A potential risk associated by exposing Cyanobacterial cells to ultrasonic irradiation is that the cell membranes may rupture, potentially releasing cyanotoxins into the water column. Interestingly, Lee *et al*., (2001) observed that ultrasonication of the *Microcystis* cells did not increase the concentration of cyanotoxins in the water column. More recent research has shown that ultrasonication of Cyanobacterial cells (for periods less than 5 mins) does not increase cyanotoxins (in this case Microcystins) but cyanotoxins may also degrade in the ultrasonic fields (Ma et al., 2005). The effects of ultrasonic irradiation upon other cyanotoxins such as cylindrospermopsin (*Cylindrospermopsis* and *Aphanizomenon*) and saxitoxins (Anabaena) have not been tested.

The evaluation of ultrasonic irradiation to control Cyanobacterial growth in lakes thus far has resulted in mixed outcomes. Nakano, et al. (2001) trialled the use of ultrasonic irradiation coupled with flushing in a large shallow hyper-eutrophic lake (1 m depth, 33 Ha) that was plagued by Cyanobacterial blooms. Whilst the use of the ultrasonic irradiation of reduced peak concentrations for chl-a from 200 ug/L to 130 ug/L (Lee, et al. 2002), the study was unable to conclusively demonstrate the effectiveness of the ultrasonic treatment upon Cyanobacterial growth.

Ahn, *et al.* (2007) used ultrasonic irradiation to control Cyanobacteria in a small eutrophic lake (2 m depth, 0.9 Ha). During the period of the year when Cyanobacterial blooms dominated the lake, chl-a concentrations remained low at approximately 10 ug/L compared to an adjacent control lake where chl-a concentrations varied between 20-87 ug/L.

The potential impacts of utilising ultrasonic irradiation to control Cyanobacteria upon other aquatic organisms are hitherto largely unknown. Ahn et al. (2007) reported that larger organisms (fishes and aquatic insects) did not seem to be affected by ultrasonication. Kotopoulis *et al.* (2009) found that acoustic pressures produced during ultrasonication surpassed the Nato Undersea Research Centre rules and proceedures (NURC) by 35 dB, and cautioned the use of ultrasonication in aquatic environments.

The use of ultrasonic irradiation of Cyanobacterial cells appears to offer a potential strategy to control of Cyanobacterial growth in small lakes where lake water can be readily recirculated through an ultrasonic unit. Further research is required to determine how this strategy might best be applied to small lakes, and to the effects of ultrasonication on aquatic ecosystems and cyanotoxin release and decay.

Sediment removal

The removal of the upper sediment layers from the lake bottom is a commonly used strategy for removing phosphorus loads from highly eutrophic lakes. One of the advantages in removing the upper sediment layer is that any Cyanobacterial resting cells (e.g. akinetes) will be also be removed.

Sediment removal should be considered a "last resort" option for reducing the risk of Cyanobacterial growth in constructed lakes. The removal of sediments from a lake may have a profound influence upon benthic organisms,

including the removal of macrophytes and fauna from the lake. In addition, sediment removal is generally confined to small lakes due to the costs associated with the removal and disposal of the contaminated sediments.

The removal of upper sediment layers may not be an effective strategy for managing Cyanobacteria in constructed lakes, particularly where stormwater inputs contribute nutrient loads sufficient for Cyanobacterial growth to occur. Lake systems with high submerged macrophyte cover are particularly susceptible to sediment removal, as the ensuing turbidity following the sediment removal may inhibit macrophyte recolonisation, which results in the reversion of the lake to an algal/CyanobacteriaCyanobacterial-dominated state.

Sediment capping
Sediment capping of in situ sediments involves the placement of a cover over the sediment to seal it off, thereby minimising the release of contaminants (nutrients) to the water column (Hart et al., 2003). Sediment capping may involve placing a physical barrier over the sediment (e.g sand or gravel) or providing an active barrier (Hart et al., 2003).

Active barrier systems are generally pervious geochemical materials that are capable of actively demobilising contaminants in the sediment pore water by adsorption or precipitation processes. A number of active barrier systems have been tested in lakes including calcium carbonate, zeolites, modified clays and kaolin amorphous derivatives (Jacobs and Forstner, 1999; Hart et al., 2003).

Both sediment capping methods offer effective strategies for reducing phosphorus release from sediments. Generally, physical barriers need to be placed during construction or following drawdown of lake water levels. Active barrier systems can be very expensive to use, and there is little information available detailing the long term effectiveness of these systems. The use of sediment capping in constructed urban lakes is unlikely to be a successful long-term strategy for managing Cyanobacterial growth due to the influence of stormwater pollutant loads upon in like water quality.

Phosphorus precipitation and inactivation
The strategy involves the use coagulants to reduce the overall available load of phosphorus available for Cyanobacterial growth. The coagulants are added to the lake water, where the coagulant binds to the bio-available phosphorus, then precipitates out of the water column as "flocs". The flocs settle down to the sediments where the phosphorus is effectively removed from the water column and locked up in a form that is unavailable for phytoplankton growth.

Coagulants commonly used to precipitate phosphorus within lakes include aluminium-sulphate, zirconium, iron and calcium salts, and some clay materials (Cooke, *et al*., 2005; Scheffer, 1998),

The effectiveness of coagulants in shallow lakes is generally low where macrophytes are present, or when the external loading of phosphorus (via stormwater) exceeds the phosphorus binding capacity of the coagulate (Welch and Cooke, 1999). The constant re-suspension of sediments due to wind action in shallow lakes also renders the use of coagulants ineffective.

Artificial destratification
Artificial destratification refers to the mixing of the hypolimnetic and epilimnetic layers within stratified lakes. Stratification generally occurs within deep lakes >5 m, although diurnal stratification will often occur in much shallower lakes.

Stratification occurs when a density gradient develops within the water column between the warmer upper layer (epilimnion) and the colder and denser bottom layer (hypolimnion). When lakes are stratified, the hypolimnion becomes depleted of oxygen and reducing conditions develop, releasing nutrients such as ammonia and phosphorus from the sediments. Under stratified conditions, Cyanobacterial species that are able to regulate their buoyancy are able to access both nutrients in the nutrient-rich hypolimnion and sunlight for photosynthesis in the epilimnion.

Aerators are commonly used in stratified lakes continually mix the water column, thus eliminating the competitive advantage of Cyanobacterial buoyancy over other non-buoyant algae (Reynolds et al., 1984). Whilst artificial destratification has been used successfully in Australia for controlling the release of nutrients from lake sediments, only limited success has been achieved controlling Cyanobacteria (McAuliffe and Rosich, 1990). It is expected that

improvements in destratification technology (e.g. mixer design) will increase mixing efficiency and improve the control of Cyanobacterial growth (Brookes et al., 2002).

Hypolimnetic withdrawal

Hypolimnetic withdrawal involves the removal of nutrient rich hypolimnetic water from stratified lakes (Nurnberg, 1987). The removal of hypolimnetic water effectively decreases phosphorus concentrations in the epilimnetic layers of stratified lake systems, thereby limiting the potential for excessive Cyanobacterial growth to occur (Nurnberg, 1987).

Hypolimnetic withdrawal is a widely used strategy for managing water quality (risk of Cyanobacterial growth) in a range lakes, varying in depth from 4.5 – 25 m (Cooke *et al*., 2005). Hypolimnetic withdrawl is only applicable to lake systems where the amount of discharged water can be replaced with sufficient inflow, so that the water level remains constant (Cooke et al., 2005).

Whilst hypolimnetic withdrawal is a relatively simple and cost effective strategy, it is unlikely that this technique could be used to effectively manage water quality within constructed urban lakes. Most urban lakes have a shallow depth profile and are relatively well mixed (in some cases shallow lakes may also exhibit diurnal stratification). Furthermore, hydraulic retention times in urban lakes are usually high, and sufficient inflow is unlikely to be available in order to maintain constant water levels.

Constructed urban lakes which regularly exhibit stratification may benefit from hypolimnetic withdrawal, however due consideration would also need to be given to the disposal of the poor quality hypolimnetic water downstream.

Algicides

Chemical control of algal and Cyanobacterial growth within reservoirs has been a widespread water quality management practice for over 100 years (Burch et al., 2002).

The most common algicides used to control Cyanobacteria in reservoirs are copper sulfate or chelated forms of copper. These are extremely effective as they act rapidly and are toxic phytoplankton (and Cyanobacteria) at concentrations that do not represent a health risk to humans (Steffensen *et al*., 1999). The chemical composition of the receiving water, particularly pH, alkalinity and dissolved organic carbon influence copper speciation and complexation, thus greatly influencing copper toxicity. Copper algicides are economical, easy to apply and are generally considered to not to cause extensive environmental damage (Burch et al., 2002).

Recent studies have shown however, that sediment bound copper and other heavy metals may impact benthic communities, zooplankton, fish and invertebrates. Copper is not biodegradable, and once it has entered the environment, its potential toxicity is controlled by its speciation or physico-chemical form (Burch et al., 2002). One of the major problems associated with the use of copper-based algicides to control Cyanobacterial growth is that copper lyses the algal cells, resulting in the release of intracellular toxins and other odorous compounds into the surrounding water (if present). This can exacerbate health risks to humans and other animals. Currently, there is little information on the minimum withholding period in relation to toxin degradation (Burch et al., 2002).

Other algicides used to control Cyanobacterial growth in lakes include potassium permanganate, simazine compounds, chlorine, lime and barley straw (Burch et al., 2002; House and Burch, 2002). Potassium permanganate, simazine and chlorine are lethal to algal cells and may result in the release of cyanotoxins. Lime is used as an algicide to coagulate and precipitate algal cells from the water column, and does not appear to cause cell lysis and toxin release (Burch et al., 2002). Recent studies have shown that the use of lime is most effective in hard water lakes (Murphy and Prepas, 1990), however dosing rates are quite high and this technique has not been extensively tested within Australian waters (considered soft waters) (Burch et al., 2002).

Considering the potential environmental and human health risks, the use of algicides is not recommended for the sustainable long-term management of Cyanobacterial growth in constructed lakes.

Biomanipulation

The biomanipulation method is often referred to as “top-down control”, and refers to the management of higher trophic organisms to maximise grazing of algae, and therefore a reduction in Cyanobacterial biomass in the lake system. There is no information on the use of biomanipulation to manage Cyanobacteria in constructed lakes.

In a review of 33 whole-lake biomanipulation experiments, Reynolds (1994) concluded that top-down effects on the lower trophic levels (phytoplankton) were inconclusive. Reynolds (2006) postulated that the manipulable linkages between phytoplankton, zooplankton, planktivorous fish and piscivores apply only to truly pelagic systems.

Boon et al. (1994) reviewed the potential use of top-down control of Cyanobacteria and concluded that zooplankton assemblages in Australian waters are quite different in composition from those of the Northern Hemisphere, and therefore unlikely to respond to manipulations of trophic structure in a similar way. The study concluded that the manipulation of trophic structure in Australian fresh waters to control Cyanobacterial blooms is therefore unlikely to be effective.

Floating macrophyte beds

Floating macrophyte beds have been increasingly used to manage water quality in lakes where other methods of water quality treatment may be constrained. This is particularly the case in many golf courses, where high nutrient concentrations in the stormwater runoff often stimulates excessive algal growth in the waterways.

The use of floating macrophytes has been widely used within the United States for well over 20 years to treat wastewater and stormwater runoff (Reddy and DeBusk, 1987). Floating macrophyte beds can be effective for managing algal growth in lakes as they remove bioavailable nutrients from the water column, thereby reducing nutrient availability to Cyanobacteria or other algae. Floating macrophyte beds are relatively simple and cost effective, and regular harvesting of the macrophytes serves to further reduce nutrient loads from the lake system.

Basil, tomato and silver beet plants growing in aquaponic units (floating plant beds) were recently trialled at Rio Tinto's Kestal Mine (Central Queensland) in order to control blue-green algal growth in a number of lake systems (Fabbro and Duivenvoorden, 2004; L. Fabbro pers. comm.). The research showed that the basil, tomato and silver beet plants were particularly effective at removing phosphorus and molybdenum from the water, essential elements that are required for Cyanobacterial growth (L. Fabbro pers. comm.).

The use of floating macrophyte beds offers a range of potential options for managing water quality in constructed urban lakes. Floating macrophyte beds could be used in situ (within the lake) or within dedicated bays as part of a lake recirculation system.

Sub-surface wetlands

Recirculating lake water through sub-surface flow wetlands may be an alternative option for removing Cyanobacterial biomass from lake systems. Sub-surface wetlands are most commonly used to treat municipal sewage, and also wastewaters from agriculture, industry and landfill, and less commonly to treat stormwater runoff.

Sub-surface wetlands remove a wide range of pollutants including nutrients, suspended solids and organic matter from the water by fine filtration, adsorption and biological processes (uptake, aerobic/anaerobic degradation, nitrification/denitrification) (Vymazal, 2005).

SC6.4.3.13 Townsville road hierarchy

SC6.4.3.13.1 Introduction

The Townsville road hierarchy is a planning tool to guide good-practice transport planning and management, with the aim of balancing the needs of both the land use and the roadway system. A road hierarchy establishes each roadway function such that appropriate objectives for that roadway and design criteria, can be developed and implemented. These objectives and design criteria are aimed at achieving an efficient road system whereby conflicts between the roadway and the adjacent land use are minimised, and the appropriate level of interaction between the roadway and land use is permitted. The road hierarchy also forms the basis of ongoing planning and system management aimed at reducing the conflict between existing incompatible functions.

The use of road hierarchy categories as part of the land use and transport network planning process enables optimisation of the relationships and key roles associated with accessibility, connectivity, amenity, and safety for all road/land users, including vehicles, bicycles, pedestrians, and public transport. The road hierarchy categories and sub-categories contained herein are pertinent and appropriate with the current transport environment in the Townsville area. As time passes, and the transport system and its relationship with land uses changes, these road hierarchy principles will require further development and refinement.

Editor's note—this sub-section deals mainly with issues relating to "Roads". Issues relating to 'Streets" are dealt with in more detail in other parts of the Development manual planning scheme policy.

(1) Integrated Regional Transport Planning Framework

Integrated land use and transport planning must be embedded and applied in a wide range of circumstances – from strategic planning to detailed design for one mode or across all modes. This road hierarchy sub-section contains specific information for managing the interface between land use and roadway systems. This sub-section is to be used with regard for the overarching planning framework. The Integrated Regional Transport Planning (IRTP) Framework for Queensland (Queensland Government, 2003) is a preliminary transport planning guide that can provide the more general guidance not covered by this road hierarchy sub-section and has been adopted by Townsville City Council.

The IRTP Framework, applies to all facets of transport planning, including:

(a) public transport, walking and cycling networks;

(b) road upgrades;

(c) new road, rail or multi-modal corridors;

(d) heavy-vehicle safety and efficiency;

(e) policy positions; and

(f) entire local government areas or regions.

The IRTP Framework aims to:

(a) reduce the need to travel and the length of trips;

(b) provide a choice of travel options for people and goods, and promote sustainable choices;

(c) make it safe and easy for people to access goods, services and destinations, particularly by public transport, walking and cycling;

(d) increase the share of trips by public transport, walking and cycling;

(e) provide for the safe and efficient delivery of freight;

(f) minimise the need for new transport infrastructure; and

(g) achieve desired outcomes using the most cost-effective package of measures.

(2) Structure of the road hierarchy

Based on the desired outcomes, directions and principles contained in the IRTP Framework, this sub-section establishes a four level road hierarchy that manages the interface between land use and roadway system and

guides system planning and management in urban and rural areas. Figure SC6.4.3.13.1 shows the basic structure of the four level road hierarchy, and the four levels are explored in more detail in SC6.4.3.13.3, and in SC6.4.3.13 Attachment A: Urban and rural traffic environments map, SC6.4.3.13 Attachment B.1: Road hierarchy elements and their objectives in urban areas, B.2: Road hierarchy elements and their objectives in rural areas, C.1: Townsville road hierarchy map (existing), C.2: Townsville road hierarchy map (future), D.1: Road hierarchy desirable performance criteria in urban areas and D.2: Road hierarchy desirable performance criteria in rural areas.

