. In addition to treating stormwater, constructed wetlands can also provide habitat, passive recreation and improved landscape amenity.

Constructed wetlands in the coastal dry tropics will generally consist of an inlet zone (sedimentation basin to remove coarse sediments, deep pools, a deep marsh macrophyte zone (i.e. a heavily vegetated area to remove fine particulates and uptake soluble pollutants) and a high flow bypass channel (to protect the macrophyte zone from scour and vegetation damage). Figure SC6.4.3.9.23 Schematic layout of a constructed wetland system and Figure SC6.4.3.9.24 Wet and dry season conditions in a constructed freshwater wetland show the key elements of constructed stormwater wetland systems.

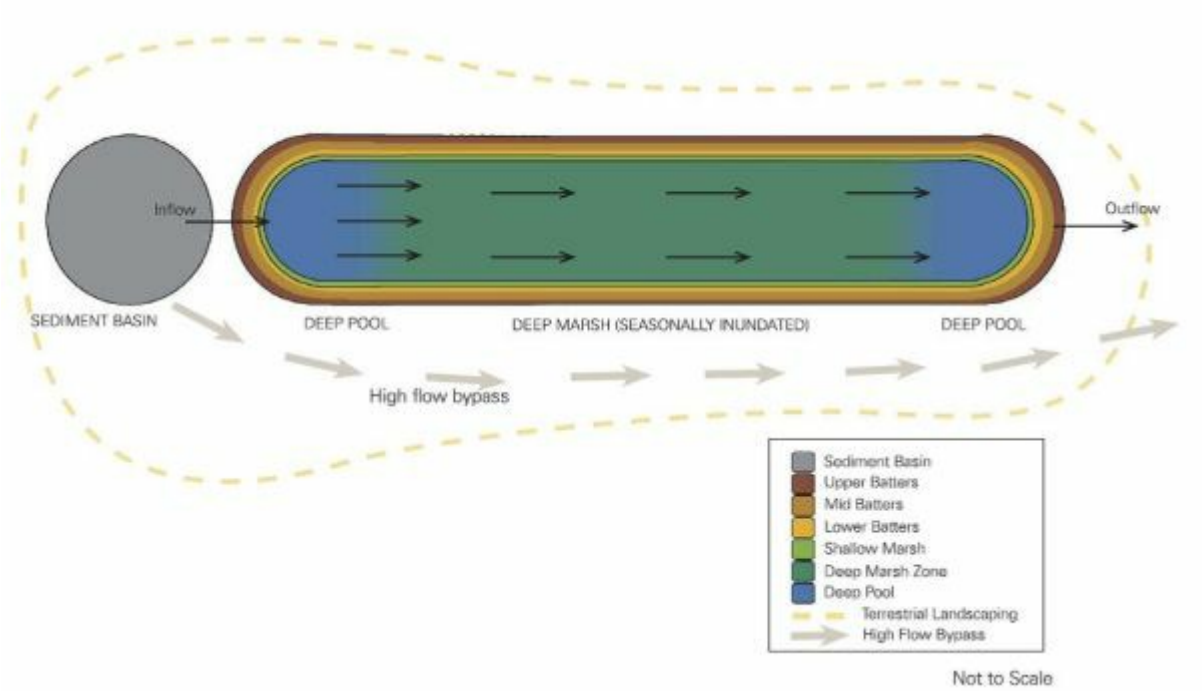

Figure SC6.4.3.9.23 Schematic layout of a constructed wetland system

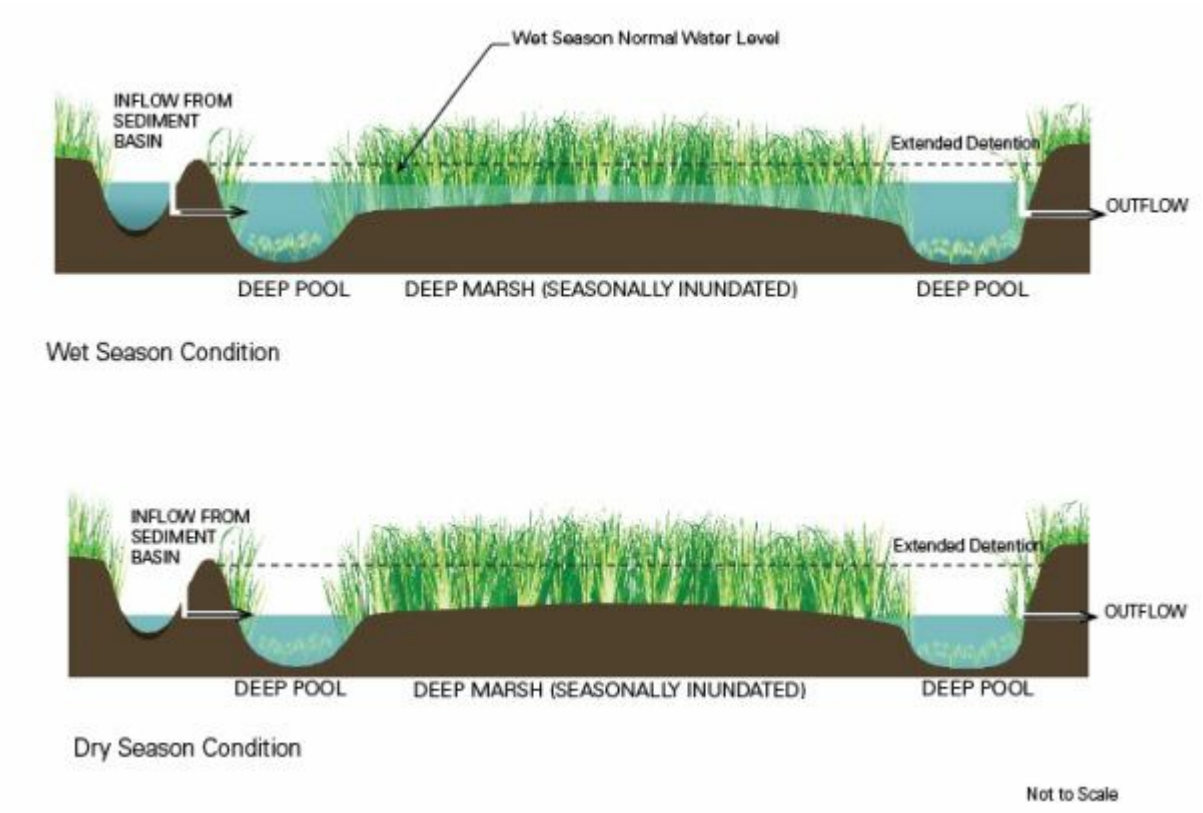

Figure SC6.4.3.9.24 Wet and dry season conditions in a constructed freshwater wetland

Constructed wetlands treat stormwater by capturing runoff and slowly passing it horizontally through a densely vegetated macrophyte zone. Soluble and colloidal (fine particles held in suspension) pollutants are mostly removed by sorption (absorption – "into" and adsorption – "onto") to biofilms on stems of wetland plants (Figure SC6.4.3.9.25). For this reason, dense vegetation is important for effective treatment and vegetation with a large stem surface area provides greatest treatment (i.e. plants with many small diameter stems are able to support more biofilms than plants with fewer, thicker stems). Emergent macrophytes are also important for:

(a) transferring oxygen to the sediments (oxygen pumps) thereby facilitating the processing and/or immobilising of pollutants captured and held within wetland sediments;

(b) aiding in the treatment of nutrient and heavy metal concentrations, either through direct uptake, or through providing a surface for biofilms and epiphytes that assist with the removal of pollutants;

(c) influencing sediment deposition and physically filtering sediment particles from the water column;

(d) influencing hydrology and hydraulics by promoting even flow distribution through the wetland;

(e) providing shade, decreasing light availability for algal synthesis;

(f) decreasing erosion by reducing wave action and flow velocities while binding soil particles with their root systems; and

(g) providing a basis for wetland food chains and supplying shelter for mosquito predators such as macroinvertebrates and fish.

(2) Design considerations - constructed wetlands

Due to the different climatic conditions, the design of constructed wetlands in the coastal dry topics differs from the design of wetlands in south-east Queensland and southern states. The following design considerations and criteria outlined below are specific to the coastal dry topics and are intended to address key requirements such as maintaining perennial wetland vegetation during the dry season; managing the potential for weed ingress and providing natural means of managing mosquito populations. Constructed wetlands in the form detailed below have not yet been constructed in the Townsville region. Therefore it is recommended that demonstration projects adopting the design guidelines detailed below are constructed and revisions/updates of this clause

made, where deemed appropriate, to reflect practical learnings and understanding of the performance and sustainability of constructed stormwater treatment wetlands in the coastal dry tropics.

Community acceptance of constructed wetlands will be driven by their aesthetics and landscape amenity value. Poorly designed and/or maintained wetlands are unlikely to gain community support; therefore, it is essential to address potential issues such as pests and weeds starting at conceptual design and continuing through implementation and long-term maintenance.

The operation of constructed wetlands involves the interaction between stormwater runoff, vegetation and hydraulic structures and the successful implementation of constructed wetlands requires appropriate integration into the landscape design. In this regard, the following sections provide an overview of the key design issues that must be considered when conceptualising and designing constructed wetlands.

(a) Landscape design

Constructed wetlands are often located within accessible open space areas and can become interesting community features. Landscape design aims to ensure that macrophyte planting fulfils the intended stormwater treatment function as well as integrating with their surrounds. Opportunities to enhance public amenity and safety with viewing areas, pathway links, picnic nodes and other elements should be exploited. Community education through signage and public art can also be explored. It is important that the landscape of constructed wetlands addresses stormwater quality objectives whilst being sensitive to these other important landscape aims.

Terrestrial landscaping provides a visual buffer and framework for the wetland system within the community and native habitat. Native trees can encourage recreational elements such as walking and bird watching. These recreational elements, as well as education in the form of descriptive panels and signs, can increase acceptance of these systems within the community.

Figure SC6.4.3.9.26 Boardwalk and public viewing area on the edge of a landscaped wetland

(b) Invasive weed control

To protect landscape amenity and the stormwater treatment efficiency of the wetland it is important to maintain, throughout the year, the design vegetation communities to avoid excessive colonisation of the wetland by weeds. Weed infestation is a major problem in the dry tropics, particularly within ephemeral waterways and stormwater treatment facilities. The wetland design presented in this chapter is based on an ephemeral wetland (i.e. it will dry periodically) and therefore, the design and management of the wetland to manage weed infestation takes on high importance. Management of weeds is achieved as follows:

(i) designing the macrophyte zone as predominately a deep marsh system (i.e. water depth 0.5 m - 0.7 m) to maintain the macrophyte vegetation by minimising the frequency and duration of wetland drying, thus permanently occupying the habitat and restricting weed colonisation opportunities;

(ii) planting dense littoral vegetation around the perimeter of the wetland to avoid the ingress of weed species. To maintain dense perennial littoral vegetation, irrigation is likely to be required, particularly during the dry season; and

(iii) during the establishment and ongoing maintenance of the wetland, prompt removal of weeds before they spread and/or set seed is of critical importance.

(c) Detention time and hydrologic effectiveness

Detention time is the time taken for each "parcel" of water entering the wetland to travel through the macrophyte zone assuming "plug" flow conditions. In highly constrained sites, simulations using quantitative computer models, such as the Model for Urban Stormwater Improvement Conceptualisation (MUSIC, CRCCH 2005), are often required to optimise the relationship between wetland detention time1 and wetland hydrologic effectiveness to maximise treatment performance. Hydrologic effectiveness is a measure of the mean annual volume of stormwater runoff captured and treated within the wetland and is expressed as a percentage of the mean. It is recommended that a notional detention time should preferably be around 48 hours to remove nutrients effectively from urban stormwater. Optimal hydrologic effectiveness in the coastal dry tropics Region is a balance between minimising overflows in the wet season and sustaining vegetation in the dry season (i.e. sizing the wetland to treat the majority of stormwater runoff while not being too large as to result in water level drawdown and drying in excess of 60–70 days in the dry season). Further discussion on hydrologic effectiveness and sizing of wetlands in the coastal dry tropics is provided in the following sections of this clause.

Editor's note—it should be noted that detention time is rarely a constant and the term notional detention time is used throughout this chapter to provide a point of reference in modelling and determining the design criteria for riser outlet structures.

(d) Hydrodynamic design

Poor wetland hydrodynamics is often identified as a major contributor to wetland operational and management problems. A summary of desired hydrodynamic characteristics and design considerations is presented in Table SC6.4.3.9.15.

Table SC6.4.3.9.15 Desired wetland hydrodynamic characteristics and associated design considerations

Hydrodynamic Characteristics	Design Considerations	Remarks
Uniform Distribution of flow velocity	Wetland shape, inlet and outlet placement and bathymetrical design of wetland to eliminate short-circuit flow paths and poorly mixed zones.	Poor flow pattern within a wetland will lead to zones of stagnant pools which promote litter, oil and scum accumulation as well as potentially supporting mosquito breeding. Short circuit flow paths of high velocities will lead to the wetland being ineffective in water quality improvement.

Inundation depth, wetness gradient, base flow and hydrologic regime	Selection of wetland size and design of outlet control to ensure compatibility with the hydrology and size of the catchment draining into the wetland. Bathymetry layout and outlet control design to compliment the botanical design and the hydrology of the wetland.	Wetland area and outlet design is critical to achieve the WSUD Objectives (e.g. target pollutant load reduction) as well as ensuring the size is adequate to sustain wetland vegetation (i.e. not too large as to result in excessive water level drawdown and drying in excess of 60 days in the dry season). Inadequate attention to the inundation depth, wetness gradient of the wetland and the frequency of inundation at various depth ranges would lead to sparse vegetation cover and/or dominance of certain plant species (especially weed species over time). This results in a deviation from the intended botanical layout of the wetland and reduced stormwater treatment performance.
Uniform vertical velocity profile	Selection of plant species and location of inlet and outlet structures to promote uniform vertical velocity profile.	Preliminary research findings have indicated that certain plant species have a tendency to promote stratification of flow conditions within a wetland leading to ineffective water pollution control and increasing the potential for algal blooms.
Scour protection	Design of inlet structures and erosion protection of banks.	Owing to the highly dynamic nature of stormwater inflows, measures are to be taken to “protect” the wetland from erosion during periods of high inflow rates.

(e) Inlet zone design considerations

The inlet zone of a constructed stormwater wetland is designed as a sedimentation basin and has two key functional roles. The primary role is to remove coarse to medium sized sediment (i.e. 125 µm or larger) prior to flows entering the macrophyte zone. This ensures the vegetation in the macrophyte zone is not smothered by coarse sediment and allows the macrophyte zone to target finer particulates, nutrients and other pollutants.

The second role of the inlet zone is the control and regulation of flows entering the macrophyte zone and bypass of flows during “above design flow” conditions. The outlet structures from the inlet zone (i.e. sedimentation basin) are designed such that flows up to the “design flow” (typically the 1 year ARI) enter the macrophyte zone whereas “above design flows” are bypassed around the macrophyte zone. In providing this function, the sedimentation basin protects the vegetation in the macrophyte zone against scour during high flows (see Figure SC6.4.3.9.27).

When the available space for a constructed wetland is constrained, it is important to ensure that the size of the inlet zone (i.e. sedimentation basin) is not reduced. This ensures the larger sediments are effectively trapped and prevented from smothering the macrophyte zone. When the site constrains the size of the constructed wetland it is the macrophyte zone of the wetland that should be reduced accordingly.

Large wetland systems usually require a gross pollutant trap (GPT) as part of the inlet zone to protect the wetland from litter and debris. The decision of whether a GPT is required or not, depends on the presence of upstream GPT measures and catchment size. The relevant local authority should be

consulted to determine if a GPT is required.

Figure SC6.4.3.9.27 Inlet zone bypassing major design flows around wetland.

(f) Macrophyte zone design considerations

The layout of the macrophyte zone needs to be configured such that system hydraulic efficiency is optimised and healthy vegetation sustained. Design considerations include:

(i) the preferred extended detention depth is 0.5 m. Deeper extended detention depths, up to a maximum of 0.75 m, may be acceptable where the wetland has a high hydrologic effectiveness and where the botanic design uses plant species tolerant to greater depths of inundation;

(ii) the longitudinal bathymetry of the macrophyte zone should grade (min 0.5% grade) smoothly from 0.7 m in depth (based on design normal water level) up to a central crest 0.5 m in depth and then back down to a maximum of 0.7 m in depth. This ensures that isolated pools of water are not created within the macrophyte zone during the dry season when the normal water level slowly draws down due to evapotranspiration;

(iii) the macrophyte zone is to have a flat cross sectional bathymetry only grading up at the edge batters. This facilitates the even distribution of flows to avoid short circuiting, creates a uniform hydraulic conveyance and maximises stormwater contact with macrophyte stems and biofilms;

(iv) the bathymetry of the macrophyte zone should be designed so that the macrophyte zone is connected to deeper open water pools (located at the inlet and outlet of the macrophyte zone) to allow mosquito predators to seek refuge in the deeper open water zones during periods of extended dry weather;

(v) the deep open water pools should be 2 m in depth to ensure that a permanent pool of water is sustained throughout the dry season. This ensures habitat is retained for fish, macroinvertebrates (mosquito predators) and submerged macrophytes;

(vi) the surface area of deep refuge pools (excluding the sediment basin) within the wetland should be between 20% and 30% of the total macrophyte area;

(vii) the constructed wetland is required to retain water permanently and therefore the base must be of suitable material to retain water (e.g. clay). If in-situ soils are unsuitable for water retention, a clay liner (e.g. compacted 300 mm thick) must be used to ensure there will be permanent water for vegetation and habitat;

(viii) particular attention should be given to the placement of the inlet and outlet structures, the length to width ratio of the macrophyte zone and flow control features to promote a high hydraulic efficiency within the macrophyte zone;

(ix) dense littoral vegetation around the perimeter of the wetland is required to avoid the ingress of weed species. To maintain dense perennial littoral vegetation, irrigation is likely to be required, particularly during the dry season. During extended dry periods (e.g. in excess of 60 days) wetland macrophytes may also require irrigation to sustain dense foliage and prevent habitat opportunities for weed species;

(x) provision to drain the macrophyte zone for water level management during the plant establishment phase should also be considered; and

(xi) the macrophyte zone outlet structure needs to be designed to provide a notional detention time (usually48 hours) for a wide range of flow depths. The outlet structure should also include measures to exclude debris to prevent clogging.

(g) Wetlands constructed within retention (or detention) basins

In many urban applications, wetlands can be constructed in the base of retention basins, thus reducing the land required for stormwater treatment. In these situations, wetland systems will occasionally become inundated to greater depths than the extended detention depth; however, the inundation duration is usually relatively short (hours) and is unlikely to affect the wetland vegetation provided there is a safe pathway to drain the wetland following flood events which avoids scour of the wetland vegetation and banks.

When designing a wetland within a retention basin, the outlet control structure of the retention basin (typically culverts) should be placed at the end of the wetland bypass channel. This ensures flood flows "backwater" across the wetland thus protecting the macrophyte vegetation from scour by high velocity flows.

(h) Vegetation types

Vegetation planted in the macrophyte zone has an important functional role in treating stormwater flows, as well as adding aesthetic value. A dense cover of perennial emergent macrophytes is essential for both stormwater treatment function and for the control of weeds. It is necessary for the macrophytes to permanently occupy the wetland habitat to limit weed colonisation opportunities. Dense perennial littoral vegetation is also important to avoid the ingress of weed species into the wetland macrophyte zone. Dense planting of the littoral zone will inhibit public access to the macrophyte zone, minimising potential damage to wetland plants and reducing the safety risks posed by water bodies.

The reader is referred to SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics for a list of suggested plant species suitable for constructed wetland systems in the coastal dry tropics. The planting densities recommended in the list should ensure that 70 - 80% cover is achieved within two growing seasons (2 years). The distribution of the species within the wetland will relate to their structure, function, relationship and compatibility with other species. The plant species in SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics are listed in accordance with the wetland zone/water depth in which they should be planted. The wetland zones are: deep marsh, shallow marsh (wetland edge), lower littoral and upper littoral.

(i) Designing to avoid mosquitoes

To reduce the risk of high numbers of mosquitoes, there are a number of design features that can be considered. Not all of these will be feasible in any one situation, but they include:

(i) providing access for mosquito predators, such as fish and predatory insects, to all parts of the water body (avoid stagnant isolated areas of water);

(ii) providing a deep permanent pool (for long dry periods or for when water levels are artificially lowered) so that mosquito predators can seek refuge and maintain a presence in the wetland;

(iii) where possible, incorporating a steep slope into the water, preferably greater than 300 or 3:1 horizontal to vertical. Note that steep edges may be unacceptable for public safety reasons, and a slope of up to 8:1 horizontal to vertical is generally used;

(iv) wave action from wind over open water will discourage mosquito egg laying and disrupt the ability of larvae to breathe;

(v) providing a bathymetry such that water draws down evenly so isolated pools are avoided;

(vi) providing sufficient gross pollutant control at the inlet such that human derived litter does not accumulate and provide breeding habitat;

(vii) providing ready access for field operators to monitor and treat mosquito larvae if required;

(viii) ensuring maintenance procedures do not result in wheel rut and other localised depressions that create isolated pools when water levels fall; and

(ix) ensuring overflow channels don't have depressions that will hold water after a storm event.

(j) Designing for maintenance access

Access to all areas of a constructed wetland is required for maintenance. In particular inlet zones and

gross pollutant traps require a track suitable for heavy machinery for removal of debris and desilting as well as an area for dewatering removed sediments. If sediment removal requires earthmoving equipment to enter the basin, then a stable ramp suitable for heavy plant will be required into the base of the inlet zone (maximum slope 1:10).

To aid maintenance, it is recommended that the inlet zone is constructed with a hard (i.e. rock) bottom. This is important if maintenance is performed by driving into the basin. It also serves an important role by allowing excavator operators to detect when they have reached the base of the inlet zone during desilting operations.

Macrophyte zones require access to the areas for weeding and replanting as well as regular inspections. Commonly, these access tracks can be incorporated with walking paths around a wetland system. Maintenance access to constructed wetland needs to be considered when determining the layout of a wetland system.

(3) Technical note: saline/brackish constructed wetlands

Urban communities in the dry tropics are often located near large estuarine river systems. In some locations it may be useful to have an optional estuarine stormwater treatment system. While estuarine systems are typically lower nutrient environments than freshwater stormwater treatment systems, a modified salt marsh community would still have considerable nutrient processing capability and could potentially provide a stormwater treatment capacity in some locations. This is a new concept that has not yet been tested and therefore should only be considered if other design solutions are not possible or practical.

If an estuarine stormwater treatment system was to be trialled/ constructed as a demonstration project, it is recommended that the model would need to consider the following list of features/design elements:

(a) drain a large stormwater runoff event over several tidal cycles;

(b) during a runoff event, extended detention depth should not exceed 0.5 m, but preferably be lower;

(c) the wetland should consist of a series of cells that would progressively fill and spill during a runoff event;

(d) the initial cell would be a sedimentation pond;

(e) surrounding the sedimentation pond and throughout the subsequent cells would support salt marsh communities (ranging from herbaceous to woody);

(f) a dry weather drainage system would allow complete drainage over a single tide cycle;

(g) the wetland would be drained by a series of runnels that would be capable of completely draining the system on a low tide sequence, thus managing potential mosquito breeding habitat;

(h) high tides (exceeding mean high tide) would be allowed to penetrate the entire system;

(i) a salinity gradient would be maintained through the system for most seasons;

(j) a series of berms and chokes would be included to ensure cells progressively fill and spill and that a salinity gradient is created and maintained;

(k) in high tidal range environments particular care will be needed in the design of the hydraulic connection between the perched salt marsh treatment system and the larger and deeper estuarine drainage channels (these environments are highly susceptible to erosion particularly after catchment development); and

(l) an important element in a estuarine system will be the wetting and drying sequence in that this will heighten the capacity to process nitrogen pollutants which are critical pollutants to near shore marine ecosystems.

The illustrations on the following page (Figure SC6.4.3.9.28 Possible design features of saline/brackish constructed wetlands), demonstrate how a saline/brackish wetland may be configured to achieve the above design criteria.

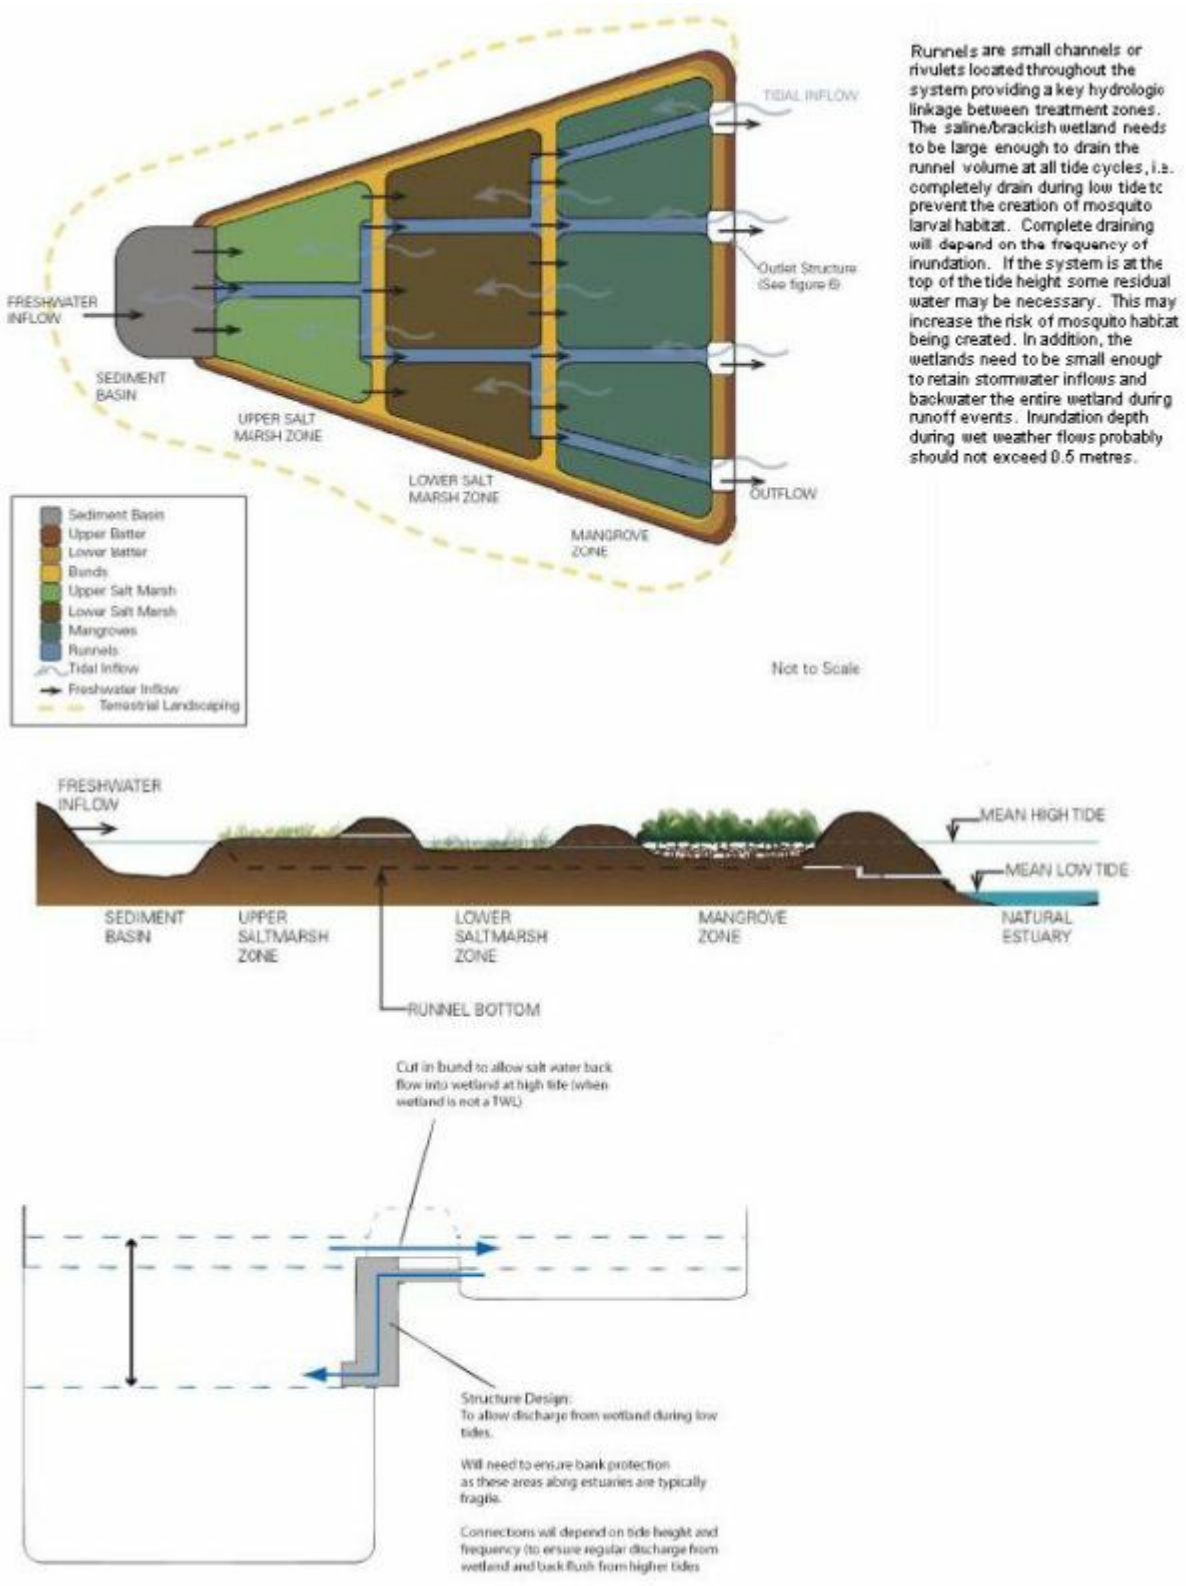

Figure SC6.4.3.9.28 Possible design features of saline/brackish constructed wetlands

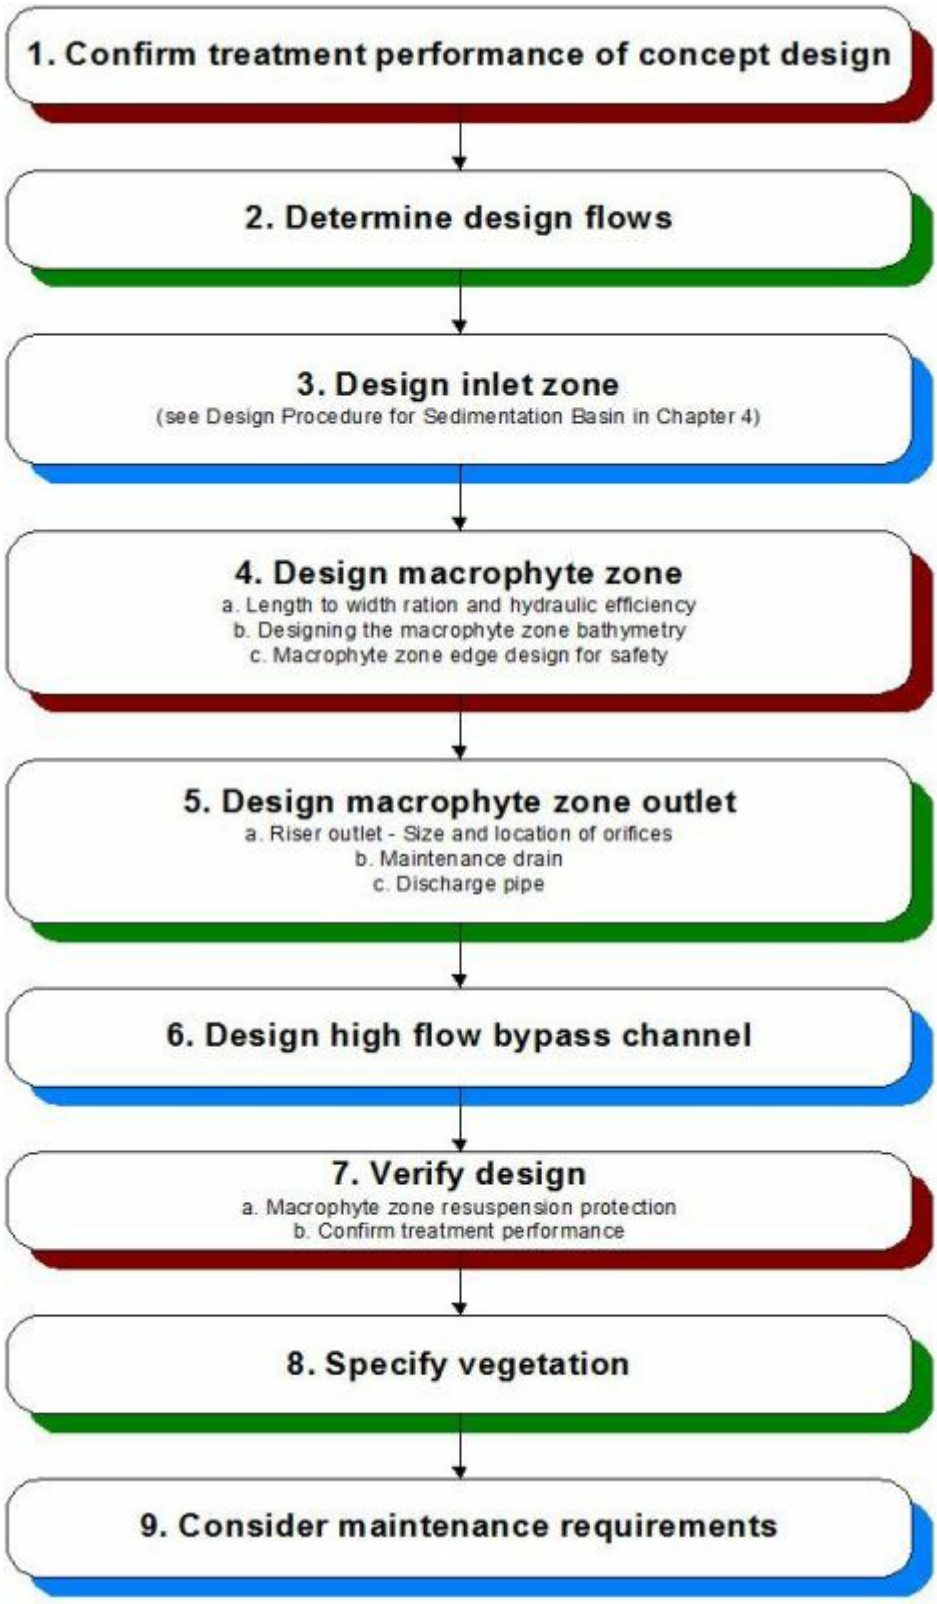
(4) Wetland design process

The key design steps following the site planning and concept development stages are:



(a) Step 1: Confirm treatment performance of concept design

Before commencing detailed design, the designer should first undertake a preliminary check to confirm the constructed wetland area (i.e. the macrophyte zone surface area) from the concept design is adequate to deliver the required level of stormwater quality improvement. This assessment should be undertaken by a WSUD specialist and can be achieved by modelling expected treatment performance in

an appropriate quantitative modelling program. Where possible, this modelling should be based on local rainfall data, the proposed configuration of the system, and based on local stormwater treatment performance data.

(b) Step 2: Determine design flows

(i) Design discharges

To configure the inlet zone and high flow bypass elements of a constructed wetland the following design flows apply:

(A) design operation flow (1 year ARI) for sizing the inlet zone (i.e. sedimentation basin) and the "control" outlet structure (i.e. overflow pit and pipe connection) discharging to macrophyte zone; and

(B) above design flow for design of the high flow bypass around the macrophyte zone. The discharge capacity for the bypass system may vary depending on the particular situation but will typically correspond to one of the following:

- minor design flow (2 year ARI) – for situations where only the minor drainage system is directed to the inlet zone; and
- major flood flow (100 year ARI) – for situations where both the minor and major drainage system discharge into the inlet zone.

(ii) Design flow estimation

A range of hydrologic methods can be applied to estimate design flows. If the typical catchment areas are relatively small, the Rational Method design procedure is considered to be a suitable method for estimating design flows. However, if the constructed wetland is to form part of a retention basin (refer to SC6.4.3.9.5(2)(g) Wetlands constructed within retention (or detention) basins) or if the catchment area to the wetland is large (> 50 ha), then a full flood routing computation method needs to be used to estimate design flows.

(c) Step 3: Design inlet zone

As outlined in SC6.4.3.9.5(2)(e) Inlet zone design considerations, the inlet zone (see example in Figure SC6.4.3.9.29 Inlet zone of a constructed wetland in Brisbane) of a constructed stormwater wetland is designed as a sedimentation basin and serves two functions: (1) pretreatment of inflow to remove coarse to medium sized sediment; and (2) the hydrologic control of inflows into the macrophyte zone and bypass of floods during "above design" operating conditions. As depicted in Figure SC6.4.3.9.30 Example of inlet zone connection to macrophyte, the inlet zone consists of the following elements:

(i) sedimentation basin "pool" to capture coarse to medium sediment (125µm or larger).

(ii) inlet zone connection to the macrophyte zone (or "control" structure as defined in normally consisting of an overflow pit within the inlet zone connected to one or more pipes through the embankment separating the inlet zone and the macrophyte zone.

(iii) high flow bypass weir (or "spillway" outlet structure to deliver "above design" flood flows to the high flow bypass channel.

Figure SC6.4.3.9.29 Inlet zone of a constructed wetland in Brisbane

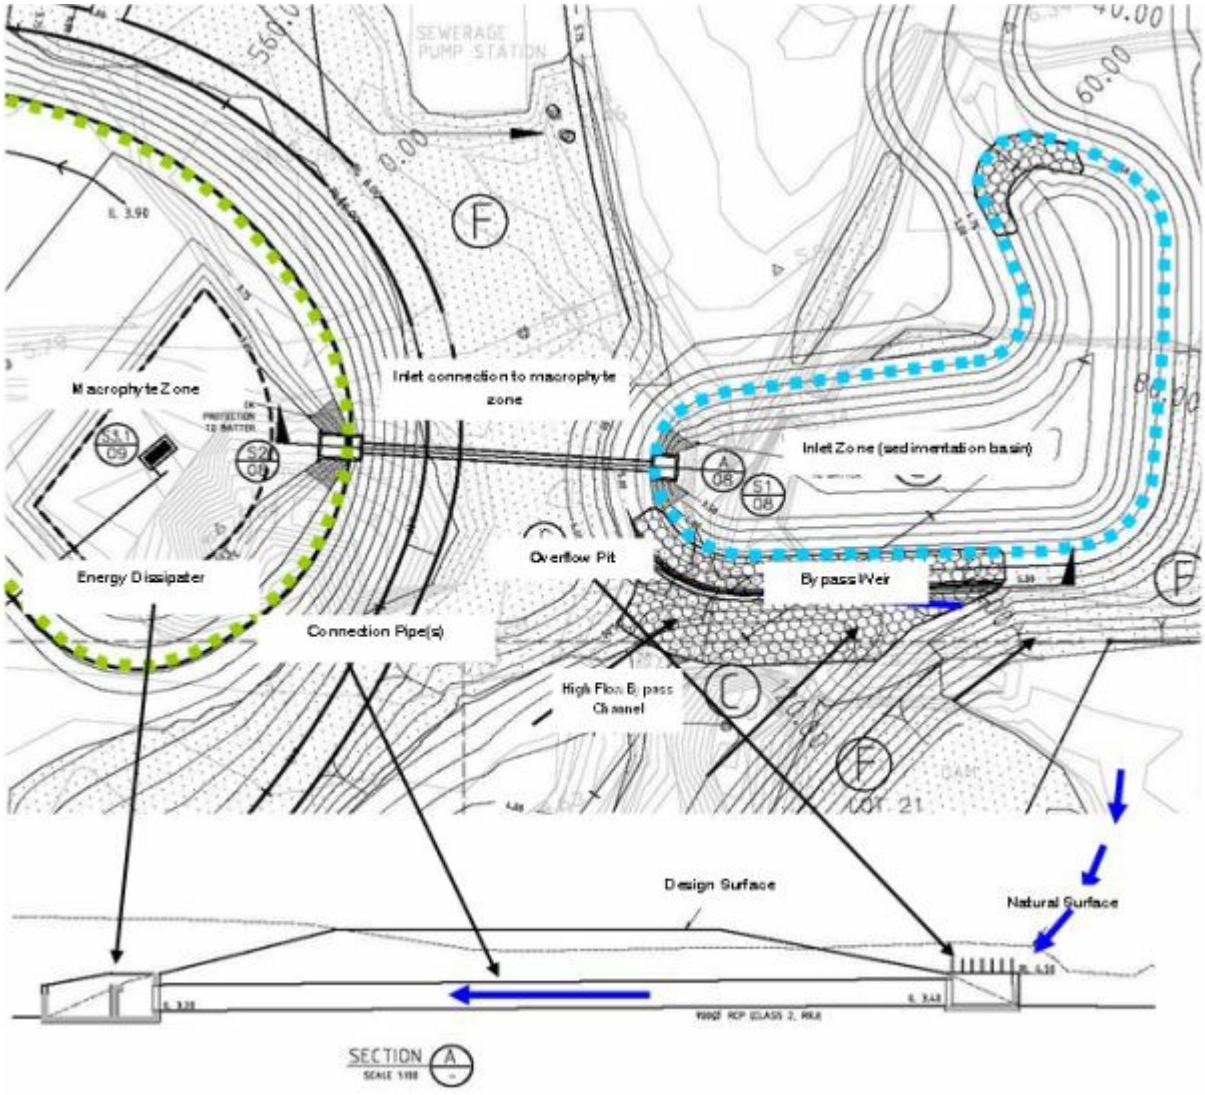


Figure SC6.4.3.9.30 Example of inlet zone connection to macrophyte zone

(iv) For more information and design guidance for each of the inlet zone elements listed above, the reader is referred to Chapter 4 Sedimentation Basins. When applying the design procedure outlined in Chapter 4, the following should be used as a guide:

(A) the inlet zone typically must comprise a deep open water body that operates essentially as a sedimentation basin designed to capture coarse to medium sized sediment (i.e. 125 µm or larger);

(B) it may be necessary for a GPT to be installed such that litter and large debris can be captured at the interface between the incoming waterway (or pipe) and the open water of the inlet zone;

(C) the crest of the overflow pit must be set at the normal water level of the inlet zone (which is typically set 0.3 m above the normal water level of the macrophyte zone);

(D) the pipe that connects the sedimentation basin to the macrophyte zone needs to have sufficient capacity to convey a 1 year ARI flow, assuming the macrophyte zone is at the normal water level and without resulting in any flow over the high flow bypass weir;

(E) the obvert of the connection pipe can be set below the normal water level of the wetland to conceal the pipe (below the normal water level) during the dry season;

(F) an energy dissipater is usually required at the end of the pipes to reduce velocities and distribute flows into the macrophyte zone;

(G) the inlet zone is to have a structural base (e.g. rock) to define the base when desilting and provide support for maintenance plant/ machinery when entering the basin for maintenance; and

(H) the high flow bypass weir ("spillway" outlet) is to be set at the same level as the top of extended detention in the macrophyte zone.

(d) Step 4: Designing the macrophyte zone

(i) Length to width ratio and hydraulic efficiency

To optimise wetland performance, it is important to avoid short circuit flow paths and poorly mixed regions within the macrophyte zone. One way to minimise this is to adopt a high length to width ratio not less than 5 to 1 for the macrophyte zone. Length to width ratios less than this can lead to poor hydrodynamic conditions and reduced water quality treatment performance.

Persson et al. (1999) used the term hydraulic efficiency (λ) to define the expected hydrodynamic characteristics for a range of configurations of stormwater detention systems (Figure SC6.4.3.9.31). Engineers Australia (2006) recommend that constructed wetland systems should not have a hydraulic efficiency (λ) less than 0.5 and preferably should be greater than 0.7.

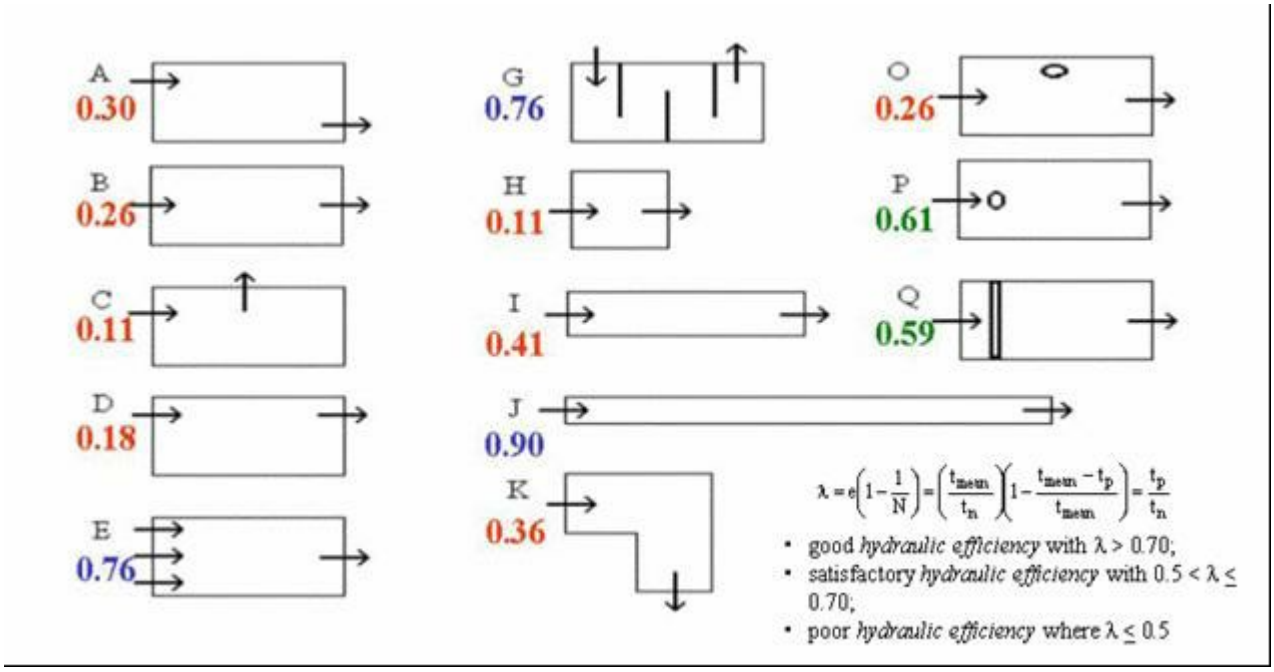

Figure SC6.4.3.9.31 Hydraulic effiency (λ) ranges

Hydraulic efficiency ranges from 0 to 1, with 1 representing the best hydrodynamic conditions for stormwater treatment. The o in diagrams O and P represent islands in the waterbody and the double line in diagram Q represents a weir structure to distribute flows evenly (Persson et al. 1999).

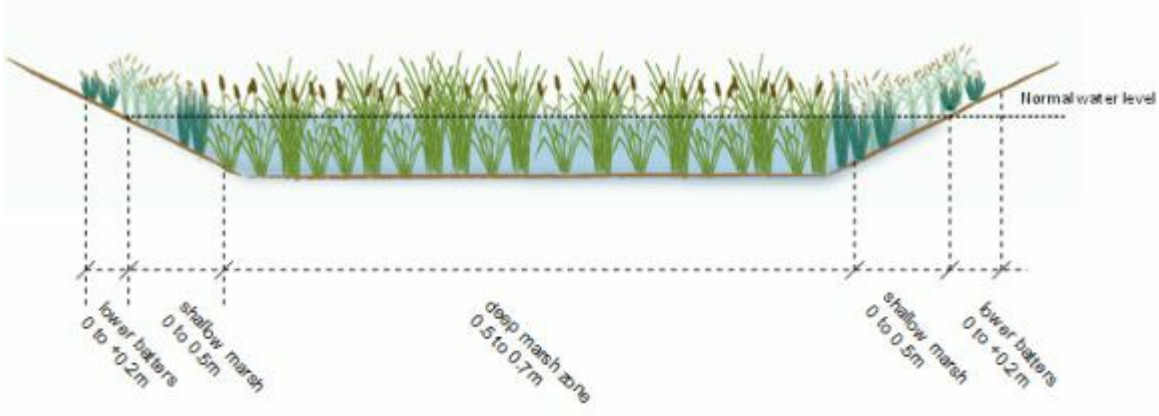
(ii) Designing the macrophyte zone bathymetry

The bathymetry of constructed wetlands in the coastal dry tropics are to be designed to ensure that macrophytes can provide adequate pollutant removal during the wet season and also be sustained during the dry season. To achieve this, the longitudinal bathymetry of the macrophyte zone should gently grade (min 0.5% grade) from 0.7 m in depth (based on design normal water level) up to a central crest 0.5 m in depth and then back down to a maximum of 0.7 m in depth. This ensures that isolated pools of water are not created during the dry season when the normal water level slowly draws down due to evapotranspiration. Smaller deep open water permanent pools at the inlet and outlet of the wetland are required to provide habitat for mosquito predators during the dry season (Refer to Figure SC6.4.3.9.23 Schematic layout of a contructed wetland system and Figure SC6.4.3.9.24 Wet and dry season conditions in a constrcted freshwater wetland). For large wetlands, this bathymetry could be repeated in series (i.e. a deep pool located between two macrophyte zones).

The macrophyte zone is to have a flat cross sectional bathymetry only grading up at the edge

batters (Figure SC6.4.3.9.32). This facilitates the even distribution of flows to avoid short circuiting, creates a uniform hydraulic conveyance and maximises stormwater contact with macrophyte stems and biofilms. This is also assisted by providing banded macrophyte planting perpendicular to the direction of flow (Figure SC6.4.3.9.33).

The deep open water pools should be 2 m in depth to ensure that a permanent pool of water is sustained throughout the dry season. This ensures habitat is retained for fish, macroinvertebrates (mosquito predators) and submerged macrophytes. Submerged macrophytes are important to provide habitat and for maintaining dissolved oxygen levels and therefore deeper pools (i.e. >2 m) should be avoided. A balance pipe connection between the deep pools is necessary to allow inflows in dry conditions to benefit and sustain the deep permanent pools. The surface area of deep refuge pool (excluding the sediment basin) within the wetland should be between 20% and 30% of the total macrophyte area. This ensures the volume of water within the pools is sufficient to maintain permanent water during the dry season but not so large that the macrophyte zone is likely to experience dry periods of greater than 60 days (due to larger inflows required to fill the pools before wetting the macrophyte zone).



Note—refer to SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics for more detail on planting zones and suitable macrophyte species.

Figure SC6.4.3.9.32 Typical cross section of a constructed wetland system showing preferred bathymetry and planting zones.

Figure SC6.4.3.9.33 Macrophyte zone banded planting (direction of flow is from left to right)

(iii) Macrophyte zone edge design for safety

Consideration of public safety is required when wetlands are located in parklands/public open space or any areas readily accessible. Reducing public safety risk can be achieved in a number of ways and the measures adopted should respond to the level of perceived risk given the particular

site characteristics.

One method of reducing the risk posed by water bodies is to design batter slopes on approaches and immediately under the normal water level (refer Figure SC6.4.3.9.34). It is recommended that a gentle slope to the water edge and extending below the water line be adopted before the batter slope steepens into deeper areas.

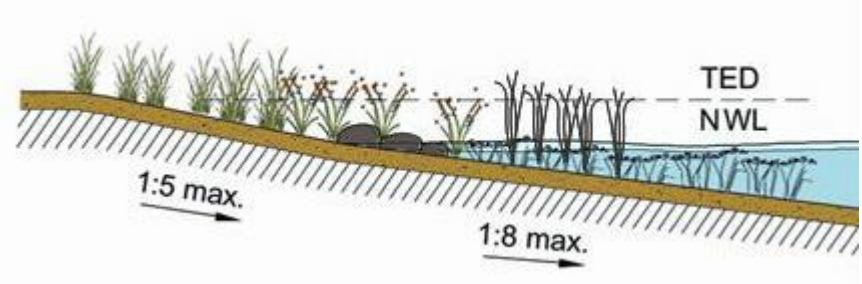


Figure SC6.4.3.9.34 Example of a wetland edge design for public safety

The safety requirements for individual wetlands will vary from site to site and requires careful consideration. The following requirements from the *Sediment Basin Design, Construction and Maintenance Guidelines* (BCC 2001) can be applied to constructed wetland systems:

- for water depths greater than 150 mm and maximum batter slope of 5:1 (H:V) or less, no fencing is required; and
- for water depths greater than 150 mm and maximum batter slope greater than 5:1 (H:V) fencing may be required.

In some cases, vertical edges are used for wetlands (refer to SC6.4.3.9.5(5) Landscape design notes). When vertical edges are used, a safety fencing/ barrier should be considered on top of concrete or stone walls where:

(A) there is a risk of serious injury in the event of a fall (over 0.5 m high and too steep to comfortably walk up/down or the lower surface has sharp or jagged edges);

(B) there is a high pedestrian or vehicular exposure (on footpaths, near bikeways, near playing/ sporting fields, near swings and playgrounds);

(C) where water ponds to a depth of greater than 300 mm on a constructed surface of concrete or stone;

(D) where the water is expected to contain concentrated pollutants; and

(E) where mowed grassed areas abut the asset.

The type of fence/ barrier to be considered should be a:

- dense vegetation at least 2 m wide and 1.2 m high (minimum) may be suitable; or
- pool fence (or similar) when there is a chance of drowning and the surrounding area is specifically intended for use by small children (swings, playgrounds, sporting fields etc.).

(iv) Macrophyte zone soil testing

Constructed wetlands are permanent water bodies and therefore the soils in the base must be capable of retaining water. Geotechnical investigations of the suitability of the in-situ soils are required to establish the water holding capacity of the soils. Where the infiltration rates are too high for permanent water retention, tilling and compaction of in-situ soils may be sufficient to create a suitable base for the wetland. Where in- situ soils are unsuitable for water retention, a compacted clay liner may be required (e.g. 300 mm thick). Specialist geotechnical testing and advice must be sought.

Wetland plants must be planted into suitable topsoil with a minimum depth of 200 mm (see SC6.4.3.9.5(6)(d) Topsoil specification and preparation). Most terrestrial topsoils provide a good substratum for wetlands, nonetheless laboratory soil testing (using Australian Standard testing procedures, e.g. AS 4419-2003: Soils for landscaping and garden use) of topsoil is necessary to ensure the topsoil will support plant and microbial growth and have a high potential for nutrient retention. Careful consideration should be given to the topsoil source and its propensity to contain weed seeds which may be viable in an ephemeral wetland habitat.

(e) Step 5: Design macrophyte zone outlet

A macrophyte zone outlet has two purposes: (1) hydrologic control of the water level and flows in the macrophyte zone to achieve the design detention time; and (2) to allow the wetland permanent pool to be drained for maintenance.

(i) Riser outlet – size and location of orifices

The riser outlet is designed to provide a uniform notional detention time in the macrophyte zone over the full range of the extended detention depths. The target maximum discharge ($Q_{max\ riser}$) may be computed as the ratio of the volume of the extended detention to the notional detention time as follows

$$Q_{max\ riser} = \frac{\text{extended detention storage volume } (m^3)}{\text{notional detention time (s)}}$$

The placement of orifices along the riser and determining their appropriate diameters is an iterative process. The orifice equation (Equation 6.2) is applied over discrete depths along the length of the riser starting at the normal water level and extending up to the riser maximum extended detention depth.

$$A_o = \frac{Q}{C_d\sqrt{2 \cdot g \cdot h}} \qquad \text{(Small orifice equation)}$$

Where

C_d	=	orifice discharge coefficient (0.67)
h	=	depth of water above the centroid of the orifice (m)
A_o	=	orifice area (m^2)
Q	=	required flow rate to achieve notional detention time (m^3/s) at the *given h*
g	=	9.79 m/s^2

As the outlet orifices can be expected to be small, it is important that they are prevented from clogging by debris. Some form of debris guard is recommended as illustrated in Figure SC6.4.3.9.35 below. An alternative to using a debris guard is to install a riser in a pit located in the embankment surrounding the wetland macrophyte zone (thus reducing any visual impact). A riser within the pit can also be configured with a weir plate (by drilling holes through the plate). An advantage of using a weir plate is that it provides an ability to drain the wetland simply by removing the weir plate entirely. Additionally, shorter weir plates may also be used during the vegetation establishment phase, thus providing more flexibility for water level manipulation.

Figure SC6.4.3.9.35 Example outlet riser assemblies with debris guards

The pit is connected to the deep pool of the macrophyte zone via a submerged pipe culvert. The connection should be adequately sized such that there is minimal water level difference between the water within the pit and the water level in the macrophyte zone. With the water entering into the outlet pit being drawn from below the normal water level (i.e. pipe obvert a minimum 0.3 m below normal water level), floating debris is generally prevented from entering the outlet pit, while heavier debris would normally settle onto the bottom of the wetland. The riser pipe should be

mounted upright on a socketed and flanged tee with the top of the pipe left open to allow overtopping of waters if any of the riser orifices become blocked. Figure SC6.4.3.9.36 and Figure SC6.4.3.9.37 show one possible configuration for a riser outlet pit.

Figure SC6.4.3.9.36 Macrophyte zone outlet arrangement

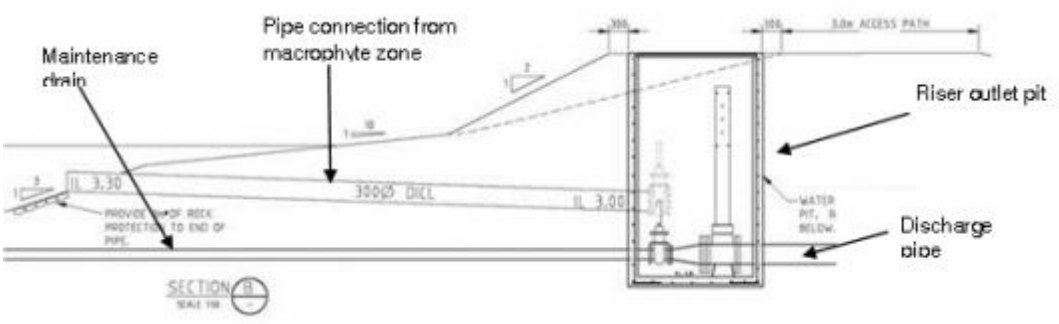

Figure SC6.4.3.9.37 Typical macrophyte zone outlet arrangement

(ii) Maintenance drains

To allow access for maintenance, the wetland should have appropriate allowance for draining. A maintenance drainage pipe should be provided that connects the low points in the macrophyte zone bathymetry to the macrophyte zone outlet. A valve is provided on the maintenance drainage pipe (typically located in the outlet pit as shown in Figure SC6.4.3.9.37), which can be operated manually. The maintenance drainage pipe should be sized to draw down the permanent pool within 12 hours (i.e. overnight). If a weir plate is used as a riser outlet, provision should be made to remove the weir plate and allow drainage for maintenance.

(iii) Discharge pipe

The discharge pipe of the wetland conveys the outflow of the macrophyte zone to the receiving waters (or existing drainage infrastructure). The conveyance capacity of the discharge pipe is to be sized to match the higher of the two discharges (i.e. maximum discharge from the riser or the maximum discharge from the maintenance drain).

(iv) Balance pipe

A balance pipe connection between the deep permanent pools in the wetland is necessary to allow inflows in dry conditions to benefit and sustain all deep pools rather than just the pool located at the inlet. The deep pools are generally 2 m in depth and may experience up to 1m of draw down during the dry season. The invert of the balance pipe should therefore be located approximately 1 m below the normal water level. A 300 mm diameter pipe is typically sufficient for a balance pipe.

(f) Step 6: Design high flow bypass channel

The bypass channel accepts “above design flow” from the inlet zone (sediment pond) of the wetland via the bypass weir (SC6.4.3.9.5(4)(c)) and conveys these flows downstream around the macrophyte zone of the wetland. The bypass channel should be designed using standard methods (i.e. Manning’s Equation) to convey the “above design flow” (SC6.4.3.9.5(4)(b)) and to avoid bed and bank erosion (see Chapter 2). Typically, a turf finish will provide appropriate protection for most bypass channel applications (but velocities need to be checked). Dense planting can be applied when appropriately designed for in terms of design roughness and management of velocities. Figure SC6.4.3.9.38 shows typical high flow bypass channel configurations.

Figure SC6.4.3.9.38 Turfed constructed wetland high flow bypass weir configuration.

(g) Step 7: Verify design

(i) Macrophyte zone resuspension protection

The principle pathway for biological uptake of soluble nutrients in wetlands is through biofilms (epiphytes) attached to the surface of the macrophyte vegetation. The biofilms, being mostly algae and bacteria, are susceptible to wash out under high flow conditions. Further, wetland surveys indicate that up to 90% of the total nutrients are stored in the sediments, therefore, the key to effective retention of pollutants is managing high velocity flows that could potentially resuspend and remobilise these stored pollutants.

A velocity check is to be conducted for design conditions, when the wetland water level is at the top of the extended detention level and the riser is operating at design capacity, to ensure velocities are less than 0.05 m/s through all zones of the wetland. The following condition must be met:

$$\frac{Q_{max\ riser}}{A_{section}} < 0.05 m/s$$

Where $Q_{max\ riser}$ = target maximum discharge (defined in Equation 6.1) (m^3/s)

Asection = minimum wetland cross-section area* (m^2) x 0.5 vegetation blockage factor**

*measured from top of extended detention

**blockage due to tall dense vegetation

(ii) Confirm treatment performance

If the basic wetland parameters established by the conceptual design phase have changed during the course of undertaking detailed design (e.g. macrophyte zone area, extended detention depth, etc.) then the designer should verify that the current design meets the required water quality improvement performance. This can be done by simulating the current design using a suitable quantitative modelling program.

(h) Step 8: Specify vegetation

Refer to SC6.4.3.9.5(5) Landscape design notes and SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics for advice on selecting suitable plant species for constructed wetlands.

(i) Step 9: Consider maintenance requirements

Consider how maintenance is to be performed on the wetland (e.g. how and where is access available, where is litter likely to collect etc.). A specific maintenance plan and schedule should be developed for the wetland, either as part of a maintenance plan for the whole treatment train, or for each individual asset. Guidance on maintenance plans is provided in SC6.4.3.9.5(7) Maintenance requirements - constructed wetlands.

(j) Design calculation summary

Following is Table SC6.4.3.9.16 Constructed wetlands design calculation summary, for the key design elements.

Click here to view **Table SC6.4.3.9.16 Constructed wetlands design calculation summary**

(5) Landscape design notes - constructed wetlands

Whilst constructed wetlands play a significant role in delivering stormwater quality objectives, they can also play an important role in creating a community landscapes and urban ecology. The following sections outline some of the landscape design issues that should be considered when designing constructed wetland systems.

(a) Objectives

Landscape design of wetlands generally requires consideration of the following objectives:

(i) integrated planning and design of constructed wetlands within the built and landscape environments ensuring that the overall landscape design for the wetland integrates with its host natural and/ or built environment;

(ii) achieving dense perennial littoral vegetation around the perimeter of the wetland to avoid the ingress of weed species. To maintain dense perennial littoral vegetation, irrigation is likely to be required, particularly during the dry season;

(iii) ensuring that the wetland planting strategy is based on the wetland design depths/zones, achieves dense perennial emergent macrophyte cover and has the structural characteristics to perform particular treatment processes (e.g. well distributed flows, enhance sedimentation, maximise surface area for the adhesion of particles and provide a substratum for algal epiphytes and biofilms);

(iv) providing maintenance access to allow for the prompt removal of weeds before they spread and/or set seed;

(v) incorporating crime prevention through environmental design (CPTED) principles; and

(vi) providing other landscape values, such as shade, amenity, character and place making.

Comprehensive site analysis should inform the landscape design as well as road layouts, maintenance access points and civil works. Existing site factors such as roads, buildings, landforms, soils, plants, microclimates, services and views should be considered. For further guidance refer to the *South East Queensland WSUD Conceptual Design Guidelines* (Healthy Waterways Partnership, 2008).

(b) Wetland siting and shapes

Constructed wetlands need to be arranged to meet hydrological and stormwater quality requirements, but also to integrate effectively into the surrounding existing landscape. The arrangement of wetland, basin and high flow bypass should be designed early in the concept design phase, to ensure that amenity of open space is enhanced.

The final shape of a wetland should provide landscape opportunities to create alternate useable spaces/recreation areas (see Figure SC6.4.3.9.39). Often different shapes to wetland edges can make pathway connections through and around these recreation areas more convenient and enhances the community perception of constructed wetlands. Pathways and bridges across planted earth bunds can be the best way of getting across or around wetlands (see Figure SC6.4.3.9.40). The materials on the bridge and pathways are important to be low maintenance and do not impede hydrological flows. Ease of access to the inlet basin for sediment and trash removal is also important to consider.

The area required for the high flow bypass can be manipulated to provide open spaces that only periodically convey stormwater flows. Further discussion of high flow bypass configuration is provided in SC6.4.3.9.5(5)(c)(iii) High flow bypass channel.

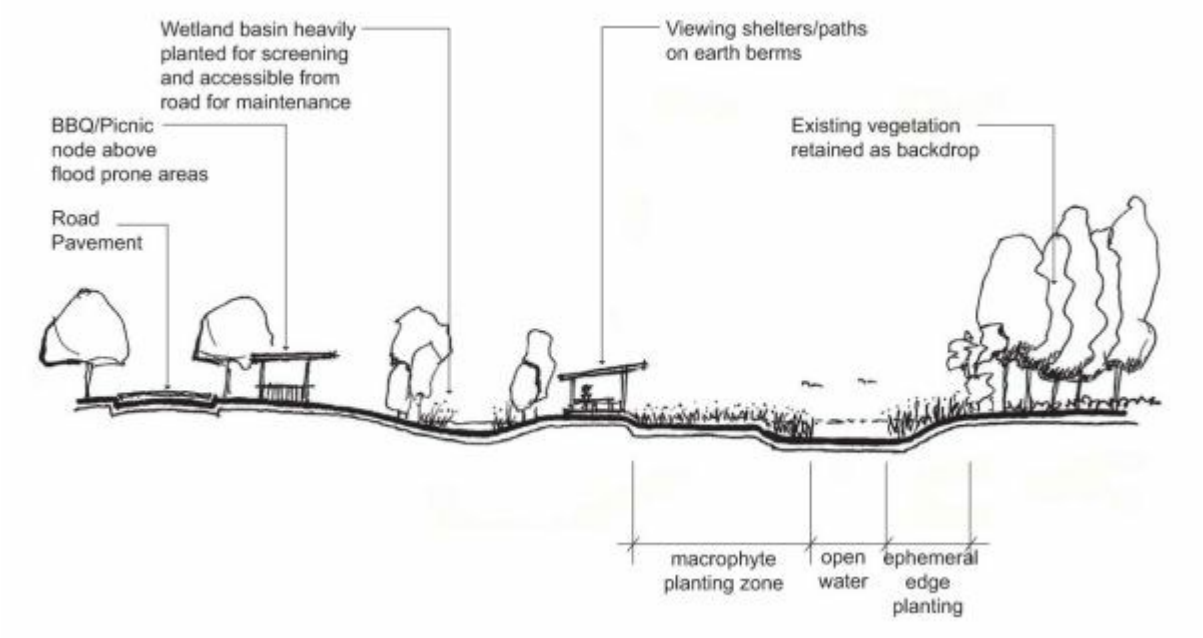

Figure SC6.4.3.9.39 Typical landscape treatments to constructed wetlands in open space areas

Figure SC6.4.3.9.40 Boardwalk treatment over wetland (left) and integration of urban art with wetland setting (right)

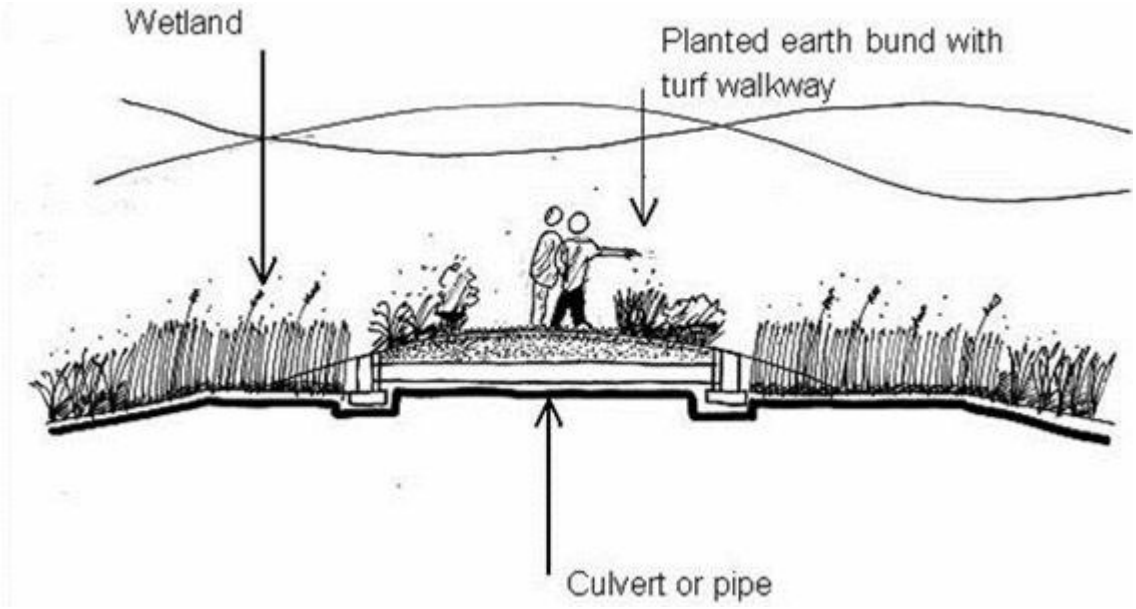

Figure SC6.4.3.9.41 Earth bund structure as wetland crossing

(c) Specific landscape considerations

Numerous opportunities are available for creative design solutions for specific elements. Close collaboration between landscape designer, hydraulic designer, civil/structural engineer and maintenance personnel is essential. In parklands and residential areas, the aim is to ensure elements are sympathetic to their surroundings and are not overly engineered or industrial in style and appearance. Additionally, landscape design to specific elements should aim to create places that local residents and visitors will come to enjoy and regard as an asset.

(i) Crossings

Given the size and location of wetland systems, it is important to consider if access is required across the wetland as part of an overall pathway network and maintenance requirement. Factors that should be considered include:

(A) the appropriateness of hardwood timber board walks given their life-cycle costs. Where walkway footings are in contact with water, council will not accept timber piers;

(B) if boardwalks are used, they should not be located near open water where they could encourage the public to feed wildlife; and

(C) earth bunds located between the sedimentation basin and macrophyte zone can be used as crossings and can be planted as a shaded walkways.

Figure SC6.4.3.9.41 illustrates a conceptual earth bund walkway.

(ii) Wetland embankments

The landscape design approach for the wetland embankments is similar to the approach taken for embankments in sedimentation basins.

(iii) High flow bypass channel

The high flow bypass channel will convey stormwater during above design flow and in some situations can form a large element in the landscape. Therefore the design of the high flow bypass needs to be carefully considered to provide recreational and landscape opportunities during times outside of above design flow events.

The key considerations for design of the high flow bypass area are as follows:

(A) no major park infrastructure including playgrounds, barbeques and amenity buildings to be located within the high flow bypass areas. Passive recreation infrastructure including seating and picnic tables are suitable provided they are of robust design;

(B) in many cases, the high flow bypass will be formed through the use of turf and in these cases the opportunity for creating more active spaces should be investigated;

(C) designers should investigate the opportunities for locating trees and other vegetation types within the bypass channel. Provided hydraulic efficiencies can be accommodated, grassed mounds and landform;

(D) grading of the embankment edge could also be explored to add variation and interest;

(E) where groundcover species other than turf are adopted, plant species should be selected to ensure appropriate response after periodic flooding;

(F) areas of large revegetation or garden beds that cut through the high flow bypass zone should use thick matting mulch types that bind well to the surface to minimise loss; and

(G) the relationship between the high flow bypass channel and the permanent water bodies should be considered in order to create interesting spaces and forms within the open space. For example, after consideration of site constraints and hydraulic parameters, designers could investigate options to separate the elements from each other or to channel both elements alongside each other. Opportunities should also be sought to achieve balanced cut and fill earthworks. Figure SC6.4.3.9.42 provides an illustration of creation of open spaces through configuration of key wetland components.