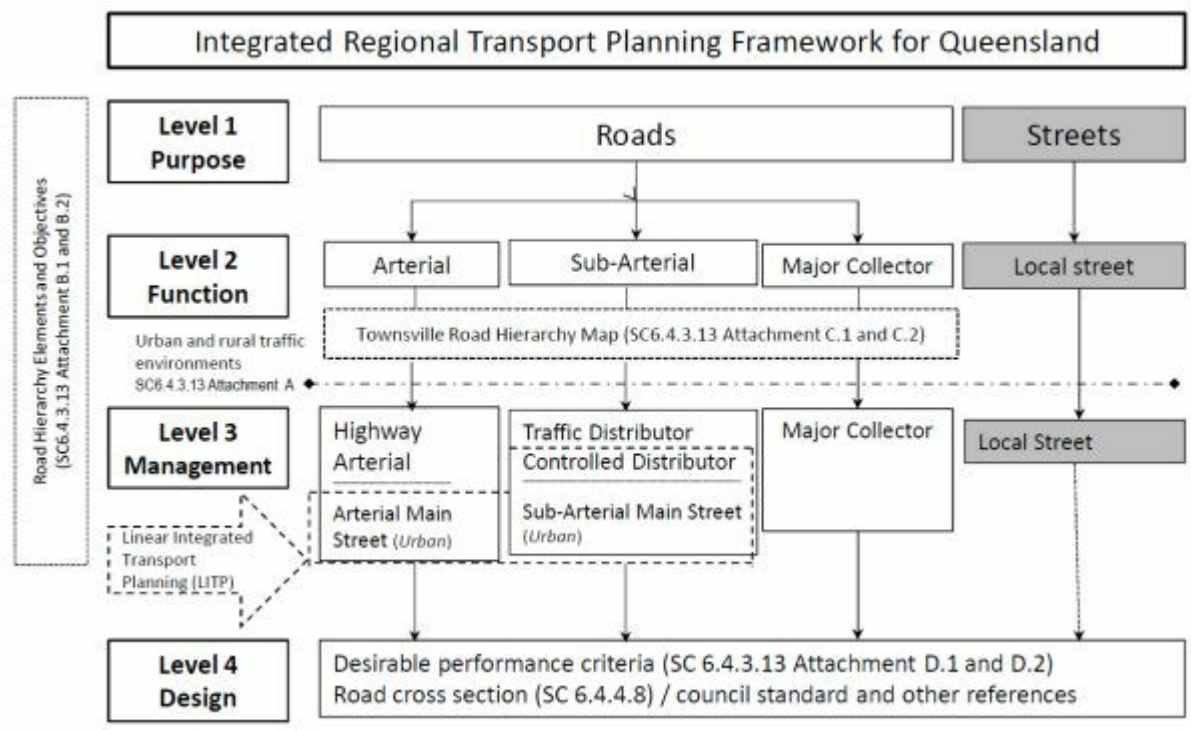

Figure SC6.4.3.13.1 Structure of the four level road hierarchy

(3) Road hierarchy objectives

The four level road hierarchy aims to meet the following objectives, and will assist council and the state government with meeting appropriate standards for roadway construction:

(a) to systematically classify roads into a framework around which council and the state government can plan and implement various land use, infrastructure construction, maintenance, and management schemes and projects such as:

(i) identifying the effects of development decisions in and on surrounding areas and roadways within the hierarchy; and

(ii) developing design that facilitates urban design principles such as accessibility, connectivity, efficiency, amenity and safety;

(b) to guide network planning and management for all modes (private, passenger and commercial/industrial transport) and users (motorised and non-motorised); and

(c) to clarify policies and decisions in designing new networks and in managing existing road systems in order to provide a rational basis for management of the network under the current or future planning schemes, for example:

(i) enabling investment and traffic management efforts to be concentrated on those links able to cope efficiently with transport needs;

(ii) enabling council and the state government to adopt appropriate standards of construction on traffic routes; and

(iii) enabling the network to be optimised to accommodate access and non-transport functions.

(d) The ways in which these objectives may be implemented within a well-formed road hierarchy include:

(i) concentrating longer distance flow onto routes in less sensitive locations;

(ii) ensuring land uses and activities that are incompatible with traffic flow are restricted from routes where traffic movement should predominate;

(iii) preserving areas where through traffic is discouraged;

(iv) identifying treatments such as barriers, buffers, and landscaping to preserve amenity for adjacent land uses;

(v) ensuring activities most closely related to frontage development, including social interaction and parking, can be given more space when environmental and access functions are allowed to predominate;

(vi) ensuring safe traffic operation by controlling access onto roads, and separating different types of traffic in higher order road corridors;

(vii) ensuring efficient traffic operation for through traffic whilst designing new roads as part of a safe system approach;

(viii) enabling the orderly planning of heavy vehicle and dangerous goods routes;

(ix) planning for and providing public transport routes;

(x) planning for and providing pedestrian and bicycle routes; and

(xi) identifying facilities for pedestrians, cycles and public transport.

(4) Scope

This document is a planning tool for all road agencies and authorities involved in land use and transport planning/management processes in Townsville. The road hierarchy elements can be applied in areas such as:

(a) planning – in designating a Strategic Transport Network for a region, consisting of roadways and other facilities for the movement of goods and people;

(b) management - in designating and programming improvements to achieve the desirable performance criteria over time for each element of the road network;

(c) environment – in managing the road network to facilitate efficient operation, which will assist in achieving environmental sustainability and improve amenity to the region's inhabitants;

(d) safety – in managing the road network by controlling access onto traffic carrying roads, providing appropriate design standards, and proper use of the network by the vehicle fleet to facilitate safe movement of all road users; and

(e) congestion management – in planning and managing the road network to ensure traffic volumes carried are appropriate to roadway functional and management attributes.

(5) Definition of urban and rural

The application of the road hierarchy requires the terms urban and rural to be defined for the purpose of this policy.

Urban	developed area which may comprise densely developed uses such as residential, commercial, industrial, education, recreation or a mix of these. In general, this is characterised by evenly spaced street lighting, kerbed streets, frequent closely spaced driveways (preferably none on traffic carrying roads). This will also include land designated for future urban development.
Rural	sparsely developed area which may comprise rural development, rural residential development, isolated pocket of urban development and environmental area. In general this is characterised by unkerbed streets, both sealed and unsealed roads, infrequent driveways and large tracts of undeveloped land. Street lighting may only be at intersections and points of safety concerns.

These terms do not necessarily align with definitions within legislation but relate to the character of the land for the purpose of providing access and thoroughfare. For the specific purpose of showing urban and rural traffic

environments for the Townsville road hierarchy, a map has been provided in SC6.4.3.13 Attachment A.

If a rural development is located in the adjacent urban fringe area or adjoined/contained a part of continuous existing network connection, it may be required to be designed similar to the adjacent road network environment, e.g. urban road cross section.

(6) Terminology

Category	Those elements of the road hierarchy defined at Level 2 of the road hierarchy.
DTMR	Department of Transport and Main Roads.
Environmental cell	Contains local streets with a slow speed and pedestrian priority environment, and generally bounded by major collector roads.
LITP	Linear Integrated Transport Plans: a means of planning between the roadway and the adjacent environment in an integrated manner.
MUTCD	*Manual of Uniform Traffic Control Devices.*
RPT	Regular public transport.
Specific cell	A part of the urban fabric that is contained within a block bordered by traffic carrying roads or other physical boundaries.
Sub-category	Those elements of the road hierarchy defined at Level 3 of the road hierarchy.
VPD	Vehicles per day.

SC6.4.3.13.2 General principles

(1) Network Linkage
Ideally, only roadway elements with the same place in the hierarchy, or one position higher or lower in Level 2 of the hierarchy, should intersect.

For example:

(a) arterial roads should only intersect with sub arterial roads and other arterials;

(b) sub-arterial roads should only intersect with arterials, other sub-arterials, or major collectors;

(c) major collectors should only intersect with sub-arterials, other major collectors, or local streets; and

(d) local streets should only intersect with collectors or other local streets.

However, road networks have evolved out of step with this linkage principle in practice.

In certain situations it may be acceptable for roadway categories separated by two positions within Level 2 of the hierarchy to intersect. For instance, a local street may intersect with a sub arterial road, or a collector with an arterial, without significant adverse ramifications. In other cases, a permeable grid local network creates too many street-road intersections, and some of these have to be blocked off to limit points of access for vehicles (creating cul-de-sacs). Paved footpath access into the local area for pedestrians and cyclists could be maintained, providing the desired pedestrian and cyclist access onto the arterial roads, without adverse impact on traffic flow, safety and local amenity.

It may even be acceptable for roadway categories separated by three positions in Level 2 of the hierarchy to intersect in certain cases. That is, a local street may intersect with an arterial road, provided it is not an uninterrupted flow facility, without significant adverse effects. This may be the case, for example, where a service road provides access directly to a two or four lane arterial road in an urban area, or two lane highway in a rural area.

Despite their development history and desired function in the road hierarchy, local streets may need to be compromised to provide connectivity for the public transport network.

(2) Size of precincts free from unwanted traffic

The spacing of arterials or traffic routes has the effect of defining the size of development areas that are penetrated only by streets. The size of these "cells" has a direct influence on issues such as the local traffic environment, whether or not "difficult traffic routes" can be avoided, the feasibility of sustaining low vehicle speeds in the local area, the number and frequency of connections to surrounding arterials, and access to bus routes around and through the area. Traffic should be distributed appropriately amongst the local streets to ensure that amenity levels are not exceeded and adequate connectivity is maintained.

The specific area and environmental cell concepts can be accommodated with relative ease as part of a new subdivision plan but it is often more difficult to impose the specific area concept onto an existing system. However, it is important to have a target in mind when assessing the requirements of the road systems in a particular area.

(a) Urban areas

While the size and shape of a specific area is commonly constrained by fixed elements such as existing infrastructure, topography and property boundaries, the idealised form is of the order of 1 km × 1 km for an urban specific area. This size would typically encompass four environmental cells, each 0.5 km × 0.5 km. The boundaries of the specific areas will be partially defined by the existing major road system, which in turn has generally been developed to a large extent as a result of historical events rather than recent planning initiatives. Other features may also be used as boundaries.

The aim is to define specific areas which:

(i) are relatively homogeneous in land use;

(ii) have only that traffic necessary for the functioning of the area, i.e. they are free of non-essential or through traffic; and

(iii) have a balance between the volume of essential traffic and the nature of the area. For example, higher volumes may be more acceptable in industrial areas than in residential areas.

(b) Rural areas

While the specific area concept is most relevant to an urban area, it also applies to rural areas, although in a slightly different context. Specific areas in rural areas should be linked by a system of through traffic carrying roads. The dimensions and form of a specific area will vary in rural areas due to the reduced development densities. As a result, specific area sizes in rural areas will be significantly larger than in urban areas.

(3) Abutting development and access to it

Restriction of access points to abutting land uses is one of the key parameters in the road hierarchy. Decisions on access points to new developments are linked to the strategic function of the road and the types of traffic and trips that it serves, as well as the type of environment intended to result. The allocation of accesses as part of a management regime is not identical to a "road classification" system, but may supplement it.

Decisions on network types, especially at the local level, will have long-term effects on the traffic character of an area, and inevitably the quality of service on the surrounding traffic routes. The road hierarchy provides a means of classifying and designing a roadway according to its purpose, function and management. It is intended that this process be carried out within the constraints of the network, as it is imperative that corridor continuity be considered. Notwithstanding past decisions that have resulted in existing constraints, this may mean that corridor continuity may need to be targeted as a long term goal.

In addition to corridor continuity, future development potential should also be addressed in the road hierarchy. The planning scheme earmarks a considerable quantity of land for future urban development, industrial, commercial or residential. Classification of existing roadways in these areas should support future amendments to the hierarchy and the associated changes in performance criteria. For example, an existing road may currently serve a collector function, but as the area is subdivided into urban development in the future, the potential future function of the road may require allowances to be conformed at an earlier time so that the

performance criteria of its future function can be met.

It is important to note that some non-residential land uses such as schools, parks and local shops have to be located within or near the specific areas they serve. These may be accessed by a sub-arterial road, or, if this is not possible, it is desirable that they are accessed via a major collector road rather than the local street environment. The conflicting land use requirements in these circumstances mean that network considerations must be carefully examined in terms of connectivity, network efficiency and compatibility between private vehicle, public transport, non-motorised and freight networks. Integrated land use and hierarchical transport planning can overcome this shortcoming to a large extent.

(4) Relationships between networks

"Cells" may be sized and have access limited to manage entry of unwanted traffic. However, different networks will have different entry criteria. As mentioned in SC6.4.3.13.2(1) above, network linkage principles may vary between motorised vehicles and active transport modes such as public transport, pedestrian and bicycle. For example, passenger transport networks are often focused on middle order roads to balance point to point travel times, network reach, connectivity and passenger safety. Similarly, freight networks will be based on specific freight criteria and result in different networks for freight when compared to other traffic networks. In some areas, freight networks may enter into small industrial cells and utilise low order roads to access depots. The overlay of modal networks is a key consideration in establishing the functional category for a specific link in the road network.

SC6.4.3.13.3 Four level road hierarchy

A four level road hierarchy has been developed, based on the functional objectives of each category or sub-category within the hierarchy. Level 1 begins with a broad distinction between roads and streets, and the following three levels listed with an increasing degree of detail with respect to functional objectives. The Levels are defined as follows:

Level 1. Purpose relates to the primary objective of the element, whether to carry through traffic or provide direct property access.

Level 2. Function relates to the relationship between the roadway and land use it serves (i.e. how the roadway serves the land use). This level of the hierarchy is common to traditional road hierarchy concepts.

Level 3. Management relates to the implementation of policies to achieve the envisaged function based upon the attributes of the element and of the adjacent land uses.

Level 4. Design relates to specification of the form of the element in order to achieve its functional objectives.

Note—the relevant standard drawings include SD-002 Typical Road Cross Sections – Collector Roads , SD-003 Typical Road Cross Sections – Sub Arterial Roads and SD-004 Typical Road Cross Sections – Arterial Roads.

(1) Hierarchy Level 1 - Purpose

Level 1 of the hierarchy defines roadways as either:

(a) roads to carry through traffic; or

(b) streets for access to property and collection of local traffic.

This classification applies to both rural and urban areas.

The definition of a roadway in one particular category serves to indicate a planning intent in relation to the functions that will be permitted on that roadway. Thus, measures are likely to be adopted on streets that relate to amenity and environmental capacity, for example, by removal of through traffic, or direction of local traffic to a particular collector road. At the other end of the scale, treatments on arterial roads will principally be related to increasing traffic carrying capacity. This would tend to be by removal of some incompatible lower order functions, such as limiting access to properties, disallowing any further new accesses, or reducing the number of intersecting roads.

Figure SC6.4.3.13.2 below illustrates the relationship between traffic mobility and land access in a functionally

classified roadway system.

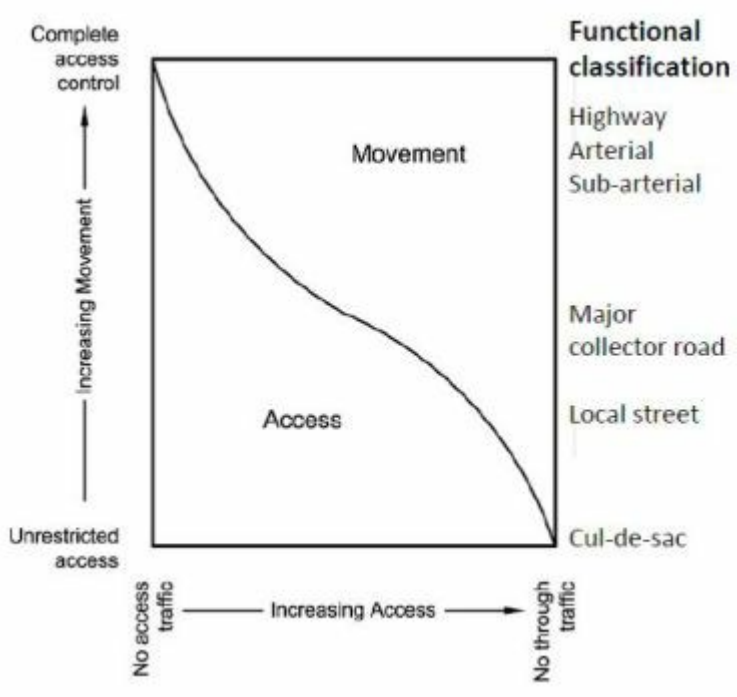

Figure SC6.4.3.13.2 Relationship between traffic mobility and accessibility

Source: Adapted from a figure in NCHRP Report 348, Access management Policies and Guidelines for Activity Centres, Transportation Research Board, Washington DC, 1993.

Note—the functional classification has been modified to suit the Townsville context.

(2) Hierarchy Level 2 - Function

Within the two broad groups of roads and streets in the first level of the hierarchy, four functional roadway categories have been identified, reflecting the different ways in which they serve land use and carry traffic.

The functional classification indicates the relative importance of the traffic mobility function as opposed to the amenity/access functions, and how these conflicting aims are to be prioritised and managed.

The four functional categories in Level 2 of the hierarchy are:

- arterial road – to carry long distance through traffic external to specific areas;
- sub arterial road – to carry through traffic between specific areas and arterial roads in a supporting role to the latter;
- collector road – to provide connectivity between the environmental cells and the traffic carrying road and to provide grouped property access; and
- local street – to provide direct property access and immediate local movements.

Based on the current and future land use zoning in the Townsville City Plan, the Townsville road hierarchy map (see SC6.4.3.13 Attachment C.1 Townsville road hierarchy map (existing) and SC6.4.3.13 Attachment C.2 Townsville road hierarchy map (future)) has been developed all Level 2 categories. To enable easier application of the road hierarchy, the same overarching objectives and category names have been applied for both urban and rural areas. It should be noted that some links are identified as a conceptual location with respect to spacing, hierarchical connectivity and continuation of links between start and end points. Therefore, if significant development is planned to occur in a large or multiple parcels of undeveloped land in either an urban or rural area, then it may be necessary to reassess that area road hierarchy plan within a whole network.

(a) Arterial road

The primary objective of arterial roads is to provide major through routes for traffic. All longer distance traffic movements should be directed onto the arterial roads. Arterial roads should form a principal

connection between major regional centres and towns. It can also serve a line haul function for public transport. Arterial roads will often be elements of the various networks with high order functions. For instance, the network of over dimension freight routes is likely to be primarily on arterial roads.

These corridors should provide for regional cycle movements, but travel speed, volume and composition is such that cycle movements should desirably be kept separate from general traffic. In general, arterial roads have high design standards for efficiency and no direct frontage access.

In rural areas it is recognised that many arterial roads have direct property access. This results from the large size of properties, the reality of limited road infrastructure and the infrequent number of vehicles with direct access. On such roadways the main goal is to provide a highly efficient traffic flow (increased speed and increased capacity), balanced with safe access.

For all arterial roads it is desirable that, over time, no new accesses are permitted and that existing accesses be removed, or at least consolidated, or turning movement restricted.

(b) Sub-arterial road

Sub-arterial roads carry through traffic and should be more convenient than using the "streets" network; therefore a high level of efficiency and safety should be provided. In general, sub-arterials do not serve the longer distance regional movements and do not provide continuity across arterials. However, they do serve to provide connections between arterial roads and may be used to provide such additional connections for through movements.

In urban areas, sub-arterial roads typically provide connection between residential, commercial or industrial areas and arterial roads. They will normally be the lowest order of road to be traversed by scheduled public transport in performing a line haul function. They may also serve to provide access to public transport at stops. These corridors may provide for cycle and pedestrian connections between local areas and the regional cycle system (if such exists). These connections would preferably be bicycle lanes on the shoulder or outer lane of sub-arterial roads rather than on the roadway with general traffic. These roads can provide consolidated access to commercial and retail developments and as a result can also cater for pedestrian movements, especially in the vicinity of such developments. The provision of consolidated access allows for turning movements to be focussed at specific, controlled locations rather than at high frequency along the roadway, thus minimising interruptions to through traffic.

In rural areas, sub-arterial roads in particular provide connections between adjacent suburbs and/or between arterials. Access may also occur, and be necessary, but these will be more widely spaced due to the larger lots.

(c) Major collector road

The objective of collector roads is to provide for the connection between the local area (local streets) and the traffic carrying roads. The form of linkage provided should predicate against the usage of collector roads within a particular area by longer distance traffic unless the trip is relevant to the area. In residential areas particularly, amenity and safety should be the most important consideration, as these roads are also intended to provide direct access to grouped properties, commercial premises, schools or community facilities.

These roads will carry public transport operating in a sweeper role, and these are likely to be school bus routes. It is necessary to ensure that the connectivity to achieve an efficient bus route does not encourage penetration by through traffic. Typically, scheduled bus routes would begin a service on collector roads, as a sweeper service, and then move to higher order links in the bus network to run as limited stop or express services.

As these roads serve as access to adjacent grouped properties, whether in residential or commercial/industrial areas, pedestrian movements need to be accommodated off the roadway. Traffic volumes should be balanced to accommodate local cycle movements on the road, and road design should create a safe environment for these vulnerable road users.

(d) Local street

The objective of local streets is to provide access to properties. In residential areas, these should be in a form to encourage a liveable and safe street environment where the motor vehicle is secondary to the pedestrian and cyclist. Through traffic should be discouraged on these streets and a lower speed environment is desirable for safety. Given the low traffic volume and potentially lower speed environment, it is appropriate for cyclists and pedestrians to share the road space. Similarly, specific facilities for pedestrians (crossings or concrete footpaths) are generally not required due to low traffic volumes and speeds. However, depending on the degree of abutting land use activity or pathway network planning, concrete pathways would provide for safety and a continuation of the pathway network.

The role of collector and local streets is complicated further as all freight, and motorised and non-motorised passenger networks can ultimately operate on these roadways, often without specific treatments.

(3) Hierarchy Level 3 - Management

Ideally, all roadways within the same category of Level 2 would be treated in the same manner. This may be achievable in a new development but existing situations or other constraints often dictate that a variety of treatments need to be available. These situations may arise for a number of reasons, not the least of which is the mixture of access and traffic functions already prevalent on many roadways.

Level 3 manages these issues through splitting the Level 2 categories into sub categories, which relate to more particular attributes of the roadway. Each sub category has objectives that are more specific than the category objectives for Level 2. The management sub categories are described broadly as follows (listed under each Level 2 category):

Arterial road

- Highway - serves longer distance movements as well as regionally and nationally significant movements. (A motorway is a highway that provides for a very high standard of travel by restricting non-motorised traffic and using only grade separated intersections.).
- Arterial - caters for longer distance movements, for example, connections between major centres.
- Arterial Main Street - caters for through traffic and, due to past land use decisions, serves adjacent retail/commercial land uses. This sub category is included in order to acknowledge its existence, and to provide for special cases, but it is not an option recommended for the future due to the difficulties of managing the conflicting access and mobility functions.

Sub-arterial road

- Traffic distributor - connects traffic generated in specific areas to the arterial roads and provides access to major developments.
- Controlled distributor - serves a similar function to traffic distributors but needs to be controlled for a particular reason, for example, it may provide frequent access for existing individual residential properties.
- Sub-arterial main street - connects traffic generated in specific areas to the arterial roads and, due to past land use decisions, serves adjacent retail/commercial land uses. This sub category is included in order to acknowledge its existence, and to provide for special cases, but it is not an option recommended for the future due to the difficulties of managing the conflicting access and mobility functions.

Major collector road

- Major collector - provides a connection between the other streets in a specific area and the traffic carrying roads, and provides access to large sites with restricted or controlled access (for example, schools, shops and multi-unit residential developments).

Local street

- Provides a connection between the other streets in a specific area and the low traffic carrying streets, i.e. less than 3,000 vpd. As it has low traffic volumes, a lower speed or a shorter length, it is better suited to

providing access to individual properties. It also provides pedestrian and recreation use service with a local traffic or pedestrian priority.

It should be noted that the arterial main street and sub arterial main street sub categories have been excluded from rural areas on the basis that these are characterised by adjacent land use/activities that are associated with urban development.

(a) Performance criteria

The preceding sections and SC6.4.3.13 Attachment B.1 and SC6.4.3.13 B.2 identify individual road hierarchy categories and their functional objectives. For the hierarchy to be an effective planning tool, means of achieving these objectives need to be identified. This has been done by specifying desirable performance criteria for each classification in Level 3 of the road hierarchy framework. It is apparent that for some management categories, a distinction needs to be drawn, with respect to performance criteria, between roadways in an urban or rural environment. Accordingly, the thresholds of the performance criteria differ between the urban and rural areas for Level 4 of the road hierarchy.
The desirable performance criteria are subdivided into three groups and described below.

(i) Functional Characteristics specify the functions or functional aspects of a roadway element.

(A) dominant linkage – what type of areas should the roadway provide service to/from;

(B) traffic carrying function – whilst volumes are not intended to define the category into which the roadway falls, this criterion provides some guidance as to the maximum volumes anticipated. These maximum volumes may not be met in non-urban areas due to the low density of development;

(C) residential, commercial, industrial access – what degree of access to each of the land use types is appropriate;

(D) desirable traffic speed environment – the desirable speed anticipated. This is not intended to define the maximum speed limit, which should be done in accordance with the MUTCD;

(E) heavy vehicle movement – whether the roadway is appropriate for heavy vehicles, other than for local access. Note that heavy vehicle volume will be important in defining road pavement and design form;

(F) dangerous goods movement – whether the roadway is appropriate for the passage of dangerous goods vehicles, other than for local access;

(G) public transport facilities – what role should the roadway serve for public transport (consistent with any public transport network planning);

(H) cycle facilities – what type of cycle facilities should be provided in the roadway corridor (consistent with any bikeway network planning). Cycle facilities would only be provided where sufficient demand is proven; and

(I) paved footpath – what type of paved footpaths (not for crossing the roadway) should be provided along the roadway. These should only be provided to satisfy a proven demand.

Note—the term paved footpath refers to a paved concrete footpath as per council standard.

The desirable performance criteria for these functional characteristics have been set to ensure the network operates effectively, efficiently and safely for its users.

(ii) Frictional Characteristics relate to the way roadside activity affects traffic use.

(A) access control – constraints imposed on direct access to adjacent development sites;

(B) parking provision – what provision for parking within the road reserve is appropriate;

(C) bus stopping provision – what provision for bus stops within the road reserve should be made

Note—indented bays also refer to bays which are clear of the through lanes as per council standard.

(D) pedestrian crossings – what type of facilities should be provided to allow pedestrians and

cyclists to cross the roadway, for example, signalised crossings, zebra crossings or pedestrian refuge islands;

Note—crossings must meet council standards and MUTCD guidelines.

(E) typical intersection spacing – the typical distance between successive intersections along that roadway;

Note—generally, 300m intersection spacing is not favourable for a corridor signal coordination plan.

(F) preferred intersection treatments – what form of intersection control is appropriate where the roadway intersects another of equal or higher classification; and

(G) number of traffic lanes – what function of road hierarchy and ultimate traffic demand should be considered.

Note—a road cross section is identified in terms of a type of kerb and channel, divided or undivided carriageways, parking, bike lanes and verge in Level 4 of the hierarchy (see SC6.4.3.13 Attachment D.1 and SC6.4.3.13 D.2).

The desirable performance criteria for these frictional characteristics are set with the intent of improving the efficiency of traffic flow and thus reducing its environmental consequences, in balance with access needs.

(iii) Impact characteristics relate to the relationship between a roadway element and amenity for adjacent land use:

(A) abutting land use types – in general, what type of land use would be appropriate or compatible with the roadway function; and

(B) land use impact amelioration – in general, what type of measures are appropriate on this roadway to reduce the immediate social and environmental impacts of traffic. Such treatments include barriers (fences, walls), buffers (vegetation), setbacks (distance to property lines and/or building fascias), streetscaping and environmental street design.

To achieve the desired traffic levels and conditions, a combination of actions will often be necessary to reduce traffic flows on some elements of the network and to increase traffic flows on other elements of the network. In order to minimise the use of lower order roads, such as local residential streets, it will be necessary to manage arterial roads in a way that makes their use more attractive than the lower order roads. Lower order roads must then be managed in a way that discourages traffic through environmental street design, such as street closures, street element length and design speed. If reactivity treatments are applied in existing areas, they must be undertaken on an area-wide basis to ensure that problems are not simply shifted from one street to another.

The desirable performance criteria for these impact characteristics are set with the intent of reducing negative social and environmental impacts of traffic flow on adjacent land uses.

The impact characteristics are important in making the adjacent land use areas more liveable and to address issues associated with the social interaction between transport and land use. Level 3 management principles for urban and rural roads are reflected in the design principles in Level 4 of the road hierarchy.

(b) Linear integrated transport plans (LITP)

There may be cases where a roadway does not readily fit into any category within the road hierarchy, due to incompatibility with the performance criteria. Under these cases, it is recommended that an LITP be developed specifically for the roadway under consideration. For example, with a key public transport corridor such as Ross River Road and Charters Towers Road, there is a need to satisfy both the traffic carrying roadway objectives, as well as the access and amenity to adjacent properties objectives. Each LITP will need to assess the roadway under consideration on an individual basis, and will therefore have

to satisfy individually tailored criteria. Figure SC6.4.3.13.3 below describes a general methodology for developing an LITP.

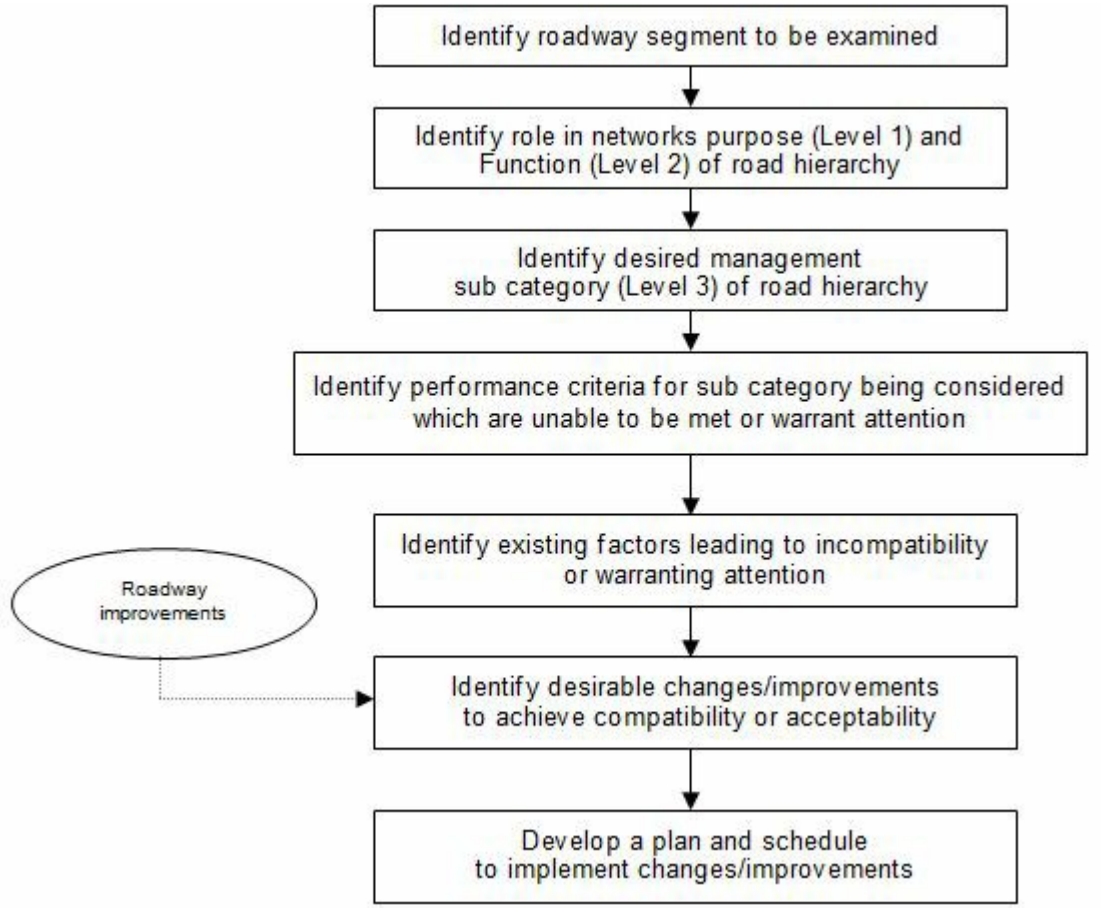

Figure SC6.4.3.13.3 Linear integrated transport planning (LITP) process

(4) Hierarchy Level 4 - Design

The fourth level of the road hierarchy framework relates to specific design criteria that are applicable to each sub category in Level 3. Level 4 aims to provide the tools with which to specify the form required of individual road hierarchy elements in order that they achieve their functional objectives. The roadway design should meet safety objectives as well as capacity and amenity objectives, where relevant. In conjunction with Level 3 objectives, it should also dictate the type of facility and design form for pedestrians, cyclists and public transport.

For each roadway, there are design elements that combine to produce a cross section or form for the roadway. SC6.4.3.13 Attachment D.1 and SC6.4.3.13 Attachment D.2 provide a set of desirable performance criteria for urban and rural areas and SC6.4.4.8 Standard drawings also includes a set of road cross sections. The design elements identified are those applicable to the road cross section away from intersections (i.e. mid-block cross section). Intersection requirements will dictate other specifications. For example, widening at intersections and future planning are an important part of defining these overall requirements. These design element details and the cross sections have been prepared for new roadways; council recognises that there will need to be variations to this to suit existing roadways (i.e. existing road forms and existing road reserve widths) in the process of network design.

It is important to note that the Level 4 specifications represent preferable specifications. There will be other constraints (e.g. topography, role in the range of networks, existing land uses, road reserve, and physical elements), which mean that the specifications may be varied from time to time. Whilst this flexibility needs to exist, it is important to keep an appropriate balance between mandatory standards, desirable objectives and constraints in order to develop an appropriate road form for each individual situation whilst still maintaining some consistency in the overall road network. The objectives and performance criteria should be maintained wherever possible.

In any case, all design criteria should be considered in line with relevant documents and proper guidelines, for example, other parts of the Development manual planning scheme policy, DTMR guidelines, AUSTROADS, MUTCD, Australian Standards, Queensland Streets, and Complete Streets for the local street level.

Note—posted speed limits are to be designated in accordance with the MUTCD-Part 4, and are required to be approved by council.

(a) **Arterial**

Administrative responsibility for roads is based on historical and political decisions as well as function within the hierarchy. Highways are administered by DTMR. The need to combine local activity planning with road planning could lead to greater local government involvement in the management of Arterial main streets. Arterials span these areas and responsibility may lie with either the state or local government.

Highway/motorway in urban/rural areas

These roads serve regionally and nationally significant movements and longer distance movements. To provide for a high standard of travel, speed environments of 100km/h or more are desirable, together with no frontage access. If frontage access does occur, then elimination of direct access from the abutting land use should be pursued.