(iv) Macrophyte zone outlet structure

Landscape design approach for the macrophyte outlet zone is similar to the approach taken for overflow pits in sedimentation basins. Refer to Chapter 4, Section 4.4.3.6 for further guidance.

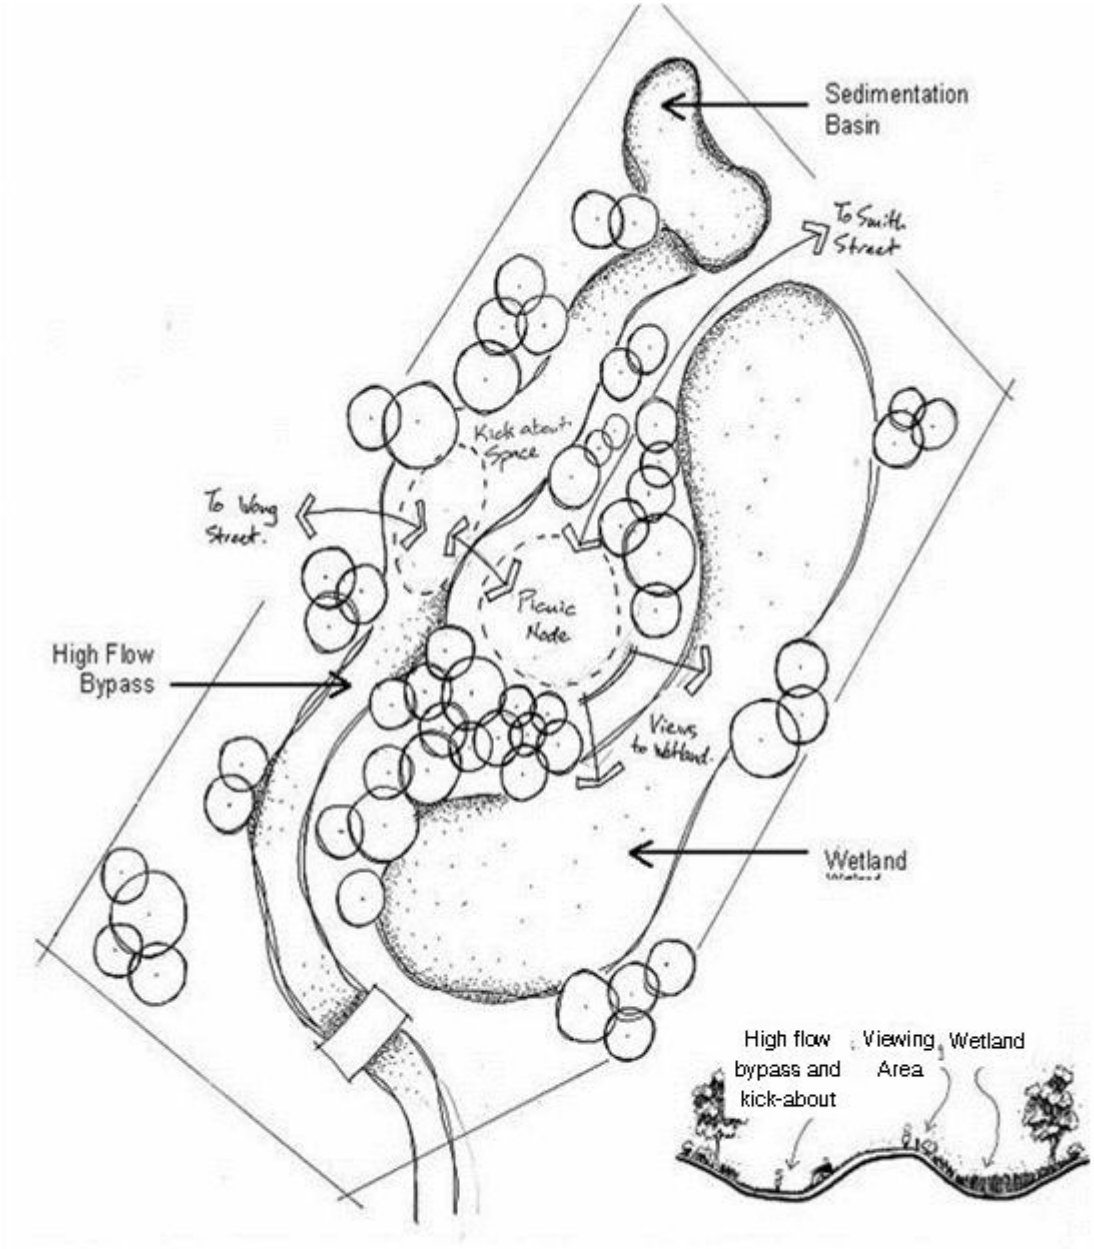
(v) Viewing areas

Refer to Chapter 4, Section 4.4.3.8 for guidance.

(vi) Fencing

Refer to Chapter 4, Section 4.4.3.9 for guidance.

Editor's note—these Chapter and Section references are to *Water Sensitive Urban Design Guidelines for South East Queensland*.



Landscape design should explore options for siting the bypass, wetland and basin and analyse the potential for enhanced amenity. This process should initially take place at the concept development phase and can be refined during the detailed design.

Figure SC6.4.3.9.42 Example relationship between high flow bypass wetland and basin and the creation of open space

(d) Constructed wetland vegetation

Planting for constructed wetlands systems may consist of up to three vegetation types:

(i) Macrophyte zone planting consisting of deep marsh (0.5 m – 0.7 m in depth at design normal water level) and shallow marsh (edges) (0.5 m – 0 m in depth at design normal water level);

Macrophyte zone planting (from 1.0 m below to 0.2 m above design water level)

SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics provides guidance on selecting suitable plant species and cultivars that deliver the desired stormwater quality objectives for constructed wetlands. Often the most effective way to meet those objectives with the macrophyte planting is to create large bands of planting perpendicular to flow that respond to designed depth zones and local biodiversity.

In general, macrophyte vegetation should provide:

(A) well distributed flows;

(B) enhanced sedimentation;

(C) maximum surface area for the adhesion of particles;

(D) a substratum for algal epiphytes and biofilms; and

(E) habitat and refuge for fauna, both terrestrial and aquatic.

This is achieved by selecting species with many small diameter vertical leaves or stems and planting the vegetation in bands. When selecting suitable species it is important to also note the ability of some species to be highly self-sustaining. Littoral planting should provide a dense buffer between the wetland and publicly accessible open space to discourage contact with the water.

(ii) Littoral vegetation (embankment) (above design normal water level) and parkland vegetation

Between the macrophyte zone and the top of the embankment, establishment of trees, shrubs and groundcovers can occur in consideration of the following:

(A) selecting groundcovers, particularly for slopes greater than 1 in 3, with matting or rhizomatous root systems to assist in binding the soil surface during the establishment phase;

(B) achieving dense perennial littoral vegetation around the perimeter of the wetland to avoid the ingress of weed species. To maintain dense perennial littoral vegetation, irrigation is likely to be required, particularly during the dry season;

(C) preventing macrophyte zone plants and ground covers from being shaded out by minimising tree densities at the water's edge and choosing species such as Melaleuca that allow sunlight to penetrate the tree canopy;

(D) locating vegetation to allow views of the wetland and its surrounds whilst discouraging the public from accessing the water body; and

(E) parkland vegetation may be of a similar species to the embankments littoral vegetation and layout to visually integrate the wetland with its surrounds. Alternatively, vegetation of contrasting species and/ or layout may be selected to highlight the water body as a feature within the landscape. Turf may be considered to achieve this goal.

(iii) Terrestrial plants, including existing vegetation, adjacent to the upper littoral edge.

(e) Safety issues

(i) General

Constructed wetlands need to be generally consistent with public safety requirements for new developments. These include reasonable batter profiles for edges to facilitate public egress from areas with standing water and fencing where water depths and edge profile requires physical barriers to public access. Fences can be substituted where possible by using dense edge plantings to deter public access to areas of open water. Dense littoral vegetation that can grow to around 2 m high and 1.5 m wide are effective in deterring public access.

(ii) Restricting access to open water

Fences or vegetation barriers to restrict access should be incorporated into wetland areas, particularly on top of concrete or stone walls where:

(A) there is a risk of serious injury in the event of a fall (over 0.5 m high and too steep to comfortably walk up/ down or the lower surface or has sharp or jagged edges);

(B) there is a high pedestrian or vehicular exposure (on footpaths, near bikeways, near playing/ sporting fields, near swings and playgrounds etc.);

(C) where water ponds to a depth of greater than 300 mm on a constructed surface of concrete

or stone. Natural water features are exempt; and

(D) where grassed areas requiring mowing abut the asset.

Barriers that may be appropriate are:

- dense vegetation at least 2 m wide and 1.2 m high (minimum) may be suitable; and
- pool fence (or similar) when there is a chance of drowning and the surrounding area is specifically intended for use by small children (swings, playgrounds, sporting fields etc.).

Dense littoral planting around the wetland and particularly around the deeper open water pools of the sediment pond (with the exception of any maintenance access points), will deter public access to the open water and create a barrier to improve public safety. Careful selection of plant species (e.g. tall, dense or “spiky” species) and planting layouts can improve safety as well as preventing damage to the vegetation by trampling.

Dense vegetation (hedge) at least 2 m wide and 1.2 m high (minimum) may be suitable. A temporary fence may be required until the vegetation has established and becomes a deterrent to pedestrians.

An alternative to the adoption of a barrier/ fence is to provide a 2.4 m safety bench that is less than 0.2 m deep below the normal water level around the waterbody. This is discussed in Chapter 4 Section 4.3.3.3 with respect to appropriate batter slopes.

(6) Construction and establishment - constructed wetlands

This section provides general advice for the construction and establishment of constructed wetlands and key issues to be considered to ensure their successful establishment and operation. Some of the issues raised have been discussed in other sections of this chapter and are reiterated here to emphasise their importance based on observations from construction projects around Australia.

(a) Staged construction and establishment method

It is important to note that constructed wetlands, like most WSUD elements that employ soil and vegetation based treatment processes, require approximately two growing seasons (i.e. two years) before the vegetation in the systems has reached its design condition (i.e. height and density). In the context of a large development site and associated construction and building works, delivering constructed wetlands and establishing vegetation can be a challenging task. Therefore, constructed wetlands require a careful construction and establishment approach to ensure the wetland establishes in accordance with its design intent. The following sections outline a recommended staged construction and establishment methodology for constructed wetlands (Leinster, 2006).

(i) Construction and establishment challenges

There exist a number of challenges that must be appropriately considered to ensure successful construction and establishment of wetlands. These challenges are best described in the context of the typical phases in the development of a greenfield or infill development, namely the subdivision construction phase and the building phase.

(A) subdivision construction - involves the civil works required to create the landforms associated with a development and install the related services (roads, water, sewerage, power etc.) followed by the landscape works to create the softscape, streetscape and parkscape features. The risks to successful construction and establishment of the WSUD systems during this phase of work have generally related to the following:

- construction activities which can generate large sediment loads in runoff which can smother wetland vegetation; and
- construction traffic and other works can result in damage to the constructed wetlands.

Importantly, all works undertaken during subdivision construction are normally “controlled” through the principle contractor and site manager. This means the risks described above can be readily managed through appropriate guidance and supervision.

(B) building phase - once the subdivision construction works are complete and the development plans are sealed then the building phase can commence (i.e. construction of the houses or built form). This phase of development is effectively “uncontrolled” due to the number of building contractors and sub- contractors present on any given allotment. For this reason the allotment building phase represents the greatest risk to the successful establishment of constructed wetlands.

(ii) Staged construction and establishment method

To overcome the challenges associated within delivering constructed wetlands a staged construction and establishment method should be adopted (see Figure SC6.4.3.9.43):

(A) Stage 1: Functional installation - construction of the functional elements of the constructed wetland at the end of subdivision construction (i.e. during landscape works) and the installation of temporary protective measures.

(B) Stage 2: Sediment and erosion control – during the building phase the temporary protective measures preserve the functional infrastructure of the constructed wetland against damage whilst also providing a temporary erosion and sediment control facility throughout the building phase to protect downstream aquatic ecosystems.

(C) Stage 3: Operational establishment - at the completion of the building phase, the temporary measures protecting the functional elements of the constructed wetland can be removed along with all accumulated sediment.

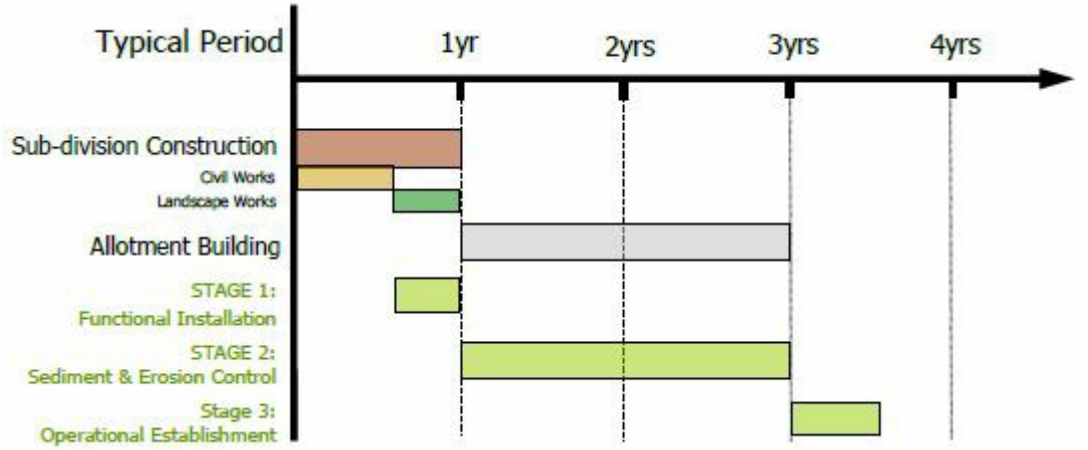


Figure SC6.4.3.9.43 Staged construction and establishment method

(iii) Functional installation

Functional installation of constructed wetlands occurs at the end of subdivision construction as part of landscape works and involves:

(A) earthworks to configure the bathymetry of the wetland;

(B) installation of the hydraulic control structures including inlet/outlet control and the high flow bypass weir;

(C) placement of topsoil, trimming and profiling;

(D) placement of turf in the High Flow Bypass channel to protect against erosion;

(E) disconnecting the Inlet Zone from Macrophyte Zone and allowing all stormwater to flow along High Flow Bypass. This effectively isolates the Macrophyte Zone from catchment flows and allows the establishment of wetland plants without the risk of being smothered with coarse sediment during the Subdivision Construction and Allotment Building Phases;

(F) planting of the Macrophyte Zone once the disconnection is in place;

(G) water level in the Macrophyte Zone can be varied as required by the rate of wetland plant maturity by opening the connection for short periods or opening the outlet control. Irrigation of edges may be required; and

(H) planting the littoral zone and providing irrigation to ensure fast establishment of dense vegetation to minimise weed growth.

Figure SC6.4.3.9.44 depicts the functional installation of a constructed wetland

(iv) Sediment and erosion control

During allotment building phases the sedimentation pond can be used to reduce the load of coarse sediment discharging to the receiving environment. The disconnection between the sediment pond and the macrophyte zone will remain in place to ensure the majority of flows from the catchment continue to bypass the macrophyte zone thus allowing the wetland plants to reach full maturity without the risk of being smothered with coarse sediment (see Figure SC6.4.3.9.45).

This means the macrophyte zone can be fully commissioned and made ready for operation once the allotment building phase is complete.

Figure SC6.4.3.9.45 Constructed wetland sediment and erosion control operation

(v) Operational establishment

At the completion of the allotment building phase the sediment pond is de-silted, the disconnection between the sediment pond and macrophyte zone is removed and the constructed wetland is allowed to operate in accordance with the design.

Figure SC6.4.3.9.46 Constructed wetland operational establishment

(b) Construction tolerances

It is important to emphasise the significance of tolerances in the construction of constructed wetland systems. Ensuring the relative levels of the control structures (inlet connection to macrophyte zone, bypass weir and macrophyte zone outlet) are correct is particularly important to achieve appropriate hydraulic functions. Generally control structure tolerance of plus or minus 5 mm is considered acceptable.

Additionally the bathymetry of the macrophyte zone must be free from localised depressions and low points resulting from earthworks. This is particularly important to achieve a well distributed flow path and to prevent isolated pools from forming (potentially creating mosquito habitat) when the wetland drains. Generally an earthworks tolerance of plus or minus 25 mm is considered acceptable.

(c) Sourcing wetland vegetation

To ensure the specified plant species are available in the required numbers and of adequate maturity in time for wetland planting, it is essential to notify nurseries early for contract growing. When early ordering is not undertaken, the planting specification may be compromised due to sourcing difficulties, resulting in poor vegetation establishment and increased initial maintenance costs. The species listed in SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics are generally available commercially from local native plant nurseries but availability is dependent upon many factors including demand, season and seed availability. To ensure the planting specification can be accommodated the minimum recommended lead time for ordering is 3-6 months. This generally allows adequate time for plants to be grown to the required size. The following sizes are recommended as the minimum:

(i) viro tubes 50 mm wide x 85 mm deep;

(ii) 50 mm tubes 50 mm wide x 75 mm deep; and

(iii) native tubes 50 mm wide x 125 mm deep.

“Floral Edges”, a system of interlocking plants within one long container is recommended for wetland planting, particularly for the deep marsh zone. The series of plants (usually five) are grown together in a single “strip” container. Generally, these “floral edges” are supplied as more mature plants with developing rhizomes (for rhizomatous species) and interlocking roots. This has been used very successfully in wetland planting previously because the larger more mature plants, often with a thick rhizome system, can survive in deeper water and are more tolerant to fluctuations in water level. The

structure of this system slows the movement of water and binds the substrate, helping to reduce erosion. The weight of the interlocking plants also prevents birds from removing them, a common problem encountered during wetland plant establishment. Nurseries require a minimum lead time of 6 months for supply of these systems.

(d) Topsoil specification and preparation

The provision of suitable topsoil in wetlands is crucial to successful macrophyte establishment and to the long term functional performance of the wetland. Wetland macrophytes typically prefer medium textured silty to sandy loams that allow for easy rhizome and root penetration. Although there are a few plants that can grow in in-situ heavy clays (e.g. phragmites), growth is slow and the resulting wetland system will have low species richness, which is undesirable. The wetland must therefore have a layer of topsoil no less than 200 mm deep and preferably 300 mm in depth for improved dry season moisture retention.

During the wetland construction process, topsoil is to be stripped and stockpiled for possible wetland reuse as a plant growth medium. Most terrestrial topsoils provide a good substratum for wetlands, nonetheless laboratory soil testing (using Australian Standard testing procedures, e.g. AS 4419-2003: *Soils for landscaping and garden use*) of the in-situ topsoil is necessary to ensure the topsoil will support plant and microbial growth and have a high potential for nutrient retention. Typically, standard horticultural soil analysis, which includes major nutrients and trace elements, is suitable for topsoils intended for wetland use. The laboratory report will indicate the soils suitability as a plant growth medium and if any amendments are required.

Careful consideration should be given to the topsoil source and its propensity to contain weed seeds which may be viable in an ephemeral wetland habitat. If a problematic weed bank is likely to be present within the topsoil then importing alternative topsoil should be considered. If the in-situ topsoil is found to contain high levels of salt, extremely low levels of organic carbon (<< 5%), or any other extremes that may be considered a retardant to plant growth, it should be rejected.

If the in-situ topsoil is not suitable and soil amendment is considered impractical or not cost effective, sandy loam topsoil should be purchased from a soil supplier. If the local topsoil is suitable but very shallow, mixing with an imported soil will be necessary to reach the required volume to ensure a minimum 200 mm deep topsoil for wetland planting.

Imported topsoils are generally suitable as wetland plant growth medium, however as for in-situ soils (above), testing is required to determine the appropriate gypsum or lime dosing rate. If the local topsoil was tested and found to be suitable but then mixed with an imported soil to meet the required volume, laboratory soil testing should be repeated.

(i) Topsoil treatments

The wetland topsoil should be tested in accordance with AS 4419-2003: *Soils for landscaping and garden use* to ensure it is appropriate for growth of vegetation. If testing finds the topsoil is not appropriate then an alternative source should be found.

Topsoils for wetlands generally do not require fertiliser treatment. Imported foreign loam will contain sufficient nutrients for vegetation growth and local terrestrial topsoil will release nutrients after the wetting process. Submersion of terrestrial soils in water causes a shift from aerobic to anaerobic processes, prompting mineralisation and decomposition of organic matter contained in the soil, thus increasing available nitrogen. When soils become anaerobic, reduction processes cause iron oxides to be released from the surface of soil particles leading to increased availability of phosphorus. The addition of nutrients (fertiliser application) can facilitate the growth of algae (including cyanobacteria (blue-green) algae), particularly when the competing macrophytes and submerged plants are in the early stages of development, increasing the likelihood of algal blooms.

The topsoil within the wetland (macrophyte zones and open water zones) may need to be treated with gypsum or lime. The application of gypsum is standard on most construction sites for the purpose of securing or flocculating dispersive soils if entrained in runoff. The use of gypsum in wetland should only occur within catchments with dispersive soils and applied at a maximum rate of 0.4 kg/m^2. The application of lime may be required where the AS4419 (2003) soil testing

identifies a potential soil pH problem (pH < 5) or where acid sulfate soils (ASS) exist in the vicinity of the wetland. The rate of lime application should be guided by soil test results, an ASS Management Plan and water quality (pH) monitoring of the wetland and inflow.

Gypsum/ lime should be applied about one week prior to vegetation planting. Subsequent application may be required at intervals depending on water quality monitoring. Application of gypsum/ lime too far in advance of planting may lead to aquatic conditions that promote algal growth (i.e. clear water with no aquatic plants competing for resources).

(e) Vegetation establishment

(i) Timing for planting

Timing of vegetation planting is dependent on a suitable time of year (and potential irrigation requirements) as well as timing in relation to the phases of development. October and November are considered ideal times to plant vegetation in treatment elements. This allows for adequate establishment/ root growth before the heavy summer rainfall period but also allows the plants to go through a growth period soon after planting, resulting in quicker establishment. Planting late in the year also avoids the dry winter months, reducing maintenance costs associated with watering. Construction planning and phasing should endeavour to correspond with suitable planting months wherever possible. However, as lead times from earthworks to planting can often be long, temporary erosion controls (e.g. use of matting or sterile grasses to stabilise exposed batters) should always be used prior to planting.

(ii) Water level manipulation

To maximise the chances of successful emergent macrophyte establishment, the water level of the wetland system is to be manipulated in the early stages of vegetation growth. When first planted, vegetation in the deep marsh zone may be too small to be able to exist in their prescribed water depths (depending on the maturity of the plant stock provided). Macrophytes intended for the deep marsh sections will need to have half of their form above the water level, which may not be possible if initially planted at their intended depth. Similarly, if planted too deep, the young submerged plants will not be able to access sufficient light in the open water zones. Without adequate competition from submerged plants, phytoplankton (algae) may proliferate.

The water depth must be controlled in the early establishment phase. This can be achieved by closing off the connection between the sediment pond and the macrophyte zone (i.e. covering the overflow pit) and opening the maintenance drain. The deep marsh zones should have a water depth of approximately 0.2 m for at least the first 6 - 8 weeks. This will ensure the deep marsh zones of the wetland are inundated to shallow depth and the shallow marsh edges remain moist (muddy) providing suitable conditions for plant establishment. Seedlings planted in the littoral zones of the wetland will require ongoing watering at a similar rate as the terrestrial landscape surrounding the wetland (SC6.4.3.9.5(5)(e)(ii) Restricting access to open water). When it is evident that the plants are establishing well and growing actively, a minimum of 6 - 8 weeks following planting, the plants should be of sufficient stature to endure deeper water. At this time, the connection between the inlet pond and the macrophyte zone can be temporarily opened to allow slow filling of the wetland to the design operating water level.

(iii) Weed control

To protect landscape amenity and the stormwater treatment efficiency of the wetland it is important to maintain, throughout the year, the design vegetation communities to avoid excessive colonisation of the wetland by weeds. Weed infestation is a major problem in the dry tropics, particularly within ephemeral waterways and stormwater treatment facilities, therefore, the design and management of the wetland to manage weed infestation takes on high importance. Management of weeds is achieved as follows:

(A) designing the macrophyte zone as predominately a deep marsh system (i.e. water depth 0.5 m - 0.7 m) to maintain the macrophyte vegetation by minimising the frequency and duration of wetland drying, thus permanently occupying the habitat and restricting weed colonisation opportunities;

(B) planting dense littoral vegetation around the perimeter of the wetland to avoid the ingress of weed species. To maintain dense perennial littoral vegetation, irrigation is likely to be

required, particularly during the dry season; and maintaining dense macrophyte vegetation in the wetland during prolonged dry conditions is necessary to avoid opening up habitat opportunities for weeds. When the macrophyte zone dries (i.e. the macrophyte zone sediments are exposed) for a period in excessive of 60 days, irrigation of the macrophyte zone may be required to achieve this.

During the establishment and ongoing maintenance of the wetland, prompt removal of weeds before they spread and/or set seed is of critical importance.

Conventional surface mulching of the wetland littoral berms with organic material like tanbark is not recommended. Most organic mulch floats and water level fluctuations and runoff typically causes this material to be washed into the wetland with a risk of causing blockages to outlet structures. Mulch can also increase the wetland organic load, potentially increasing nutrient concentrations and the risk of algal blooms. Adopting high planting density rates and if necessary applying a suitable biodegradable erosion control matting to the wetland batters (where appropriate), will help to combat weed invasion and will reduce maintenance requirements for weed removal. If the use of mulch on the littoral zones is preferred, it must be secured in place with appropriate mesh or netting (e.g. jute mesh).

(iv) Watering

Regular watering of the littoral vegetation during the plant establishment phase is essential for successful establishment and vigorous growth. The frequency of watering to achieve successful plant establishment is dependent upon rainfall, maturity of planting stock and the water level within the wetland. However, the following watering program is generally adequate but should be adjusted (i.e. increased) as required to suit site conditions:

(A) week 1-2 3 visits/ week;

(B) week 3-6 2 visits/ week; and

(C) week 7-12 1 visit/ week.

After this initial 3 month period, irrigation will still be required, particularly during the dry season. Watering requirements to sustain healthy dense vegetation should be determined during ongoing monitoring and maintenance site visits.

(v) Bird protection

During the early stages of wetland establishment, water birds can be a major nuisance due to their habit of pulling out recently planted species. Interlocking planting systems (i.e. where several plants are grown together in a single container such as “floral edges”) can be used, as water birds find it difficult to lift the interlocking plants out of the substrate unlike single plants grown in tubes.

(7) Maintenance requirements - constructed wetlands

Wetlands treat runoff by filtering it through vegetation and providing extended detention to allow sedimentation to occur. In addition, they have a flow management role that needs to be maintained to ensure adequate flood protection for local properties and protection of the wetland ecosystem.

Maintaining healthy vegetation and adequate flow conditions in a wetland are the key maintenance considerations. Weeding, planting, mowing and debris removal are the dominant tasks (but should not include use of herbicides as this affects water quality). In addition, the wetland needs to be protected from high loads of sediment and debris and the inlet zone needs to be maintained in the same way as sedimentation basins (see Chapter 4). Routine maintenance of wetlands should be carried out once a month.

(a) The most intensive period of maintenance is during plant establishment period (first two years) when weed removal and replanting may be required. It is also the time when large loads of sediments could impact on plant growth, particularly in developing catchments with poor building controls. Debris removal is an ongoing maintenance function. If not removed, debris can block inlets or outlets, and can be unsightly if in a visible location. Inspection and removal of debris should be done regularly. Typical maintenance of constructed wetlands will involve:

(i) irrigation of the littoral zone plants (especially during dry periods) to prevent the ingress of invasive weeds;

(ii) prompt removal of weeds before they spread and/or set seed is of critical importance;

(iii) desilting the inlet zone following the construction/ building period;

(iv) routine inspection of the wetland to identify any damage to vegetation, weed growth, scouring, formation of isolated pools, litter and debris build up or excessive mosquitoes;

(v) routine inspection of inlet and outlet points to identify any areas of scour, litter build up and blockages;

(vi) removal of litter and debris;

(vii) removal and management of invasive weeds;

(viii) repair to wetland profile to prevent the formation of isolated pools;

(ix) periodic (usually every 5 years) draining and desilting of the inlet pond;

(x) watering of wetland macrophytes during prolonged dry periods (in excess of 60 days);

(xi) water level control during plant establishment;

(xii) replacement of plants that have died (from any cause) with plants of equivalent size and species as detailed in the planting schedule; and

(xiii) vegetation pest monitoring and control.

Inspections are recommended following large storm events to check for scour and damage.

(b) All maintenance activities must be specified in a maintenance plan (and associated maintenance inspection forms) to be developed as part of the design procedure (SC6.4.3.9.5(4)(i) Step 9: Consider maintenance requirements). Maintenance personnel and asset managers will use this plan to ensure the wetlands continue to function as designed. To ensure maintenance activities are appropriate for the wetland as it develops, maintenance plans should be updated a minimum of every three years. The maintenance plans and forms must address the following:

(i) inspection frequency;

(ii) maintenance frequency;

(iii) data collection/ storage requirements (i.e. during inspections);

(iv) detailed clean-out procedures (main element of the plans) including:

(A) equipment needs;

(B) maintenance techniques;

(C) occupational health and safety;

(D) public safety;

(E) environmental management considerations;

(F) disposal requirements (of material removed);

(G) access issues;

(H) stakeholder notification requirements; and

(I) data collection requirements (if any); and

(v) design details.

An approved maintenance plan is required prior to asset transfer to the local authority. Refer to the guidelines or direction from the relevant local authority for more specific guidance on requirements for asset transfer.

An example operation and maintenance inspection form is included in the checking tools provided in SC6.4.3.9.5(8)(c) Operation and maintenance inspection form. These forms must be developed on a site specific basis as the configuration and nature of constructed wetlands varies significantly.

(8) Checking tools - constructed wetlands

A number of checking aids has been developed for designers and council development assessment officers. In

addition, SC6.4.3.9.5(6) Construction and establishment provides general advice for the construction and establishment of wetlands and key issues to be considered to ensure their successful establishment and operation, based on observations from construction projects around Australia.

(a) Design assessment

The checklist in Table SC6.4.3.9.17 presents the key design features to be reviewed when assessing a design of a wetland. These considerations include configuration, safety, maintenance and operational issues that should be addressed during the design phase. Where an item results in an "N" when reviewing the design, referral should be made back to the design procedure to determine the impact of the omission or error. In addition to the checklist, a proposed design must have all necessary permits for its installations. Council development assessment officers will require supporting evidence/ proof from the developer that all relevant permits are in place.

Click here to view **Table SC6.4.3.9.17 Wetland design assessment checklist**

(b) Construction (during and post)

The checklist in Table SC6.4.3.9.18 presents the key items to be reviewed when inspecting the bioretention basin during and at the completion of construction. The checklist is to be used by Construction Site Supervisors and local authority Compliance Inspectors to ensure all the elements of the bioretention basin have been constructed in accordance with the design. If an item receives an "N" in Satisfactory criteria then appropriate actions must be specified and delivered to rectify the construction issue before final inspection sign-off is given.

Click here to view **Table SC6.4.3.9.18 Wetland construction inspection checklist**

(c) Operation and maintenance inspection

The example form in Table SC6.4.3.9.19 should be developed and used whenever an inspection is conducted and kept as a record on the asset condition and quantity of removed pollutants over time. Inspections should occur every 1 - 6 months depending on the size and complexity of the system. More detailed site specific maintenance schedules should be developed for major constructed wetland systems and include a brief overview of the operation of the system and key aspects to be checked during each inspection.

Click here to view **Table SC6.4.3.9.19 Wetland maintenance checklist**

(d) Asset transfer (following on maintenance period)

Land ownership and asset ownership are key considerations prior to construction of a stormwater treatment device. A proposed design should clearly identify the asset owner and who is responsible for its maintenance. The proposed owner should be responsible for performing the asset transfer checklist. Table SC6.4.3.9.20 provides an indicative asset transfer checklist.

SC6.4.3.9.6 Plant selection for WSUD systems in the coastal dry tropics

(1) This clause provides guidance on selecting appropriate plant species for water sensitive urban design (WSUD) systems where the plants have a functional role in stormwater treatment and/ or erosion protection. Selecting suitable plant species is critical to the long term landscape amenity, functional performance and structural integrity of WSUD systems.

Due to the strong seasonal rainfall patterns in the dry tropics, weed infestation is a major problem, particularly within ephemeral waterways and stormwater treatment facilities. The vegetation design to manage weed infestation takes on high importance and requires special consideration to achieve the following objectives:

(a) maintain, throughout the year, a dense cover of the design vegetation to occupy habitat and avoid excessive colonisation by weeds;

(b) manage potential weed ingress from edges by sustaining perennial littoral vegetation;

(c) in bioretention systems the vegetation must be able to tolerate long dry periods, periodic inundation and free draining sandy soils;

(d) provision of irrigation to wetland littoral zones; and

(e) provision of irrigation to bioretention systems designed without saturated zones.

Careful selection of plant species and by adopting suitably high planting densities can significantly reduce costs associated with weed management.

(2) A list of recommended plant species for various WSUD systems, including appropriate planting densities, is provided in the following tables:

(a) Table SC6.4.3.9.21 A1 Groundcover plant species list for swales (incorporating buffer strips), bioretention swales and bioretention basins and Table SC6.4.3.9.22 A2 Shrub and tree plant species list for bioretention basins:

(i) swales (incorporating buffer strips);

(ii) bioretention swales; and

(iii) bioretention basins; and

(b) Table SC6.4.3.9.23 A3 Macrophyte and groundcover plant species list for wetlands and sedimentation basins and Table SC6.4.3.9.24 A4 Shrub and tree plant species list for wetlands and sedimentation basins:

(i) sedimentation basins; and

(ii) wetlands.

The plant species lists in Table SC6.4.3.9.21 A1 and Table SC6.4.3.9.22 A2 are not exhaustive and other plants may be used provided their physiological and structural characteristics match the characteristics of the plant species listed in the tables.

Non-indigenous natives and exotics should only be considered when there is a specific landscape need and the species has the appropriate growth form and habit. If non-indigenous natives and exotics are chosen, careful consideration should be given to the potential impacts on downstream receiving ecosystems. Species (including natives) that have the potential to become invasive weeds should be avoided.

(3) Swales (and buffer strips), bioretention swales and bioretention basins - plant selection

(a) Required plant characteristics

Planting for bioretention basin elements may consist of up to three vegetation types:

- groundcovers for stormwater treatment and erosion protection;
- shrubbery for screening, glare reduction and character; and
- trees for shading, character and other landscape values.

For specific guidance on plant species the designer is directed to Table SC6.4.3.9.21 A1 and Table SC6.4.3.9.22 A2 which outline plant species suitable for the coastal dry tropics. The designer should also refer to any relevant local guidelines.

(i) Groundcovers

The plant (groundcover) species listed in Table SC6.4.3.9.21 A1 have been specifically selected, based on their life histories, physiological and structural characteristics, to meet the functional requirements of swales, buffer strips and bioretention systems (i.e. bioretention swales and bioretention basins). Bioretention systems must have filter media with a minimum depth of 400 mm for groundcover plants to provide an adequate depth of aerobic soil for healthy root development.

Plant species selected for bioretention systems must be able to tolerate free draining sandy soils and be capable of withstanding long dry periods punctuated by short periods of temporary inundation. The addition of saturated zones in bioretention systems will help retain moisture during the dry season where supplemental irrigation is not provided. Suitable plants species are listed in Table SC6.4.3.9.21 A1. Where irrigation of bioretention systems is provided, a more diverse range of species may be selected to achieve the desired landscape aesthetic provided they are tolerant of the filter media conditions and have the required features to fulfil the functional roles of the WSUD element. In general, the plant species in Table SC6.4.3.9.21 A1 have the following features:

(A) they are able to tolerate short periods of inundation punctuated by longer dry periods. For bioretention systems these dry periods may be reasonably severe due to the free draining nature (relatively low water holding capacity) of bioretention filter media. In the dry tropics climate irrigation of bioretention vegetation will be required unless saturated zones are provided to maintain soil moisture;

(B) they generally have spreading rather than clumped growth forms;

(C) they are perennial rather than annual;

(D) they have deep, fibrous root systems;

(E) groundcover plants can be turf, prostrate or tufted;

(F) prostrate species would typically be low mat forming stoloniferous or rhizomatous plants; and

(G) tufted species would typically be rhizomatous plants with simple vertical leaves.