These roads should also provide the primary freight routes and dangerous goods routes, and carry coach traffic between centres and regular public transport (RPT) bus traffic under a line haul mode. Any pedestrian and cycle facilities in urban areas should be located separately from the carriageways and protected accordingly. Crossing provisions should be grade separated. Grade separated intersections are desirable for all facilities in this category, although this will essentially be driven by volume demand or safety issues rather than hierarchy.

The road reserve width will often be dictated by the need for adjacent service roads, buffer zones and ancillary uses in the road corridor (e.g. cycle facilities, bus lanes). Divided carriageways are desirable to optimise safety and driver comfort. However, a two lane undivided cross section may be appropriate for low traffic volumes on a rural highway, provided there are sufficient overtaking opportunities. Whilst cycle facilities, pedestrian paths and bus lanes may be provided in the overall corridor, these facilities should desirably be separated from the through roadway and therefore represent an additional carriageway within the overall corridor. In rural areas, it is recognised that the demand for these adjacent facilities will generally be low.

Abutting land use types should be non-sensitive to vehicular traffic and generally not have frontage or direct access to the roadway. Uses associated with traffic such as highway service centres with amenities may be deemed appropriate in some locations based upon a needs assessment. In such cases, these would be provided with high quality direct access. Design standards for highways will primarily be set according to a high design speed and to maximise road user safety. In particular, the provision of wider shoulders is important in high speed locations.

In urban areas, grade separated intersections on urban roadways should be spaced at least 2 km apart. Intersections at grade on existing highways should be spaced no less than 1 km apart and are generally found to be between 1 km and 2 km apart.

In rural areas, if some land use provides for frontage access due to historic events, then any works undertaken to reduce this frontage access will enhance the traffic carrying capability of the highway in terms of both volume and speed. Whilst volumes may be low, the high traffic speeds mean that safety issues are important at access locations and reductions in the frequency of accesses will reduce the crash rate. Provision of pedestrian and cycle facilities will generally be related to demand and the need for a link associated with network planning. Grade separated intersections should be spaced between 4 km and 8 km, with a maximum spacing of 12 km.

Arterial in urban/rural

Arterials cater for external or intra-regional traffic and traffic between suburbs or major centres. These facilities should preferably have no direct access for all land uses. However, they often do have direct

accesses due to past land use decisions, so longer term access limitations and land use amalgamation should be pursued so that the traffic carrying role can be progressively enhanced.

The design standards are set to achieve a balance between safety and efficiency. In this case, spacing of intersections will often control the design speed and hence other design elements. There will be many existing situations where the road design is constrained by elements such as the road reserve, property access and road width. In such situations, an individual design form will need to be developed to suit the constraints, whilst still achieving the arterial road objectives.

The policy is to pursue no direct access from individual properties to arterial roads. Examples of alternative treatments include:

(i) side street entry to corner blocks; and/or

(ii) combining driveways; and/or

(iii) creating rear lane access; and/or

(iv) creating easements to service multiple properties.

To facilitate efficient traffic movement, a higher speed environment is desirable. Limits of 80 km/h for new arterial roads and 70 km/h for existing arterial roads and where physical constraints exist in urban areas, and up to 100 km/h in rural areas are recommended. Speeds in excess of the above stated speed are generally not appropriate with intersections at grade and high traffic volumes.

These roads may provide the primary freight routes and often provide secondary freight routes. Selected routes may be appropriate for dangerous goods movement. They accommodate inter urban and inter centre coach traffic and RPT bus traffic under a line haul mode with priority treatment. Any bus stops should be separate from the through traffic lanes.

Pedestrians should preferably be located separately from the carriageways, and pedestrian crossings provided at signalised points. Cycle facilities can be provided in exclusive bike lanes or on the road shoulder on roads with a speed limit less than 80 km/h, provided AUSTROADS guidelines are met. In locations where the speed limit is higher than 80 km/h, and where a high percentage of school cyclists are likely, or where there is a cycle accident history or identified potential, consideration should be given to locating these facilities separate from the carriageway.

A number of traffic lanes have to be acquired, with a minimum of a four to six lane carriageway for ultimate traffic growth, and provision made for a proper width to cater for kerb and channel, medians, bus stops and bike lanes. For the interim, a two lane undivided cross section may be appropriate for a low traffic volume environment whilst achieving affordability, sufficient overtaking opportunities, vehicle breakdown, stopping or turning vehicles and bicycles. However, divided carriageways are desirable to optimise safety and driver comfort.

The abutting land use should preferably be less noise sensitive, or alternatively should include building and site designs that minimise impacts from adjacent traffic flows.

In urban areas, intersections are generally configured at grade for this sub-category. Signalised or roundabout control is generally appropriate although high volumes may necessitate grade separation. Intersections should be spaced a minimum of 500 m apart.

In rural areas, direct access can be tolerated due to low volumes and limited frequency. However, appropriate safety levels must be achieved and the aim should be to remove such accesses over time. Intersections are generally configured at grade for this sub-category. Priority control is generally appropriate and intersections should be spaced a minimum of 1km apart due to the higher speed environments. However, a proper intersection type has to be assessed and determined using traffic analysis.

Arterial main street in urban areas

This category is directed at existing situations in urban areas, including villages, where a group of commercial land uses exists, generally on both sides of an arterial road. In these situations a decision

needs to be made, dependent on the value of these uses, whether the traffic carrying and access functions should coexist, or whether a bypass or parallel route upgrade is warranted. If it is decided that these functions should coexist, whether in the short or long term, measures will need to be developed as part of an LITP to address this mix.

These design standards are primarily aimed at safety and ensuring pedestrian mobility in conjunction with parking and vehicle access. Traffic volumes may be so high that amenity to roadside activities is limited. However, as these are arterial roads, traffic volumes should not be moderated except by bypassing where feasible.

Speeds on these facilities should be kept sufficiently low to provide for safe pedestrian crossing at controlled points and to maintain environmental amenity for adjacent land uses, but still allow for efficient traffic movement. These roads should provide for pedestrian movement on both sides with crossing at controlled points, and with bicycle lanes on the road to avoid mixing with denser pedestrian traffic.

Limiting the frequency of property access is important for the traffic carrying capacity and also for the amenity levels associated with significant pedestrian traffic in the 'main street precinct'. Streetscaping would assist in ameliorating visual and audible land use impacts.

A number of traffic lanes will have to be acquired to enable four lane or six lane carriageways (if a corridor is likely to take a key public transport route associated with the adjacent land use, e.g. potential exclusive PT lane) for ultimate traffic growth and provision made for proper width to cater for kerb and channel, medians, indented bus bays to reduce delay to through traffic and bike lanes. Opportunities should be sought to bypass freight movements. This category is generally inappropriate as a dangerous goods route.

Intersections may be closely spaced along these facilities due to past planning and land use decisions. Desirably, to avoid queue interaction, intersections should be spaced a minimum of 150m apart.

This sub category is included in order to acknowledge its existence, and to provide for special cases, but it is not an option recommended for the future due to the difficulties of managing the conflicting access and mobility functions. Within the rural road hierarchy, "Arterial Main Street" is not considered appropriate.

(b) **Sub arterial road design standards**

(i) **Traffic distributor in urban/rural**

These traffic carrying roads are the key supplement to the arterial road network. They should connect between arterials and specific areas and should be more convenient than using the internal streets. Consequently, a higher level of efficiency and safety should be provided. Volumes are carrying preferably up to 25,000 vpd for amenity, as abutting land uses should be non-sensitive.

To make these roadways more attractive than internal streets, a higher speed environment is desirable. Speed environments of between 70 km/h~80 km/h in urban and up to 100 km/h in rural areas are recommended. The policy is to pursue no direct access to individual properties. Examples of treatments include:

(A) side street entry to corner blocks;

(B) combining driveways;

(C) creating rear lane access;

(D) creating easements to service multiple properties.

In the preferred design form, access should be restricted and be managed through treatments such as amalgamated entry points or side streets as discussed above. This would be the treatment pursued as part of any new development. Access for major developments, multi-unit

dwellings, schools, child care centres, and/or commercial uses may be provided along these routes, provided it is controlled through channelisation or signals.

These roads may serve as secondary freight routes. Nominated routes may be appropriate for dangerous goods movement. They could accommodate RPT traffic under a sweeper mode. Any bus stops should be located separately from the through traffic lanes.

In most circumstances, specific provision for control of pedestrian movements should be provided and roadside parking will be discouraged. Usually, the prime concern will be the movement of traffic, so traffic management techniques could be applied (such as access minimised by consolidation of development accesses or side road access to sites). Noise and visual amenity impacts on surrounding uses should be managed through site considerations and/or road treatents.

Cycle facilities can be provided in exclusive bike lanes or on the road shoulder on roads with a speed limit less than 80 km/h, provided AUSTROADS guidelines are met. In locations where the speed limit is higher than 80 km/h, where a high percentage of school cyclists are likely or where there is a cycle accident history or identified potential, consideration should be given to locating these facilities separate from the carriageway.

A number of traffic lanes have to be acquired, with a four lane carriageway for ultimate traffic growth, and provision made for a proper width to cater for kerb and channel, medians, bus stops and bike lanes. For the interim, a two-lane undivided cross section may be appropriate for a low traffic volume environment whilst achieving affordability, sufficient overtaking opportunities, vehicle breakdown, stopping or turning vehicles and bicycles. However, divided carriageways are desirable to optimise safety and driver comfort.

In urban areas, paved footpaths are required on one or both sides depending on the demand of pathway usage to abutting land use and traffic facilities (e.g. bus stops) with pedestrian crossings at controlled points. Intersections at grade are appropriate for this management type. Signalised or roundabout control is generally appropriate although priority controlled intersections may be acceptable; this will be determined by a traffic analysis study. Intersections are typically spaced 250~400m apart.

In non-urban areas, although access is restricted in the preferred design form, individual lot accesses are acceptable, particularly if the access points are widely spaced and properties are well set back. Pathways are only required where the road serves an identified pedestrian linkage, with pedestrian crossings at controlled points. Roundabouts or priority control are generally appropriate, although this will be determined by a traffic analysis study.

(ii) **Controlled distributor in urban/rural**

The hierarchical objective of this sub-category is to maintain the traffic carrying function as a primary role but also to allow frontage and parking (with appropriate conditions) to achieve an environment whereby "overlooking" can enhance personal safety. The controlled distributor should be used where adjacent frontage development exists, or is planned. It can be expected to be used where residences are within reasonable walking and cycling distance of regularly accessed community destinations, e.g. schools, shops.

A number of traffic lanes have to be acquired, with a four lane carriageway for ultimate traffic growth and provision made for a proper width to cater for kerb and channel, medians, bus stops and bike lanes. For the interim, a two lane undivided cross section may be appropriate for a low traffic volume environment whilst achieving affordability, sufficient overtaking opportunities, vehicle breakdown, stopping and turning vehicles and bicycles. However, divided carriageways are desirable to optimise safety and driver comfort.

To satisfy the competing demands of traffic carrying efficiency and property access/on street parking, it is important to separate parked cars and turning vehicles from the through traffic lanes.

This will require carriageway widths greater than a traffic distributor. The verge widths need to include landscaping, pathways and separation. This will be an important factor in subdivision planning when determining the lot layout and road reserve needs.

These design standards are primarily aimed at safety and ensuring pedestrian mobility in conjunction with parking and vehicle access.

In the conventional sub-arterial design case it is desirable to have no direct access to individual properties; however, consolidated access along the controlled distributor would be acceptable if the appropriate form of traffic control can be provided at these points.

This category of road is a response to relatively unique situations and often evolves as a result of previous planning decisions. By definition, these are roads where an aspect such as speed or vehicle composition up to 20,000 vpd is controlled. Such control may be:

(A) limiting speed to 60 km/h where frequent direct residential or commercial frontage exists;

(B) limiting volumes to avoid excessive pressure on abutting land uses;

(C) limiting heavy vehicle usage to protect the amenity of abutting uses; and

(D) limiting speed and/or usage of particular vehicle types where alignment constraints exist.

On roads where frequent access to adjacent land uses exists and cannot be removed or consolidated, measures should seek to achieve safe access while retaining the convenience and efficiency of the route for through traffic. This may include a lower speed environment, but it should not be so low as to cause rat running elsewhere, for example, 60 km/hr in urban areas and 60~80 km/h in rural areas. Other measures could include the protection of adjacent parking by indented bays, bicycle paths, and landscaping. A longer term aim should be to reduce access if opportunities arise.

Access for individual lots should be controlled using one or more of the following measures:

- central median (no right turns) ;
- turning lane separate from through traffic lane;
- large lot frontage;
- lot layout to avoid on street visitor parking (large lots); and
- adjacent properties having adjacent driveways.

When a road is designated as a controlled distributor, an LITP should be prepared to identify the need to control any aspect(s) of this road, and the most appropriate form(s) of control.

(iii) **Sub arterial main street in urban areas**

This category is directed at situations where a group of commercial land uses exists, generally on both sides of a sub arterial road. On these stretches of road a decision needs to be made, dependent on the value of these uses, whether the traffic carrying and access functions should coexist, or whether a bypass or parallel route upgrade is warranted.

If the traffic carrying and access functions need to, or should coexist, whether in the shorter or longer term, management measures will need to be developed as part of an LITP to address the coexistence of these two functions.

In contrast to the arterial sub-category, the traffic environment on sub arterial roads may be restricted to improve the amenity for pedestrians and users of the adjacent developments. Measures may be taken to reduce some traffic use of the road, for example, during peak periods, and opportunities should be sought to bypass freight movements.

This category is generally appropriate as a bus route, and indented bays should be provided to reduce delay to through traffic. This category is generally inappropriate as a dangerous goods route.

Speeds should be kept low to improve amenity to pedestrians and abutting land uses, and should be no greater than 60 km/h. Volumes should be no greater than 15,000 vpd in order to maintain amenity to abutting land uses. These roads required a balance between accessibility and mobility, using environmental street design or streetscaping.

In special cases, a number of traffic lanes will have to be acquired to enable four lane or six lane carriageways for ultimate traffic growth (if a corridor is likely to take a key public transport route associated with the adjacent land use, e.g. potential exclusive PT lane), and provision made for a proper width to cater for kerb and channel, medians, bus stops and bike lanes. For the interim, a two lane undivided cross section may be appropriate for a low traffic volume environment, whilst achieving affordability, sufficient overtaking opportunities, vehicle breakdown, stopping and turning vehicles and bicycles. However, divided carriageways are desirable to optimise safety and driver comfort.

This category should provide for pedestrian movement on both sides with crossings at controlled points, and with bicycle lanes on the road to avoid mixing with denser pedestrian traffic. Intersections should be controlled by way of signalisation or roundabouts, although priority intersections may be appropriate. Spacing of intersections is site specific, based on past planning and land use decisions, although a minimum spacing of 150m is desirable to avoid queue interaction. Within the non-urban road hierarchy the ‘Sub-Arterial Main Street’ is not considered appropriate.

(c) **Major collector road**

Major collector roads provide a connection between the local streets and the traffic carrying roads and mark a shift in the environment between roads and streets. The design standards place a greater emphasis on travel time efficiency and strict guidelines for safety and environmental amenity should be adhered to on these roads.

Traffic flow levels commonly accepted range from 3,000 vpd up to 12,000 vpd. Access to multi-unit residential developments, schools or shopping centres may well be via major collectors. Individual residential lot access to these roads should be restricted, and generally a speed environment of 60 km/h to provide for safety and amenity while ensuring travel times are reasonable. Heavy vehicle and dangerous goods movement should be restricted in residential areas, with the exception of service vehicle movement. Buses will generally operate in a sweeper role and indented bays may be required to maintain safety at some locations.

Pathways and bicycle lanes should be provided on one or both sides of the road. However, in non-urban areas, pathways are generally not required unless network planning deems it appropriate. Some controlled pedestrian crossing points may be required in urban areas, particularly where traffic volumes are higher. Kerbside parking could be provided for in urban areas.

Intersections are typically spaced 80m to 100m in urban areas and up to a maximum 200m in non-urban areas. Intersection control would generally be either by roundabout or priority control. These roads should have two or four lane carriageways, depending on the degree of frictional and impact characteristics criteria that apply.

Environmental street design may be required in urban areas to moderate speeds and minimise through traffic penetration. Streetscaping would also assist in ameliorating visual and noise impacts to abutting land uses.

(d) **Local streets**

Level 3 sub categories mainly relate to managing and providing treatments for residential streets in the road hierarchy. However, consideration must also be given to non-residential local streets, e.g. in industrial and commercial areas. It should be noted that this document will not deal specifically with

"streets" (as per Level 1), but the following principles may be appropriate for general application across various council standards and requirements.

Streets have as their function to facilitate public interaction and movement through a place or neighbourhood. Local Streets must allow for the safe and efficient movement of all users, provision for parked vehicles, the provision of public utilities, access to allotments and streetscaping.

The management of these streets is less restrictive due to low traffic volumes, property access and parking. Volumes should be limited to below 3,000 vpd and the speed environment to 30~50 km/h in urban areas to ensure amenity for abutting land uses, it is noted that posted speeds will be at 50 km/hr, and to a maximum 60 km/h in rural areas to ensure reasonable travel times.

Heavy vehicles and dangerous goods movement should be restricted in residential areas, with the exception of service vehicles and public transport. Kerbside bus stops are generally appropriate, although indented bays may be required to maintain safety at some locations.

The provision of pathways is generally not necessary, although this may be appropriate in some instances as a requirement of network planning. No specific pedestrian crossing provision is required. No special cycle facilities are needed as these users should be able to share the road space due to the low traffic volumes and speeds.

No specific parking provision is required on these streets.

Intersection spacing is a minimum of 40~60m in urban areas and 100m in rural areas. Some intersections may be controlled by roundabouts; otherwise, priority control should be sufficient. These streets should have a two lane cross section, or one lane where necessary, with reasonable travel efficiency.

Environmental street design may be required in urban areas to moderate speeds and minimise through traffic penetration. Streetscaping would also assist in ameliorating visual impacts on abutting land uses.

If significant development occurs in the future in rural areas, then it may be appropriate to reclassify these streets as ‘major collector’ if the catchment size or density increases significantly. Accordingly, allocations should be made in the network planning.

In urban areas, the primary design objective is to maximise safety and amenity for adjacent properties and adjacent activities/users (i.e. pedestrians, cyclists, car parking, children playing). The most important design standard in this regard is the maximum design speed. Travel time efficiency will be compromised over safety and amenity aspects by appropriate subdivision design. Such design includes consideration of the maximum volume (by catchment size), the design speed (by street length) and the travel time efficiency (by connectivity of streets). It is this category of roadway whereby design standards are well defined because of the clear principles set out in such documents as *Queensland Streets* and *Complete Streets.*

In rural areas, the primary design objective is to minimise the cost of roadway provision whilst still maintaining acceptable performance levels (as a result of the very low volume use). Travel time efficiency will be compromised over safety and amenity aspects. There may be an issue with dust nuisance, which may be one of the factors considered when determining whether the road should be sealed or not. The low traffic volumes anticipated on some collector streets requires the need for a single lane cross section alternative, as well as the two lane form. There may also be a demand for the provision of horse trails within the road verge, and in this case a widened verge may be required to cater for these.

(e) **Non residential local street**

Similar roles apply to collector streets in commercial (including CBD) and industrial areas. Generally, higher traffic volumes can be tolerated on such streets than accepted in residential areas. Fewer lots would be served in commercial and industrial areas by these streets than low density residential areas,

due to the high trip generation of the land uses. Significantly higher heavy vehicle proportions and tolerances for environmental factors such as noise would be acceptable on such streets in industrial areas.

Key performance criteria for collector streets in industrial areas are as follows:

(i) traffic volumes not greater than 3,000~6,000 vpd depending on the environmental cell type;

(ii) speed environment of 50~60 km/h;

(iii) provision of parking lanes on both sides of the street;

(iv) provision of bike lane on the carriageway;

(v) provision of paved pathway on either or both sides of the street; and

(vi) sufficient heavy vehicle turning radius at access points or in cul-de-sacs.

SC6.4.3.13 Attachment B1 Road hierarchy elements and their objectives in urban areas

LEVEL 1: PURPOSE							
	Roads						Streets
• to carry through traffic							• to provide local property access; and • to collect local traffic
LEVEL 2: FUNCTION							
Arterial roads			**Sub-arterial roads**			**Major collector roads**	**Local streets**
• through traffic movements across town; • longer distance strategic traffic movements; • primary connection between suburbs and employment, economic, education or entertainment centres; • line haul public transport task; • primary freight and dangerous goods routes; and • regional cycle movements.			• through traffic between arterial roads; • connections between local areas and arterial roads; • access to public transport; • through movement of public transport; • regional – local cycle movements; and • pedestrian movements.			• balance between carry traffic and access within the specific area; • direct access to grouped properties; • access to public transport; • pedestrian movements; and • local cycle movements.	• direct access to properties; • pedestrian movements; and • local cycle movements.
LEVEL 3: MANAGEMENT							
Highway/ Motorway	**Arterial**	**Arterial main street***	**Traffic distributor**	**Controlled distributor***	**Sub-arterial main street***	**Major collector**	**Local street**
The aim of management policies for these categories will be to facilitate:							
• longer distance traffic movements between towns; and • regionally and nationally significant movements.	• longer distance traffic movements between suburbs and other centres.	• longer distance traffic movements; • access to commercial properties; • car parking; • pedestrian movements. *Treatment may involve preservation of aspects of local amenity in balance with traffic operation*	• connection of local areas to arterial roads; • through movements between arterial roads; and • access to major developments	• connection of local areas to arterial roads; • access to properties (certain existing cases) • car parking; and • pedestrian movements. *Treatment may control some aspects of traffic operations to ameliorate impacts*	• connection of local areas to arterial roads; • access to commercial properties; • car parking; and • pedestrian movements. *Treatment may involve preservation of aspects of local amenity in balance with traffic operations.*	• connection of local streets to arterial roads; • access to grouped/ commercial properties and community facilities; • car parking; and • pedestrian movements *Treatment may involve preservation of aspects of local amenity in balance with traffic operations.*	• connection of local streets with traffic carrying roads; and • access to individual adjacent properties • connection to other local streets.
LEVEL 4: DESIGN							
According to relevant guidelines and codes including SC6.4 Development manual planning scheme policy, DTMR guidelines, AUSTROADS, MUTCD, *Queensland Streets*, Australian Standards and *Complete Streets* for the local streets level.							

Note—* Only permitted in existing cases or special cases. Therefore treatment may involve preservation of existing land use but discouraging further access points to the adjacent land development.

SC6.4.3.13 Attachment B2 Road hierarchy elements and their objectives in rural areas

LEVEL 1: PURPOSE						
	Roads					Streets
• to carry through traffic						• to provide local property access; and • to collect local traffic
LEVEL 2: FUNCTION						
Arterial roads		**Sub-arterial roads**		**Major collector roads**		**Local streets**

A bus stop provision is required to be integrated with the paved footpath system

Traffic study will determine, e.g. TIA (Traffic Impact Assessment)

SC6.4.3.14 Traffic impact assessments

SC6.4.3.14.1 Introduction

A traffic impact assessment (TIA) is a process of compiling and analysing information on the impacts that a specific development proposal is likely to have on the operation of roads and transport networks. The assessment will not only consider general impacts relating to traffic management (road efficiency and safety), but will also consider specific impacts on land use environment and all road users including on-road public transport, pedestrians, cyclists and heavy vehicles.

Developers should refer to the *Guide to Traffic Management* produced by Austroads as a primary reference, and in particular, *Part 12: Traffic Impacts of Development.* The TIA sub-section has been produced to supplement Part 12 by establishing criteria for low, moderate and high traffic impact developments, and to supply additional information pertinent to particular land uses, climate and traffic characteristics in Townsville. If a discrepancy exists between this document and the *Guide to Traffic Management*, this sub-section will prevail.

(1) TIA scope and purpose

(a) TIA purpose

Council requires a TIA in order to:

(i) assess the adequacy of the existing or future transportation system to accommodate additional traffic generated by a proposed development, redevelopment or land use change; and

(ii) to assist in determining what improvements may be required to transport infrastructure (e.g. roadways, pathways, public transport and traffic facilities, parking, etc.) to maintain a satisfactory level of service for the Townsville community.

Within the context of the matters outlined above, the aim of this sub-section is to ensure that:

- traffic impact assessment of developments is undertaken in a uniform manner leading to consistent treatment of similar developments;
- the level of impact assessment is appropriate for the level of potential impacts;
- a road or a road network continues to operate at an agreed level of service following the opening of a development;
- both "soft" solutions (e.g. road use management such as alternative routes) and "hard" solutions (e.g. changes to infrastructure) are considered when mitigating impacts;
- the needs of all road users are considered and appropriate facilities (e.g. bicycle lanes, footpaths, bus lanes, intersection widening or upgraded intersection controls) are provided in a timely manner;
- a development is considered within its proposed environment and not in isolation from nearby features such as intersections, footpaths and other driveways;
- cumulative impacts on transport networks of other developments in an area or region are considered; and
- road safety and environmental impacts (both natural and built) are considered.

(b) TIA scope

A TIA may be required where a development affects the function, safety and efficiency of the transport network. The requirements for a TIA are outlined in this policy sub-section.

The scope of a TIA will depend on the location, type and size of the development and the ability of the road network to handle traffic generated by the development. Therefore, some developments will require an extensive and detailed TIA, while others will require only a brief TIA.

(2) How to use this document

The following steps will guide the applicant in determining the level of TIA required with regard to land use and traffic environment perspectives.

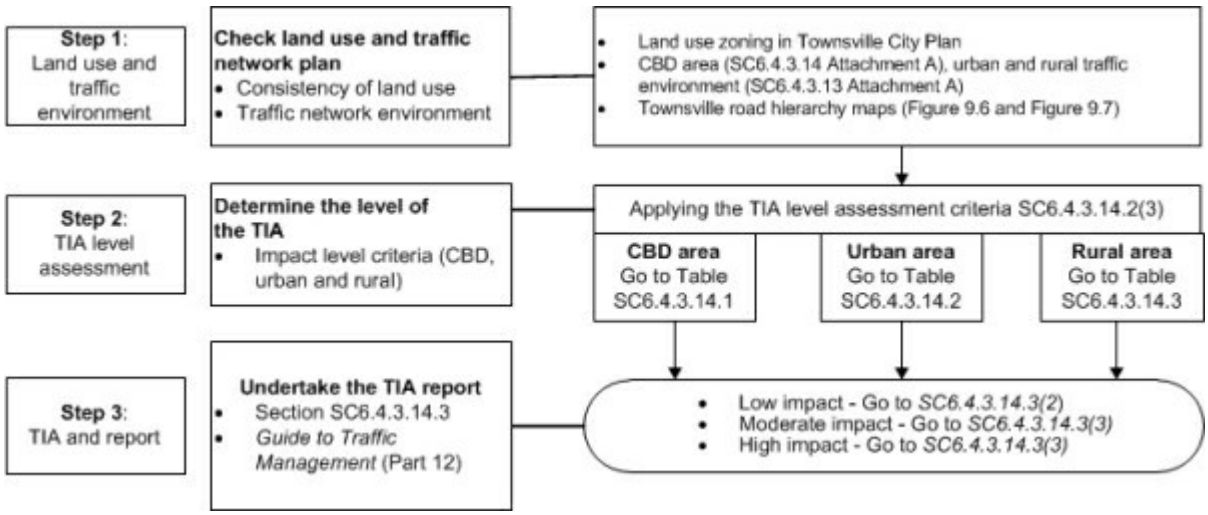

Figure SC6.4.3.14.1 How to use SC6.4.3.14 Traffic impact assessment guidelines

(3) Terminology

AADT	Annual Average Daily Traffic
CBD	Central Business District as per the *Townsville CBD Master Plan* or Attachment A.
DTMR	Queensland Department of Transport and Main Roads
DoS	Degree of saturation
Inconsistent development	development that is not consistent with the planning scheme, or development that is inconsistent as described in Section 650 in the *Planning Act 2016*.
Level of dervice (LOS)	a qualitative measure using a sequence of letters from A through F to describe the quality of operational conditions within an intersection, transit or a roadway link. Refer to the *Highway Capacity Manual for details*.
PCE	Passenger Car Equivalent
PCU	Passenger car unit
PT	Public transport
TIA	Traffic impact assessment
Traffic facility	roads, streets, bikeways, highways, their networks, terminals, traffic signs, public transport/car park and abutting lands related to all modes of transportation, i.e. people, vehicles, goods.
Transportation demand management (TDM)	the application of strategies and policies to reduce travel demand (specifically that of single-occupancy private vehicle), or to redistribute this demand in space or time.
Trip	a single or one-direction person or vehicle movement.

Trip generation	the total number of trips measured in trip ends (i.e. trip production or trip attraction) entering and exiting the site for the defined period, e.g. one hour, one day etc.
VPD	Vehicles per day

SC6.4.3.14.2 Determining the level of the TIA

The scope, intent and degree of traffic impact will vary. This will depend on the land use of the proposed development, direct access locations and current land use zoning. For example:

- development based on the current land use zoning and character of the locality;
- location of the development: CBD, urban, rural area;
- the existing and future planned transport network;
- direct access to the external road hierarchy system;
- staging, size and type of the development;
- the traffic environment at the time of the proposal;
- existing approved (but not delivered) development within the area;
- current development applications within the area; and
- any strategic planning determining future land uses such as the Townsville State Development Area.

(1) Land use environment

Due to the different desirable service standards in the CBD/Urban and Non-urban areas, council has different impact assessment thresholds depending on whether the development is in the CBD, urban or rural traffic environments. These areas are defined as follows:

(a) *The CBD* (see SC6.4.3.14 Attachment A); or

(b) *Urban* area – with the exception of the CBD, refer to the map in SC6.4.3.13 Attachment A; or

(c) *Rural area* – areas not in the urban area, or CBD, refer to the map in SC6.4.3.13 Attachment A.

These TIA land use traffic environment definitions relate to the character of the land for the purpose of assessing the traffic impacts on the site and the adjacent network.

(2) Three levels of the TIA

For each of the development locations identified above, and in conjunction with the defined Townsville Road Hierarchy system, (SC6.4.3.13 Townsville road hierarchy) there are three different levels of traffic impact assessment. The anticipated level of impact will require different methodologies of traffic forecasting and analysis, as described below.

Low impact (SC6.4.3.14.3(2) Low TIA report):

The development is likely to have a very minor impact as the land use is consistent with the Townsville City Plan but a review is still required to ensure potential traffic issues are assessed in terms of traffic safety and amenity issues, etc. A low level TIA report will comprise of a statement of impact, and a corresponding statement of proposed mitigation measures and measures to optimise the network.

Moderate impact (SC6.4.3.14.3(3) Moderate/High TIA Report):

The development is likely to have a moderate traffic impact on the surrounding existing and future land uses, traffic network and operations. For a moderate level TIA Report, either a manual forecasting or mesoscopic traffic simulation modelling (e.g. SIDRA Network, Aimsun or an equivalent model) or microscopic traffic simulation modelling (e.g. Aimsun or an equivalent model) (Refer to SC6.4.3.14.4.2(a)) may be a suitable methodology of traffic forecasting due to:

- a moderate threshold, in terms of additional or new traffic generated as defined by the CBD/Urban/Non-urban TIA impact level assessment criteria;
- insignificant impact on existing and future transport and traffic systems, e.g. no additions or changes to the road hierarchy system; and
- the characteristics of the road network in the immediate vicinity of the development.

Note—if broader traffic network modelling (e.g. masterplan) has been recently done in that area (i.e. less than two years old), a high impact assessment may be assessed at the moderate level (upon confirmation with council), as long as the development is consistent with the land use or assumptions made within the previous modelling study.

High impact (SC6.4.3.14.3(3) Moderate/High TIA Report):

The development is likely to have a high impact on the surrounding existing and future land uses, traffic network and operations. For a high level TIA report, which does require a comprehensive assessment approach, council encourages the use of an appropriate traffic modelling program, e.g. EMME (for strategic traffic modelling), Aimsun, or an equivalent model, (Refer to SC6.4.3.14.4.2(a)) particularly where:

- additions or changes to the road hierarchy system are proposed, i.e. a new/changed arterial, sub-arterial or major collector road; or
- significant trip behaviour changes and impacts are expected, as defined by the CBD/Urban/Non-ruban TIA impact level assessment criteria, e.g. trip generation, trip distribution, mode choice and trip assignment; or
- changes to council's and/or DTMR's future major traffic network programmes are proposed.

Note—occasionally a TIA may have a high anticipated impact, but the area of impact is restricted to a corridor rather than a network within the TIA area. In this circumstance, either a manual forecasting or mesoscopic traffic simulation modelling may be a suitable methodology of traffic forecasting.

(3) Applying the TIA impact level assessment criteria

Use Table SC6.4.3.14.1 to Table SC6.4.3.14.3, whichever is relevant to the location of the development, i.e. CBD, Urban, or Non-urban area, and assess the development against the TIA impact level assessment criteria whilst also taking into account the following:

(a) the applicant must consider the actual or potential traffic impacts of all land/development under their common ownership or control (for example, by a joint venture agreement), at one location.

Editor's note—The phrase "at one location" means all adjacent land of the applicant, the property lines of which are contiguous or nearly contiguous at any point, or separated by other land of the applicant, or a public or private street, road, highway, or utility right-of-way or other public or private right-of-way.

Editor's note—"All land/development" includes existing development and planned/potential development.

An applicant must not avoid the intent of this policy sub-section, and that of Townsville City Plan, by submitting partial or segmented applications or approval requests for development plans, subdivisions, etc. If the properties will form an integrated or complementary development, council expects the applicant to submit one consolidated TIA report based on the integrated level of impact;

(b) if the criteria that apply are spread across two or more impact columns, the highest level of impact will apply. For example, if the development is low for all criteria, except for one criterion that is in the high column, a high level TIA will be required;

(c) Council may require additional information as part of the traffic impact assessment at the Information and Referral stage of an application for a Development Permit, which will be decided on a case by case basis;

(d) if the proposed development land is zoned for rural purposes but the development proposed is an urban land use that will either be surrounded by a rural traffic environment or adjoin an urban area, Table SC6.4.3.14.2 Urban TIA impact level assessment criteria must be used, rather than Table SC6.4.3.14.3 Rural area TIA impact level assessment criteria;

(e) council may request a more thorough analysis if negative impacts on traffic facilities have been identified, or if particular factors of the development cause concern to the safety, efficiency and operation of the transport network; and

(f) if the proposed development has roads that are not identified in the Road Hierarchy Map (e.g. in the development of new subdivision plans), a new link(s) road hierarchy in the subjected development area may be proposed by the developer, with council's agreement.