Most of the groundcovers listed in Table SC6.4.3.9.21 A1 are widespread, occurring throughout the coastal dry tropics. However, alternative locally occurring species that display the required features may be selected to tailor the species list to match the native vegetation associations of the area

and to compliment surrounding vegetation communities.

(ii) Shrubs and trees

Shrubs and trees are not a functional requirement within swales, bioretention swales or bioretention basins, but can be integrated to provide amenity, character and landscape value. Planting trees and shrubs in bioretention systems requires the filter media to have a minimum depth of 800 mm to avoid root interference with the perforated subsurface drainage pipes. They must also be accompanied by densely planted shade tolerant groundcover species with the characteristics outlined above. Trees and shrubs are to be managed so that the ground cover layer is not out-competed. To avoid over-shading, trees and shrubs should be planted at low densities. Periodic thinning of the upper vegetation layers may also be required. In general, tree and shrub species that can be incorporated into bioretention systems have the following general features:

(A) trees need to be able to tolerate short periods of inundation punctuated by longer dry periods. These dry periods may be reasonably severe due to the free draining nature (relatively low water holding capacity) of bioretention filter media. In the dry tropics climate irrigation of bioretention vegetation will be required unless saturated zones are provided to maintain soil moisture;

(B) they need to have relatively sparse canopies to allow light penetration to support dense groundcover vegetation;

(C) have shallow root systems and root systems that are not known the be adventurous “water seekers” to reduce the risk of root intrusion into subsurface drainage pipes;

(D) trees must not be deciduous; and

(E) preferably native and occur naturally in the local area.

The shrubs and trees listed in Table SC6.4.3.9.22 A2 are recommended as they display the above features.

Most of the shrub and tree species listed in Table SC6.4.3.9.22 A2 are widespread, occurring throughout the coastal dry tropics. However, alternative locally occurring species that display the required features may be selected to tailor the species list to match the native vegetation associations of the area and to compliment surrounding vegetation communities.

(b) Plant species selection

Well established uniform groundcover vegetation is crucial to the successful operation of swale and bioretention system treatment elements. As a result, plant species selection needs to consider both the aesthetic and functional requirements. The functional plant traits required for effective water treatment are different for different devices. For example:

(i) swales – require plants with vigorous growth and a spreading habit to hold soil in place against flow. They should also be suited to growth in wet clay soils. Examples include turf grasses, tufted grasses and sedges;

(ii) bioretention swales - require plants with vigorous growth and a spreading habit to hold soil in place against flow. They should be drought tolerant and suited to growth in sandy soils. Examples include turf grasses, tufted grasses and sedges;

(iii) bioretention basins – plants should be drought tolerant and suited to growth in sandy soils. Examples include grasses, shrubs and trees. A diverse mix is recommended; and

(iv) when selecting plant species from Table SC6.4.3.9.21 A1, consideration must be given to the following factors:

(A) other WSUD objectives such as landscape, aesthetics, biodiversity, conservation and ecological value;

(B) region, climate, soil type and other abiotic factors;

(C) roughness of the channel (Manning’s *n* roughness factor) (for swales); and

(D) extended detention depth (for bioretention systems).

Typical heights of each plant species and comments relating to shade and salt tolerances and soil moisture requirements are provided in Table SC6.4.3.9.21 A1 and will help with the selection process.

The low growing and lawn species are suitable for swale elements that require a low hydraulic roughness. The treatment performance of bioretention systems, in particular, requires dense vegetation to a height equal to that of the extended detention depth. Therefore, a system with a 300 mm extended detention depth should have vegetation that will grow to at least 300 mm high. Turf is not considered to be suitable vegetation for bioretention basins. The stems do not grow high enough and the root structure of turf is not suitably robust to ensure the surface of the bioretention filter media is continuously broken up to prevent clogging.

Included in Table SC6.4.3.9.21 A1 is a recommended planting density for each plant species. The groundcover planting densities should ensure that 70-80 % cover is achieved after two growing seasons (2 years) given adequate irrigation and weed control. High density planting to avoid weed ingress is particularly important in the dry tropics due to the climatic conditions which favour opportunistic (colonising) seasonal weed species. High density planting also ensures runoff does not establish preferential flow paths around the plants and erode the swale/ bioretention surface. Dense vegetation is also required to ensure a uniform root zone, which is particularly important in bioretention systems.

If prostrate shrubs that form scrambling thickets are used (in place of or in conjunction with the plant species in Table SC6.4.3.9.21 A1) they should be planted at high densities (8-10 plants/m²) and may require pruning to ensure even plant cover and to maintain an even root distribution below ground.

(c) Vegetation establishment and maintenance

Swales, buffer strips and bioretention basins are living systems and require two years of establishment before the vegetation matures and reaches fully functional form. During this establishment period, regular site monitoring and maintenance is critical to the success of these systems. In addition, specific requirements for plant stock sourcing, topsoil selection and testing and vegetation establishment, as detailed in the relevant WSUD element chapters, are necessary to maximise successful vegetation establishment and system treatment performance. Particular reference is made to the sections titled “Landscape Design Notes”, “Maintenance Requirements” and “Construction and Establishment” for guidance on vegetation establishment and maintenance procedures. The “Construction and Establishment” section also details a staged implementation approach by which the functional elements of the WSUD system are protected from building site runoff and associated sedimentation, weeds and litter during the building phase.

Table SC6.4.3.9.21 A1 Groundcover plant species list for swales (incorporating buffer strips), bioretention swales and bioretention basins

S Swale,
BS Bioretention Swale,
BB Bioretention Basin
Strongly recommended – perennial, vigorously growing species with appropriate traits for good pollutant removal

Scientific Name	Common Name	Application	Form	Height (mm)	Planting Density[1] (Qty/m²)	Comments
Atriplex muelleri	Salt Bush	BB	Prostrate	100	2-3	Very common low prostrate mat in saline areas, silver foliage highly ornamental
Bacopa monnieri	Bacopa	BB	Prostrate	100	6-8	Not suitable for sandy soils with low water holding capacity, Native to region prostrate herb
Bothriochloa pertusa	Indian Couch	S, BS, BB	Turf		Seeded or rolled	Tolerates prolonged dry periods
Carex fascicularis	Tassel Sedge	S	Tufted	1000	6-8	Not suitable for sandy soils with low water holding capacity,
Carex polyantha	Creek Sedge	S	Tufted	To 900	6-8	Not suitable for sandy soils with low water holding capacity,

Scientific Name	Common Name	Application	Form	Height (mm)	Planting Density[1] (Qty/m^2)	Comments
Cymbopogon refractus	Barbed Wire Grass	S	Tufted	300	8-10	Does not tolerate prolonged dry periods
Cyperus haspan	Haspan Flatsedge	S	Tufted	400	8	Suitable for, sandy soils, perennial, native to region
Cyperus javanicus		S	Tufted	1400	8	Suitable for, sandy soils, perennial, native to region
Cyperus polystachyos	Bunchy Sedge	S	Tufted	600	8	Suitable for both sand and clay soils, perennial, native to region, tolerates salinity
Cyperus scariosis#		S		900	8	Suitable for, sandy soils, perennial, native to region, tolerates salinity levels may suppress *Urochloa mutica* (para grass)
Dianella longifolia var. longifolia	Pale Flax-lily	S, BS, BB,	Tufted	300-800	8	Shade tolerant, native to region
Eragrostis elongata	Lavender Grass	S, BS, BB			8	Annual or weak perennial, best in rockeries and roadsides
Fimbristylis dichotoma		BS, BB	Tufted	750	8	Suitable for, sandy soils, perennial, native to region
Fimbristylis ferruginea	Rusty Finger Rush	BS, BB	Tufted	650 -800	8	Suitable for, sandy soils, perennial, native to region, salt tolerant
Fimbristylis tristachya		BS, BB	Tufted	600	8	Suitable for, sandy soils, perennial, native to region
Gahnia aspera	Saw Sedge	S	Tufted	1000	6	Not suitable for sandy soils, native to region, difficult to propagate
Gahnia sieberiana	Red-fruited Sword Sedge	S	Tufted	1500-3000	6	Aesthetic, difficult to propagate
Imperata cylindrical#	Blady grass	S, BS, BB	Tufted	500	8	Only use when it occurs in natural surroundings, native to region,
Juncus usitatus#	Common Rush	S, BS, BB	Tufted	500	8-10	Not suitable for sandy soils
Lomandra hystrix	Creek Matt Rush	S, BS, BB	Tufted	1000	6	Shade tolerant, native to region
Lomandra longifolia	Matt Rush	S, BS, BB	Tufted	500-1000	6	Shade tolerant, native to region
Paspalum distichum	Water Couch	S, BS, BB	Turf	To 500	Seeded or rolled	Not suitable for sandy soils, native to region
Paspalum vaginatum cv 'Saltene'	Salt Water Couch	S, BS, BB	Turf	To 500	Seeded or rolled	Salt tolerant, native to region
Platyzoma microphyllum	Fern	BB	Fern	150-500	8	Not suitable in areas expecting prolonged dry periods , Native to region
Eragrostis spartinoides	Love Grass	S, BS, BB	Grass	600	8	Native to region
Sporobolus virginicus	Marine Couch	S, BS, BB	Turf	To 400	Seeded or rolled	Salt tolerant, Native to region
Themeda triandra	Kangaroo Grass	S, BS, BB	Tufted	300-500	6-8	

Note—planting density indicates the mean number of plants per square metre for the species spatial distribution within the zone. The planting

densities recommended are suggested minimums. Any reduction in planting density has the potential to reduce the rate of vegetation establishment, increase the risk of weed invasion, and increase maintenance costs. S = Swale, BS = Bioretention Swale, BB= Bioretention Basin

Table SC6.4.3.9.22 A2: Shrub and tree plant species list for bioretention basins

Note—trees not suitable for systems requiring flow conveyance (i.e. swales and bioretention swales) due to shading reducing growth of ground cover.

Scientific Name	Common Name	Form	Height (m)	Planting Density[2] (Qty/m[2])	Comments
Breynia oblongifolia	False Coffee Bush	Shrub	1-2	2-4	Native to region
Corymbia tessellaris	Moreton Bay Ash	Tree	10-20		Suitable for sandy soils, native to region
Aidia racemosa		Shrub	10-15		Native to region, tolerates high winds
Atractocarpus fitzalanii	Ivory Curl Tree	Shrub	3-10		Native to region
Eugenia reinwardtiana	Cedar Bay Cherry	Tree	1-3		Native to region
Leptospermum polygalifolium	Wild May	Shrub	1-4	2-4	Sunny position, native to region
Myoporum acuminatum	Coastal Boobialla	Shrub	0.5-6	2-4	Sun or semi-shade, salt tolerant, native to region
Albizia canescens	Townsville Siris	Tree			Native to region, rare
Buckinghamia celsissima		Tree	20-30		Native to region
Chionanthus ramiflorus	Native Olive	Tree	6-8		Native to region
Colubrina asiatica		Tree			Salt tolerant
Cupaniopsis anacaroides	Beach Tuckeroo	Tree	8-15		Suitable for sandy soils, native to region
Callistemon(Melaleuca) viminalis	Weeping Bottle Brush	Tree	5-10	<1	Requires moist soils during establishment but tolerates dry periods once established
Eucalyptus raveretiana	Black Ironbox	Tree			Tolerates high winds
Eucalyptus tereticornis	River Blue Gum	Tree	20-50m		Native to region
Ganophyllum falcatum		Tree	10-25		Native to region
Lophostemon grandiflorus		Tree	8-12		Native to region, tolerates high winds, periods of flooding and fire
Melaleuca dealbata	Cloudy Tea Tree	Tree	5-15		Native to region, tolerates high winds, periods of flooding and fire
Melaleuca fluviatilis		Tree			Native to region, tolerates high winds and periods of flooding, forms a root mat good for erosion cotrol
Mimusops elengi		Tree	10-15		Suitable for all soil types, native to region, tolerates high winds

Note—planting density indicates the mean number of plants per square metre for the species spatial distribution within the zone. The planting densities recommended are suggested minimums. Any reduction in planting density has the potential to reduce the rate of vegetation establishment, increase the risk of weed invasion, and increase maintenance costs.

(4) Wetlands and sedimentation basins - plant selection

Due to the strong seasonal rainfall patterns in the dry tropics, weed infestation is a major problem, particularly within ephemeral waterways and stormwater treatment facilities such as wetlands and sediment basins. Therefore, the design and management of these systems to manage weed infestation takes on high importance. Management of weeds is achieved through the plant selection and landscape design as follows:

- planting dense littoral vegetation around the perimeter of the wetland to avoid the ingress of weed species. To maintain dense perennial littoral vegetation, irrigation is likely to be required, particularly during the dry season; and
- designing the macrophyte zone as predominately a deep marsh system (i.e. water depth 0.5 m - 0.7 m) to maintain the macrophyte vegetation by minimising the frequency and duration of wetland drying, thus permanently occupying the habitat and restricting weed colonisation opportunities.

During the establishment and ongoing maintenance of the wetland, prompt removal of weeds before they spread and/or set seed is of critical importance.

(a) Required plant characteristics

Planting for wetlands and sedimentation basins may consist of two vegetation types:

- macrophytes and groundcovers for stormwater treatment, erosion protection and weed management. The macrophytes are divided further into several different zones as outlined in Table SC6.4.3.9.23 A3; and
- shrubbery and trees for screening, shading, character and other landscape values.

For specific guidance on plant species the designer is directed to Table SC6.4.3.9.23 A3 and Table SC6.4.3.9.24 A4 which outline plant species suitable for the coastal dry tropics.

(i) Macrophytes and groundcovers

The plant species listed in Table SC6.4.3.9.23 A3 have been specifically selected based on their life histories and physiological and structural characteristics, to meet the functional requirements of wetland systems. Plant species suitable for wetlands will also be suitable for edge planting around sedimentation basins. The following sections address wetlands specifically as they have very defined vegetation requirements for stormwater treatment. This includes consideration of the wetland zone/ depth range, typical extended detention time (typically 48 hrs) and extended detention depth (typically 0.5 m).

Other species can be used to supplement the core species listed in Table SC6.4.3.9.23 A3 provided they have the required features to fulfill the functional roles of the wetland zone. Careful consideration of the water depth range and wetland hydrological regime (water depth and inundation period) is also required to assess the suitability of alternate species for constructed wetlands. Wetland plants in the dry tropics must be able to tolerate large water level variations and dry periods of up to 60 days. Short growing emergent macrophytes will not be suitable for the deep marsh zone as they will become over inundated. As a guide, emergent macrophytes require 1/3 of their foliage to extend above the water level 80% of the time. However, during the plant establishment phase emergent macrophytes require 50% of their foliage above the water level.

In general, the species in Table SC6.4.3.9.23 A3 have the following features:

(A) they grow in water as either submerged or emergent macrophytes, or they grow adjacent to water and tolerate periods of inundation (typically sedge, rush or reed species);

(B) they generally have spreading rather than clumped growth forms;

(C) they are perennial rather than annual;

(D) they generally have rhizomatous growth forms;

(E) they have fibrous root systems; and

(F) they are generally erect species with simple vertical leaves (e.g. Juncus spp, Baumea spp).

(ii) Shrubs and trees

Shrubs and trees are not a required element of wetlands or sedimentation basins but can be integrated to provide amenity, character and landscape value. Shrubs and trees (generally only planted in the littoral zones) should be accompanied by dense shade tolerant groundcover species

as an understorey to occupy habitat and provide a weed ingress barrier. Table SC6.4.3.9.24 A4 provides a list of shrubs and trees that are natives to the coastal dry tropics and are suitable for planting in the littoral zone (i.e. on the batters) around wetlands and sedimentation basins.

Littoral zone vegetation is primarily for weed management (to avoid weed ingress into the macrophyte zone), batter stabilisation, aesthetics and to restrict public access, rather than for stormwater treatment. For this reason, species that do not have all of the above structural features, but fulfill the primary littoral zone requirements (e.g. weed management and erosion protection) and landscape objectives may still be acceptable for inclusion in this zone (refer to the "Landscape Design Notes" section in the relevant WSUD chapter).

(b) Plant species selection

Plant species listed in Table SC6.4.3.9.23 A3 are recommended as core species for wetland planting. These plant species have been grouped into a wetland macrophyte zone according to their preferred water depth and the hydrologic conditions of the zone. The perennial wetland plants must be able to tolerate large water level variations and periodic drying (potentially of up to 60 days duration). In general, the deep marsh emergent macrophytes must be capable of a standing water level of 0.5 m – 0.7 m punctuated with short episodes of extended detention (up to 1.2 m in total water depth) and seasonal drying.

While individual plant species can have very specific water depth requirements other species can be quite adaptive to growing across various zones over time. It is however, recommended that the suggested zones and plant groups are adhered to for planting purposes. Plant species listed against the shallow marsh and lower batters are only suited for edge planting in wetlands and sedimentation basins. Planting densities recommended should ensure that 70-80 % cover is achieved after two growing seasons (2 years). This is particularly important for weed management and therefore the recommended planting densities should not be reduced.

Suitable plant species for the littoral zone that surrounds wetlands and sedimentation basins have also been recommended in Table SC6.4.3.9.23 A3. The littoral zone relates to the berms, batters or embankments around the systems. Plants that have a drier habit should be planted towards the top of batters, whereas those that are adapted to more moist conditions should be planted closer to the water line. High density planting of the littoral zone is required to provide a barrier (by occupying habitat) to prevent weed ingress into the wetland or sediment basin.

(c) Vegetation establishment and maintenance

To maximise the success of plant establishment in wetland macrophyte zones specific procedures are required in site preparation, stock sourcing, vegetation establishment and maintenance. Reference is to be made to procedures detailed in SC6.4.3.9.5(5) Sourcing wetland vegetation as follows:

(i) sourcing plant stock (SC6.4.3.9.5(6)(c) Sourcing wetland vegetation):

(A) lead times for ordering plants; and

(B) recommended planting systems/ products;

(ii) topsoil specification and preparation SC6.4.3.9.5(6)(d) Topsoil specification and preparation):

(A) sourcing, testing and amendment; and

(B) top soil treatments (e.g. gypsum, lime, fertiliser); and

(iii) vegetation establishment (SC6.4.3.9.5(6)(e) Vegetation establishment):

(A) weed control;

(B) watering; and

(C) water level manipulation.

Constructed wetlands are living systems and they require two years of establishment before the vegetation matures and reaches fully functional form. During this establishment period, regular site monitoring and maintenance is critical to the success of these systems. Reference must also be made to the SC6.4.3.9.5(7) Maintenance requirements – constructed wetlands and SC6.4.3.9.5(6) Construction and establishment – constructed wetlands for guidance on maintenance procedures and vegetation

establishment.

Similarly, the vegetation planted in sedimentation basins require an equivalent vegetation establishment period (i.e. 2 years) and level of attention to site preparation, stock sourcing, vegetation establishment and maintenance to ensure success. Reference must be made to the sections entitled “Landscape Design Notes”, “Maintenance Requirements” and “Construction and Establishment” in Chapter 4.

(d) Vegetation selection for mosquito management

Species selected should have a stiff, thin, upright growth habit. This allows mosquito predators to access all wet areas and control mosquito larvae. Species with a spreading habit such as turf grasses or wide strappy leaves such as Typha can isolate pockets of water where mosquitoes can breed and avoid predation.

Table SC6.4.3.9.23 A3: Macrophyte and groundcover plant species list for wetlands and sedimentation basins

Key to Table SC6.4.3.9.22 A3:

Zone		Depth*(m)	Form	
P	Permanent Pool	2.0– 0.7	S	Submerged macrophyte
DM	Deep Marsh	0.7 – 0.35	E	Emergent macrophyte
SM	Shallow Marsh	0.35 – 0	Am	Amphibious
LB	Lower Batters	0 – +0.5**	A	Annual Groundcover
UB	Upper Batters	+0.5- +1.0**	Sh	Shrub
			Tr	Trees

* ‘Depth’ refers to depth below permanent pool water level

** ‘+’ denotes levels above permanent pool water level

Strongly recommended – perennial, vigorously growing species with appropriate traits for good pollutant removal.

Scientific name	Common name	Zone	Type	Perennial or Annual	Height (mm)	Planting Density[2] (Qty/m²)	Comments
Isolepis inundata	Swamp Club-rush	SM	Emergent Macrophyte		To 300	6-8	High surface area; rapid growth
Oryza australiensis	Native Rice	SM	Emergent Grass	Perennial	2500		Attracts birds, native to region
Actinoscirpus grossus		DM	Emergent	Perennial	3000	6	Suitable for clay soils
Baumea articulataarticulate#	Jointed Twig-rush	DM	Emergent	Perennial	1000-2000	6-8	Slow growth, plant solo
Eleocharis sphacelata#	Tall Spike-rush	DM	Emergent	Perennial	500-2000	6-8	Plant solo, rhizomes can restrict growth of other plants; slow establishment, flow resistant,
Leersia hexandra	Swamp Ricegrass	DM	Emergent	Perennial	2000	6	Tolerates periods of flooding, fire resistant
Lepironia articulataarticulate#	Grey Rush	DM	Emergent	Perennial	600-2300	4-6	Tall grey sedge from Hidden Valley, very ornamental, popular in wetland plantings
Phragmites australis#	Common Reed	DM	Emergent	Perennial	5000	6	Native to region, forms dense swards
Phragmites karka (vallatoria)#	Spiny MudgrassTropical Reed	DM	Emergent	Perennial	1000-2000	6	Native to region

Scientific name	Common name	Zone	Type	Perennial or Annual	Height (mm)	Planting Density[2] (Qty/m[2])	Comments
Schoenoplectus litoralis	Shore Club-rush	DM	Emergent	Perennial	600-1500	4-6	Tolerates salinity
Schoenoplectus validus #	River Club-rush	DM	Emergent	Perennial	600-1600	4-6	
Scleria poiformis		DM	Emergent	Perennial	2200	6	Requires irrigation
Thoracostachyum sumatran	Sedge	DM	Emergent	Perennial	2500	6	
Eleocharis dulcis#	Water Chestnut	DM & SM	Emergent	Perennial	1000-1500	4-6	Plant solo, flow resistant
Oryza australiensis	Native Rice	DM & SM	Emergent	Perennial	2500	6	Attracts birds, native to region
Carex polyantha#	Creek Sedge	LB	Emergent Macrophyte	Perennial	To 900	6-8	
Cyperus digitatus	Sedge	LB	Amphibious Sedge	Wet Season Annual	500-1500	8	
Cyperus iria	Rice Flat Sedge	LB	Amphibious Sedge	Wet Season Annual	600	8	Tufted growth
Cyperus tenuispica		LB	Amphibious Sedge	Wet Season Annual	400	8	Suitable for sand and clay solids
Fimbristylis littoralis	Fimbry	LB	Amphibious Sedge	Wet Season Annual		8	Native to region
Juncus pristmatocarpus	Branching Rush	LB	Emergent Macrophyte	Perennial	300-600	6-8	
Phyla nodiflora		LB	Herb	Perennial	200		Native to region
Schoenoplectus lateriflorus		LB	Amphibious Sedge	Wet Season Annual	700	8	
Schoenoplectus praelongatus		LB	Amphibious Sedge	Wet Season Annual	350	8	
Ceratophyllum demersum	Hornwort	P	Submerged	Perennial	600		Native to region
Myriophyllum dicoccum	Water Milfoil	P	Submerged	Perennial or Annual	To 200	1	
Myriophyllum filiforme	Water Milfoil	P	Emergent Aquatic Herb	Dry Season Annual	150	1	
Myriophyllum verrucosum	Red Water-milfoil	P	Submerged	Perennial	100-1500	1	Native to region
Najas tenuifolia	Water Nymph	P	Submerged	Perennial	500	1	
Potamogeton crispus	Curly Pondweed	P	Submerged	Perennial	To 4500	1	Growth can be dense, native to region
Potamogeton octandrus	Pondweed	P	Submerged	Perennial	To 4500	1	
Potamogeton tricarinatus	Pondweed	P	Submerged	Perennial		1	

Scientific name	Common name	Zone	Type	Perennial or Annual	Height (mm)	Planting Density[2] (Qty/m[2])	Comments
Vallisneria gigantea	Ribbonweed	P	Submerged	Perennial	To 3000	1	Rapid growth; salt tolerant (1500 ppm),
Vallisneria nana	Ribbonweed	P	Submerged	Perennial	700	1	Native to region
Ischaemum australe	Zipper Grass	SM	Amphibious Grass	Perennial	1500	6	Forms dense swards
Ischaemum rugosum		SM	Amphibious Grass	Perennial	1200	6	Native to region
Schoenoplectus mucronatus#	Club Rush	SM		Perennial	0.35-1.0m	8	Native to region
Cyperus scariosis	Sedge	SM & LB	Amphibious Sedge	Perennial	800	8	Native to region, salt tolerant
Fimbristylis dichotoma#		SM & LB	Amphibious Sedge	Perennial	1000	8	Native to region
Juncus usitatus#	Common Rush	SM & LB	Emergent Macrophyte		300-1200	8-10	Rapid growth
Dianella longifolia var. longifolia	Pale Flax-lily	UB	GrassLily	Perennial	300-800	6-8	Aesthetic; shade tolerant
Lomandra filiformis spp. filiformis	Wattle Mat-rush	UB	Tufted	Perennial	150-500	6-8	Shade tolerant when established, native to region
Lomandra longifolia #	Spiny-headed Mat Rush	UB	Tufted	Perennial	500-1000	4-6	Shade tolerant, native to region
Sorghum plumosum	Plume Sorghum	UB	Grass		To 4000	6	Growth can be dense
Themeda triandra	Kangaroo Grass	UB	Grass	Perennial	750	8	Requires local propagation, does not tolerate water logged soils
Cyperus polystachyos#	Bunchy Sedge	UB & LB	Sedge	Perennial	To 600	6-8	Suitable for sand and clay soils, Native to region, salt tolerant
Gahnia siberiana	Red-fruited Sword Sedge	UB & LB	Tufted	Perennial	1500-3000	4-6	Aesthetic. difficult to germinate

Note—planting density indicates the mean number of plants per square metre for the species spatial distribution within the zone. The planting densities recommended are suggested minimums. Any reduction in planting density has the potential to reduce the rate of vegetation establishment, increase the risk of weed invasion, and increase maintenance costs.

Table SC6.4.3.9.24 A4: Shrub and tree plant species list for wetlands and sedimentation basins

Scientific name	Common name	Zone	Form	Height (mm)	Planting Density [3] (Qty/m2)	Comments
Callistemon viminalis	Weeping Bottle Brush	UB	Tree	5.0-10.0	<1	Moist, medium to heavy soils, tolerates dry periods once established
Eucalyptus coolabah		UB	Tree		<1	
Livistona decora		UB	Tree		<1	Native to region
Lophostemon suaveolens	Swamp Box	UB	Tree	5.0-25.0	<1	Moist sandy soils
Melaleuca leucadendron	Weeping Paperbark	UB	Tree		2-4	
Melaleuca nodosa	Prickly-leafed Paperbark	UB	Tree	2.0-7.0	2-4	Deep sands and moist sandy soils
Melaleuca viridiflora		UB	Tree		2-4	Native to region
Nauclea orientalis	Leichardt Tree	UB	Tree		<1	Native to region, tolerates high winds and periods of flooding
Pandanus cookii	Screw Pine	UB	Tree		<1	Native to region, tolerates high winds, periods of flooding, fire resistant, will drop leaves
Myoporum acuminatum	Coastal Boobialla	UB	Shrub	0.5-6.0	2-4	Sun or semi-shade, salt tolerant Native to region

Note—planting density indicates the mean number of plants per square metre for the species spatial distribution within the zone. The planting densities recommended are suggested minimums. Any reduction in planting density has the potential to reduce the rate of vegetation establishment, increase the risk of weed invasion, and increase maintenance costs.

SC6.4.3.10 On-site sewerage facilities

SC6.4.3.10.1 Introduction

This sub-section provides standards, advice and guidelines for applicants in the design, installation and siting of wastewater treatment and disposal systems.

The principle underpinning the use of on-site wastewater treatment and disposal is that all design, installation and construction will meet the demands of a development, whilst having full consideration of the effects to public health and ensuring that adverse impacts on environmental values are avoided.

Council will apply these guidelines when processing applications involving on-site sewerage facilities or servicing of development outside of reticulated sewerage supply areas, or applications incorporating the use of an on-site sewerage facility.

Editor's note—development within SC2.5 Natural resources overlay map-Water resource catchments (OM-09) or Natural assets environmental importance overlay map (OM-08) will need to consider additional setback requirements, including requirements for exclusions of infrastructure in some instances when applying the standards of this policy.

Editor's note—before an on-site sewerage facility can be installed on a property, the applicant is required to apply for a permit to install the treatment facility on that property. Applications to install an onsite sewerage facility are to be lodged with the Hydraulic and Building Services Unit of council as part of the plumbing/drainage application. Applicants should also refer to the On-site sewerage facilities for non-sewered properties guidelines which provides details on the application and installation stages of an on-site sewerage facility. This document may be found on council's website.

(1) Terminology

Unless noted otherwise all terms have the same meaning as given in the *Plumbing and Drainage Act* 2002 (the PD Act), the *Standard Plumbing and Drainage Regulation* 2003 and the relevant Australian/New Zealand Standard or Australian Standard. If a definition given in the relevant Australian/New Zealand Standard or Australian Standard is inconsistent with the PD Act or Regulation, the PD Act or Regulation prevails to the extent of the inconsistency.

Intermittent water course	A natural or artificial channel, identifiable by recognisable bed and banks, along which rain water or storm water usually or occasionally flows. The term does not include a closed conduit for conveying storm water.
Top bank	The same meaning as outer bank as defined in the *Water Act 2000.*

(2) Reference and source documents that are to be read and applied in conjunction with this policy sub-section are as follows:

AS/NZS 1546.1 *On-site domestic wastewater treatment units-septic tanks*
AS/NZS 1547:2000 *On-site domestic wastewater management*
AS/NZS 3500.2:2003 *Sanitary Plumbing and Drainage*
Environmental Protection Act and all subordinate legislation, in particular the *Environmental Protection (Waste Management) Regulation 2000* (Design Rules)
National Construction Code Volume 3 – Plumbing Code of Australia
Plumbing and Drainage Act 2002 (and associated Regulations)
Queensland Plumbing and Wastewater Code

Editor's note—council has specifically referred to AS/NZS 1547:2000 *On-site domestic waste water management* and is, for the purpose of this policy, the adopted standard to be read and applied in conjunction with this policy sub-section.

SC6.4.3.10.2 Application guidelines

(1) The following section details the design standards and reporting requirements for wastewater treatment systems generally, to assist applicants in demonstrating they have met the requirements of the Townsville City Plan.

(2) Development which is not connected to council's sewerage system and is not within a reticulated service area will require an on-site sewerage disposal report to demonstrate the effective and safe disposal of sewerage on-site, having particular regard to the nature of the development proposed, demands the development will place on a system, the land and surrounding environment and known hydro-geologic, public health or otherwise constrained concerns.

The report should be prepared by a professional engineer or hydraulic consultant, to document a site and soil evaluation and design of disposal facility as per procedures, reporting requirements and standards outlined AS/NZS1547:2000.

(3) As a minimum, the on-site sewerage disposal report submitted in support of an application should provide detailed information on the following; the report should:

(a) provide sufficient information for deciding whether or not a development area, subdivision, or lot is suitable for on-site system(s);

(b) provide detailed site-specific information identifying the site-and-soil characteristics to be taken into account when selecting and designing an on-site system;

(c) identify, analyse, and evaluate any risks posed by site-and-soil characteristics which might compromise the long-term effectiveness of the on-site system(s);

(d) identify, analyse, and evaluate any risks of contamination of groundwater or surface water and of associated health risks; and

(e) specify measures required to reduce and monitor such risks.

Editor's note—the flow rates should be determined using Appendix 4.2D (H in 2012 standard) *Typical Domestic Wastewater Flow Design Allowances* in AS/NZS 1547:2000.

(4) The designer's report/design, at a minimum, must comply with the requirements of the AS/NZS 1547:2000. For the purposes of reporting, Table 3.1 of AS/NZS 1547:2000 Part B; Unsewered subdivision proposals, Sections 2 (Subdivision design) and Section 3 (System Design) as well as Section 4 of AS/NZS 1547:2000 are considered relevant and should be used as a primary guide for preparing reports as it outlines the essential stages and implementation processes required. To the extent relevant, reporting should also consider the requirements of the *Queensland Plumbing and Wastewater Code.*

(5) The designer must undertake (or have undertaken) soil testing as necessary to enable an appropriate design to be completed. This may include but not be limited to the following: soil percolation tests; bore holes; test pits and soil textural analysis. The report should consider the following points when carrying out a site and soil evaluation:

(a) the determination of potential effluent disposal problems. These may include gullies, rock formations, hollows, or inconsistent soil texture, both on and off the property;

(b) the consideration of previous and current weather conditions in the determination of the site's suitability for effluent disposal;

(c) the demonstration that the disposal area is located above the 5 per cent AEP;

(d) the site plan showing the setback requirements (for buildings, pools, bores, permanent and intermittent water courses, vehicular traffic areas and drains etcetera) both on and off the property, which may influence the location of the disposal area;

(e) a proposed land application area that shall not be cut, filled or modified in any way after the site evaluation has been carried out. If this does occur the designer must be informed so that appropriate amendments can be made to the design; and

(f) the designer is to make their recommendation based on the site and soil evaluation carried out.

In addition to the above, the following must also be reported on:

(i) topography and drainage;

(ii) climate data and statistics;

(iii) groundwater information (extractive bores, uses and quality);

(iv) infrastructure (existing and proposed);

(v) potential for cumulative effects on receiving environments;

(vi) off-site impacts;

(vii) presence of any fill material;

(viii) geotechnical hazards;

(ix) setback distances;

(x) potential for environmental or public health impacts; and

(xi) site plans (individual or multiple lots).

Much of the Townsville coastal plain is derived from Quaternary alluvium which in many places has been transported and reworked as a result of changes in drainage patterns over time. This has resulted in varying soil texture types occurring in both top and sub-soil zones with a variety of geometries that cannot be assumed on a broad-scale. In recognition of this fact, site soils assessments should form part of all future reports. This approach provides for a representative assessment of the respective area's soils and enables the determination of the land capability and hydraulic loading required for the development (eg LTAR, DIR/DLR).

The soil assessment should be able to provide information on the suitability of different methods of wastewater disposal based on soil textures and hydraulic properties of the actual soils in the area of interest. In order to develop an appropriate level of confidence in the results presented, the details, locations and results of soil sampling and hydraulic property testing should accompany any report submitted.

Site specific data relating to soil properties must be utilised for any method employed as this is the media through which any potential impacts or mitigation caused by wastewater disposal must pass through. Any assessment that does not include this data collection and input carries with it an inherent risk of inaccurate prediction of effluent transport and behaviour and may even accentuate the utilisation of inappropriate system and disposal methods.

(6) Water tables in tidal areas are to be determined to the minimum accepted tidal water table in seaside areas that experience tidal influence (for example Cungulla, Magnetic Island, Cleveland Palms). The minimum water table level is taken to be the contour level of 2.25 m (Australian Height Datum). This allows for an astronomical tide of 4.1 m. Therefore, to determine vertical separation distances, this level must be taken into consideration. A site and soil evaluation may indicate the presence of a higher water table. This, along with wet weather water tables, shall be taken into consideration.

To assist applicants, the following report structure can be used in preparing an On-site sewerage disposal report, when read and applied in conjunction with relevant provisions found in AS/NZS1547:2000, including procedures outlined in sections 4.1.3.4 and 4.2.3.2 of AS/NZS1547:2000

(a) Site and soil evaluation report (all references are to AS/NZS1547:2000)

(i) Details of the site and soil evaluation personnel confirming:

- past experience of site and soil evaluation assessments;
- successful completion of an accredited training program (if applicable);
- knowledge of the regulatory assessment requirements; and
- professional liability for the interpretation of, conclusions drawn from and recommendations made as a result of the site evaluation.