Note—if any of the above conditions apply, or more details are required, council encourages a pre-lodgement meeting to be arranged prior to commencing the TIA.

Table SC6.4.3.14.1 CBD area TIA impact level assessment criteria

Criteria	Impact		
	Low	Moderate	High
Trip generation	New or additional trip generation in a peak hour of <10 trips directly accessing a street[1].	New or additional trip generation in a peak hour of 10 to 100 trips directly accessing a street. New or additional trip generation in a peak hour <100 trips directly accessing a major collector, sub-arterial, arterial, or highway[1].	New or additional trip generation in a peak hour of more than 100 trips.
Commercial vehicles	3 or less new or additional commercial vehicles per day.	More than 3 and up to 100 new or additional commercial vehicles per day.	More than 100 new or additional commercial vehicles per day.
Car parking	An increase or decrease of 9 or less on-site car park spaces. Loss of 2 or less line marked on-street car parks and no loss of loading zones.	An increase or decrease of 10 or more on-site car park spaces. Loss of 3 or more line marked on-street car parks, or any loading zones.	

Public transport	No impact on any bus zone or taxi operations.	Relocation of any bus zone or taxi rank. Impacts on the bus interchange or bus routes.	
Transport system	No change to existing transport network operation.	Change to permitted vehicle movements at a T-intersection.	Change of permitted vehicle movements at a crossroads or multiple intersections.

Note—1. Refer to Figure 9.6 Townsville road hierarchy map (existing) and Figure: 9.7 Townsville road hierarchy map (future).

Table SC6.4.3.14.2 Urban area TIA impact level assessment criteria

Criteria	Impact		
	Low	**Moderate**	**High**
Trip generation	New or additional trip generation in a peak hour of <20 trips directly accessing a street[1].	New or additional trip generation in a peak hour of 20 to 300 trips directly accessing a street. New or additional trip generation to a major collector, sub-arterial, arterial, or highway[1].	New or additional trip generation in a peak hour of more than 300 trips directly accessing a road system.
Commercial vehicles	5 or less new or additional commercial vehicles per day in a residential area. Less than 10 new or additional commercial vehicles per day in a non-residential area.	More than 5 and up to 300 new or additional commercial vehicles per day in a residential area. More than 10 and up to 300 new or additional commercial vehicles per day in a non-residential area.	More than 300 new or additional commercial vehicles per day.
Car parking	Increase or decrease of 9 or less on-site car park spaces. Loss of 2 or less line marked on-street car parks, or loading zones.	Increase or decrease of 10 or more on-site car park spaces Loss of between 3 or more line marked on-street car parks, or loading zones.	
Public transport	Relocation of any bus zone or taxi rank.	Impacts on the bus interchange or bus routes.	
Transport system	No change to existing transport network operation.	Changes to the connectivity between local streets and collector roads.	Changes to the connectivity between arterial and sub-arterial roads.

Note—1. Refer to Figure 9.6 Townsville road hierarchy map (existing) and Figure: 9.7 Townsville road hierarchy map (future).

Table SC6.4.3.14.3 Rural area TIA impact level assessment criteria

Criteria	Impact		
	Low	**Moderate**	**High**
Trip generation	New or additional trip generation in a peak hour of less than 30 trips directly accessing a street[1].	New or additional trip generation in a peak hour of 30 to 300 trips directly accessing a street. New or additional trip generation directly accessing a sub-arterial, arterial, or highway[1] <300.	New or additional trip generation in a peak hour of more than 300 trips.
Commercial vehicles	Less than 30 new or additional commercial vehicles per day.	More than 30 and up to 300 new or additional commercial vehicles per day.	More than 300 new or additional commercial vehicles per day.
Public transport	Relocation of any bus zone or taxi rank.	Impacts on the bus interchange or bus routes.	
Transport system	No change to existing transport network operation.	Changes to the connectivity between local streets and collector roads.	Changes to the connectivity between arterial and sub-arterial roads.

Note—1. Refer to Figure 9.6 Townsville road hierarchy map (existing) and Figure: 9.7 Townsville road hierarchy map (future).

(4) Collaborative traffic impact assessments
If the anticipated traffic impact is determined to be of significant impact on the existing or future transportation system due to its location, development type, or land use characteristics, the traffic impact assessment may require a more strategic and holistic assessment to be prepared collaboratively with council and any other relevant stakeholders.

(5) Associated reports
Road Safety Audit - If the TIA Report indicates that significant safety issues may occur, the developer must engage a qualified road safety engineer to undertake an independent Road Safety Audit, in line with the *Guide to Road Safety Part 6*, Austroads 2006-2009c.

Noise - A road noise assessment may be required if there is a forecasted volume that will increase traffic over 3000 VPD (link traffic) in the subjected TIA study scope, or if noise sensitive receptors are identified. Refer to sub-section SC6.4.3.15 Noise and vibration assessment guidelines for more information.

SC6.4.3.14.3 TIA report requirements
The TIA will be used to help evaluate whether the development is appropriate for the site and what type of transportation improvements may be required. The TIA Report should address any traffic issues outlined in this document and the *Guide to Traffic Management Part 12*: *Traffic Impacts of Development* (Austroads, 2009).

The TIA report must identify the type and amount of additional traffic expected to be generated by the proposed development on the adjacent transport network and include recommendations on any site specific and external upgrading or network management works required to cater for short-term and long-term traffic and transportation planning.

It is important that early contact be made with the Planning and Development Division of council during the TIA process. This should commence at the outset and continue as required during the course of TIA preparation. For example, if council's concerns about access to the council road network are identified early, this may be able to be addressed through minor amendments to the on-site layout of the development. For larger developments, it may be appropriate to consult with council regarding consideration of the project's scope, methodology and other possible planning consideration during the development of the initial project concept.

(1) General requirements

The TIA Report must demonstrate that the proposed development is consistent with the traffic and transportation aims of the planning scheme for that area. The intent of the TIA is to evaluate *worst case traffic scenarios*. For example, if several different uses are proposed, the land use with the greatest overall traffic impact must be assumed in the study, unless the applicant specifies the uses for the site.

(a) TIA consultant qualifications

A low impact TIA report may generally be prepared by the developer. However, if existing traffic facilities need to be changed, then recommendations for mitigation must be made by a Registered Professional Engineer of Queensland (RPEQ) qualified person at a minimum. The moderate or high impact TIA is to be prepared by an impartial professional traffic/transportation consultant who is appropriately experienced and holds current RPEQ qualification. The document must be certified by the appropriately qualified and experienced RPEQ.

(b) Report documentation

The TIA Report must fully document the approach, methodology, and assumptions of the analysis. It must clearly explain the reasons for any adjustments to the trip generation rates and assumptions used for trip distribution and assignment. Figures (drawings and maps) are to be used to help illustrate these assumptions. The report must summarise the results of the Level of Service (LOS) calculations in tabular or map form, and include figures showing the traffic volumes for the project alone and for each scenario. The report must also include any mitigation measures, appropriately tested by the model. All worksheet and analysis input and output data must be included as appendices to the report, if applicable.

(c) Impact on other stakeholders

If there are other jurisdictions or stakeholders impacted within the area of influence, for example, DTMR, Queensland Rail (QR), or Bus/taxi companies, the consultant should arrange a scoping meeting with all relevant agencies to discuss the issues. This will provide improved coordination and reduce the potential for later revisions to the TIA.

(d) Updating an existing TIA

A TIA requires updating when the amount or character of traffic is significantly different from an earlier study; for example, changes to the land use, road hierarchy or road networks. Any traffic study may also need to be revised if the study is older than 2 years and council determines that the existing conditions have changed enough to invalidate the study results or if the initial study assumes an incorrect build out period. A TIA may require updating sooner in rapidly developing areas and not as often in slower developing areas. In these cases, consultation with council is recommended.

(e) Possible additional requirements

At times, council may extend the study to additional street segments and/or intersections on the public street system. Council will make this determination based on the scale, location, and/or nature of the proposed development and the condition or state of development of the street network in the vicinity of the site.

(2) Low TIA report

1. Justification for low impact assessment;
2. A brief description of the development in terms of site location, direct site access(es), land use, size and expected year of completion;
3. Analysis/Findings, e.g. impact on existing traffic facilities, heavy vehicles turning path and other safety issues;
4. Recommendations and Mitigation; and
5. Appendices if applicable.

(3) Moderate/high TIA report

Executive summary

- a brief description of the development (site location, internal layout, all site access(es), land use/size and year of completion);
- a brief overview of trip generation and analysis result (LOS), Degree of Saturation (DoS) and Average Delay;
- parking demand; and
- mitigation plan and conclusion/recommendation.

Note—desirably, the executive summary should be no longer than five pages, complete in itself, and not dependent on supplementary data included by reference.

1. Introduction and summary

1.1 Justification for moderate or high impact assessment

1.2 Study objectives and scope

- Time horizon - year of completion assuming full build-out and occupancy and 10 years after total completion. This also needs to be assessed at key stages of the development, or if traffic environment changes have occurred in the meantime
- TIA Area – where:
  - (a) the amount of additional traffic likely to be generated is more than 5% of existing total links and intersection volumes during a peak hour; or
  - (b) the likely increase in the proportion of heavy vehicle traffic is more than 5% during a peak hour associated with the development.

2. Proposed development

2.1 Land use and intensity;

2.2 Site plan/layout;

2.3 Phasing and timing; and

2.4 Specific information of the proposed development (operation hours, number of employees, type of service vehicles, etc.).

3. Existing conditions

3.1 Study area land use:

- existing land use/zoning; and
- anticipated future development (background); land use/traffic network.

3.2 Existing traffic analysis:

- roadway system;
- traffic volumes and analysis;
- active mode facilities (public transport stops/route, pathway, bike lane, trip end facilities);
- parking (car park type, operation, existing/potential car park demand);
- traffic accident data (traffic safety); and
- other.

4. Traffic forecasting and analysis

4.1 Method of projection.

4.2 Background traffic (each horizon year):

- traffic model calibration or validation if applicable; and
- forecasting and analysis.

4.3 Site traffic (each horizon year):
- trip generation;
- trip distribution;
- modal split;
- trip assignment; and
- analysis.

4.4 Summary of analysis (with/without development scenario).

5. Improvement analysis

5.1 Improvements to accommodate background traffic.
5.2 Additional improvements to accommodate all site traffic.
5.3 Alternative improvement.
5.4 Need for any improvements (e.g. TDM).
5.5 Status of improvements already funded, programmed, or planned.
5.6 Independent road safety audit, if required.
5.7 Summary.

6. Parking

6.1 Method of projections
6.2 Parking demand forecasting and analysis (including all service vehicles and bikes)
6.3 Site circulation and parking layout (including all service vehicles)

7. Public transport and pathway

7.1 Possible/desirable PT system.
7.2 Internal/external pathway network system (type, location).

8. Recommendation

8.1 Site access/circulation plan.
8.2 Roadway improvement:
- on-site;
- off-site; and
- phasing, if appropriate.

8.3 PT, bicycle and pathway system.
8.4 Other.

9. Conclusion

10. Special analysis/issues (if applicable, refer to SC6.4.3.14.4(8))

11. RPEQ Certification

Appendices

SC6.4.3.14.4 Essential technical guidance

(1) Existing conditions

(a) Traffic count data
Traffic trends and counts data may be available from DTMR and council. Traffic data must reflect existing normal conditions and should not be used if more than two years old at the time of the TIA submission or if significant changes have occurred at or near the count location or as otherwise requested by council. The traffic consultant or the applicant is responsible for providing traffic counts that are not available through DTMR or council.

(b) Traffic accident and safety
Accident data is available from the State traffic accident reporting system and can be obtained through Data Analysis at the Queensland Department of Transport and Main Roads. Accident data requests should be made as early as possible to enable the information to be provided in a timely manner.

(2) Traffic forecasting and analysing

(a) Townsville Strategic Traffic Model 2011 (TSTM11)

Townsville Strategic Traffic Model 2011 (TSTM11 on the Emme platform) has been developed and calibrated with various Townsville traffic survey results, 2011 demographics and network conditions. Its ownership has been established between council and DTMR.

Associated with land use development, council has used the Townsville Growth Model to develop future demographic data, in 5 year intervals up to 2036.

Upon request, or following a pre-lodgement meeting agreement, TSTM11 and future demographic data are available to use under license among council/DTMR and the applicant. Also, depending on the process of council/DTMR traffic model development, meso/micro simulation models for other areas will be available, such as CBD SATURN. Council encourages the use of these models, as they have been developed for the agreed network structure and their methodology is transparent and consistent for all users. For background traffic forecasting, the use o f data TSTM11 must be used in the first instance. Data obtained from TSTM11 for background traffic forecasting must be calibrated to existing traffic volumes at the time of analysis.

All traffic modelling data should be calibrated and validated at the time of the assessment prior to using the data and details of this process are required to be included in the report. It should be acknowledged that TSTM11, especially, is intended for use with high level traffic network modelling and is not designed for small size or individual lots of development. It is important to apply the correct level of traffic modelling work/methodology to forecast the traffic demand associated with the development.

Council retains intellectual property ownership rights to the latest data for council purposes. Applicant must ensure that any consultants engaged to undertake this work are aware of this stipulation.

Any updated or developed input/output traffic modelling data as part of the TIA study, must be submitted. If the applicant intends to develop new traffic modelling as part of the TIA report, council encourages the use of the same platform of traffic modelling, i.e. EMME, Sidra Intersection and Aimsun. If the applicant uses an alternative equivalent traffic model, this must be agreed to by council prior to the TIA commencing. The agreement will cover issues such as network structure, demographic data and methodology.

(b) Trip generation rates

The trip generation rates for the residential component of dwellings are 8 VPD per dwelling in non-urban areas and 10 VPD per dwelling in CBD/Urban areas, unless actual survey data is available. In the same manner, all considered trip generation rate data must be provided in the TIA Report as source or reference data. Consideration must also be given for other ancillary uses proposed on the land. In the absence of specified trip generation rates within council documentation, the DTMR's Guidelines for Assessment of Road Impacts of Development, 2006 and Road Planning and Design Manual must be used.

(3) Traffic analysis performance criteria

The results of the traffic analysis must be compared using the Measure of Effectiveness (MOE), as set out in Table SC6.4.3.14.4 below.

Table SC6.4.3.14.4 MOE based on the traffic characteristics and type

Facility	Type	Measure of effectiveness (MOE)
Intersections	Unsignalised or prioritised control	Average delay (seconds per vehicle) Delay to critical movements (seconds) Degree of Saturation (DOS) Queue length for critical movements (metres or vehicles)
	Traffic signals	Average delay (seconds per vehicle) Delay to critical movements (seconds) Degree of Saturation (DOS) Queue length for critical movements (metres or vehicles)
	Roundabouts	Average delay (seconds per vehicle) Delay to critical movements (seconds) Degree of Saturation (DOS) Queue length for critical movements (metres or vehicles)
Interrupted flow, e.g. Urban/CBD network		Average travel speed (km/hr) Volume/Capacity ratio
Uninterrupted flow, e.g. Non-urban/highway network		Density (PCU/km/lane) Volume/Capacity ratio
Two-lane uninterrupted flow, e.g. Non-urban/highway network		Average travel speed (km/hr) Volume/Capacity ratio
Pedestrian		Space (m^2/person) in queuing area Speed (person/min/m) in walkway
Transit		Headway (minutes or veh/hr) Passenger loading (m^2/person) Reliability (%)

Source :*Transportation Research Board, Highway Capacity Manual,* 2010.

The type and level of analysis and evaluation will include documentation of LOS for intersections. A saturation flow rate and all parameters for analysis should be considered in accordance with the SIDRA Intersection user guide and default parameters unless field measurements at the study area would indicate a more appropriate value. In this case, all source or reference data must be provided in the TIA report.

(4) The conversion of vehicle numbers to PCE
Table SC6.4.3.14.5 shows the conversion of vehicles (as classified by Austroads) to comparative number of passenger car equivalent (PCE) for the determination of trip generation, intersection capacity and LOS analysis.

Table SC6.4.3.14.5 Calculating passenger car equivalent

Austroads *Guide to Traffic Management Part 12* **vehicles classifications**	**Passenger Car Equivalent (PCE)**
Classes 1 to 2 i.e. short vehicles	1 PCU
Classes 3 to 5 i.e. light to medium trucks	2 PCU
Classes 6 to 9 i.e. heavy trucks	3 PCU
Classes 10 to 12 i.e. B-doubles, Triple Road Train	5 PCU

(5) Desirable service standard for links
According to the given MOE in Table SC6.4.3.14.4, the threshold for acceptable operation is the upper limit of LOS ‘D’ for CBD/urban roads and LOS ‘C’ for rural roads although the next level of LOS ‘E’ or ‘D’ could be accepted where weekend peaks are the defining event and occur on recreational routes.