(ii) desk top study as per relevant section of 4.1A2;

(iii) site and soil check as per relevant section of 4.1A3;

(iv) soil assessment items as per relevant section of 4.1A4; and

(v) evaluation of results as per relevant section of 4.1.4.

(b) Design report

(i) Details of land application facility designer confirming:

- past experience designing on-site sewerage disposal facilities;
- successful completion of an accredited training program;
- knowledge of the regulatory design requirements; and
- professional liability for the interpretation of, conclusions drawn from and recommendations made as a result of the design.

(ii) Documentation of the design process, including:

- system selection as per section 4.2A4;
- soils and LTAR/DLR values as per section 4.2A5; and
- design flows as per section 4.2A6.

(iii) Reserve area as per section 4.2.3.4,

(iv) Distribution system as per section 4.2.3.6,

(v) Nutrients as per section 4.2.3.6

(vi) Rainfall surface flow control as per section 4.2.3.7

(vii) Land use activity as per section 4.2.3.8

(viii) Site plan

- north point;
- full property description;
- name of person who evaluated the site;
- scales of 1:200 or 1:500;
- predominant wind direction;
- location, height, density and type of vegetation;
- access roads, tracks, vehicle manoeuvring areas, storage areas;
- test boreholes/pits;
- fall of land;
- setbacks;
- water supply bores, top banks of water courses, lakes, ponds, unlined stormwater drainage channels, dams;
- buildings, fences, property boundaries, pedestrian paths, walkways, recreation areas, retaining walls, in-ground swimming pools, in-ground potable water tanks; and
- primary and reserve land application areas.

It is the designer's responsibility to carry out their duties in accordance with the AS/NZS 1547:2000, the *Queensland Plumbing and Wastewater Code* (where relevant), and any other relevant legislation and supported by good engineering practice.

(7) Design flows

Any consideration of design flow should utilise guideline appendices of AS/NZS1547:2000 and incorporate allowance for peak usage and occupancy.

(8) System selection and land application design

The selection of the appropriate wastewater treatment system and disposal method should be based on the individual characteristics of the lot in question and any reporting recommendations based on investigation (as outlined in this policy sub-section). The assumption of a single type wastewater system being utilised across all lots in any subdivision application is not recommended.

Any system proposed for a lot should comply with all relevant Codes and Standards such as AS/NZS1546.1 and the *Queensland Plumbing and Wastewater Code*. Water balance and nutrient loadings need to be considered prior to the determination of appropriate lot sizes.

The assessment of soil properties (texture and hydraulic) assists in determining ideal rates of application and

also the suitability of proposed methods of disposal. The Queensland Water Recycling Guidelines (2005) provide indicative concentrations of total nitrogen (TN), total phosphorous (TP) and total dissolved solids (TDS).

It is recommended that a two stage approach be undertaken for supporting the final determination of lot sizes in a given subdivision and which is based on the suitability of the soils to certain methods of wastewater disposal, as well as any requirements of Townsville City Plan, including any applicable overlay provisions. The results of the site and soil assessment inform the selection of an appropriate system and subsequent land application design

SC6.4.3.10.3 Design considerations

(1) Set back distances

Set back distances are to comply with the requirements of the Queensland Plumbing and Wastewater Code and AS/NZS1547:2000.

Council may consider viral die off and nutrient decay calculations as a means of justifying a reduced set back distance from the following features:

(a) top bank of an intermittent water course; or

(b) easement boundary of an unlined open stormwater drainage channel or drain.

The consideration of reduced setback distances are subject to the requirements of the Townsville City Plan, which may require increased setback distances to watercourses or in some instances, development to be placed outside of riparian or wetland buffer areas as detailed in the Water resources catchment overlay code or the Natural assets overlay code. Furthermore, it will be necessary for applications to demonstrate that there will be no adverse environmental impacts, taking into consideration cumulative impacts from other development, to place infrastructure near a watercourse, wetland or open stormwater drainage channel/drain.

SC6.4.3.11 On-site water supply

SC6.4.3.11.1 Introduction

(1) Objectives

(a) The objective of this sub-section is to outline the requirements for the design and supply of potable water and non-potable water where development is located outside of a reticulated water supply area.

(b) Specifically, the following overall objectives are sought to be achieved as identified by the Townsville City Plan:

(i) to ensure adequate water supplies are available for people and fire-fighters to defend buildings from bushfires and to suppress other property fire;

(ii) ensure that development is provided with a reliable and safe supply of on-site water supply when located outside of a reticulated water supply area;

(iii) ensure that on-site water supply facilities are efficient;

(iv) ensure that on-site water supply facilities do not compromise environmental values;

(v) ensure that on-site water supply facilities are not subject to sources of contamination; and

(vi) ensure the safety and wellbeing of residents and the protection of water quality and other environmental values.

(2) Scope

(a) This sub-section sets out the requirements for development located outside of reticulated water supply area for the provision of potable and non-potable water supply facilities.

(b) This sub-section contains guidelines and statements for the design of potable water supply facilities and non-potable supply, including for fire protection.

(c) This sub-section may be applied to areas where a reticulated water supply exists and an alternative supply is sought to supplement the reticulated supply.

(3) Applicability

(a) This sub-section is to be used for assessment against the following codes where development is required to provide water supply outside of a reticulated water supply area:

(i) 6.6.1 Rural zone code (Cungulla Precinct);

(ii) 8.2.2 Bushfire hazard overlay code;

(iii) 8.2.9 Water resource catchment overlay code;

(iv) 9.2.3 Reconfiguring a lot (subdividing one lot into two lots) and associated operational work code;

(v) 9.4.4 Reconfiguring a lot code;

(vi) 9.4.5 Self-assessable works requirements code; and

(vii) 9.4.7 Works code.

(4) Terminology

Available roof area	means the whole of the roof area of every building on the lot included in a development application
Blackwater	is defined as: - the waste discharged from the human body into a toilet; and - the waste used for discharge.

Drinking water or potable water	water of a quality suitable for drinking, cooking and personal bathing. The standards that define potable water are described in the Australian Drinking Water Guidelines.
Drinking water supply system (water supply system)	all aspects from the point of collection of water to the consumer (can include catchments, groundwater systems, source waters, storage reservoirs and intakes, treatment systems, services reservoirs and distribution systems, and consumers).
Greywater	means wastewater from a bath, basin, kitchen, laundry or shower), whether or not that wastewater is contaminated with human waste.
Greywater treatment plant	a treatment plant, approved and installed under the *Plumbing and Drainage Act 2002.*
Hazard	a biological, chemical, physical or radiological agent that has the potential to cause harm.
Non-potable water	water that is not of drinking water quality, but which may still be used for other purposes, depending on its quality.
On-site water supply	is defined as a private, non-mains supply, such as water that is not provided as a reticulated council supply.
Required fire-fighting capacity	the volume of water required to comply with Part E of the *Building Code of Australia*.
Service reservoir/tank	a storage for drinking water, generally within the distribution system, used to meet fluctuating demands, accommodate emergency requirements and/or equalise operating pressures.

SC6.4.3.11.2 On-site water supply general requirements

(1) This section outlines the on-site water supply systems suitable for use in the Townsville local government area.

(2) The on-site systems may be used in combination with one another to deliver a reliable supply of potable and non-potable water.

(3) Any on-site water supply should use water efficiently and minimise the whole of lifecycle cost for that infrastructure.

(4) Any on-site water supply should not adversely affect environmental values.

(5) Unless water is known to be of potable quality (e.g. from a drinking water supply system) it should be regarded as non-potable and used appropriately (fire fighting, irrigation of landscaping).

(6) On-site water supplies must not be subject to hazards and hazards must be managed appropriately to ensure a safe supply is available at all times for potable use in addition to fire-fighting requirements.

(7) Water supplied to the public must not constitute a public health risk

(a) Under the *Food Act 2006*, food businesses must ensure water used in their business (which may include roof harvested rainwater) complies with the requirements of the *Australia New Zealand Food Standards Code*, Standard 3.2.3.

(b) The *Australia New Zealand Food Standards Code*, Food Safety Standard 3.2.3 – *Food Premises and Equipment*, requires food businesses to use potable water for activities conducted on the premises. Where businesses do not have access to a potable water source, they must be able to demonstrate that the water is safe to use. Non potable water may only be used when it will not affect food safety i.e. the washing of non-food contact surfaces such as floors.

(c) The water must be of a potable quality unless the food business can demonstrate that the non-potable water will not adversely affect the safety of the food handled by the business.

(d) Food businesses must ensure the water they use for food related activities conducted at their premises is potable (safe for human consumption).

These activities include:

(i) washing food or ingredients;

(ii) cooking;

(iii) adding to food and drinks;

(iv) making ice;

(v) cleaning of food contact surfaces;

(vi) cleaning of food containers and utensils; and

(vii) personal hygiene.

(8) Council may set conditions of approval dealing with the following matters (but not limited to):

(a) a maximum volume of ground water extraction for the development based on the findings of the groundwater resource assessment study;

(b) annual review of the effect of the authorised level of extraction in light of regional ground water level data collected from all relevant observation bores in the district. If regional ground water levels are declining, council may limit the previously authorised level of extraction, in terms of pumping rate or duration or both;

(c) maintenance of safe access to bores for inspections by council staff; and

(d) on-going monitoring, including:

(i) provision of a report recording ground water levels each month for 6 months; and

(ii) regular testing of ground water quality (e.g. for nitrates and bacteria) if the ground water is to be used for potable purposes. If levels are found to be above the relevant drinking water quality standard, provision for an alternative potable source of water will be required.

(9) The following on-site water supplies are permitted (SC6.4.3.11.12 Water resource catchment overlay):

(a) rainwater harvesting (tanks);

(b) groundwater (bore water);

(c) surface water;

(d) carted drinking water;

(e) recycled water (reclaimed water); and

(f) greywater (non-potable from manual supply service).

(10) The following on-site water supplies are not considered appropriate for supply:

(a) recycled carted water; and

(b) greywater – (potable supply from permanent structure).

SC6.4.3.11.3 Water quality for on-site supplies generally

(1) The *Australian Drinking Water Guidelines* (ADWG) are the standards for potable water for use in the Townsville area. SC6.4.3.11 Attachment A sets out the potable drinking water requirements to be achieved.

Editor's note—the current *Australian Drinking Water Guidelines* cover a range of topics, including management of water supply systems, water quality (microbiological, physical, chemical and radiological) and monitoring.

(2) The following information should be used in undertaking testing of water quality.
References:

(a) AS 5667.1:1998.

Editor's note—physical and chemical samples:
Use a bottle supplied by the laboratory or thoroughly clean a plastic bottle about one litre in volume (ie. Soft drink bottle), then rinse several times with the sample before filling.

Transport the sample directly to the laboratory on the day of sampling if possible, otherwise refrigerate and deliver within 24 hours of collection.

DO NOT FREEZE SAMPLE.

Editor's note—microbiological samples
Collect sample in sterile bottle provided by the laboratory, or in a 250 ml sterile container which can be bought from a Pharmacy. Do not rinse out the bottle with sample.

Remove cap, fill bottle leaving a small air space, then replace cap without touching the insides of the cap or bottle.
Transport the sample directly to the laboratory on the day of sampling if possible, otherwise refrigerate and deliver within 24 hours of collection.

DO NOT FREEZE SAMPLE.

Editor's note—pumped supply:
Pump for four hours to remove stagnant water from the bore hole and pipes before sampling.

If the bore runs dry before four hours are up, let it stand until it can be pumped again, then pump again until dry, repeat this process once more, then sample.

Note pumping time, type of pump, type of casing, depth, age of bore, etc. (this information can be useful to the laboratory for

interpretation of results).

SC6.4.3.11.4 Rainwater harvesting (tanks)

Editor's note—HB 230:2008 Rainwater tank design and installation handbook—provides practical information for the collection, use and storage of rainwater.

(1) A tank installed for a building must have sufficient collection and storage capacity to provide an acceptable contribution for its external and/or internal connections and their associated water use, having regard to the following:

(a) the local rainfall pattern;

(b) the roof catchment area; and

(c) the area available for the location of the rainwater tank.

(2) Installed tanks must ensure they comply with the requirements of the *Public Health Regulation 2005*. The legislation stipulates a "relevant tank"— a tank or other receptacle that is used or intended to be used for holding or storing water — must have at every opening:

(a) mosquito-proof screens that:

(i) are made of brass, copper, aluminium or stainless steel gauze;

(ii) have a mesh size of not more than 1 mm;

(iii) are installed in a way that does not cause or accelerate corrosion; and

(iv) stop mosquitos passing through the openings; or

(b) flap valves that, when closed, stop mosquitoes passing through the openings.

(3) A tank must have suitable measures to prevent:

(a) insects (mosquitoes) and other fauna from breeding inside the tank;

(b) if a wet system supplies the tank— insect (mosquito) and fauna-proofing for each pipe opening that supplies the tank, with screen mesh with an aperture of no greater than 1 mm; and

(c) vermin from entering the tank.
The following are acceptable:

(i) screen mesh with an aperture of no greater than 1 mm, made of brass, copper, aluminium or stainless steel gauze to prevent the intrusion and breeding of insects (mosquitoes) and other fauna;

(ii) flap valves at each opening of the tank; and

(iii) a vermin trap.

(4) A tank must have suitable measures to prevent contaminants from entering the tank especially having regard to the potential nature and level of contaminants within the locality and on-site uses.

A tank must have a minimum of 20 litres of first flush from the roof catchment area so that potentially contaminated rainwater is diverted and discarded before entering the tank where the tank is connected to:

(a) a shower or wash basin; or

(b) a swimming pool; or

(c) kitchen or hot water service; or

(d) another fixture required by a local government in a local planning instrument.

Editor's note—for those with a rainwater supply, it is important to check regularly to ensure that first-flush devices are working properly. It is also important to keep the roof catchment clean — bird droppings, peeling paint and dirt on the roof are the biggest sources of contamination. Guttering should be cleared regularly and overhanging branches should be kept to a minimum, because they can be a source of debris and allow birds and small animals access to the roof.

Editor's note—HB 230:2008 *Rainwater tank design and installation handbook*—provides practical information for the collection, use

and storage of rainwater.

(5) The occupier of a place where a rainwater tank is installed (or if there is no occupier, the owner of the premises) must ensure that the tank is maintained at all times to ensure a reliable supply.

(6) Where in a reticulated water supply area, water from a tank must not contaminate the potable water within a reticulated town water supply system. Where tank/s are installed, the reticulated town water supply system is protected from the potential of back-flow by the installation of:

(a) a back-flow prevention device that complies with AS/NZS 3500:2003; or

(b) for a tank, a dual-check valve with an atmospheric port.

(7) A tank stand and the support base of a tank must be capable of withstanding loads likely to be imposed. The base of the tank is well supported by a ground treatment in accordance with the manufacturer's specifications and standard drawings for that tank.

(8) Where a premises is providing tank water supply and required to also install a static water supply for fire fighting purposes, applicants will need to also comply with SC6.4.3.11.11 Requirements for fire fighting.

(9) Where a tank is installed to supply water to the plumbing fixtures, the tank must have appropriate and clear signage to warn that the water in the tank is suitable for drinking.

(10) All water tank overflows are to be connected to or able to discharge to a lawful point of discharge.

(11) Development proposing to utilise a rainwater tank must determine that adequate rainwater volume can be collected to meet the annual water demand.

Editor's note—calculating the maximum amount of rainwater that can be collected from the available roof area can be completed using the following formula.

run-off (litres) = A x (Rainfall – B) x roof area

"A" is the efficiency of collection and values of 0.80-0.85 (that is, 80-85% efficiency).

"B" is the loss associated with absorption and wetting of surfaces and a typical value of 2 mm per month (24 mm per year) can been used.

"Rainfall" should be expressed in mm and "roof area" in square metres (m^2).

For example, the run off from a 200 m^2 roof which receives 750 mm of rain per year, with an efficiency of collection of 80% (A = 0.80) and loss of 2 mm per month (B = 24) would be: Run-off = 0.8 x (750-24) x 200 = 116,160 Litres (or 116.2 kL).

(12) If the maximum volumes are less than the annual water demand, then either the catchment area will need to be increased or water demand will need to be reduced or an alternative and supplementary source will need to be nominated.

SC6.4.3.11.5 Groundwater (bore water)

(1) In Queensland, the Department of Natural Resources and Mines (DNRM) manages access to and use of underground water.

The right to take underground water is either established under the *Water Act 2000* (the *Water Act*) or granted under a "licence" or "water allocation". The drillers' licensing arrangements under the *Water Act* ensure all water bore drillers are properly skilled and that their work meets minimum standards.

Editor's note—information on water bore drillers and bore drilling requirements can be found on the DNRM website.

(2) Each lot created or use proposed is to be provided with a proven and available long term sustainable resource of potable groundwater, properly licensed as required, supplemented where practical, with an alternative supply such as rainwater.

Editor's note—water from a deep, encased and well maintained bore and/or from a confined aquifer will generally not need treatment after addition to a rainwater tank, but the chemical quality of some groundwater is not suitable for drinking.

(3) Only groundwater that is compliant with values cited in the *Australian Drinking Water Guidelines* (ADWG) should be used.

Editor's note—key health parameters for groundwater are arsenic, nitrate, fluoride and health-related heavy metals. Salinity is an important aesthetic parameter.

Editor's note—groundwater from shallow or unconfined aquifers is readily contaminated by agricultural, industrial or urban activities and generally should not be used as a source of drinking water unless it has been recently tested for microbial and chemical quality and is compliant with guideline values cited in the ADWG.

(4) Water treatment devices/technologies to improve the aesthetic values, microbial and chemical quality of water are to be installed to ensure that all ground water achieves the guideline values cited in the ADWG. Methods used to treat groundwater must be certified by a registered professional in the field of ground water quality and must be installed and commissioned prior to occupation of the use (except where water supply is combined with fire fighting water).

(5) Any proposed ground water extraction, when combined with existing levels of extraction in the area, is to be sustainable on both a local and regional level. The average annual demand for ground water must not exceed the average long term recharge in the area.

To demonstrate compliance with the above criteria, council may request that a Groundwater resource assessment be undertaken by a qualified hydro-geologist.

A Groundwater resource assessment should include, at a minimum:

(a) consideration of information available from previous studies and new information collected as part of the investigation;

(b) consideration of the maximum ground water extraction rate attainable, proposed pumping rates, land slope, flooding, drainage, geology, ground water recharge potential, local experience, proximity to and protection from potential contaminants, soil characteristics (colour, texture, structure, permeability and presence of rock), percolation testing, direction of ground water flow, seasonal fluctuation in ground water levels, and the current degree of district and local extraction;

(c) a comparison between the average annual ground water demand and the average annual ground water recharge, on a local and a district level;

(d) the results of drilling and testing of an adequate number of bores, supplemented with ground water modelling where necessary, to ensure a thorough and accurate investigation of the ground water resources available. Bores are required for two purposes, namely, for interference testing and for regional ground water level observation;

(e) results of independent and simultaneous pumping of test bores, and measurement of water levels to check for localised pumping interference with any existing and proposed neighbouring bores. Pumping tests should be undertaken for a minimum of 8 hours duration and pumped at the rate the pump is intended to be operated in the proposed development. The available draw down in neighbouring bores during the test must not be reduced by greater than 20% when compared to available draw down in these bores prior to pumping;

(f) if bore interference is found to be greater than 20% of the available draw down, supplementary pumping tests must be undertaken to measure the effect of reducing either the pumping rate, the duration of pumping, or both, until the resulting interference is within this level;

(g) water quality testing to determine whether extracted water will be of a potable quality, including where relevant, written advice from a registered professional in the field of ground water quality. Appendix A outlines appropriate standards for bore water testing (potable uses);

(h) investigation of previous land uses and the possibility of contamination of aquifers to determine the quality of ground water;

(i) details of the pump type, capacity and pumping curve for bores; and

(j) preparation of a report detailing all the studies and works undertaken, the resource assessment findings and assumptions made.

(6) Methods used to treat groundwater to meet health and aesthetic guidelines must be certified by a registered professional in the field of ground water quality.

(7) For licensing and construction requirements for underground water the local DNRM office should be consulted.

Editor's note—before considering sinking a water bore refer to fact sheet Drilling for water on the DNRM website.

(8) The bore shall be constructed to ensure that contamination of the groundwater source does not occur, either during construction or operation.

(9) The bore head shall be mounded to prevent ponding and stagnation of water around the bore to eliminate the possibility of mosquitoes breeding and problems caused by flies or odour.

(10) All drainage shall be directed away from the bore.

(11) Bores nominated to supply potable water supply are to be appropriately site away from sources of contamination, including on-site sewerage facilities. For further details relating to on-site sewerage facilities, refer to the sub-section SC6.4.3.10 On-site sewerage facilities for non-sewered properties.

(a) On-site sewerage treatment facilities shall be placed as far away as possible from ground water bores used for potable groundwater supply. Minimum allowable distances are to be in accordance with the *Plumbing and Drainage Act 2002* and relevant codes and regulations established pursuant to the *Plumbing and Drainage Act,* which are applicable at the time of making application for development approval.

(b) New land parcels or existing land within non-sewered areas must provide evidence prior to the sealing of the plan of survey or the commencement of the use that an appropriate on-site sewerage treatment facility can be designed and accommodated within each proposed lot in addition to the potable supply of ground water.

SC6.4.3.11.6 Surface water

(1) Surface water includes water derived from dams, creeks, rivers and streams.

(2) The use of surface water is generally considered permissible only when in a non-urban zone (excluding rural residential).

(3) Surface water supplies are more prone to contamination from sources such as animal and human waste and algal blooms.

(4) Due to the potential for contamination, surface water is not recommended as a source of drinking water unless additional treatment processes such as filtration and disinfection are in place.

(5) Unless drinking water quality can be assured through disinfection and routine testing, surface water should be utilised for purposes other than drinking such as irrigation and toilet flushing and fire fighting. Treatment may still be necessary for non-drinking uses.

(6) Water subject to potential contamination from human or livestock waste, such as dams, rivers and creeks, can contain a wide range of pathogenic organisms including chlorine-resistant Cryptosporidium. Water of this type may not be suitable for drinking even after disinfection.

(7) Surface water that is protected from human and livestock waste can be used and should be demonstrated.

(8) Surface water must be able to provide a reliable year round supply of water for both potable and fire-fighting purposes and should be demonstrated.

(9) Potable water quality:

(a) When used, pumped or captured surface water should be added to a storage tank in one action, then treated and allowed to stand for at least one hour before use.

(b) Where surface water is to be the primary source of a potable water supply, the quality of water extracted is to be of a potable quality and meet aesthetic, chemical and microbial requirements.

(c) Water treatment devices/technologies to improve the aesthetic values, microbial and chemical quality of water are to be installed to ensure that all surface water achieves the guideline values cited in the ADWG.

(d) Methods used to treat surface water must be certified by a registered professional in the field of water quality and must be installed and commissioned prior to occupation of the use (except where water supply is combined with fire fighting water).

(10) Each surface water pump point must be metered (or where there are multiple, collectively recorded), with the meter maintained, read and the volume pumped recorded on a quarterly basis.

(11) Any proposed surface water use is to be sustainable on both a local and regional level. The average annual demand for surface water must not exceed the average long term recharge in the area to ensure ground water supplies are maintained.

(12) To demonstrate compliance with the above criteria, council may request that a groundwater resource assessment be undertaken by a qualified hydro-geologist.

SC6.4.3.11.7 Carted drinking water

(1) The use of carted drinking water supply is only used as a supplementary/secondary supply measure to ensure a long term and sustainable supply of water to a premises.

(2) Water cartage is necessary in some instances to supplement existing rainwater supplies.

Editor's note—if rainwater collection is limited by the size of storage tanks or roof catchment areas or a lack of rain, drinking water supplies may need to be augmented with carted water.

(3) Carted water is not be used as a sole source of supply except as a temporary use.

(4) Carted water is to be stored in water tanks as outlined in SC6.4.3.11.8 Rainwater harvesting tanks.

(5) Drinking water is recognised as a food. Water carters/carriers may need to be registered as a food business if the supply of additional potable water is needed.

(6) When using carted water, it is advisable to ensure the water carter can provide evidence that water supplied will be safe to drink. This evidence could include: any authorisations issued for the purpose of supplying drinking water; the identity and quality of the source water; proof that tankers used are suitable for the purpose of carrying drinking water (for example, not likely to have carried other materials that would contaminate drinking water).

(7) Ensure that carted water supplied for drinking is disinfected at the point of supply (such as the rainwater tank) as this provides protection against contamination introduced during filling of the water tanker and during transport to the point of supply.

SC6.4.3.11.8 Recycled water

(1) Recycled water is any water that has been used at least once and then supplied for reuse, either treated or untreated. Without appropriate treatment, recycled water may contain a range of contaminants.

Editor's note—for example, water used for the final rinse in a commercial laundry is only lightly contaminated and thus may be used again, untreated, for the first wash cycle. On the other hand, sewage must be treated at a sewerage treatment plant before it can be recycled for any purpose.

Recycled water from sewerage treatment plants is put into different classes depending on its microbiological quality. These classes range from Class A+ (the highest) to Class D (the lowest).

(2) The use of recycled water can reduce the demand on alternative supplies that are potable.

(3) Recycled water can be used where it is demonstrated that it is safe to do so and does not adversely affect the environment, adjoining properties or constitute a public health risk.

(4) Recycled water is not to be used for potable water, food preparation or topping up of pools or spas, but may be appropriate for private and commercial purposes such as irrigation and possibly toilet flushing, car washing and dust suppression (or similar), including for fire-fighting.

(5) Recycled water when used for watering plants and lawns (source of irrigation) can be an effective means of saving water provided some sensible precautions are undertaken, including watering several locations to

prevent salts and other contaminants from accumulating in the soil and rotation of irrigation using mains or rainwater to help flush salts from the soil.

(6) Signage must be erected at sources of recycled water use to advise that the water is not suitable for drinking.

(7) The static storage of recycled water must be separately stored from other sources of potable water.

(8) The quality of the water will determine the permitted uses and businesses using recycled water are required to obtain approval and adhere to any specified conditions.

(9) The storage of untreated water for more than 24 hours (bacteria and organic contaminants in water will cause it to turn septic and produce strong and offensive odours).

(10) Recycled or untreated water is not allowed to pool or run-off onto other properties, into watercourses, public space or the stormwater system.

SC6.4.3.11.9 Non-restricted water supply risks

(1) Selecting an alternative supply, consideration must be given to the potential health concerns, sensible practices and disinfection options available as well as the location, rainfall patterns, supply required and overall cost (initial and maintenance).

Editor's note—advice on the use of on-site water supply:

- ensure water is collected from the most suitable and safest source available;
- determine what microbial or chemical contaminants are in the surrounding environments and what effects they may have on the water used;
- treat water if necessary to make it safe. This could involve the removal of solids, chemicals and microorganisms;
- ensure collection sources for rain water such as roofs and gutters are kept free of extraneous matter such as leaves and bird droppings;
- ensure a first flush system is used for all rain water collection to ensure that the first water collected during a rain fall event is discarded thereby reducing the amount of microorganisms entering the tank;
- ensure tanks which are used to store water are cleaned out regularly to remove any build up of sludge or debris. This reduces the potential risks of chemical or microbiological contamination of the water;
- where water is supplied by a water carrier, it should be sourced from a potable water supply. The carrier should have hoses which are in good operating condition and are capable of being effectively cleaned and sanitised. The water carriers should only used for the purpose of carrying potable water, the operator should be able to provide documentation showing this;
- ensure all equipment that is used to collect and store the water is suitable and well maintained;
- ensure all equipment used in the collection and storage of water is well positioned to minimise the risk of contamination;
- ensure all water storage equipment is vermin proof; and
- monitor the water regularly to ensure that the conditions of the water have not changed and any treatments being undertaken are appropriate to ensure its safety. It is important to remember that some water sources such as bore water may have a very high mineral load. While this may not affect the safety of the water, it may affect the quality, flavour and hardness and have an undesirable effect on the equipment that is used. It is recommended that water is tested by an accredited laboratory on a regular basis to ensure the steps that have been put in place are still adequate to maintain the safety of the water.

  For advice on what constitutes good quality water see the *Australian Drinking Water Guidelines 2011* available from the National Health and Medical Reserch Council's website.

SC6.4.3.11.10 Requirements for non-potable water supply

(1) The *Plumbing Code of Australia* requires that a non-drinking water supply:

  (a) must only be connected to outlets clearly identified for non-drinking use and must be limited to the uses specified in the Code; and

  (b) is not to have a cross connection with a drinking water service.

Editors note—if non-potable water is adequately treated, its quality will improve and it can be used for a wider range of purposes. Some examples of non-potable water used are:

- class A recycled water from a sewage treatment plant used for dust suppression, car washing, landscape irrigation or irrigation of sporting ovals;
- quarry water used for dust suppression and landscape irrigation;
- swimming pool backwash water used for toilet flushing;

- agricultural waste water used for crop irrigation; and
- creek, dam, and river water used for dust suppression.

SC6.4.3.11.11 Requirements for fire-fighting supply

Editor's note–fire fighting uses large amounts of water. If fire fighters need to leave a site to obtain more water, that site will be undefended and may be damaged or lost. If fire fighters don't have access to adequate water supplies at a site they may not even attempt to defend the site because it will be unsafe.

Editor's note - Where the building Code of Australia and applicable Queensland Building Codes provide standards for the installation of fire fighting appliances, the provisions of those standards shall prevail.

The purpose of this section is to outline adequate and accessible water supplies required for fire-fighting purpose and to ensure that they are available for people and fire-fighters to defend from fires. Suitable water supplies and appliances shall be provided and easily accessible at all times.

(1) The minimum dedicated amount of water for fire-fighting purposes is 10,000L of stored (static water) for a property less than 2500 square metres in area and at least 20,000L of stored (static water) for property greater than 2500 square metres. The amount of stored static water must be available and accessible at all times.

Editor's note—some development may require more water to comply with the Building Code of Australia or to ensure that an adequate supply to available to service a particular development where that development is likely to require increased fire fighting capacity.

(2) Fire-fighting water supply needs to be provided and easily accessible at all times, although it does not need to be drinkable (potable).

(3) A dedicated water tank for the storage of fire-fighting water is the accepted standard. Where alternatives are provided, it should be demonstrated that the water supply will be available and accessible at all times.

(4) Where not using a dedicated fire fighting storage tank, the outlet for the internal fixtures is located above the point at which the tank will contains the dedicated amount for fire-fighting purposes.

(5) Fire-fighting water supplies (including pipelines, hydrants, fittings and storages) are:

- (a) provided before building construction commences;
- (b) designed, located and fitted to ensure reliablity during a fire (eg: polypipes are buried or shielded - refer to the National Plumbing and Drainage Code AS3500);
- (c) properly maintained and accessible at all times by emergency vehicles;
- (d) tanks must be located so that a vertical clearance of 4m to overhanging obstructions is achieved (vegetation, power lines);
- (e) a cleared area on either side of the tanks, a minimum of 6m, to allow fire-fighting vehicles and crews access to the tanks; and
- (f) tanks should avoid be located on slopes, including access to, greater than 12 per cent.

Editor's note: A fire truck has to be within about 3 metres from a water supply to be able to pump from it.

Editor's note: Plastic tanks dedicated for fighting purposes are not recommended, however if they are submerged, they may be acceptable.

(6) At least one tank is within 100m of the building which has fire brigade tank fittings. If the tank is underground, it has an access hole of 200mm (minimum) to allow access for suction lines.

(7) A water supply for fire fighting purposes must be clearly marked and identified by emergency services and others. Where a dedicated tank for storage of fire fighting water is used, the tank must have appropriate signage to warn that the water in the tank is not suitable for drinking.

Editor's note—The following is applicable for development within the Water resource catchment overlay map OM-09 (Schedule 2 of Townsville City Plan) and where development is to address the assessment criteria of the Water resource catchment overlay code found in Part 8.2.9 of the Townsville City Plan.

SC6.4.3.11.12 Water resource catchment overlay

(1) To demonstrate the protection of water quality, ecological values and other environmental values, applicants may be asked to provide groundwater resource assessment where the proposed development is to use any ground resource as outlined in SC6.4.3.11.5(5).

(2) No on-site water supply infrastructure, including underground pipe, is to be located such that it will not change the physical integrity of waterways, wetlands, lakes, springs and riparian areas.

(3) On-site water supplies may only be from harvested rainwater (tanks) or ground water (where undertaken and demonstrated sustainable by a ground water assessment) and may be supplemented by carted water.

(4) Recycled water or greywater is not to be used to protect the water catchment from potential contamination.

(5) The capture of ground surface water is not permitted.

(6) A ground water level observation bore is to be installed adjacent to the site. The observation bore must be installed remote from all production bores to ensure there is no local interference to ground water levels at the observation bore.

(7) Council may set conditions of approval dealing with the following matters:

- (a) a maximum volume of ground water extraction for the development based on the findings of the groundwater resource assessment study;
- (b) annual review of the effect of the authorised level of extraction in light of regional ground water level data collected from all relevant observation bores in the district. If regional ground water levels are declining, council may limit the previously authorised level of extraction, in terms of pumping rate or duration or both;
- (c) maintenance of safe access to bores for inspections by council staff; and
- (d) on-going monitoring, including:
  - (i) provision of a report recording ground water levels each month for 6 months; and
  - (ii) regular testing of ground water quality (e.g. for nitrates and bacteria) if the ground water is to be used for potable purposes. If levels are found to be above the relevant drinking water quality standard, provision for an alternative potable source of water will be required.

SC6.4.3.12 Constructed lakes

SC6.4.3.12.1 Introduction

(1) Purpose

The purpose of the policy sub-section is to provide standards, advice and guidelines for the design, construction and maintenance of constructed lakes in the Townsville area.

Well designed and maintained lakes can add considerable value to the urban environment including improved visual amenity, recreational opportunities, and wildlife habitat.

Lakes built in the dry tropics region of Townsville operate under a range of challenging climatic conditions, and maintaining a healthy water body can be difficult to achieve. The extended dry season combined with high rainfall events during the wet season mean that lakes often undergo rapid changes in state. A healthy water body can very quickly develop poor water quality and algal blooms that are unsightly and a potential threat to public health.

A number of constructed lakes have been built in and around the Townsville area and are experiencing numerous problems. These include:

(a) weed infestations (terrestrial and aquatic);

(b) excessive siltation;

(c) highly turbid waters;

(d) poor water quality;

(e) stratification;

(f) frequent algal blooms;

(g) fish kills; and

(h) limited maintenance access to remove built up silt, debris and weeds.

The burden of rectifying these lakes and satisfying community expectations has been incurred by council. As a consequence, council has identified a need to regulate the construction of lakes within the Townsville area.

Editor's note—Part 9.4.2 Healthy waters code of the Townsville City Plan provides assessment matters for applications involving lakes to specifically consider, in addition to other relevant sections of the Townsville City Plan.

(2) Objectives

This sub-section outlines the information that should be lodged with a particular development application if that development includes a lake.

Note—this sub-section is intended to provide the necessary guidance to design a sustainable healthy lake in the Townsville area. However, due to the challenging climatic conditions experienced in Townsville and the low number of examples of constructed lakes, this sub-section does not guarantee performance, and proponents should be aware that lake designs in accordance with this sub-section do not exempt the proponent from any necessary post construction maintenance and rehabilitation prior to handover.

(3) Principles

(a) Lake designs should aim to enhance biodiversity through revegetation, establish linkages with existing vegetation communities, and be supportive of public interaction and education. Lakes designs should provide enhanced landscape aesthetic and amenity for surrounding residents through the installation of improved passive recreation facilities i.e. paths and trails.

(b) The primary intent and range of uses for the lake is to be clearly defined by the proponent. The design intent must be accompanied by concept plans showing location and layout with respect to the development. Council will consider applications that are sustainable for their intended use, have no negative impact on surrounding environments and have been designed to minimise on-going maintenance.

(c) Uses preferred by council:

(i) The preferred lake with regards to long term sustainability, weed and water level management is a saline lake. Although less diverse than fresh water lakes, the operation of saline lakes are considered more robust for Townsville conditions.