(6) Desirable service standard for intersection/access
Any intersection analysis should demonstrate that the delays would be less than that shown in Table SC6.4.3.14.614.6 up to the ten year horizon after completion of the development. If they are not, improvements to the intersection layout and/or changes to the proper method of control must be assessed.

Table SC6.4.3.14.6 Desirable Service Standard for intersection/access operation

Criteria	Acceptable levels	
	CBD and urban	**Rural**
Signalised intersection	Control delay less than 55 seconds per vehicle (LOS D) or Degree of Saturation less than 0.9	NA
Roundabout	Control delay less than 35 seconds per vehicle (LOS D) or Degree of Saturation less than 0.85	Control delay less than 25 seconds per vehicle (LOS C) or Degree of Saturation less than 0.8
Priority intersection or give-way stop controlled intersection	Control delay less than 35 seconds per vehicle (LOS D)or Degree of Saturation less than 0.8	Control delay less than 25 seconds per vehicle (LOS C) or Degree of Saturation less than 0.7
Left or right turning lanes	Less than available storage length within 95 percentile queue	Less than available storage length within 90 percentile queue

Note—The delays above equate to the upper limit delay of Level of Service C or D for approach-based and intersection wide assessment. LOS is defined solely by control delay (2010 *Highway Capacity Manual*). LOS E means the intersection/approaches are at capacity.

(7) Parking

Adequate parking must be provided to meet site-generated demands and be consistent with the most current version of the references. If the consultant conducts a survey, or uses other source data, the car parking demand must be compared against SC6.4.3.5 Car parking and public transport facilities guidelines, with the greater car parking demand being applied. In considering car parking for a specific type of development, the consultant must use data from at least two different sources, or use the data compiled from both a survey and one source data, with the greater level of car parking demand being applied. All surveys or source data must be from a similar land use to the proposed development.

Specific dimensions, parking angles, and parking ratio requirements are addressed in the planning scheme and planning scheme policies (SC6.4.3.5 Car parking and public transport facilities guidelines), and Austroads Cycling Aspects of Austroads Guides.

Editor's note - From time to time, council may introduce incentive programmes that impact on parking requirements. Information on any incentive programmes is available from council.

(8) Special analysis/issues

Council may request specific traffic analyses relevant to the proposed development. These include details about access management, a TDM plan, cut-through traffic and residential quality of life analysis, truck estimates, Intelligent Transport System (ITS) strategies, pedestrian/bicycle safety, signage and access, safe routes to school, emergency routes, etc.

(9) Mitigation plans and conclusion

All mitigation plans identified as necessary to serve the proposed development should be listed in the TIA report, along with the timing of implementation.

During construction, private approaches should be located, and configured in such a manner as to avoid disruption to the public street system. If changes to traffic controls are proposed, warrants should be reviewed and documented in the report. Reference should also be made to SC6.4.6.30 Control of traffic.

The TIA report must provide a preliminary overall master plan map, and recommendations, and include the status (funded, programmed, or unfunded) of any existing traffic upgrading plans.

(10) TIA report appendices

The following appendices should be included in the TIA report submitted to council:

(a) raw traffic count data - average daily and peak hour turning movement traffic count data collected and/or obtained from other sources;

(b) printouts of analysis results - input/output; e.g. aaSIDRA;

(c) all traffic network modelling work as an electronic copy - e.g. network attribute data, demographic data and other relevant files (macro, excel etc);

(d) photographs of the site;

(e) additional tables or figures not included in the TIA report;

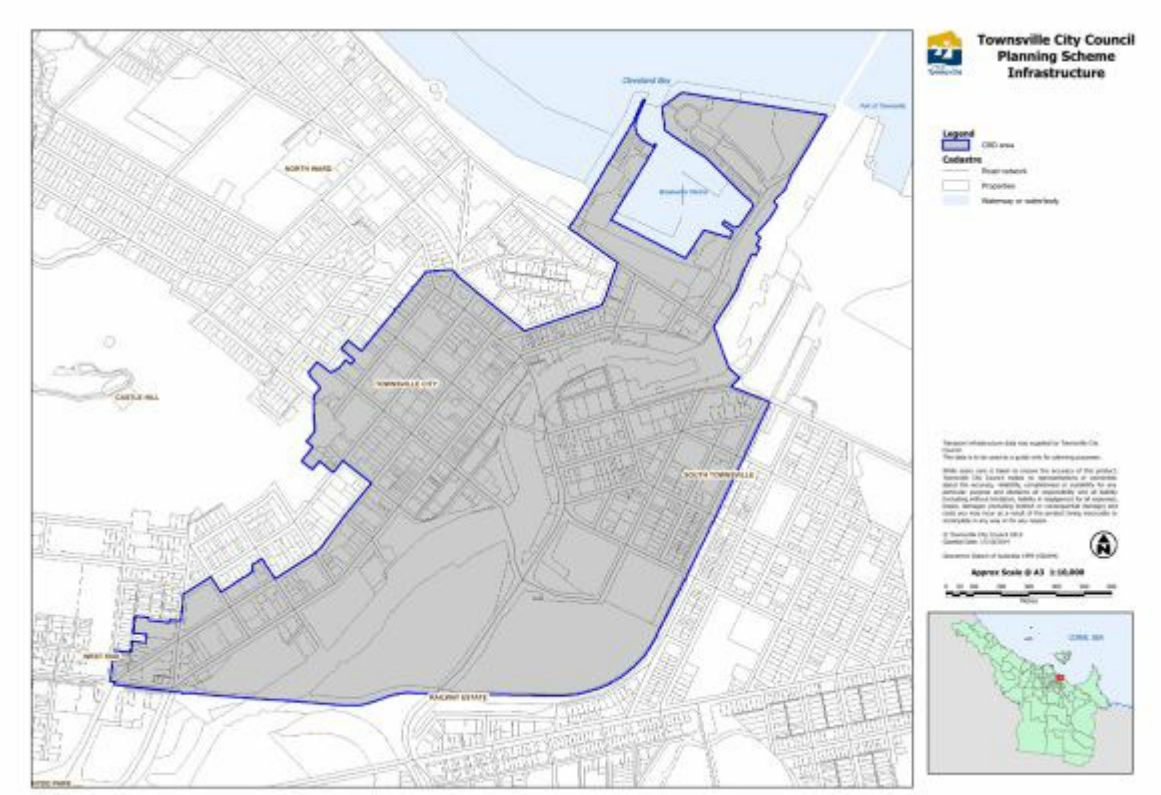
(f) description of methodologies and assumptions used in analysis;

(g) worksheets used in analysis - i.e. signal warrant, LOS, queuing, capacity etc.;

(h) notes on the outcomes of any meetings in regards to the development; and

(i) variations to the standard report (template) – RPEQ certification of any non-conformances with requirements.

SC6.4.3.14 Attachment A: Map of the CBD



Click here to view PDF high resolution map.

SC6.4.3.15 Noise and vibration assessments

SC6.4.3.15.1 Introduction

(1) Purpose

The purpose of this sub-section is to:

(a) provide information to developers and other related parties for use during the planning, construction, and operational stages of a development;

(b) provide guidance on preparing a noise or vibration impact assessment report; and

(c) ensure that development is managed in a way which prevents nuisance from the effects of noise and vibration on the health, community well-being and quality of life of an individual or the community, and wildlife.

(2) Terminology

Unless noted otherwise all terms have the same meaning as given in the most recent version of the *Environmental Protection Act 1994*, the E*nvironmental Protection Regulation 2008*, the *Environmental Protection (Noise) Policy 2008* and the relevant standards. If a definition given in the relevant standards is inconsistent with the Act or Regulation, the Act or Regulation prevails to the extent of the inconsistency.

Background creep	a progressive increase in background noise levels due to new noise generating activities locating in an area.

(3) Reference and source documents

(a) Queensland authorities/legislation:

Department of Transport and Main Roads (DTMR) – *Policy for development on land affected by environmental emissions from transport and transport infrastructure,* 10 May 2013
Department of Transport and Main Roads (DTMR) – *Road Traffic Noise Management: Code of Practice*
Department of Transport and Main Roads, Main Roads Technical Standard, *MRTS15 Noise Fences*
Environmental Protection Act 1994
Environmental Protection (Noise) Policy 2008 (EPP Noise).
Queensland Development Code MP Part 4.4 – Buildings in a Transport Noise Corridor.

(b) Australian standard/guideline:
Department Environment Heritage Protection - *Noise Measurement Manual 2013*
Department Environment Heritage Protection - *Planning for Noise Control 2016*
Environment Protection Authority (NSW) NSW Industrial Noise Policy 2000
AS1055.2: *Acoustics – Description and measurement of environmental noise – Application to specific situations.*
AS2107: *Acoustics – Recommended design sound levels and reverberation times for building interiors.*

(c) Austroads

AP-R277/05 - Modelling, Measuring and Mitigating Road Traffic Noise
Guide to Road Design Part 6B: Roadside Environment

SC6.4.3.15.2 Noise and vibration

Noise is often described as unwanted sound and, by its very nature, can cause varying degrees of nuisance. Some sounds are considered to be annoying by some people but not by others. However, in general, the louder the sound, the greater the annoyance or nuisance caused.

The nature and character of a sound, even at low levels, may also cause annoyance. Sound can have a number of characteristics and can be described in many ways. It is not possible to fully categorise every form of sound. However, this policy is intended to provide guidance for the majority of commonly experienced sounds. "Noise" has become synonymous with "sound" in common language. In this policy, noise will generally mean sound.

Furthermore, sound is defined in Queensland legislation to include vibration and therefore levels of acceptable vibration

are also included.

SC6.4.3.15.3 Development assessment

Preventing noise problems is always better than attempting to rectify noise impacts after the development and trying to resolve problems may not be always possible and can be costly. The management hierarchy under the Environment Protection (Noise) Policy 2008 (EPP Noise) is "to the extent that is reasonable to do so".

(1) Firstly - avoid; or

(2) Secondly - minimise; or

(3) Lastly - manage.

Council encourages development that is sympathetic to the amenity of a location, and minimises the occurrence of background creep. Where proposed uses are likely to increase noise levels at a locality, or be affected by existing noise sources, a noise (and vibration) impact assessment may be required or requested.

If the noise impact assessment report reveals that the use or activity has the potential to create nuisance or exceed acoustic quality objectives as prescribed by *Environmental Protection (Noise) Policy 2008* (EPP Noise), the developer will need to demonstrate by way of a noise (and vibration) control plan how the environmental values (noise) will be enhanced or protected to meet the standard as part of any submission for an operational works permit, or a compliance permit.

SC6.4.3.15.4 Noise and vibration impact assessments

(1) Subdivision layouts must be designed to ensure that acoustic mounds and acoustic fences over 1.8m are not included in lots with setbacks adjacent to the acoustic structure of 3m or less.

In support of the assessment provisions specified in the Townsville City Plan, a noise (and/or vibration) impact assessment report maybe in situations where:

(a) a new development is proposed that will create significant noise (e.g. new industry, or commercial premises with refrigeration, air conditioning or exhaust equipment); or

(b) a new noise-sensitive development is proposed in an area where existing noise sources are present (e.g. an existing industrial site, or a future or existing major road, is located nearby); or

(c) a new development will generate a significant amount of traffic noise, i.e. traffic volumes increase by around 3000 vehicles per day or more (determined by a Traffic Study Assessment); or

(d) building work including rock breaking, drilling or piling or other noisy activities are proposed; or

(e) it is required by council in order to complete an assessment of the proposed development.

The assessments are to be undertaken by a suitably qualified and experienced acoustic practitioner (e.g. a member of the Australian Acoustical Society, the Institution of Engineers, the Association of Australian Acoustical Consultants or a person with other appropriate professional qualifications).

(2) Information provided in an assessment report should include at least the following:

(a) background:

(i) the name and qualifications or experience of the person(s) preparing the assessment;

(ii) the project description, including proposed or approved hours of operation; and

(iii) the relevant guideline or policy that has been applied.

(b) impact assessment process:

(i) results of background and any other noise measurements (noise impact assessments need to consider not only existing developed property adjacent to the planned facility, but also any nearby undeveloped residential land);

(ii) meteorological conditions (wind speed and direction, temperature, atmospheric pressure and humidity) and other relevant details at the time of the measurements;

(iii) details of instruments and methodology used for noise measurements (including reasons for

settings and descriptors used, frequency weighting, height of microphone above the ground and distance to reflective surfaces calibration details);

(iv) a site map showing all noise sources, measurement locations and potential noise receivers; and

(v) any tonality impulsiveness or other noise characterises and all assumptions of noise propagation and attenuation due to distance, topography, barrier, etc, and

(vi) noise criteria applied to the project.

(c) impact mitigation and compliance:

(i) noise predictions for the proposed activity;

(ii) a comparison of noise predictions against noise criteria;

(iii) a discussion of proposed mitigation measures, the noise reduction likely and the feasibility and reasonableness of these measures; and

(iv) how compliance can be determined practically.

Editor's note—where it is demonstrated that noise and/or vibration is to have an adverse impact on a sensitive development to an acceptable and manageable level, attenuation treatments will need to be incorporated into the development to ensure that the sensitive development is protected from the identified adverse impacts. Treatments may need to address specific zone code requirements, particularly where street activation is sought from development.

SC6.4.3.15.5 Noise and vibration control plans

Where an impact assessment demonstrates that noise is likely to exceed thresholds contained within the *Environmental Protection (Noise) Policy 2008* or other relevant document or Australian Standard, a noise (and vibration) control plan will need to be submitted.

Editor's note—the noise assessment should have regard to the following – Queensland Development Code Part 4.4 – *Buildings in a Transport Noise Corridor*. Australian Standards AS1055.2 and AS2107;*or Department Environment Heritage Protection Noise Measurement Manual 2013* or *Environmental Protection Act 1994* and *Environmental Protection (Noise) Policy 2008* (EPP Noise); or *Department of Main Roads Road Traffic Noise Management – Code of Practice.*

Note—where in the vicinity of an airport, detailed designs showing how construction can ameliorate noise impacts are to be submitted in accordance with AS2107.

SC6.4.3.15.6 Information to include in a noise and vibration control plan

Aim	Typical actions
Community Relations **Editor's note—**noise and vibration control plans should describe the approaches to be applied when consulting with, and notifying the community where necessary. Large projects may also be required to develop a community relations plan which includes consultation, notification, and complaint management. Where this is the case the following is to be included in any noise (and vibration) control plan.	(a) Identify all noise and vibration sensitive receivers. Include characteristics of, and risks exposed to, existing buildings, fences, trees, property boundaries and services (within at least 1km for blasting operations). (b) Contingency actions must be developed if the relevant noise/vibration limits will be exceeded. (c) A complaints management system should be devised which includes corrective and preventative actions. (d) Consultation with and information supplied to nearby residents and other sensitive uses.
Hours of operation/construction schedule	Information regarding opening hours or hours of operation in accordance with the relevant planning scheme provisions. For construction hours, refer to SC6.4.5.2.1(2) Hours of work. Scheduling works at periods where people are least affected will also reduce impacts, and should flow on from consultation with the community (as above).

Potential noise and vibration generating activities	The choice of plant and equipment employed on the project can have a direct effect on noise and vibration levels. By selecting equipment of an appropriate size with low vibration generation characteristics, and by ensuring that the equipment is being operated correctly and that noise and vibration reduction devices are operating efficiently, the number of complaints received can be greatly reduced.
Potential noise and vibration mitigation methods	For construction, rock breaking, drilling, and/or piling the following mitigation methods should be considered: (a) maximising the distance between the noisy activities and noise sensitive land uses; (b) undertaking noisy fabrication work offsite where possible; (c) maintaining any pre-existing barriers or walls onsite as long as possible; (d) including construction barriers in the project design; (e) using building and stockpile materials as noise barriers during the earthworks phase which may be used in the final landscape design; and (f) installing purpose built noise barriers, acoustic sheds and enclosures. Road and rail noise attenuation will be considered in the following order of preference; a combination may also be provided: (g) a buffer between noise receptor and receiver; (h) service roads between noise receptor and receiver; (i) larger lots closest to the noise source that allow dwelling units to be set back from the noise source to achieve the applicable reduction level; (j) architectural treatments For class 1-4 buildings see *MP 4.4 Buildings in a transport noise corridor.* (k) incorporating mounding and landscaping into the design Noise barriers are to be provided in accordance with the principles of the Department of Transport and Main Roads *Code of Practice Chapter 5: Integrated Noise Barrier Design;* and (l) providing an acoustic fence: A detailed design is to be submitted as soon as possible in the planning process. Design and construction of barriers must meet MRTS15 *Noise Fences*. The acoustic fence must not be located on the road reserve, but within the boundary line of the abutting property. Refer to SC6.4.4.8 Standard drawings SD002, SD003 and SD004. Where acoustic reports identify that levels will be exceeded, all uses should be provided with attenuation requirements designed by suitably qualified consultants that will enable the use to meet the prescribed standard.
Noise and vibration monitoring	Where appropriate in relation to the use or activity. Include details such as monitoring equipment, standard employed, monitoring frequency, on-site meteorology, activity logs, and results handling procedure.