(ii) Where fresh water lakes are proposed, the proponent should consider other alternatives such as heavily vegetated constructed wetlands which can provide open water views and water treatment benefits (refer to SC6.4.3.9 Water sensitive urban design guidelines). The proponent must clearly indicate how water level variations will be managed and proposed alternative sources of water to maintain lake water levels within acceptable variations.

(iii) The following are not encouraged by council:

(A) brackish lakes, including saline lakes that receive large freshwater inflows;

(B) lakes that receive untreated stormwater (i.e. stormwater that has not been treated to achieve the requirements of the SC6.4.3.9 Water sensitive urban design guidelines, or untreated overflows);

(C) lakes that are greater than 3 m in depth from wet season normal water level to finished bed level;

(D) lakes that impact on the sustainability and health of local aquifers or adjacent waterways;

(E) lakes that promote primary and secondary human contact activities such as boating, swimming, fishing and skiing;

(F) lakes that are used for flood management purposes;

(G) lakes for stormwater harvesting;

(H) lakes that result in the removal of existing significant vegetation;

(I) lakes that disturb natural waterways i.e. are located within the natural waterway alignment; and

(J) lakes that are primarily designed as a source of fill for development (i.e. to raise the level of the development site).

(d) Lakes should be constructed off-line to minimise any disturbance to the passage of aquatic fauna. Off-line systems facilitate lake draining and maintenance, if necessary. Should in-line diversion structures be proposed to supply constructed lakes (e.g. diversion weirs) suitable arrangements must be made to maintain connectivity (i.e. fish passage) and stream base flows or environmental flows.

(4) Terminology

Aquifer	A geological formation saturated with water that contains and transmits water.
Brackish lake	A lake that is permanently or temporarily in a state between fresh and saline. For the purposes of this policy salinity levels range between 1,000 – 15,000 mg/L. Brackish lakes include fresh water lakes with saline intrusions, groundwater dominated brackish lakes or saline lakes with freshwater input. Brackish lakes are not encouraged Townsville.
Constructed lake	An artificial body of permanent open water with recreational values with either an edge fringed with emergent macrophytes or a hard edge. While submerged macrophytes may occur throughout the water column, the dominant feature is open water. For the purposes of comparing with a constructed wetland, a lake is a water body that has greater than 30% of its area as open water (i.e. less than 70% as emergent macrophytes). For the purposes of this document, a constructed lake is considered to be a receiving water body, and does not contribute to the mandatory water quality improvements outlined by the State Planning Policy.

Constructed wetland	An artificial, shallow body of water that consists of heavily vegetated macrophyte zones and deep pools that support a range of aquatic vegetation across the majority of the waterbody area. A constructed wetland has less than 30% of its area as open water (i.e. more than 70% as emergent macrophytes). The inlet zone and deep pools of a constructed wetland may, for instance, resemble a pond, but the dominant feature of the system is the macrophyte zone, containing emergent marsh, rush and reed vegetation that can withstand wetting and drying cycles. The structure and function of constructed wetland systems means they can remove pollutants from stormwater runoff through enhanced sedimentation, fine filtration and biological uptake (refer to SC6.4.3.9 Water sensitive urban design guidelines).
Dam	An artificial body of permanent open water provided as a source of water. In the context of this policy a dam can be used as a storage mechanism to provide lake top-up water.
Environmental value	Values or uses of water that support healthy ecosystems and contribute to public benefit, safety and health. Environmental values are typically determined through a transparent process involving government, industry groups and the community. Environmental values require protection from the effects of pollution and discharges.
Fresh water lake	A lake that receives treated stormwater runoff inflows only and is not influenced by tidal inundations or saline groundwater intrusions. Typically salinity levels are less than 1,000 mg/L
Lake catchment	The area from which all stormwater runoff flows into a lake.
Macrophytes	Large, submerged or emergent aquatic plants.
Normal water level (NWL)	The normal operating water level of the lake system, as defined by the lake outlet.
Primary contact	With regards to constructed lakes includes recreational activities that result in the immersion of the body in the water. These include swimming, skiing, diving and wading.
Receiving water body	A water body that receives stormwater runoff from the catchment under consideration. For the purposes of this policy constructed lakes and natural wetlands are included in the definition of receiving waters, but constructed wetlands that have been built primarily for the purpose of stormwater (or wastewater) treatment, are not. Saline lake - A lake that is permanently in a saline state, whether tidally influenced or as a result of groundwater intrusions. Salinity levels are at or above 15,000 mg/L permanently.
Secondary contact	With regards to constructed lakes includes recreational activities that result in some contact with the water but not the immersion of the body in the water. These include boating and fishing.
Sediment	Solids (typically sand, silt and clay) that are transported by water and deposited from suspension. Considered to be a "contaminant" as defined in the *Environmental Protection Act* (1994) or any latest version of this act / legislation / documents.
Stormwater	Surface water that runs off land or structures on land following a rain event (including piped flows).

Stormwater quality improvement devices (SQIDs)	Devices used to improve the health of the receiving waters by reducing the amounts of pollutants that enter waterways from stormwater runoff. Types of SQIDs include trash racks, gross pollutant traps, sediment basins, constructed wetlands, bio-retention devices and swales.
Water body	A water body, whether constructed or natural, that has defined bed and banks. A water body can be fresh or saline and can be tidally influenced.
Waterway	Means any of the following (whether or not temporarily dry: river, creek, stream, gully or drainage channel, including the bed and bank, whether modified or not. This term includes waterways indicated on the Townsville City Plan maps.
Water quality indicators	A water quality indicator is a physical, chemical and biological property of water that can be measured in a quantitative way (e.g. pH, temperature). The resulting water quality data enables trends or changes in water quality to be determined over time.
Water quality objectives (WQOs)	Measurable values for the quality of receiving waters to ensure that Environmental Values of those waters are safeguarded.
Water sensitive urban design (WSUD)	WSUD is an approach to water management in urban areas with the "interactions between the urban built form (including urban landscapes) and the urban water cycle as defined by the three urban water streams being potable water, wastewater and stormwater" (Engineers Australia 2003).

(5) Reference and source documents

(a) Queensland state legislation

Editor's note—design of a constructed lake may also need to consider relevant Queensland state legislative requirements as listed below or any latest version of these acts/legislation/documents.

SC6.4.3.12.2 Minimum requirements

(1) The proponent must clearly demonstrate through design, investigation and monitoring that the proposed lake will:

(a) be sustainable for its intended use;

(b) have no negative impact on surrounding environments;

(c) provide a high level of amenity to surrounding land uses;

(d) have no adverse impacts on flood capacity;

(e) be safe due to minimisation of hazards; and

(f) be designed to minimise on-going maintenance.

(2) General requirements

A suitably qualified and Registered Professional Engineer of Queensland (RPEQ), with specific water sensitive urban design and lake design experience, must undertake or oversee all aspects of the constructed lake design. As constructed lakes will often involve significant landscape input, a suitably qualified landscape architect registered with the Australian Institute of Landscape Architects (AILA) should also work with the RPEQ.

The design must comply with all relevant requirements of:

(a) the requirements of the Townsville City Plan and, specifically, Part 9.4.2 Healthy waters code and any other applicable development codes;

(b) this sub-section;

(c) reference and source documents listed in SC6.4.3.12.1(5), in general;

(d) any development approval conditions relevant to the design; and

(e) any specific relevant and reasonable request, sought by council in writing.

The RPEQ shall sign all plans associated with the lake, certifying that the design, subsequent construction and performance criteria complies with this section.
Regardless of final ownership of the proposed lake, the proponent is to follow the requirements of this sub-section.

(3) Minimum functional requirements

The following are considered minimum requirements for the sustainable healthy operation of a lake:

(a) lake depths of 1.5 m to 3 m to finished bed level at the wet season normal water level (preferably 2-2.5 m). A minimum lake depth of 1.5 m is considered necessary to allow maintenance equipment such as floating weed harvesters to access lakes;

(b) sufficient inflow to sustain lake water levels within acceptable variations;

(c) upstream water quality treatment devices (SQIDS) to ensure inflows to the lake meet the requirements of the State Planning Policy and SC6.4.3.9 Water sensitive urban design guidelines. Untreated overflows must by-pass constructed lakes;

(d) floating aquatic vegetation minimised within the lake to reduce potential organic carbon loads;

(e) shaped and oriented to minimise dead spots. Where possible lake shapes should be orientated in the direction of the prevailing wind to improve mixing;

(f) suitable outlet configuration to manage lake water levels to facilitate plant and lake establishment, and on-going management actions (i.e. lower lake level by gravity);

(g) measures to pass high flows (i.e. untreated over flows) around the lake;

(h) sufficient liner (e.g. clay) at the lake floor to ensure the system minimises seepage losses, and in some cases to stabilise the lake bed (i.e. cover marine clays);

(i) integration of the lake within the site constraints;

(j) sufficiently strong embankments and overflow structures to manage peak flows and erosion;

(k) suitable access for heavy machinery in various locations to enable management actions (i.e.de-silting, weed and debris removal);

(l) edge treatments that minimise potential weed ingress;

(m) consideration of public safety issues and hazards (i.e. edge treatments, access to water, CPTED principles, flood capacity);

(n) sufficient measures to minimise algal bloom development (e.g. sufficient lake turnover and/or other strategies for managing algal growth such as mechanical aerators and mixers, ultrasonic treatments etc.);

(o) protection and appreciation of existing natural assets such as significant trees, marine plants, billabongs and wetlands;

Editor's note—applicants should also refer to Part 8.2.5 Natural assets overlay code and SC6.9 Natural assets planning scheme policy for additional information.

(p) sufficient measures to control pests (including bird population control) and mosquitoes including providing a habitat for predators;

(q) enhanced biodiversity through revegetation; and

(r) enhanced landscape aesthetic and amenity for surrounding residents through installation of improved passive recreation facilities i.e. paths and trails.

SC6.4.3.12.3 Development application requirements for constructed lakes

(1) Information for development applications

All drawings and documents submitted to council for approval shall be prepared by a suitably qualified person.

(a) MCU/ROL applications

The proponent will be required to submit a constructed lake concept design report with comprehensive management plans to support a development application for reconfiguring a lot (ROL) or material change of use (MCU) or operational works, where the proposed development includes a lake.

A separate stormwater quality management plan will be required to support the concept design report where a fresh water lake is proposed.

Table SC6.4.3.12.1 provides a checklist of items for submission at the MCU/ROL stage.
Additional plans/reports may be required to meet necessary state legislation requirements due to the proposed works, or other requirements of the Townsville City Plan.

(b) Operational works applications

Following approval from council and other relevant government agencies of concepts submitted as part of the ROL/MCU application, detailed design documents will be required for operational works approval. Detailed design documents shall be in both graphic and written form and contain sufficient information to enable council to assess compliance with the applicable codes.

The detailed design submission for operational works approval must include:

(i) constructed lake detail design report (updated from the ROL/MCU submission);

(ii) construction drawings – civil/landscape;

(iii) constructed lake technical specifications;

(iv) soil erosion sediment control plan;

(v) constructed lake monitoring plan (updated from the ROL/MCU submission);

(vi) constructed lake maintenance plan (updated from the ROL/MCU submission);

(vii) groundwater assessment and management plan (updated from the ROL/MCU submission); and

(viii) acid sulfate soils management plan, where required, and generally in accordance with the relevant State Planning Policy and its referenced documents.

Editor's note—additional reports/plans may be required to meet necessary regulatory and/or Townsville City Plan requirements due to the proposed works.

(2) Construction

Construction can only commence following operational works approval. Works are to be carried out in accordance with the approved drawings and specifications and any associated management plans as a result of the development assessment process.

(3) Constructed lake landscape plan

A constructed lake landscape plan is required at the ROL/MCU stage and is to be refined as part of the operational works submission in consultation with council.

Constructed lakes will most likely be included in developments to provide a high amenity focal point for residents. The lake designs should aim to enhance biodiversity through re-vegetation and establishing linkages with existing vegetation communities, public interaction and education.

Landscape plans are to be provided and prepared by a suitably qualified landscape architect/designer, registered with AILA.

The landscape plan should demonstrate that the lake blends into surrounding environment (built and natural) and protects and enhances natural features such as significant trees and existing aquatic habitats (i.e. streams, billabongs, freshwater wetlands, saltmarshes). Landscape designs are to consider the principles of crime prevention through environmental design (CPTED).

At the ROL/MCU stage plans are to be developed that show:

(a) existing ground levels;

(b) the proposed lake footprint with respect to the development;

(c) road and lot layout;

(d) existing and retained vegetation;

(e) natural features and receiving environments;

(f) edge batter treatments including provision for irrigation where applicable;

(g) proposed lake operating levels (dry, normal and wet) and base levels;

(h) topsoiling and lining;

(i) adjacent levels including roads, property boundaries and floor levels;

(j) setbacks, buffers and landscaping;

(k) accesses;

(l) inlets and outlets including treatments to minimise visual impact;

(m) activities to be carried out in the area adjacent to the lakes e.g. parks and car parks;

(n) photographs showing examples of design intent and character;

(o) educational opportunities such as signage and public art; and

(p) highest astronomical tide and 50 year flood levels.

Figure SC6.4.3.12.1 Example of a lake landscape plan

Constructed lake landscape plans are to be updated as part of the operational works submission, including planting details (refer to SC6.4.3.12.5(12) Step 12), landscape surface treatment plans, landscape details and specifications. The use of endemic plant species is to be encouraged.

Landscape design can play an important role in overcoming negative community perceptions to certain lake treatments such as tree plantings where residents in the past have deliberately removed trees and shrubs due to concerns with pests. Signage explaining the function of each element in the overall design can help educate local residents.

(4) Constructed lake recreation plan

A constructed lake recreation plan is required at the ROL/MCU stage and is to be refined as part of the operational works submission in consultation with council.

A recreational management plan is to be developed by a suitable qualified landscape architect/designer registered with AILA in association with a recreational consultant and must include details on proposed activities including pedestrian movement and signage.

Lakes designs should provide enhanced landscape aesthetic and amenity for surrounding residents through the installation of improved passive recreation facilities such as paths, trails, viewing platforms, picnic and playground nodes. Lake recreational areas are to be designed so that they are available to all groups of the population, i.e. it should consider all abilities. The lake design and associated parklands must be:

(a) consistent with the area's social and recreational master plans; and

(b) cognisant with local planning and other issues.

Designs should also be mindful of the amount of space a proposed lake will take and how this will impact on other recreational activities to ensure a balance land use outcome. Consideration should also be made to other amenity values such as shade, character and multi-use.

Linkages between the lake and recreational master plans are also to be provided (e.g. footpaths, cycleways, etc.).

(5) Constructed lake monitoring plan

A constructed lake monitoring plan is required at the ROL/MCU stage and is to be refined as part of the operational works submission. The monitoring plan is to set out the testing schedule and frequency for monitoring lake health. Water quality monitoring will be critical in assessing the on-going performance of the lake and provide the basis for remedial and adaptive management activities. Costs associated with monitoring must be included in the life cycle costing (SC6.4.3.12.5(18) Step 18) and must be separated from other costs.

The proponent will be required to develop a water quality strategy including water quality objectives to maintain environmental values of the lake, receiving waters and ground water, where applicable. Water quality objectives will be required to be derived for local conditions in accordance with the *Queensland Water Quality Guidelines 2009.* When deriving suitable values for the water quality strategy the proponent must take into consideration local water quality values of source and receiving waters, together with local aquifer water quality, if applicable.

A summary of all water quality results will also be required for handover purposes. Council will not consider handover until all monitoring results and reports are received.

Minimum monitoring requirements

(a) weekly in-situ testing using a multi-probe for pH, turbidity, DO, temperature and EC at 0.5 m depth intervals from surface to lake bed at the lake inlet and outlet;

(b) weekly laboratory testing (NATA approved) for algal counts, TN and TP. Surface samples at the inlet and outlet are required;

(c) weekly measurements of lake water level;

(d) monthly laboratory testing (NATA approved) for E.coli, TSS, turbidity, NH3, TKN, Nitrate/Nitrite, TN, TP, FRP, Al (soluble). Surface samples at the inlet and outlet are required;

(e) trapping of adult mosquitoes at the lake site (weekly during the wet season from the on-set of the first wet season rains, fortnightly to monthly other times);

(f) larval surveys from shallow flooded vegetated areas around the lake (weekly during the wet season from the on-set of the first wet season rains, fortnightly to monthly other times);

(g) fortnightly water level and EC measurements of groundwater from installed monitoring wells (where shallow groundwater is observed); and

(h) annual bathymetry of lake bed to determine sediment accumulation.

Reporting

Quarterly reports are to be submitted to council summarising the water quality monitoring results. The reports shall also include summaries of local climatic conditions, including daily rainfall and shall also include any observations made during the period (e.g. visual water quality, odours, algal biomass, fish kills etc.). Copies of lab testing results are to be included in an appendix to the report. Water quality exceedences (considering trigger values derived to maintain environmental values of the lake, receiving water body and groundwater, if applicable) are to be clearly identified. The reports shall also detail any corrective measures that may have been taken.

Quarterly reports are to be submitted within 1 month of the last monitoring event in the quarter.

An annual report will be required to assess the overall performance of the lake based on the monitored and observed data throughout the monitoring period. The report should detail performance with respect to the intended design and actions taken to meet the intended performance.

Corrective actions and adaptive management

Table SC6.4.3.12.2 provides indicative target values for lake health relevant for Townsville for the range of physico-chemical indicators to be tested on a weekly basis. The values have been derived from the *Queensland Water Quality Guidelines* and are provided for guidance only.

The proponent must derive local water quality objectives in accordance with the procedures outlined in the

Queensland Water Quality Guidelines (DERM, 2009). This will involve definition of the water type, selection of indicators, selection of reference sites, collection of reference data and derivation of guideline values based on the reference data.

Parameter	Freshwater	Mid-Upper Estuarine
pH	6.5 - 8.0	7.0 - 8.4
DO	>6 mg/L	>6 mg/L
TDS	<1,000 mg/L	>15,000 mg/L
TN	0.35 mg/L	0.3 – 0.4 mg/L
TP	0.01 mg/L	0.025 – 0.04 mg/L
Turbidity	1 - 20 NTU	8 - 25 NTU
Chl-a	5 ug/L	4- 10 ug/L

Table SC6.4.3.12.2 Suggested target values for physico-chemical indicators.

Table SC6.4.3.12.3 provides target values for the management of cyanobacteria (blue green algae) and mosquitoes. The presence of cyanobacteria can present a significant hazard to lake users. The values for cyanobacteria have been derived from the *Guidelines for Managing Risks in Recreational Water.*

Parameter	Freshwater lake	Saline lake
Cyanobacteria	≤500 cells/mL *Microcystis aeruginosa* or biovolume equivalent ≤0.04 mm^3/mL combined total of all cyanobacteria	Refer to guidance provided in the 'Guidelines for Managing Risks in Recreational Water' (National Health and Medical Research Council, 2008)
Mosquito larvae	1 larvae per 2 ladle dips (300mL ladle)	1 larvae per 2 ladle dips (300mL ladle)

Table SC6.4.3.12.3 Suggested target values for cyanobacteria and mosquito populations.

Where weekly testing indicates values above derived water quality objectives or biological indicators, corrective actions are to be taken as soon as possible. Exceedance or other lake health issues such as fish kills and odour problems shall be reported immediately to council and the Department of Environment and Heritage Protection (EHP). The source of the exceedance should be identified as soon as possible.
Typical corrective actions include:

- contacting council and EHP as soon as an exceedance is identified;
- identifying the cause of the water quality or biological indicator problem. This includes reviewing monitoring and operational data, climatic data, upstream sources, internal lake processes etc. Discussions with designers, council/EHP may be required to gain a better understanding of the problem and determine possible actions;
- increasing the frequency of monitoring of parameters of concern;
- minimising potential impacts to downstream receiving environments e.g. temporarily block outlets; and
- undertaking remedial action on items identified as potential sources e.g. upstream water quality improvement devices.

An important component of the monitoring plan will be the adaptive management strategies to be developed for algal blooms and mosquito outbreaks. The following provides guidance on suitable adaptive management strategies for a adaptive management of algal blooms and adaptive management of mosquito outbreaks.

Adaptive management of algal blooms
Design of lakes in Townsville must include an algal management strategy as defined in SC6.4.2.12.5(8) Step 8. The algal management strategy is intended as a proactive response and not a reactive response to cyanobacterial blooms.

When a cyanobacterial bloom occurs in a freshwater lake, it will be necessary to follow the recommended actions detailed in the *Queensland Water Quality Guidelines*. For algal blooms in saline lakes, refer to the algal guidelines for coastal and estuarine waters in the *Guidelines for Managing Risks in Recreational Waters.*

Adaptive management of mosquito outbreaks
Larval counts of 1 per 2 ladles (300 mL ladle) are indicative of possible mosquito problems for adjacent residents (Warchot and Whelan, 2008), however resident complaints or significant numbers of mosquitoes in adult trapping may also be cause for mosquito control.

Where mosquito problems are encountered a number of actions can be followed:
- identifying the source and cause of the breeding;
- rectification of surface depressions that may lead to isolated pools;
- clearing collected debris that may be in and around the lake;
- draining areas identified with large mosquito breeding;
- ensuring suitable native fish species are present in the lake; and
- use of a suitable insecticide/larvicides.

Use of insecticides can quickly control mosquito breeding, but is not recommended as a long term strategy due to potential issues with insecticide resistance, long term cost of maintaining a mosquito control program and the possibility of the insecticide applications not being able to target all areas of breeding (Warchot and Whelan, 2008).

Ecologically friendly insecticides include (Whelan and Warchot, 2008):
- Bacillus thuringiensis var. Israelensis;
- Bacillus sphaericus; and
- Methoprene.

(6) Constructed lake maintenance plans

A constructed lake maintenance plan is required at the ROL/MCU stage and is to be refined as part of the operational works submission in consultation with council. A final approved constructed lake maintenance plan will be required prior to asset handover.

The constructed lake maintenance plan shall be a living document that can be updated should there be any changes during construction. The plan must include all expected maintenance associated with the constructed lake and associated infrastructure such as pumps, recirculating wetland and landscape treatments.

The maintenance plan is intended to ensure that the lake functions as intended and is not prone to weed

infestations or decreased amenity values. The maintenance plan must clearly set out:

(a) expected maintenance activities;

(b) frequencies;

(c) roles and responsibilities;

(d) maintenance procedures;

(e) equipment requirements;

(f) product specifications;

(g) occupational health and safety;

(h) public safety;

(i) environmental protection;

(j) disposal;

(k) accesses;

(l) emergency responses; and

(m) notification requirements.

Maintenance forms must be developed as part of the plan and filled in and stored during inspections and maintenance.

The costs of expected maintenance activities must be included in life cycle costing (SC6.4.2.12.5(18) Step18), and must be separated from other costs. The maintenance plan will need to consider lake monitoring and adaptive management to ensure maintenance responses to monitoring exceedences.

The maintenance plan must clearly describe activities required during establishment, defects liability period and those following asset handover. Intensive maintenance will most likely be required during the first few years during lake and plant establishment. This is also the time when the lake is most vulnerable to sediment loads from construction activities. Design drawings are to be included as part of the maintenance plan.

The maintenance plan must consider lake accesses as detailed in SC6.4.2.12.5(14) Step 14, and maintenance draining as outlined in SC6.4.2.12.5(10) Step 10.

Typical maintenance actions include:

- routine inspections of the lake for vegetation health, weed infestations, scour, litter and debris and mosquitoes;
- routine inspection of inlets and outlets for sediment build up, scour, litter and blockages;
- removal of litter and debris;
- removal and management of invasive weeds;
- periodic de-silting;
- replacement of plants that are damaged or have died with equivalent plants;
- regular irrigation of plants during establishment;
- repairs due to vandalism; and
- mosquito control including repair to lake edges to prevent the formation of isolated pools.

Inspections for removal of debris should be done regularly and removed whenever observed. Scour around the inlets and outlets should be checked following large storm events.

Construction drawings

All drawings submitted to council for approval shall be prepared by a suitably qualified person and shall conform to the standards detailed in SC6.4.2.5 Details on drawings.

Annual lake bathymetry surveys are to be provided to council with estimates of sediment accumulation from the original constructed levels.

As constructed plans are to be provided following handover to council either as an annotated set of the original plans (where variations to the original design are minor) or otherwise as a new site survey.

(7) Constructed lake technical specification

The technical specification shall clearly set out the scope of the works, roles and responsibilities, certification and sign-off and construction hold points. The specifications shall be in accordance with the construction plans and provide flexibility to allow additional field investigation and design modification due to unexpected conditions encountered during construction

(8) Soil erosion management plan

A soil erosion management plan shall clearly identify measures to manage erosion and sediment control during construction and be guided by principles set out in:

- *Best Practice Erosion and Sediment Control*; and
- *Erosion and Sediment Control – A Field Guide for Construction Site Managers*.

The soil erosion management plan shall include:

(a) project and site description (topography, drainage, soils, rainfall);

(b) potential impacts from construction activities including a risk assessment;

(c) soil management measures including a plan showing proposed measures; and

(d) responsibilities, monitoring and maintenance.

The plan must also detail contingencies in the event of unplanned discharges including remediation.

The plan should be a living document that can be modified if site conditions change or if the adopted measures fail to perform as expected.

(9) Soil and groundwater assessment and management plan

A soil and groundwater assessment management plan is required at the ROL/MCU stage and is to be refined as part of the operational works submission. This will be an update from the concept design phase in consultation with council and shall include assessment of any additional soil and groundwater information gained since the concept design stage. Refer to SC6.4.3.12.5(3) Step 3. The soil and groundwater assessment plan should include:

(a) site description including local soil and groundwater characteristics;

(b) field investigation work including any test pitting, monitoring well installation etc.;

(c) laboratory testing and interpretation;

(d) monitoring data and interpretation;

(e) assessment of acid sulfate potential;

(f) identification of problematic soils e.g. sodicity, dispersive soils, peats etc.;

(g) assessment of the shallow groundwater regime, if present; and

(h) groundwater risks and management options

(10) Acid sulfate management plan

When an acid sulfate management plan is deemed necessary, the plan should clearly identify the risk of contamination to the environment and measures to manage the risk. The plan must detail:

(a) construction sequences;

(b) impacts of dewatering;

(c) liming requirements;

(d) exposure of materials;

(e) monitoring requirements;

(f) action plans for unplanned acidification of ground or surface waters; and

(g) responsibilities, reporting and auditing.

(11) Maintenance and handover

(a) Necessary maintenance will be defined in the maintenance plans provided during the ROL/MCU submission and updated during the operational works approval stage. Updates may be required should the designs change during construction and may require the approval of council.

For the purposes of maintenance and the handover, a constructed lake is deemed to include the lake open water body and edge treatments. The limits of each are defined below:

(i) lake water body: all areas to wet season normal water level; and

(ii) edge treatments: all areas from lake wet season normal water level to the edge of the buffer zone (see below).

The lake buffer zone is considered necessary to provide sufficient width to allow maintenance activities (including access by machinery) to be undertaken to all areas of the lake, provide a passage for fauna and provide water quality buffering for untreated overflows entering the lake. A minimum width of 25 m is suggested. Where the proponent proposes a reduced width they must clearly demonstrate that the width is sufficient to maintain the aforementioned functional requirements of this edge treatment.

The proponent is also responsible for any rectification works on areas outside of the constructed lake should the operation of the lake negatively impact on outside areas.

(b) Defects liability period

The defects liability period for the lake water body and edge treatments will commence following practical completion and continue for at least:

(i) 5 years after 90% of all houses are constructed within the lake stormwater catchment, provided the lake is constructed, established and functioning at plan sealing; or

(ii) 5 years after the lake is constructed, established and functioning where the lake is not directly fed from stormwater runoff.

Prior to establishing the lake system, the lake shall be drained and de-silted, where necessary, to establish the lake system as per the detail design.

(c) Handover

At the completion of the defects liability period, a handover meeting will be scheduled between the developer (or representative), maintenance personnel and council.

The council may engage an independent auditor to assess handover and is under no obligation to accept the asset if it does not meet the performance requirements as described in the constructed lake conceptual design report, detailed design report and this sub-section.

Council will only accept the lake once the lake is demonstrated to meet the performance requirements as detailed in the design reports and monitoring plans. The council will require demonstration through a minimum of 5 years of continuous monitoring data (as defined in the monitoring plan) on the performance of the lake system.

Council will require a final survey of the lake floor prior to handover. Where sediment accumulation is in excess of that anticipated the proponent will be required to drain and de-silt the lake and re-establish the lake as per the design. Handover cannot occur until the re-established lake performance is demonstrated over a continuous 5 year period.

As constructed plans are to be provided following handover to council either as an annotated set of the original plans (where variations to the original design are minor) or otherwise as a new site survey.

SC6.4.3.12.4 Lake health considerations

(1) A constructed lake is an artificial body of permanent water with either an edge fringed with emergent macrophytes or a hard edge. While submerged macrophytes may occur throughout the water column, the dominant feature is open water (typically at least 30% of the total area).

Urban runoff entering a constructed lake must have sufficient treatment.

For the Townsville region this includes load reduction from the urban runoff component of:

- 80% reduction in total suspended solids;
- 65% reduction in total phosphorous;
- 40% reduction in total nitrogen; and
- 90% reduction in gross pollutants.

The design of constructed lakes needs to consider the complex behaviour, in particular, the alternate states that lakes can operate under depending on a number of influences and stressors.

Key factors affecting lake health:

(a) nutrients;

(b) light and turbidity;

(c) organic carbon loads;

(d) lake detention time;

(e) salinity;

(f) water level and depth;

(g) mixing; and

(h) temperature.

The designer must also be aware that constructed lakes are community assets and issues such as pest and weed control and integration into the overall landscape design should be considered at the concept design and planning stage.

(2) Lake conceptual model – alternate states

The conceptual model of how lakes transition between alternate states is presented in Figure SC6.4.3.12.2.

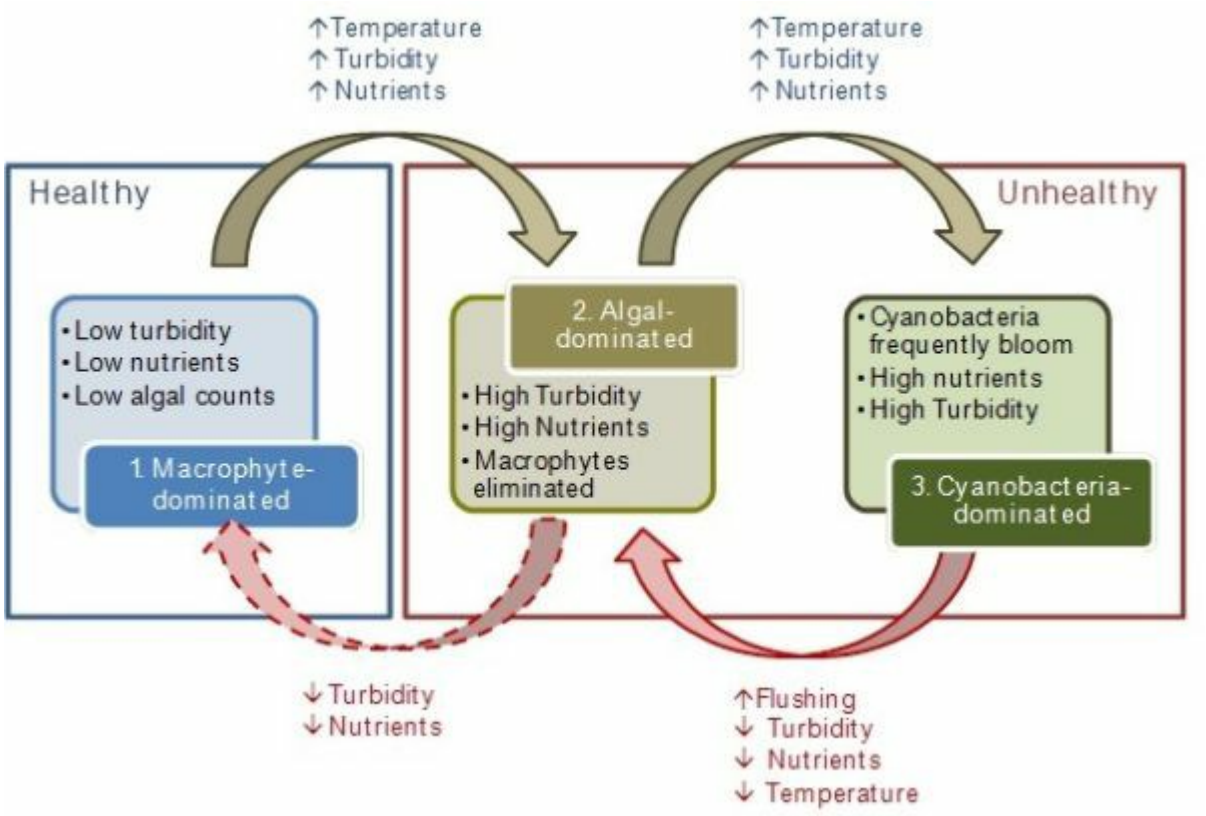

Figure SC6.4.3.12.2 Conceptual model of the alternative states observed in shallow lakes

The alternate states model considers that freshwater shallow lakes may exist as (after Moss, 1998):

- a macrophyte dominated state with clear water; or
- a turbid state dominated by phytoplankton; or
- a cynobacterial (blue-green algae) dominated state

The key driving mechanisms between each of the alternative states are nutrient levels and turbidity. The switch between the alternative states is typically triggered by the exceedance of a critical turbidity threshold. The critical turbidity thresholds required to trigger a switch from one state to another are likely to differ between lake systems and are also influenced by other environmental factors, such as lake detention times and temperature (Scheffer, 1998). Figure SC6.4.3.12.3 (below) illustrates the switch between alternative states.

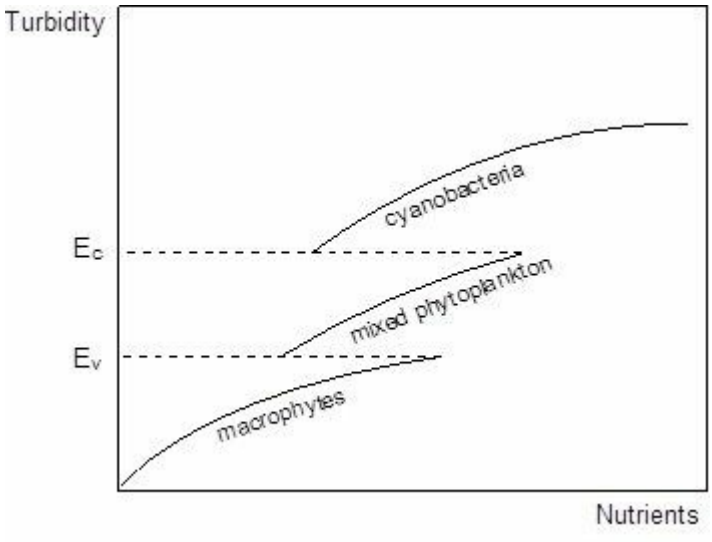

Figure SC6.4.3.12.3 Switch between alternative states

(a) Macrophyte dominated lake

A healthy lake is typically dominated by macrophytes (emergent and submerged water plants).

Macrophyte dominated lakes help maintain low turbidity via the uptake of nutrients, prevention of re-suspension of sediments and provision of refugia for zooplankton against predators (Scheffer, 2001).

Macrophyte dominated lakes are reasonably robust to increased nutrient loads, which allows the macrophyte biomass to increase and thereby maintain low turbidity (Scheffer et al., 2001) i.e. the macrophyte dominated system provides positive feedback to increases in nutrients, enhancing their own growing conditions (Scheffer et al, 2001).

(b) Macrophyte to Phytoplankton state

High nutrient concentrations can lead to an increase in phytoplankton biomass and biofilm growth on the macrophytes, leading to increased turbidity and decreased light penetration which can cause a rapid collapse of the macrophyte community (Scheffer, 2001).

The switch to a phytoplankton state is considered problematic with regards to lake heath as this state inhibits the growth of macrophytes (mainly due to low light penetration) and maintains high turbidity levels. Once a lake has switched to a phytoplankton dominated state, restorative efforts to reduce turbidity and re-establish macrophyte communities are extremely difficult.

(c) Phytoplankton to Cynobacteria state

The switch from a phytoplankton dominated state to a Cynobacterial dominated state is generally triggered in response to increased turbidity and water temperatures (Scheffer, 1998). Whilst both Cyanobacterial and phytoplankton (non-Cyanobacterial) communities may dominate over a range of nutrient concentrations, a critical turbidity level exists above which the Cynobacteria will become dominant (refer to Figure SC6.4.3.12.4).

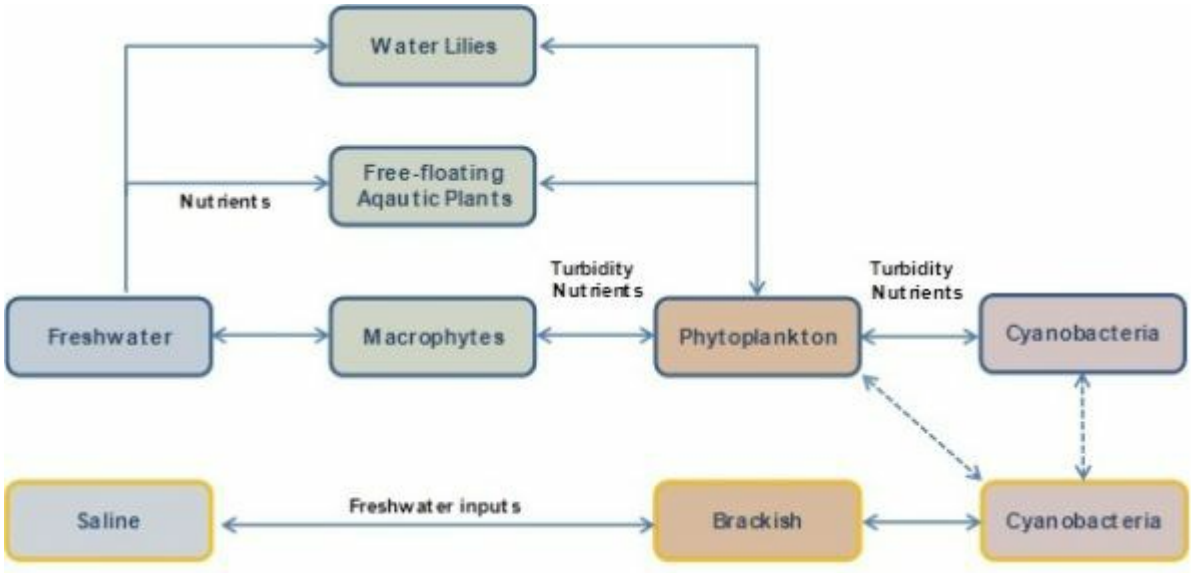

Figure SC6.4.3.12.4 Fresh and saline lakes alternate states

In saline lakes, alternate states are triggered by freshwater inputs, which result in brackish lakes that are highly susceptible to Cyanobacteria blooms. Brackish lakes do not tend to develop a phytoplankton state in response to freshwater inputs, unless salinity levels are reduced to fresh water levels (i.e. 1,000 mg/L TDS salinity or less).

(3) Factors affecting lake health

The following section relates to freshwater lakes, where algal management can be difficult to achieve in Townsville.

Saline lakes are generally less susceptible to algal blooms, although marine species of algae do exist. Saline lakes are less likely to experience aquatic weed infestations and seasonal water level variations are less problematic to manage.

(a) Nutrients

Nutrients of concern for urban lake health include nitrogen, phosphorous and trace metals. Nutrients (particulate and soluble) are typically delivered to lakes through stormwater runoff. Nutrients may also be delivered to lakes via in-situ soils, breakdown of organic matter and groundwater processes. Other site conditions such as perched water tables and waterlogged areas (e.g. where anaerobic condition exists) can also promote the formation of nutrients into bio-available forms.

Particulate nutrients associated with suspended solids will typically settle to the bottom of lakes and provide a reservoir of nutrients, which can be released back to the water column under appropriate conditions, whereas soluble inorganic nutrients are readily bio-available to phytoplankton.

High nutrient levels also favour growth of aquatic weeds such as Salvinia (Salvinia molesta), Water hyacinth (Eichhornia crassipes) and Water lettuce (Pistia stratiotes) and other floating species such as native and introduced water lillies. These floating species provide a continual source of organic matter (carbon) to lake sediments. The decomposition of organic matter can deplete oxygen within the lake water column and sediments, resulting in the release of soluble nutrients back to the water column which is then available for phytoplantkton and Cyanobacterial growth. Depletion of oxygen and/or the development of Cyanobacterial blooms can also lead to fish kills, animal death and a risk to public health.

Many Cyanobacteria species are able to obtain nitrogen from the atmosphere, thus nutrient management in lakes typically focuses on phosphorous.

Note—guidance on suitable treatments is included in SC6.4.3.9 Water sensitive urban design guidelines. Areas close to the coast or water draining to the coast can be more susceptible to nutrient hazards. Regional hazard maps can be used to identify potential areas of concern where more detailed mapping and investigation (e.g. soil and groundwater analysis) can occur.

(b) Light and turbidity

Light penetration and turbidity are important factors that trigger switches between alternate states, as described earlier. Recent studies (Scheffer et al., 1997) have shown that the abundance of Cyanobacteria is more highly correlated to underwater light conditions than to phosphorous concentrations. In shallow lakes, the probability that Cyanobacteria will dominate the algal community will depend strongly upon diminishing light levels attributed to increases in turbidity (Scheffer, 1998). Increases in Cyanobacterial biomass therefore provides a positive feedback, further favouring the development of Cyanobacterial blooms.

Note—macrophyte dominated lakes help to maintain low turbidity, as well as providing a mechanism for nutrient uptake. This reduces the opportunity for phytoplankton or Cyanobacterial dominated states which are characterised by high turbidity. Submerged and emergent macrophytes should be encouraged, and floating aquatic plants which contribute to shading and organic carbon loads discouraged. In Townsville, constructed lake depths are limited to 3 m below wet season normal water level, which should encourage light penetration and establishment of submerged plants.

(c) Organic carbon loads

The primary source of organic carbon in urban lakes is typically from leaf litter in stormwater runoff, floating aquatic plants and emergent and submerged macrophytes when within the lake when they decompose. Floating aquatic plants provide a highly bio-available carbon source as they tend to have soft and non-fibrous tissues. Aerobic decomposition of accumulated organic loads at lake beds result in a depletion of oxygen and can cause anaerobic conditions (depending on the amount of organic load available). In situations where organic material is still available under anaerobic conditions, anaerobic bacterial activity can lead to the release of highly bio-available nutrients back to the water column (Lawrence and Breen, 1998). This can result in subsequent algal blooms and poor water quality.

Note—minimise the input of leaf litter into urban lakes through upstream treatment measures. Avoid floating aquatic plants where possible. Creating lake edges that encourage emergent macrophytes will inhibit the establishment of floating attached plants such as water lilies, which tend to grow from lake edges to the centre.

Floating aquatic weeds such as Salvinia molesta are more difficult to manage. Maintaining low lake nutrient levels will minimise proliferation. This includes the provision of submerged macrophytes, which maintain oxygen to lake sediments, reducing opportunities for nutrients to be available for floating plants and phytoplankton.

The lake design should provide suitable access to the lake water body for removal of floating aquatic weeds by mechanical harvesters. A minimum water depth of 1.5 m should be provided for harvesting equipment. Suitable access must also be provided heavy machinery to manoeuvre when collecting the weed and debris.

(d) Lake detention times

Lake detention time plays an important role in managing lake algal biomass and thus reducing the risk of Cyanobacterial growth. Lake detention time, simply put, is the time it takes for the entire lake volume to be displaced via inflows to the lake. Generally there are two ways in which lake water is displaced, either via episodic events that displace the entire lake volume (washout) or from constant inflows (flushing).

Algal growth rates are dependent on nutrients, light, temperature and hydrologic conditions. Algal population growth can occur rapidly, and algal bloom concentrations may develop within weeks. It is possible to manage the formation of algal blooms by removing algal biomass from lake systems via the manipulation of lake detention times.

In Townsville, urban lakes that rely on catchment inflows will typically experience long detention times (>100 days) during the dry season, significantly longer than the time required for algal populations to reach bloom concentrations. Probabilistic approaches, such as those used in Brisbane and Mackay (20 percentile detention time for a constructed lake should not exceed 20 days), are not particularly relevant for Townsville conditions, as these conditions cannot be demonstrated to be achieved on average, regardless of catchment to lake size, unless alternative sources of top up water are available.

Algal management is thus a key design consideration for urban lakes reliant on catchment inflows in Townsville. A number of options are available to the designer including a flushing and/or recirculation strategy. These are discussed in more detail in SC6.4.3.12.15(8) Step 8 – Algal management and SC6.4.3.12 Attachment A Alternative Strategies for Managing Cyanobacterial Growth.

During the short wet season, lake detention times are significantly shorter and the risk of algal blooms are less, although the potential still exists during summer drought conditions.

Note—where possible the designer should consider saline lakes with tidal flushes or consider alternative options to freshwater lakes such as constructed wetlands. Where freshwater lakes are proposed, a suitable algal management strategy will be a key design consideration. Lake depths should also be minimised where possible (preferably between 1.5 and 2.5 m) to reduce any necessary pumping requirements for recirculation.

(e) Salinity

Cyanobacteria dominance is highly sensitive to changes in salinity (Paerl, 1988). Brackish lakes are often dominated by Cyanobacteria due to the tolerance of many Cyanobacterial species to low salinity. Saline lakes subject to freshwater inflows, particularly during the wet season, are thus highly susceptible to Cyanobacteria blooms. In Townsville, brackish lakes (1,000 to 15,000 mg/L TDS), or saline lakes with freshwater inputs should be avoided.

Note—avoid brackish lakes or brackish conditions that may occur in lakes (e.g. saline lakes subjected to large freshwater inflows). Preference is for lakes to permanently operate as either saline (>15,000 mg/L TDS) or fresh (<1,000 mg/L TDS) at all times.

(f) Water level and depth

Lake water level variation and depth play an important role in maintaining macrophyte dominance, and thus resistance to algal blooms. Shallow lakes (<3 m) are more favourable to macrophyte growth, where light penetration is higher and conditions suitable for macrophyte reproduction and establishment. Shallow lakes will typically have a higher threshold turbidity level before switching to a phytoplankton

state (Scheffer, 1998), and therefore have more resistance to increased turbidity and nutrient levels.

Shallow lake depths (<3 m) are also less prone to stratification and subsequent problems associated with the release of nutrients from anaerobic sediments.

Water level variation due to evaporation in Townsville can be greater than 1 m in lakes reliant on catchment inflows. This has direct implications for the health and survival of edge treatments such as emergent macrophytes, which help to reduce the proliferation of floating aquatic plants and ingress of weeds, and thus play an important role in managing the health of urban lakes.

Alternately, saline lake edge treatments such as salt couch are highly sensitive to water level variations and do not survive well when exposed to extended periods of inundation.

Note—lake depths from normal wet season operating levels to finished bed level are limited to 3 m in Townsville, but preferably in the range of 2.0 to 2.5 m. A suitable impervious base (e.g. compacted clay liner) should be provided to minimise seepage losses for lakes reliant on catchment inflows. Lake edge treatments should be such that the width of the exposed batter due to water level variations is minimised. Within the zone of water level variation edge batters at 1V:3H are preferred.

For saline lakes water level variations should be minimised as far as possible, preferable to less than 0.3 m. Salt couch edge treatments are particularly sensitive to long periods of inundation.

(g) Mixing

Mixing and turbulence within lake systems limits the formation and accumulation of Cyanobacterial blooms (Wagner-Lotkowska, 2004). Well mixed conditions can be achieved by ensuring good hydraulic efficiency, shallow lakes (<3 m), maximising wind induced turbulence and providing lake flushing. Mixing can also be accomplished by mechanical means including aerators, mechanical mixers and internal recirculation.

Note—lake configurations should provide length to width rations of 3L:1W or greater. Inlets and outlets should be at opposite ends of the lake. Dead end zones or square edges are to be avoided.

Where possible, align lakes in the direction of the prevailing winds to maximise wind induced turbulence. The prevailing wind for Townsville during the critical winter dry season is south easterly. The base of the lake should be flat to promote even wind mixing. Isolated deep pockets should be avoided.

(h) Weed control

Weed infestation is a major problem in the dry tropics and has been observed to be a significant maintenance burden for existing lakes in the Townsville area. To maintain amenity and minimise on-going maintenance the proponent must detail specific actions (design and management) to address potential weed ingress, both terrestrial and aquatic. Aquatic weed problems are mainly associated with fresh water lakes in the Townsville region and the following design notes are primarily related to weed control in fresh water lakes.

Note—provide a densely vegetated perennial lake edge to create a barrier for weed ingress. This vegetative barrier must be designed so as to be capable of surviving expected water level variations. This may include the provision of irrigation during the dry season.

Include submerged macrophytes to fresh water lakes, to maintain oxygen to lake sediments, thus minimising the opportunities for highly bio-available nutrients to be released and available for floating plants.

Minimise nutrient and organic loads to the lake.

Avoid the inclusion of floating aquatic vegetation (e.g. water lilies) that can contribute to organic loads to the lake, thus supporting weed infestations such as Salvinia, Water hyancinth and Water lettuce.

Provide suitable access for prompt removal of terrestrial and aquatic weeds.

Figure SC6.4.3.12.5 Examples of aquatic weeds - Salvinia (L) and Water Lettuce (R)

Figure SC6.4.3.12.6 Example of water lilies (L) and weed infestation at a lake edge (R)

SC6.4.3.12.5 Constructed lakes design steps

These guidelines are a step by step outline to support development applications where involving reconfiguring a lot (ROL) or material change of use (MCU), where a proposed development includes a lake, and subsequent Operational Works requirements. Council will require considerable detail at the ROL/MCU stage to fully assess the merits of proposed lake. This includes field investigations to characterise the soils and groundwater at the proposed site.

(1) Step 1: Design intent

The primary intent for the lake is to be clearly defined. The design intent must be accompanied by concept plans showing location and layout with respect to the development as well as existing vegetation and receiving environments. The principles in SC6.4.3.12.1(3) include constructed lake uses preferred by council.

(2) Step 2: Determine lake type

(a) Saline lake

In Townsville, due to the extended dry season, the preferred constructed lake with regards to long term sustainability, weed and water level management is a saline lake, where possible. Although less diverse than fresh water lakes, the operation of saline lakes are considered more robust for Townsville conditions. Saline lakes should not be configured to receive fresh water inflows as this can result in brackish conditions which are highly susceptible to the development of Cyanobacterial blooms. This can include stormwater runoff or pumped fresher inputs during the wet season where the source water is from estuaries. The proposed method of inflow, control and water level management must also be stated. Refer to SC6.4.3.12.5(4) Step 4 (e.g. pumped or gravity control).

(b) Fresh water lake

Where fresh water lakes are proposed, the proponent should consider other alternatives such as heavily vegetated constructed wetland systems which can provide open water views and water treatment benefits (refer to SC6.4.3.9 Water sensitive urban design guidelines).

In the case that a fresh water lake is decided upon, the proponent must demonstrate that the lake is configured to receive treated stormwater inflows only (as per the requirements of SC6.4.3.9 Water

sensitive urban design guidelines). Untreated overflows should by-pass constructed fresh water lakes. A separate Stormwater quality management plan (SQMP) must be submitted detailing upstream water quality devices and expected improvements via MUSIC modelling.

Editor's note—SC6.4.3.8 Stormwater quality management plans for development provides guidance to applicants on the preparation of SQMPs, including the use of MUSIC modelling.

The proponent must also clearly demonstrate how water level variations will be managed and proposed alternative sources of water to maintain lake water levels within acceptable variations (refer to SC6.4.2.12.15(7) Step 7).

(c) Brackish lakes
Brackish lakes should be avoided in Townsville. Freshwater Cyanobacteria are particularly responsive to changes in salinity, often resulting in dramatic alterations in dominance (Paerl, 1988). Brackish lakes are often dominated by Cyanobacteria due to the tolerance of many Cyanobacterial species to low salinity.

(3) Step 3 – Site soil and groundwater assessment
A soil and groundwater assessment will be required to characterise local soil and groundwater and demonstrate that the proposed lake will not negatively impact on the local groundwater (considering seasonal fluctuations) and avoids problematic soil areas (e.g. high organic contents, peats, sodic soils).

Where contaminated sites are identified, thorough soil and groundwater assessments will be required and remediation plans developed. Groundwater modelling will also be required to demonstrate that proposed lakes do not or are not negatively impacted by adjacent contaminated sites. Specialist geotechnical/hydrogeological advice will be required to assess risks and develop remediation plans.

A site and soil evaluation must be undertaken in accordance with AS/NZS 1547. Field investigations and laboratory testing are required to sufficiently classify soils, determine the requirements for lining, identify possible PASS and sodicity issues and seasonal groundwater fluctuations. More detailed investigations such as Acid sulfate soils testing will be required in the detailed design stage, if deemed necessary.

Editor's note—Part 9.4.2 Healthy waters code sets out requirements for acid sulfate soils, including the reporting and management requirements to be achieved.

Installation of a series of shallow groundwater wells will be required to sufficiently characterise the shallow groundwater regime (if this occurs) and possible groundwater related impacts and risks due to the proposed lake. Monitoring of water levels at fortnightly intervals over a continuous full dry and wet season will be required as a minimum to support the lake design. The monitoring wells will be required to be available following the lake construction for monitoring purposes, and should be provided with lockable standpipes. A typical shallow monitoring well is indicated in Figure SC6.4.3.12.7 below.

Soil and groundwater investigations must identify potential risks and possible management options and further testing and monitoring required. This also includes assessments on nutrient hazard, which will require soil and groundwater nutrient characterisation. Other site conditions such as perched water tables, waterlogged areas where anaerobic condition exists are to be identified as these can promote the formation of nutrients into bio-available forms.

Additional design and investigation may be required during the detail design stage to manage identified risks.

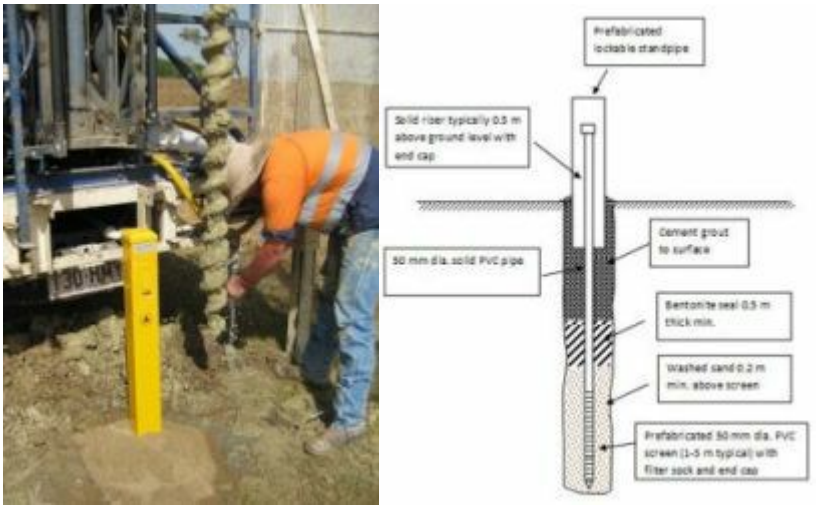

Figure SC6.4.3.12.7 Typical monitoring well installation

(4) Step 4 – Lake inflows and outflows

(a) Lake inflows will depend on the type of lake proposed. Inflows to fresh water lakes will be governed by catchment dependent stormwater runoff. As the source of inflow is typically limited to urban runoff entering the lake, water level variations of one metre or more could be expected throughout the year.

Saline lakes typically have a constant source of water available, and as such water level variations will depend on the configuration of inlets and outlets in such cases. For example water level fluctuations can be maintained constant throughout the year with pumped delivery.

Whether designing saline or fresh water lakes, inlets and outlets must be configured to maintain the intended operation of the lake as either a saline or fresh water system, this includes preventing tidal influences to fresh water lakes, and large fresh water inputs to saline lakes (e.g. stormwater inflows or pumped fresh water during the wet season where the source of water is from estuaries).

Maintaining the intended type of lake (i.e. fresh or saline) will minimise possible detrimental impacts to the aquatic flora and fauna that establishes within the lake.

Lake outflows are typically associated with evaporation and seepage losses as well as overflows controlled by the lake outlet.

Depending on the lake system proposed sufficient information must be provided to council to define both inflow and outflow. Typical details that should be defined (where relevant) include:

(i) catchment area draining to the lake, including characteristics (land use, per cent impervious);

(ii) drainage network connecting to the lake (existing and proposed);

(iii) upstream water quality improvements (applicable to freshwater lakes only);

(iv) source of water, quality and sustainability;

(v) pump or gravity diversions to the lake including required rates and necessary controls; and

(vi) outflow type including provision for water level manipulation and maintenance draining.

(b) Freshwater lake considerations

(i) Water quality improvements

Catchment inflows contributing to freshwater lakes must be demonstrated to achieve the minimum water quality improvement targets. A separate Stormwater quality management plan is required detailing upstream stormwater quality improvement devices and demonstrates through MUSIC modelling expected water quality improvements.

Editor's note: SC6.4.3.8 Stormwater quality management plans for development provides guidance to applicants on the preparation of SQMPs, including the use of MUSIC modelling.

Target pollutant load reductions for new developments relevant to Townsville are:

(A) 80% reduction in Total Suspended Solid;

(B) 65% reduction in Total Phosphorous;

(C) 40% reduction in Total Nitrogen; and

(D) 0% reduction in gross pollutants (>5 mm particles).

Modelling is to consider 6 minute rainfall data for Townsville for the period 1970-1983 (mean rainfall 1,165 mm). Upstream stormwater quality improvement devices must be designed in accordance with SC6.4.3.9 Water sensitive urban design guidelines.

(i) Modelled catchment inflows

The expected inflow volume and seasonal variation is to be modelled, considering catchment characteristics and upstream treatment devices. Modelled inflows must only account for treated flows entering the lake, overflows are not to be included. Modelling of catchment inflows must be undertaken at a suitable time step to accurately model diversions to treatment devices. Typically this is at 6 minute intervals for urban catchments. Modelled inflows can be transformed to daily aggregates for further interrogation such as water balance modelling to review lake water level variation. MUSIC modelling used to demonstrate upstream water quality improvements can be adapted to provide catchment inflow series at daily time steps.

(5) Step 5 – Determine a preliminary lake layout

Develop a preliminary layout within the site constraints. The preliminary layout should consider:

(a) soils and groundwater;

(b) topography;

(c) waterways and flood plains;

(d) existing vegetation;

(e) surrounding environments;

(f) flora and fauna;

(g) natural features such as significant trees, exiting aquatic environments (billabongs, wetlands, marine plants);

(h) coastal management and erosion prone zones;

(i) buffer distances; and

(j) easements and service corridors.

Baseline surveys are critical at this stage to fully understand site constraints and opportunities. These include topographic, drainage, vegetation and flora and fauna surveys. Soils and groundwater assessments must be presented in a separate report as detailed in SC6.4.3.12.5(2) Step 2. Delineation of the highest astronomical tide (HAT) level and mean high water spring tide level (MHWS) will also inform the potential impact on erosion prone zones. For Townsville these levels correspond to:

- HAT = 2.254m AHD; and
- MHWS = 1.254m AHD.

Site reconnaissance and review of aerial photographs must be undertaken at this stage to fully understand the site constraints and opportunities.

Based on climatic conditions for Townsville, the maximum fresh water lake area (at wet season normal water level) is considered at 2.5% of the contributory catchment (considering 50% impervious fraction). Refer to SC6.4.3.12.5(7) Step 7. Smaller areas may be necessary for algal management (refer to SC6.4.3.12.5(8) Step 8).

The lake configuration should consider shapes that avoid dead end zones or result in poorly mixed waters.

Minimum length to width ratios of 3L:1W are recommended to ensure good hydraulic efficiency.

Where possible the orientation of lakes should be in a north west/south east alignment corresponding with the dry season prevailing wind. Lakes should not include islands as these can create poor water circulation and provide a refuge for birds that can contribute to nutrient loads to the lake.

Preliminary layouts should make provision for batters, edge treatments and buffers (refer to SC6.4.3.12.5(11) Step 11). These can add considerably to the overall lake area above the normal lake water level and can impact on the final layout.

Lakes should avoid areas where poorly structured soils (e.g. high organic content, peats, sodic soils), high acid sulfate potential and/or high nutrient hazard is identified.

Lake layouts must also demonstrate that the lake blends into surrounding environments and enhances natural features. Consideration must also be given to linking with recreational and landscape master plans for the area as well as public interaction and education opportunities.

Lakes should also avoid constricted flood ways where flow velocities can be high during flood events.

Editor's note: Applicants should refer to Part 8.2.6 Flood hazard overlay code for details of flood across the Townsville region.

(6) Step 6 –Lake bathymetry

A lake stage/storage/area curve must be developed for council review, including allowance for lake batters (refer to to SC6.4.3.12.5(11) Step 11 for typical acceptable edge treatments). The bathymetry should consider the proposed shape within the site constraints. The depth of the lake must be between 1.5 and 3 m, preferably in the range of 2-2.5 m. Lake depth is considered from wet season normal water level to finished lake bed level.

Depths greater than 3 m are more prone to stratification, which can potentially lead to the release of nutrients to upper waters when they de-stratify, potentially increasing the risk of phytoplankton blooms, particularly Cyanobacteria (toxic blue green algae). A minimum depth of 1.5 m must be provided to allow maintenance equipment such as floating weed harvesters to access lakes.

(7) Step 7 – Undertake water balance modelling

Water balance modelling is required to review the seasonal water level variation of lakes. The proponent must demonstrate to council the expected water level variation over a minimum 10 year continuous modelling period.

The general form of the water balance equation is given by:

$S=I-O$

where

S=storage, I=inflow, O-outflow

(a) Inflows:

(i) catchment runoff entering the wetland (see SC6.4.3.12.5(4) Step 4); and

(ii) direct precipitation over the lake.

Other inflows such as groundwater and base flow are difficult to quantify and can only be considered where sufficient data supports their use. As a conservative approach these can be ignored.

(b) Outflows:

(i) evaporation losses (determined from the stage/storage/area curve, as derived from SC6.4.3.12.5(6) Step 6 and typical daily evaporation rates for Townsville);

(ii) lake outflows/overflows; and

(iii) seepage losses.

(c) Water level variation

Water balance modelling must demonstrate that lake water level drawdown from wet season normal water level does not exceed 1 m once every 10 years on average and less than 0.7 m on a more frequent

basis (on average once every 2 years or less).

Based on climatic conditions for Townsville, the maximum fresh water lake area (at wet season normal water level) is considered at 2.5% of the contributory catchment (considering 50% impervious fraction).

(d) The overall size of the lake will also need to consider algal management issues, as described in SC6.4.3.12.5(8) Step 8. Where algal management options consider recirculation through a wetland, water balance modelling must also include the impacts from inclusion of the recirculation wetland. Refer to SC6.4.3.12.5(8) Step 8.

Designers must be aware of the implications of water level variations with respect to edge treatment survival and visual amenity. Design steps should be taken to limit water level variation to no more than 1 m once every 10 years and 0.7 m once every 2 years, and this may require the inclusion of:

(i) a lake liner to minimise seepage losses; or

(ii) provision for lake top-up.

Designers may need to consider hard edge treatments to minimise visual impact in high amenity areas or supplementary irrigation to maintain lake edge vegetation. SC6.4.3.12.5(11) Step 11.

Photos: Shaun Leinster

Figure SC6.4.3.12.8 Examples of impacts due water level variations

(e) Lake top-up

Where designers consider lake top-up to maintain lake water levels, suitable sustainable sources are to be considered. These may include the use of harvested stormwater and groundwater for fresh water lakes. Where groundwater is proposed the proponent must undertake necessary hydrogeological investigations to demonstrate that the proposed pumping does not detrimentally impact on the local groundwater resource. The quality of the groundwater must also be demonstrated to not negatively impact on the health of the lake.

Lake top-up for saline lakes must maintain the salinity of the lake at greater than 15,000 mg/L. This may require the provision for salinity control on pumped delivery to lakes from estuaries to ensure wet season fresh water pulses are not delivered to the lake.

Potable mains supply is not considered an acceptable source for lake top-up.

Where harvested stormwater is considered for lake top-up for fresh water lakes sufficient storage must be available. The volume of storage required can be estimated from the water balance modelling, but as a general guide is in the order of 15 ML per hectare of lake per annum to maintain constant water levels throughout the year, where the lake area is taken at the wet season normal operating level.

Storages can be constructed storages or use of natural underground aquifers. Constructed storages to provide sufficient top up for Townsville fresh water lakes are typically not considered practical due to the significant volumes that would be required (typically in the order of the total lake volume), although dedicated storage dams may be considered.

When considering aquifer storage opportunities, hydrogeological investigations will be required to determine the feasibility, which will include assessing the capacity of the aquifer to store water and the potential impact on the native groundwater and other users. Storage of water in shallow aquifers is not recommended due to the possible impact on adjacent structures and possible water logging. Design guidance on aquifer storage and recovery (ASR) is outside the scope of this guideline. Specialist hydrogeological advice must be sought should this option be pursued.

(8) Step 8 - Algal management

A key design consideration for algal management in lakes is the management of trigger mechanisms such as nutrients and turbidity, and the removal of algal biomass from the lake water body before bloom concentrations occur. Algal biomass removal rates should be at least equal to the in-situ algal growth rate. Algal biomass removal can be facilitated via a number of methods including lake flushing or removal through a recirculating wetland. Other methods are available and are included in SC6.4.3.12 Attachment A: Alternative strategies for managing Cyanobacterial growth.

Photos: Shaun Leinster

Figure SC6.4.3.12.9 Examples of blue-green algae

A probabilistic approach based on lake residence time has been adopted in Queensland, such as the Brisbane City Council's *WSUD guidelines for Pond and Lake Design* and also *Mackay Planning Scheme Policy 15.15* – Constructed lakes for minimising the risk of Cyanobacterial growth in constructed lakes. These recommend a 20th percentile residence time for lakes not exceeding 20 days.

The Mackay Planning Scheme Policy 15.15 – Constructed lakes also stipulates that where the lake residence time criteria is exceeded, then water can be recirculated through a wetland at a rate that ensures lake turnover every 20 days. A minimum wetland residence time of 5 days is also stipulated to provide sufficient contact time (two growing cycles) for algal biomass removal.

The effectiveness of a recirculation strategy using surface wetlands for algal management in Townsville is still largely unknown and the required recirculation rates for Townsville conditions are also currently unknown. However recirculating lake water through surface flow wetlands is considered a sound approach with respect to removal of suspended solids (and thus turbidity) and nutrients in lake water, two key triggers for changes in state for shallow lakes.

Whichever algal management method is proposed, the proponent must clearly demonstrate that the strategy is effective in removing algal biomass to minimise the opportunities for algal blooms.

In the absence of further information, proponents proposing constructed lakes in Townsville must demonstrate that the entire lake volume is "flushed" through the lake within a 20 day period for the control of algal biomass. As rainfall dependent catchment inflows in Townsville will result in extended periods where full lake volume turnover is not achieved (e.g. >100 days during the dry season), other sources such as diverted surface water and groundwater will be required. The rate of diversion can be estimated simply as follows:

Required lake inflow rate (m3/d) = lake volume (m3)/20 days

Where flushing is adopted, the source of water used must have a nutrient, turbidity, algal bio-mass less than or equal to the lake water and salinity ranges should be maintained for the intended lake type (refer to Table SC6.4.3.12.2 Suggested target values for physico-chemical indicators).

(a) Recirculating wetlands

Where no external flushing supply is available, provision for a recirculating wetland for algal management should be made. The following design criteria are considered:

(i) recirculation of the full volume of lake water through the wetland every 20 days;

(ii) minimum wetland contact time of 5 days;

(iii) treated water re-entering the lake must have turbidity, nutrient and algal biomass levels less than or equal to the lake water; and

(iv) water re-entering the lake must be at opposite ends from where water is abstracted from the lake to avoid short circuiting of treated flows.

This strategy does not guarantee that no algal blooms will occur and proponents must also develop an adaptive management plan for algal blooms.

For the above design considerations, the approximate size of the recirculating wetland is 1.5 times the area of the lake based on an average wetland depth of 0.3 m. Smaller recirculating wetlands can be considered where the proponent can demonstrate that algal biomass removal rates are greater rates than those assumed in the above derivation. For example, ultrasonic treatments of recirculated lake flows can potentially reduce algal biomass concentrations, thus reducing the recirculating wetland size. A further alternative may be the use of floating macrophyte beds, which can remove bio-available nutrients from the water column, and can be used within the lake or as part of the recirculation strategy. This option will require regular harvesting of the floating macrophytes to reduce nutrient loads from the lake.

Design of the recirculating wetland must consider maintaining the health of the wetland and associated vegetation. This requires the recirculating wetland to be operated continuously throughout the dry season to maintain a permanent pool of water over the majority of the wetland area. To minimise recirculation rates the recirculating wetland is considered as a shallow planted system, without deep pool areas. This differs from stormwater treatment wetlands where deep pool zones are included, and typically cover up to 20% of the total area in the dry tropics (refer to SC6.4.3.9 Water sensitive urban design guidelines).

An average wetland depth of 0.3 m is considered sufficient for recirculating wetlands and will include shallow to deeper zones supporting a range of emergent macrophytes from shallow marsh (0-0.2 m), marsh (0.2-0.35 m) and deep marsh (0.35-0.5 m). The wetland area needs to be sized to provide a 5 day treatment time, considering the minimum recirculation rate determined for the lake volume (refer to above). In this case the wetland area can be estimated as follows:

Recirculating wetland area = 5 days x recirculating pump rate (m3/d)/ave wetland depth (0.3 m)

The overall configuration of the recirculating wetland must consider inlets and outlets at opposite ends and minimum length the width ratios of 5L:1W to maintain good hydraulic efficiency and thus mixing throughout the wetland. Wetland shapes must avoid dead end zones and possible short circuiting. Designers are directed to SC6.4.3.9 Water sensitive urban design guidelines for further advice on the design of constructed wetlands.

(9) Step 9 – Select final lake layout

Following approval of concepts presented to council, the final lake area must be selected considering the soil and site constraints from SC6.4.3.12.5(3) Step 3 and SC6.4.3.12.5(5) Step 5, depth ranges within those indicated SC6.4.3.12.5 (6) Step 6, acceptable water level variations derived from SC6.4.3.12.15(7) Step 7 and additional allowances where recirculating wetlands are proposed for algal management SC6.4.3.12.5(8) (Step 8).

The final lake configuration must consider shapes that avoid dead end zones or result in poorly mixed waters. Minimum length to width ratios of 3L:1W are to be provided to ensure good hydraulic efficiency.

The final lake layout will need to integrate with the approved landscape and amenity plans for the development, development road layouts, accesses and required civil works.

(10) Step 10 –Design of inlets, outlets and other hydraulic structures

Lake inlets and outlets should be located at opposite ends of the lake to promote uniform movement of water through the lake and avoid short circuiting of flow. The design of inlet and outlet structures will depend on the type of lake proposed. Inlets and outlets must be designed for minimum maintenance and must make provision for scour control at pipe outlets.

Inlets and outlets must not be subject to blockage through excessive silt and debris build up and/or excessive vegetation. Design actions may include:

- provision of stone pitching at inlets and outlets to prevent vegetation growth; or
- suitable screens to minimise debris ingress.

Inlets and outlets structures are to result in minimal visual impact and may be hidden under boardwalks or amongst rocks, for example.

The proponent is to provide engineering calculations for the design of lake hydraulic structures, the design of which will differ depending on whether a fresh water or saline lake is proposed. The designer is directed to other parts of SC6.4 Development manual planning scheme policy as relevant, the *Queensland Urban Drainage Manual*, and the *Road Drainage Manual* for more design guidance on specific hydraulic design of pipes and pits and erosion protection at pipe outfalls.

The influence of tidal variation including storm surge, wave setup and impacts of climate change must be detailed to council. For the purposes of design the following tide levels are noted for the Townsville region (Townsville Harbour, QDOT, 1998):

Tidal plane	mAHD
Highest Astronomical Tide (HAT)	2.254
Mean High Water Springs (MHWS)	1.254
Mean Sea Level (MSL)	0.1
Mean Low Water Springs (MLWS)	-1.13
Lowest Astronomical Tide (LAT)	-1.86

The designer must consider the potential impacts of sea level rises due to climate change and make provisions in the design for such increases.

In the case of saline lakes proponents must clearly indicate how lake flushing will be achieved and any necessary pumping equipment, control and telemetry systems that may be required to facilitate operation.

(a) Inlets

Inlets to lakes may be gravity diversion of treated stormwater runoff or pumped delivery from adjacent water bodies (e.g. from estuarine river systems).

Stormwater inflows

In the case of piped stormwater flows to lakes, pipe inverts from upstream catchments should be set no lower than lake wet season normal operating level. This will avoid permanent water within the pipe drainage system and maintain hydraulic capacity of the connecting pipe drainage. Suitable erosion protection at the pipe outfall must be provided to prevent scour. Refer to QUDM, 2007.

Photos: Shaun Leinster

Figure SC6.4.3.12.10 Examples of concealed inlets to lakes

Provision for a gross pollutant trap may also be required to capture litter and leaf matter prior to discharge to the lake.

Where a separate inlet sedimentation zone is proposed, the designer is directed to the SC6.4.3.9 Water sensitive urban design guidelines for further advice.

Pumped inflows

Pipe outfalls to lakes for pumped delivery may be submerged, however suitable backflow prevention devices must be installed to prevent possible draining of the lake.

Photos: Ralph Williams

Figure SC6.4.3.12.11 Pump intake from Ross River – note blocked screen (L), and pumping infrastructure including sump and control equipment (R)

Pumped delivery systems must consider aspects such as the control of delivery to the lake. This may include the control of the pumping regime through tidal cycles and preventing fresh water being pumped to the lake. The expected pumped volumes with respect to the lake volume should be demonstrated to allow sufficient flushing. A flow meter on the discharge side of the pump is recommended. Suitable arrangements must be made in case of pump failure to ensure minimum flushing rates are maintained. This may include a standby pump. Provision for internal lake recirculation may also be required where extended periods of fresh water during the wet season at the source of pumping prevent delivery to the lake.

(b) Outlets

Lake outlets can be configured in a number of ways and will determine the normal wet season operating level. Lakes for flood mitigation purposes are not encouraged in Townsville region and should by-pass high flows, thus the design of lake outlets will only need to consider design inflows (e.g. connecting pipe capacity or pumped diversion rate) and any incidental rain over the lake.

Impacts of possible tailwater effects at pipe outlets must be considered when sizing outlet pipes. Refer to QUDM, 2007 for further guidance.

In the case of fresh water lakes, ingress of tidal waters to the lakes must be prevented. Water levels to HAT (2.15 m AHD) must be considered in this case. Allowances for tidal surges should also be made.

Outlets must be designed to minimise potential blockage. An overflow path (e.g. weir) should be provided in case of outlet structure blockage. This will minimise potential damage to vegetated edge treatments.

Overflow pit and discharge pipe
Overflow pits can be located within the lake water body, with the crest of the pit defining the normal lake wet season operating level.
The design should consider:

(i) pit dimensions such that pit capacity is greater than the connecting culvert capacity;

(ii) suitable pit grate to protect against clogging by debris;

(iii) minimal visual impact;

(iv) prevent local fauna such as ducks from entering the pit; and

(v) capacity to drain the lake for maintenance.

Additional guidance is provided in the SC6.4.3.9 Water sensitive urban design guidelines.

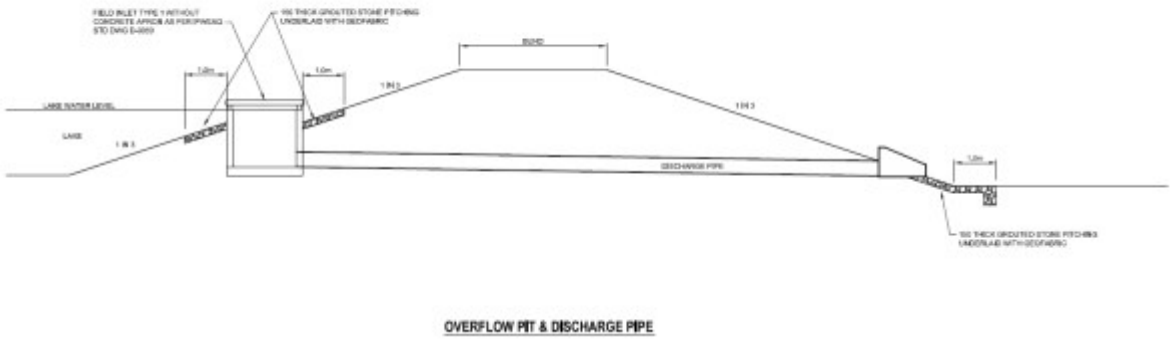

Figure SC6.4.3.12.12 Typical overflow pit and discharge pipe details

Outlet pit and discharge pipe
Outlets may also consider submerged pipes connecting the lake to an outlet pit with a discharge pipe. The lake normal water level may be set via an open ended riser pipe or a weir plate in the outlet pit. Either can be configured to be easily removed to facilitate maintenance draining.

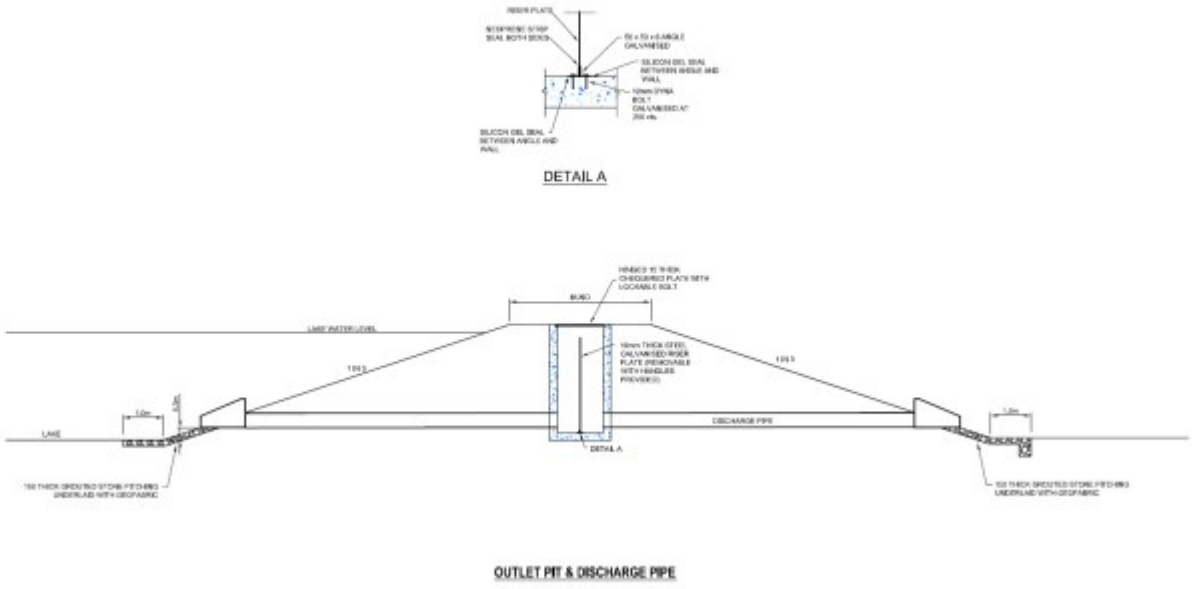

Figure SC6.4.3.12.13 Typical outlet pit and discharge pipe details

Overflow weir

Lake outlets may also be controlled via an overflow weir with weir levels set at the normal wet season operating level. This may also include outlet culverts that effectively operate similar to a weir i.e. the culvert invert defines the normal wet season operating level.

Suitable erosion protection such as rock pitching must be provided at lake outlets and overflows.

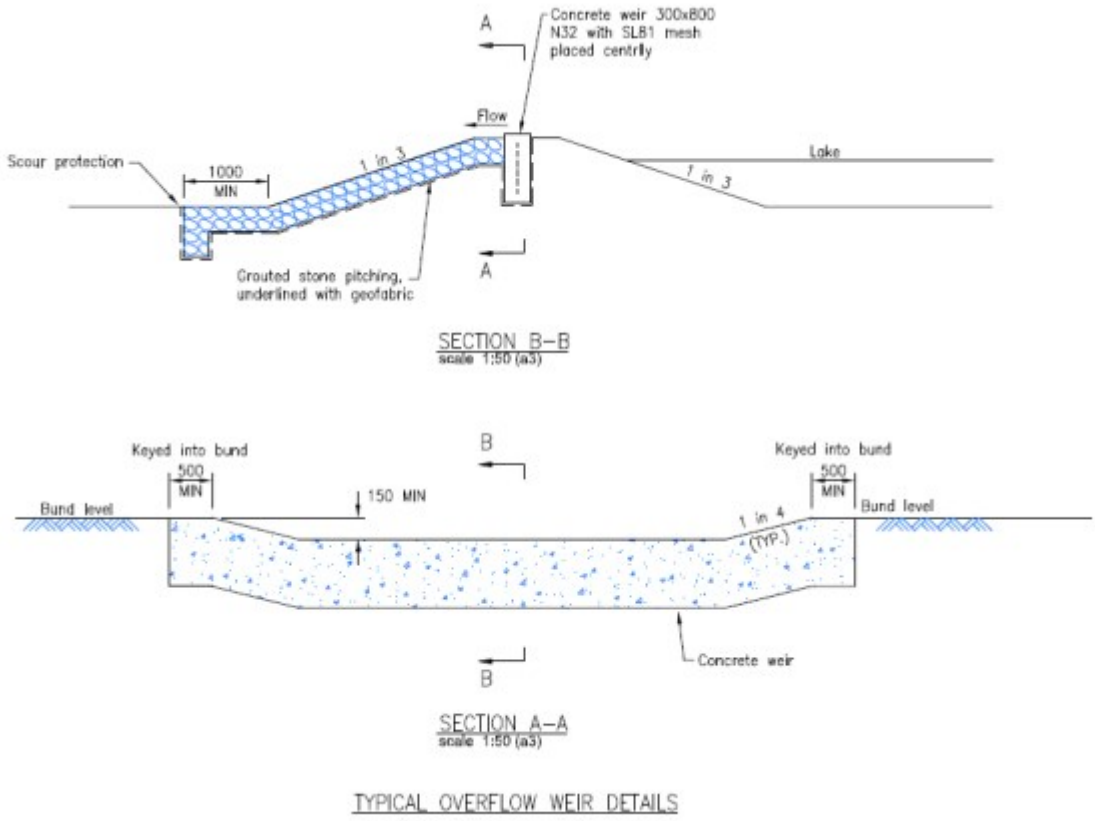

Figure SC6.4.3.12.14 Typical overflow weir detail

(c) Interconnections between lakes

Where separate interconnected lakes are proposed, suitable connections between lake water bodies must be provided. This may include open channel/weir connections or culvert connections. The design

must consider:

(i) maintaining good hydraulic efficiency and mixing between water bodies;

(ii) minimising head losses between water bodies during operation;

(iii) maintaining access between the lake water bodies; and

(iv) provision for lake drawdown during maintenance.

Where open channel/weir connections are proposed, the designer must consider the potential impact of any necessary recirculation strategy. In such instances, preference is for submerged pipe connections, to maintain hydraulic interconnection between lake water bodies during the dry season when lake operating levels are below wet season normal water levels. As lake water level variations of up to 1 m are considered, submerged pipes obverts should be at least 1 m below normal wet season operating levels.

Where gravity drainage is proposed for lake maintenance, interconnecting pipes will need to consider inverts that facilitate adequate drawdown of all connected water bodies.

(d) Maintenance drain

Provision for a maintenance drain must be made to allow the lake to be drained for periodic maintenance. This drain can be a manually driven gravity drain or where gravity drainage is not possible provision for pumping must be made. The proponent must state the proposed method of draining and where pumping is proposed suitable access must be allowed for pump maintenance. The cost of pumping must also be considered in any life cycle costing (refer to SC6.4.3.12.5(18) Step 18).

The operation of the maintenance drain should ideally allow lake drawdown within seven days, although for large lakes this may not be possible.

The proponent must considered impacts of lake draining on potential acid generating conditions that may occur as well as the potential impacts on downstream receiving bodies due to the draining.

The maintenance drain must also facilitate water level management during establishment, particularly for establishing lake edge vegetation.

(11) Step 11 - Design of lake edges and batters

Lake edges play an important role in weed management for lakes. Edge treatments must also consider large water level variations (up to 1 m are allowed on an infrequent basis and 0.7 m on a more frequent basis, refer to SC6.4.3.12.5(7) Step 7), including visual amenity aspects and survival of edge vegetation. Edge treatments must consider public safety (refer to SC6.4.3.12.5(17) Step 17).

To minimise exposed edge width due to water level variations, batters slopes at a minimum 3H:1V are preferred. Flatter slopes above wet season normal water level are permitted depending on the final treatment. Where turf areas are proposed batter slopes of no more than 5H:1V must be provided to allow mowing. Typical edge treatments for both fresh and saline lakes are indicated in Figure SC6.4.3.12.15.

At the ROL/MCU stage the proponent must indicate the type of edge treatments proposed, including the structure and mix of edge treatment (refer to SC6.4.3.12.5(12) Step 12).

At the operational works stage, lake edges must be considered based on an updated water balance based on the final lake layout to confirm expected water level variations established from preliminary layouts.

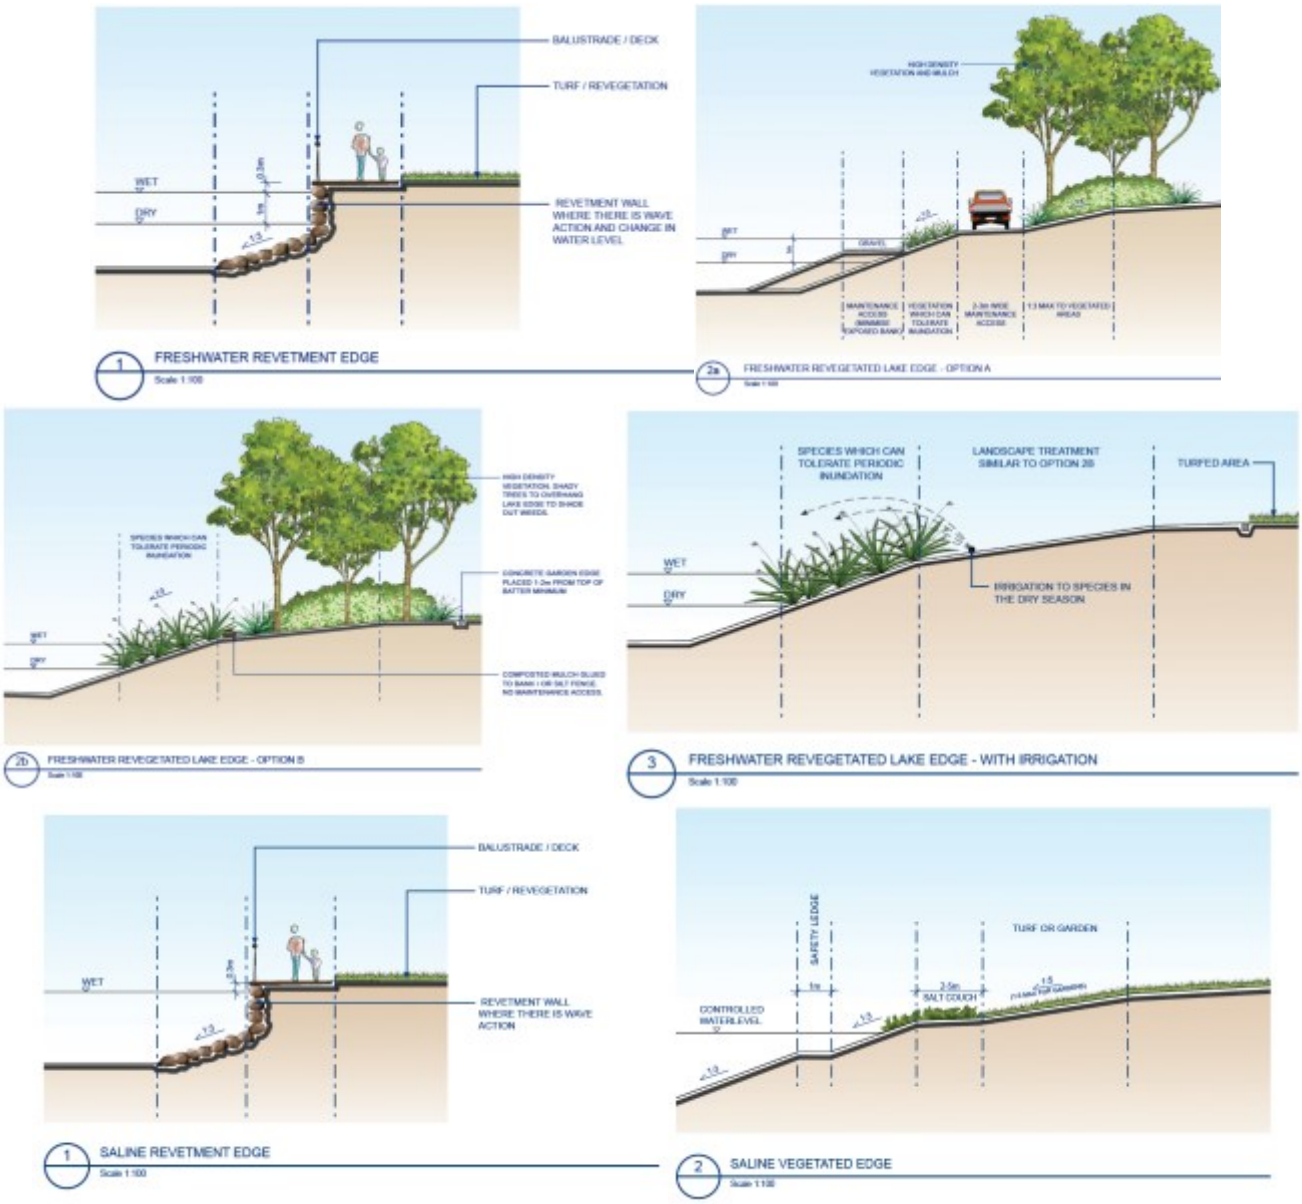

Figure SC6.4.3.12.15 Typical examples of edge treatments for fresh and saline lakes

(12) Step 12 –Vegetated lake edge treatments

Editor's note—applicants should also refer to 9.4.3 Landscape Code and Development manual planning scheme policy sub section SC6.4.3.6 Landscape policy.

The structure and mixture of vegetation of the proposed lake edge will be a key design consideration for a well performing edge treatment. Lake edge treatments should aim to re-establish a mix of local indigenous species including trees, shrubs, groundcovers and grasses that complement and enhance the amenity of the area. Adjacent parkland vegetation may consider similar species to lake edges to integrate the lake with the surrounds, or alternatively different species may be used to provide a contrast to highlight the lake as a feature within the landscape.

At the ROL/MCU stage the proponent should indicate the proposed structure and mix of vegetation for the proposed lake, together with the proposed methods for establishing and maintaining healthy vegetation. The expected lake water level variations are also required.

Editor's note—guidance on typical options for varying lake edge conditions are presented previously in SC6.4.2.12.5(11) Step 11, and can be adapted to suit specific requirements of the proposed lake.

For operational works approval the proponent should clearly detail proposed treatments including:

- plant species;
- location with respect to lake water level;
- planting density and layout; and
- planting methods.

Planting details should be indicated in plan and section in the detail design drawings. Guidance on plant species suitable for the Townsville region is provided in SC6.4.3.9 Water sensitive urban design guidelines and SC6.4.3.6 Landscape policy.

Various types of treatments can be used and the type and density will be a key design consideration for the effective performance of the treatments. Broadly edge treatments can include:

- perennial sedges and rushes (emergent macrophytes);
- ground covers;
- shrubs;
- turf;
- trees; and
- mulches.

A minimum planting of 1 m vertically above wet season normal water level is considered necessary to provide stable edge treatments.

Successful establishment of vegetated lake edges will include:
Good soil preparation including a minimum 200 mm topsoil. Soils are to be amended where necessary to be considered as agronomically acceptable. Topsoils are to be laboratory tested to AS4419-2003 *Soils for landscaping and garden use* to ensure topsoil suitability for plant growth. Topsoils must not contain weeds or susceptible to acid generation which may kill off plants. Amendments such as lime and gypsum may be required.

- selection of an appropriate planting time. Planting toward the end of the dry season is preferred to take advantage of early wet season rains.

- maintaining good moisture for plant growth during establishment. This may include; supplementary irrigation and mulching;
- protection from disturbance during establishment;
- replacing damaged or dead plants; and
- removing weeds both prior to and during establishment.

(a) Perennial sedges and rushes (1.0 m below to 0.2 m above wet season NWL)
Sedges and rushes provide a soft natural edge to lakes. The use of sedges and rushes are important in minimising weed ingress and provide a dense barrier to the lake edge minimising human contact with water and thus reducing safety risks. It is important that sedges and rushes are planted in high densities (20 plants/m^2) and permanently occupy the edge to limit the opportunities for weed establishment. Typically dense vegetation at least 1.2 m high and 2-3 m wide will be suitable.

Photos: Shaun Leinster

Figure SC6.4.3.12.16 Examples of edges treatments with sedges and rushes

Plant selection must be able to survive the expected water level variations and may require supplementary irrigation to ensure survivability during the dry season. Tall, small diameter stemmed, self-sustaining plants that distribute themselves by producing large quantity of seed are preferred.

Where possible, shade should be provided over sedges and rushes to minimise the potential ingress of weed species such as Para grass. Shade can be provided through planting of trees species adjacent to the lake edge. Aspect also plays an important role for shade considerations, with south facing banks providing good shade opportunities to lake edges.

(b) Ground covers and shrubs (greater than 0.2 m above wet season NWL)
Groundcovers and shrubs can be provided above the lake normal water level to help stabilise lake batters and provide aesthetic/landscape feature. Groundcovers and shrubs should be less than 1 m in height to maintain open visible areas. Groundcovers and shrubs are particularly useful where batter slopes greater than 3H:1V are proposed. For slopes greater than 3H:1V, ground covers with matting and rhizomatous root systems can assist binding the soil surface during establishment.

Photos: Shaun Leinster

Figure SC6.4.3.12.17 Examples of edge treatments using ground covers

(c) Turf
Turf treatments can be used to highlight the water body as a feature within the landscape and encourage recreational use adjacent to the lake. For maintenance purposes, batter slopes for turf treatments must be not greater than 5H:1V. Supplementary irrigation will most likely be required to maintain turf health.

For saline lakes, salt couch is a typical suitable edge treatment. Salt couch is particularly sensitive to extended periods of inundation and should be above the normal wet season water level. Salt couch extending 2-5 m from the water edge over a wide flat (10H:1V) area is preferred.

(d) Trees

Trees provide an important function in the overall performance of lake edges where perennial sedges, rushes and shrubs are proposed. Trees provide shade which helps minimise ingress of weeds such as Para grass. In such cases, the tree location must be within close proximity to the edge such that shading is achieved. Tree densities of 1 2 per m^2 are recommended.

When selecting tree species, preference is for deep rooted species. Careful consideration must be made when grass and tree species are mixed together as grasses can kill off trees when establishing. Use of ground covers around trees are preferred. Ground cover legume species are preferred with trees, however legume tree species should be avoided (e.g. acacias).

It is likely that suitable education signage will be required around areas with tree planting to describe the function of trees with respect to the lake. Past experience with lakes in residential areas around Townsville has seen residents removing trees due to the desire for increased lake views and the perception that the native vegetation encourages snakes.

(e) Mulches

A variety of mulches are available to provide erosion protection and aid vegetation establishment at lake edges. The suitability of mulches will depend on the vegetation proposed and batter slopes. Typically, mulches should be bio-degradable and are usually 50-100 mm thick. Typical mulches include:

(i) straw/sugar cane mulches: are particularly useful for grass establishment where water for irrigation is limited. They are also useful where dispersive clay soils exist. Typically used in flat slope areas (less than 10H:1V), but can be used on steeper;

(ii) slopes with the use of tackifiers or with biodegradable mesh anchoring;

(iii) hydromulching: typically used for grass establishment, but will usually require greater watering requirements than straw mulch treatments. Adhesive binders and fertilizers are typically incorporated into hydromulch mixtures, together with fibrous matrix of wood or paper pulp and grass seed. Hydromulching is particularly suited to steeply sloping sites or areas with difficult access;

(iv) bush mulches: includes mulches such as bush mulch, bark and wood chip and are most suited to shrub and tree areas. They are not suited to areas where grasses are proposed and should only be used where tube stock planting is planned;

(v) compost blankets: particularly suited to revegetation of steep slopes with grasses and plants. Also useful when topsoil placement is difficult or insufficient topsoil is available;

(vi) bonded fibre matrix: a fibrous glued type mulch, highly suitable for vegetating steep slopes, particularly in wet environments. This form of mulch treatment can be moulded to form effective erosion control barriers, and may be suitable in lieu of silt fences near lake edges; and

(vii) rock mulching: mostly applicable to areas where plants establishment is difficult or in high amenity areas. Rock mulches are prone to siltation and should only be used when absolutely necessary.

(13) Step 13 – Maintaining flood capacity

The proponent must demonstrate to council that the operation of the lake must have no adverse impact on flood capacity, this includes the capacity of upstream catchments contributing to the lake and regional flooding where lakes are located on floodplain areas. Specialist hydraulic advice will need to be sought to confirm flood capacity.

Lakes in Townsville are not intended for flood management purposes. High flow by-pass provisions will be required where applicable. Standard design procedures such as Manning's equation can be used to size the high flow channels. Suitable stabilisation such as turfing must be provided and must be suitable for the expected velocity ranges.

Lakes must also make provision for an emergency overflow in the case outlets become blocked. This may include an overflow spillway (refer toSC6.4.3.12.5(10) Step 10) or demonstration that embankments are sufficiently strong to withstand overtopping. Erosion protection must be provided at overflow points.

(14) Step 14 - Lake maintenance access

The proponent must clearly indicate the location of accesses for lake maintenance. The minimum access requirements for lakes include:

(a) de-silting including dewatering pads at specified locations;

(b) debris removal;

(c) weed removal (floating and terrestrial);

(d) inlets and outlets and other hydraulic structures; and

(e) pumps and switch gear, where applicable.

Accesses should be blended into the general landscape of the lake so as to soften the impact. This may include incorporating perimeter access track as walking trails, screening of high impact accesses or incorporating into viewing areas.

Accesses must be sized to provide sufficient space to undertake the work, including sufficient turnaround areas.

Accesses for heavy machinery (e.g. excavator) must be designed for a 20 tonne capacity and of sufficient width to allow turnaround. Access provisions must also consider the maximum reach of heavy machinery (e.g. 10 m for an excavator). Access ramp slopes are to be no greater than 5H:1V. Public access to heavy machinery access points must be restricted.

The location of accesses for debris removal will need to consider prevailing wind conditions during both the wet and dry season together with lake orientation. This will determine likely collection zones for debris. Prevailing wind directions for Townsville are:

- April to November: South easterly; and
- December to March: North easterly.

Note—dewatering pads must be of sufficient distance from residential dwellings and commercial premises so that odours are unlikely to cause offense.

Provision for access to the main lake water body must be made to allow access for mechanical weed harvesters for removal of floating or submerged weed. A boat ramp type access is considered acceptable.

Figure SC6.4.3.12.20 Examples of aquatic weed removal methods

Provision for de-silting must be made at lake inlet zones. This includes a suitable ramp to the base on the inlet zone. Provision of a hard base to the inlet bay must be made to indicate when the floor of inlet zone is reached by machinery operators. A hardstand dewatering pad at the inlet zone must be provided and graded to drain back to the inlet zone. Other de-silting accesses may be necessary should sediment accumulation be anticipated at other areas of the lake.

Suitable access must be available at all inlet and outlet structures. Where inlets and outlets are concealed under decks, amongst rocks and plantings, the proponent must demonstrate how access will be achieved at these points.

Vehicle access around the lake perimeter is to be provided for incidental monitoring and maintenance such as mowing, weed removal, mosquito larvae monitoring and removal. This can be incorporated as part of pedestrian trails around the lake.

Access to all pump and switch gear installations must be made and must allow for provision for pump replacement (i.e. crane access).

Where lake fountains are proposed pumping equipment should be located at the shoreline and not within the lake to allow easier access for maintenance.

Sufficient accesses must be provided to minimise vehicles driving on lake edges where wheel ruts can form. These can potentially provide a habitat for mosquito breeding.

(15) Step 15 - Vector control

A mosquito baseline survey/audit must be completed for all proposed lakes to establish the existing mosquito populations prior to construction. This baseline information should consider seasonal variations in mosquito populations and would likely require regular monitoring for an entire wet and dry season period prior to lake construction.

The proponent must detail design actions that minimise the occurrence of mosquitoes due to the proposed lake and associated installations such as any necessary recirculating wetlands and pump sumps. Standard design practices to minimise mosquito breeding include (adapted fromSC6.4.3.9.5(2)(i) Designing to avoid mosquitoes):

(a) providing access for mosquito predators, such as fish and predatory insects, to all parts of the water body (avoid stagnant isolated areas of water). Native fish species must be used;

(b) where possible, incorporating a steep slope into the water, preferably greater than 3H:1V;

(c) wave action from wind over open water will discourage mosquito egg laying and disrupt the ability of larvae to breathe;

(d) providing a bathymetry such that water draws down evenly so isolated pools are avoided;

(e) providing sufficient gross pollutant control at the inlet such that human delivered litter does not accumulate and provide a breeding habitat;

(f) providing suitable access to likely debris collection points (refer to SC6.4.3.12.5(14) Step 14) for removal of any accumulated debris;

(g) providing ready access for field operators to monitor and treat mosquito larvae, if required;

(h) ensuring maintenance procedures do not result in wheel rut and other localised depressions that create isolated pools when water levels fall;

(i) ensuring pits and sumps are provided with lockable galvanised lids that prevent access to mosquito adults;

(j) ensuring overflow channels do not have depressions that will hold water after a storm event;

(k) aquatic plants such as Water Hyacinth, Salvinia and water lilies can provide a breeding medium for some mosquito species whose larvae attach to these plants under water. These plants should be removed immediately if encountered. Suitable access must be provided to facilitate floating weed removal (refer to SC6.4.3.12.5(14) Step 14);

(l) appropriate landscaping in areas surrounding lakes to ensure proper drainage. Surrounding areas with poor drainage (e.g. flat lake edge batters) can become mosquito breeding grounds; and

(m) limit water level variations where possible.

Further advice on suitable native fish species for mosquito control is available from the Department of Primary Industries. Permits for stocking lakes with native fish local to the area are not required. Care must be taken with the suitable fish selection to ensure no environmental harm from fish stocked in lakes, which can easily make their way into downstream rivers and creeks etc.

A mosquito monitoring program must be established for the proposed lake. Monitoring is to include adult trapping, at the lake site and larval surveys for areas that include water retained in shallow flooded vegetated areas. Typically monitoring frequencies will be intensive (weekly) during the wet season (December to March), and less frequent during other times (fortnightly to monthly).

Larval surveys can be undertaken by sampling water with a 300 mL ladle. As a general guide a larval density of 1 larvae per 2 ladle dips or higher is likely to indicate a potential mosquito problem for adjacent residents (Warchot and Whelan, 2008). Mosquito problems may also be identified from adult trapping indicating significant pest numbers or resident complaints.

An adaptive management strategy must also be developed for control of mosquitoes.

(16) Step 16 - Bird control

Lake designs must consider actions that discourage the establishment of large waterbird populations. Large bird populations can cause lake water quality issues due to additional nutrient and faecal contamination, and reduce local biodiversity by damaging native vegetation. Large bird populations in urban residential areas also can create nuisance issues such as noise and faecal droppings.

A number of design actions are available to control bird populations. These include:

(a) densely vegetating lake edges with sedges and rushes to inhibit access to shallow water for feeding;

(b) selecting non-roosting trees such as eucalyptus;

(c) avoiding ground covers and shrubs that support roosting or breeding of species such as ibis (e.g. some melaleuca species);

(d) discouraging opportunities for feeding including educational signage; and

(e) providing suitable refuse collection around picnic areas.

Note—islands in lakes should not be provided in lakes as these can attract and create a refuge for birds, for example Ibis.

(17) Step 17 - Public safety

Lake designs must consider public safety and be designed in accordance with the crime prevention through environmental design (CPTED) principles. The proponent must demonstrate how the lake will achieve and manage these outcomes.

Lake edge treatments play an important role in public safety. Various suitable lake edge treatments are provided in SC6.4.3.12.5(11) Step 11 and SC6.4.3.12.5(12) Step 12. Lake edge treatments can be formed to create a barrier to open water access through dense edge plantings or balustrades where revetment edges are planned.

Where vegetated edges are proposed, the designer must consider the requirement for steeper batter slopes (3H:1V) below normal operating levels to minimise exposed edge width. Suitable vegetation selection will be important where a vegetated barrier is provided. Safety ledges can also be provided just below normal operating level where access to the water body is available. Refer to SC6.4.3.12.5(11) Step 11.

Lake designs must minimise areas of concealment and ground covers should be chosen to maintain an open visible aspect.

Lake boardwalks and viewing platforms must be demonstrated to be safe for public use, including suitable barriers for children.

Adequate signage must be provided to indicate suitability for recreation activities (e.g. no swimming), and potential threats from local fauna (e.g. beware of crocodiles).

Passive recreation facilities such as paths and trials must not create a trip hazard and designed so that they are available to all groups of the population i.e. it should consider all abilities. Safe distances from paths to lake edges should be considered.

(18) Step 18 –Life cycle costing

Life cycle costs for the proposed lake must be determined over a life span of 30 years. The life cycle costs must include acquisition, construction, establishment, operation, monitoring, maintenance, replacement and disposal costs. The costs must also clearly indicate “who pays,” i.e. developer costs and council costs. This includes costs associated with pumping infrastructure, including power and carbon offsetting costs and those associated with monitoring (e.g. water quality, mosquito monitoring).

Comparisons of lake life cycle costs with a similar parkland area not containing a lake are to be provided to council.

The life cycle cost plan is to include an extended dry season and a longer than normal wet season every 5 years.

This information will be used by council to assess the financial sustainability of the lake system, to make design refinements with the proponent and to identify whether additional funds will be sought from proponents to manage the lake following handover to council ownership.

SC6.4.3.12 Appendix A - Alternative strategies for managing Cyanobacterial growth

The following is taken from DesignFlow, 2010. *“Constructed Water Bodies in Urban Areas of SEQ – Critical Analysis of Recirculation Strategy”*. Prepared for Water by Design.

Mechanical removal

Cyanobacterial surface scums may be mechanically removed using booms dragged behind boats and the concentrated Cyanobacterial scum on the surface pumped off. This technique is not widely used for the management of Cyanobacterial blooms as Cyanobacterial biomass will be present throughout the water column, and therefore only a small proportion of the algal biomass will be removed.

Atkins *et al.* (2001) reported the use of flocculation and mechanical removal techniques to manage a *Microcystis aeruginosa* bloom in the Swan River, Perth. A mixture of bentonite clay and polyaluminium chloride was used to flocculate and sink the *Microcystis cells* prior to mechanical removal using oil spill equipment.

The mechanical removal of Cyanobacterial biomass offers the advantage of also removing nutrient loads from the water body, however the disposal of the odorous and often toxic biomass may be problematic.

Ultrasonic treatment

Ultrasonic irradiation of Cyanobacterial cells is a relatively new strategy that has been proposed for managing Cyanobacterial growth in lakes. Many of the common bloom forming Cyanobacteria are characterised by the presence of gas vacuoles which enable the Cyanobacterial cells to regulate their position within the water column. The presence of gas vacuoles provides a competitive advantage to Cyanobacteria over the majority of other algal groups, as it enables the Cyanobacteria to scavenge nutrients from the hypolimnion (lower strata of the water column) and to optimise their exposure to light within the epilimnion (upper strata of the water column).

Lee *et al.*, (2001) investigated the use of ultrasonic irradiation as an alternative strategy for controlling Cyanobacteria, and found that the gas vacuoles of Cyanobacteria (*Microcystis viridis* and *M. aeruginosa*) were disrupted following brief exposure to ultrasonic irradiation, resulting in about 80% of the Cyanobacterial cells settling out. Decreased photosynthetic activity was observed following irradiation, suggesting that the ultrasonic treatment also inflicted damage to the photosynthetic apparatus of the Cyanobacteria.