SC6.4.3.16 Rear lane design

SC6.4.3.16.1 Introduction

The following design principles set out standards, advice and guidelines for consideration where a proposed development includes the creation of a new rear lane or development of land that has a frontage to an existing or historic rear lane.

(1) Purpose of rear lanes:

- (a) to provide vehicular access to the rear of premises;
- (b) by nature and by design, to provide streets where pedestrians, cyclists and vehicles have shared use, but which do not create a more direct through route than provided by the adjoining street network;
- (c) used to alleviate access difficulties along frontage roads, such as where the lots are narrow, or along roads or streets carrying high volumes of traffic; and
- (d) in some cases, to improve both the streetscape and to relate the domestic environment more closely to the street frontage;

(2) Design of rear lanes should be undertaken in accordance with other relevant sections of the Development manual planning scheme policy including SC6.4.4.1 Geometric road design, SC6.4.4.2 Pavement design and SC6.4.3.6 Landscape policy.

(3) Design of rear lanes should have regard to the *Crime Prevention through Environmental Design Guidelines for Queensland* (CPTED).

Editor's note—for all setbacks, please refer to the relevant parts of the Queensland Development Code.

SC6.4.3.16.2 New rear lanes - development standards

This section outlines development standards and provides guidance and advice to inform appropriate development outcomes for the creation rear lanes associated with new development.

(1) Design outcomes

- (a) Rear lanes should be functional and provide good visibility and manoeuvrability. Development of rear lanes should:
  - (i) provide enough width to allow safe vehicle passage and turning into an out of garages, movement of pedestrians and cyclists, and with sufficient room for service vehicles;
  - (ii) enable easy and safe access from driveways;
  - (iii) utility services must be located with easy access for maintenance (including water, sewerage, stormwater drainage, gas, electricity, telecommunications, etc.) with appropriate clearances in accordance with minimum requirements;
  - (iv) ensure that subdivision of lots with rear lane frontage addresses the principal street, for example, that the letterbox is on the street and not the rear lane; and
  - (v) a minimum of one and a half on-street car spaces (unmarked) must be provided within 25m walking distance to each allotment. The car park may not be located within the rear lane.
- (b) Rear lanes are to be designed having regard to *Crime Prevention Through Environmental Design Guidelines for Queensland* (CPTED) principles, in particular:
  - (i) ensure rear yards of properties can be fenced in accordance with CPTED principles;
  - (ii) lighting of the rear lane is to meet road safety requirements and CPTED principles, while minimising overspill of light into abutting properties, impacting on amenity; and
  - (iii) ensure that boundary treatment and landscaping do not conceal recesses or provide opportunities for anti-social behaviour.
- (c) Rear lanes should be designed to accommodate the needs of abutting property owners and the streetscape, in particular:
  - (i) landscaping is to be designed to be low maintenance, without impacting on CPTED requirements;
  - (ii) landscaping to rear lanes should not impede any pedestrian or vehicle access; and

(iii) landscaping within rear lanes should not create recesses or provide uninvited opportunities for anti-social behaviour. As a guide, grass, ground cover, or visually permeable low-level vegetation are acceptable. Trees and shrubs that provide visual screening of activity are to be discouraged;

Editor's note—landscaping should otherwise be undertaken in accordance with the 9.4.3 Landscape code of Townsville City Plan.

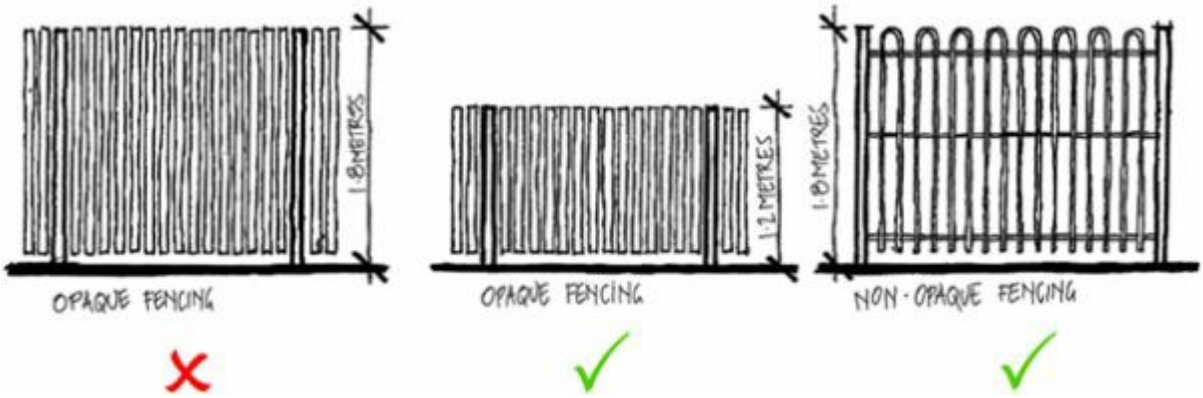


Figure SC.6.4.3.16.1 Inappropriate and appropriate screen fencing types at various heights

(iv) landscaping must not obstruct traffic movements and sightlines, particularly at driveways and intersections;

(v) the use of rear lanes as a short-cut route should be discouraged, as this may introduce through traffic travelling at high and unsafe speeds and reduce the amenity; and

(vi) a minimum of one off-street car park is to be provided per allotment.

(vii) fencing can be provided to the boundary fronting rear lanes to provide security, discourage uninvited access and enhanced amenity. The following advice is provided in respect of fencing, which should be in accordance with CPTED principles. Figure SC6.4.3.16.1 provides examples of inappropriate and appropriate fencing for rear lanes, in addition to the following:

(A) screen fencing and gates that are opaque should not be more that 1.2m in height;

(B) screen fencing and gates may be more 1.2m in height if they are non-opaque (e.g. pool fencing) but should not be greater than 1.8m in height;

(C) screen fencing and gates that are opaque and higher than 1.2m should be setback a minimum of 3 m from the rear lane boundary; and

(D) boundary fencing between properties, if opaque and higher than 1.2m, is to taper down to 1.2m to the rear lane boundary from a setback distance of 3m.

(2) Rear lane design standards

(a) Traffic flows on rear lanes should not exceed 100 vpd.

(b) Reserve widths for rear lanes must allow for:

(i) a road reserve width appropriate to allow for vehicle turning paths to access allotments and to contain stormwater drainage flows;

(ii) all services located within the rear lane maintaining appropriate clearance as per relevant standards and requirements;

(iii) water mains and connections for allotments provided to correlate to the addressing of the properties;

(iv) sewer mains and connections for allotments provided in accordance with SC6.4.3.21; and

(v) stormwater in accordance with SC6.4.4.4 Stormwater drainage design.

(c) Rear laneways should not exceed 75m in length, in order to maintain a maximum design speed of 30km/hr based on an intersection speed of 20km/hr.

(d) Horizontal and vertical alignment should incorporate curves to encourage low vehicle speeds by creating an environment where drivers are actively discouraged from driving above 30 km/hr.

(e) Traffic calming can be achieved through acceptable geometric methods.

(f) Rear lanes must be designed so that they are used as a short-cut between streets.

(g) street lighting must comply with SC6.4.3.20.

(h) intersections of rear lanes with other lanes and other streets must comply with SC6.4.4.1.

(3) Consideration of the final desired built form of adjacent lots being serviced will be a consideration to ensure sufficient operating space and clearance is achievable for waste collection vehicles. Access for emergency vehicles must also be a consideration.

Editor's note—the Development manual planning scheme policy sub-section SC6.4.3.22 Waste management provides additional information regarding waste collection standards.

SC6.4.3.16.3 Historic rear lanes

(1) The following design standards, advice and guidance are provided for consideration when addressing applications for reconfiguring a lot and involving a historic rear lane and where a historic rear lane forms a road frontage to the development.

Editor's note—while the following information is provided to guide development involving the historic rear lanes of Townsville, the principles may be useful for consideration of other existing rear lanes that are not historic.

SC6.4.3.16.4 Development intent for historic rear lanes

(1) Rear lanes are an inherent part of the historic make-up and character of some of Townsville's oldest suburbs, particularly South Townsville and Railway Estate. Historic rear lanes have been identified through studies undertaken by council as being worthy of preservation, as they contribute towards the unique character and amenity of Townsville's older suburbs. Importantly, historic rear lanes have influenced the character and built form.

(2) The purpose of this section is to ensure the character of historic rear lanes does not diminish, and to enhance the existing character provided by the rear lanes. Further, it is intended to discourage inappropriate development outcomes adjacent to these rear lanes.

(3) This part seeks to clarify the characteristics of development that are appropriate to historic rear lanes and therefore provide guidance and certainty to all stakeholders, whilst also adhering to best practice with regard to CPTED principles.

SC6.4.3.16.5 Description of historic rear lanes

(1) Description

Principally, rear lanes are found in Railway Estate and South Townsville. The use of the term "historic rear lanes" generally refers to historic rear lanes associated with land zoned as Character residential zone under Townsville City Plan.

The dominant physical characteristics of the historic rear lanes are as follows:

(a) rear lanes are typically 6m wide;

(b) they are between 50m and 350m long, with the majority being approximately 110m long;

(c) rear lanes are straight and occasionally intersect with other rear lanes;

(d) where sealed, the bitumen is approximately 2.7m to 3m wide and is in the centre of the rear lane. The space on either side of the bitumen is an unsealed landscaped grass verge;

(e) some rear lanes have not been sealed;

(f) rear lanes are generally one lane with two-way access;

(g) most properties with access to a rear lane have primary access via the street, however, some properties fronting Boundary Street, for example, have primary access via the rear lane only; and

(h) rear lanes are sometimes the primary point of access for local infrastructure such as sewerage and

water.

SC6.4.3.16.6 Development standards

(1) This section outlines development standards to guide appropriate development to retain and enhance the historic character of rear lanes.

Development affecting rear lanes should:

(a) ensure rear lanes remain functional and provide good visibility and manoeuvrability;

(b) provide appropriate width to enable safe and efficient vehicle movement, including for service vehicles;

(c) enable easy and safe access into and out of sheds, carports and garages;

(d) not create a more direct through-route alternative for vehicles, cyclists or pedestrians than the adjoining street network;

(e) be designed to ensure rear yards of properties can be fenced in accordance with CPTED principles (Queensland);

(f) ensure that boundary treatment and landscaping do not conceal recesses or provide opportunities for anti-social behaviour; and

(g) ensure that subdivision of lots with rear lanes addresses the principal street, for example, that the letterbox and water connection are on the street and not the rear lane.

(2) Waste collection vehicles will not service a rear lane unless the design facilitates safe vehicle access and operating conditions for a waste collection vehicle.

Editor's note—the Development manual planning scheme policy sub-section SC6.4.3.22 Waste management provides additional information regarding waste collection.

(3) Subdivision of lots in areas with rear lanes should be "vertical", down the centre of the block (see "b" in Figure SC6.4.3.16.2), creating two similar-sized rectangular blocks (approximately 10 m wide). This is consistent with lot sizes in parts of Workers Cottage precinct and South Townsville precinct in the Character residential zone, where the existing character of the lot sizes of some sites in Townsville's older suburbs is 10m wide by either 40m or 50m deep.

(4) Where subdivision of lots in areas with rear lanes is proposed to be "vertical", down the centre of the block, primary vehicular access via the rear lane is permitted.

(5) Where lots are configured in a "hatchet" configuration, as shown in "a", "c" and "d" in Figure SC6.4.3.16.2, primary vehicular access is not permitted via the rear lane. Generally, primary vehicular access to the block is to be from the street, with the exceptions as noted in Figure SC6.4.3.16.2 (b and c).

(6) Some properties that border Boundary Street in South Townsville may have exceptional circumstances in relation to the scenarios outlined in Figure SC6.4.3.16.2. These will be assessed on their individual merits.

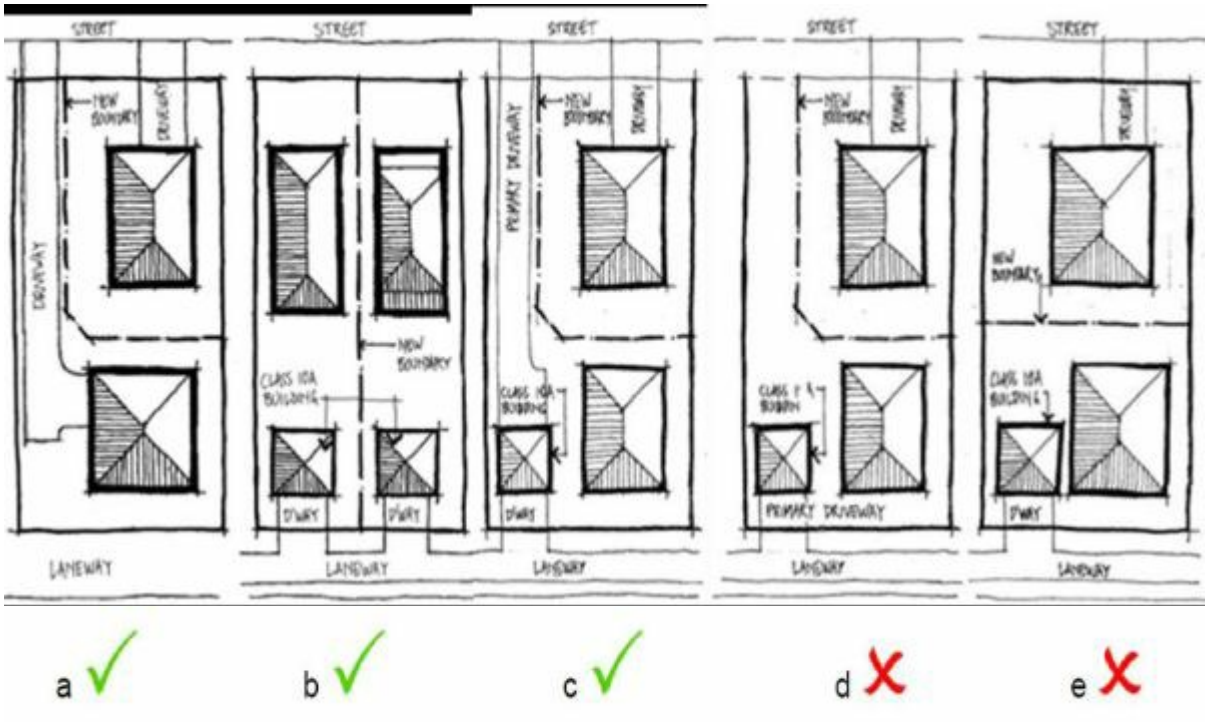

Figure SC6.4.3.16.2 Unacceptable and acceptable lot reconfiguration and access for properties adjacent to rear lane

(7) Crime prevention through environmental design considerations.

Editor's note—applicants should also have regard to *Crime Prevention through Environmental Design Guidelines for Queensland* in addition to the below specific guidelines.

(a) Lighting should be provided for buildings with vehicular or pedestrian access to rear lanes. Appropriate lighting may include sensor lighting, installed overlooking the driveway or pathway respectively.

(b) Tilt panel doors or other doors should not open directly onto the rear lane.

(c) Rear yards of properties may be fenced to support CPTED principles and improve amenity, security (casual surveillance) and vistas.

(d) Rear boundary fence gates to rear lanes are encouraged to increase activation of the space.

(e) Fencing can be provided to the boundary fronting rear lanes to provide security, discourage uninvited access and enhanced amenity. The following advice is provided in respect of fencing and should be provided with regards to the principles of CPTED. Figure SC6.4.3.16.1 provides an example of inappropriate and appropriate fencing for rear lanes, in addition to the following:

  (i) Fences or walls along a street frontage have a maximum height of 1.2m where solid, or 1.8m where that portion of the fence above 1.2m high is at least 50% transparent.

(f) Historic rear lanes are generally not used for on-street parking with the exception of short-term parking by service vehicles. Parking should be discouraged through approved treatments, including landscaping, surface finish and limited signage (if necessary).

(8) Landscaping and driveways

(a) Landscaping, where provided to rear lanes should create local amenity and beautification of its environs and must be in keeping with established character of the particular rear lane.

(b) Landscaping, where provided within rear lanes should not conceal recesses or provide uninvited opportunities for anti-social behaviour. This can be achieved with grass, ground cover, or visually permeable low-level vegetation. Trees and shrubs that provide visual screening of activity are to be discouraged.

(c) Landscaping must not obstruct traffic movements and sightlines, particularly at driveways and

intersections.

(d) Driveways are to be constructed in accordance with the sub-section SC6.4.3.17 Driveways.

SC6.4.3.17 Driveways

SC6.4.3.17.1 Introduction

This sub-section details standards and provides advice and guidelines to assist in the design and construction of driveways (domestic, industrial, commercial and rural property access), location, and other aspects in relation to their impact on pedestrians, cyclists, other vehicles, stormwater and neighbours.

Note—the technical details depicted and described in SC6.4.4.8 Standard drawings must be adhered to.

(1) Reference and source documents to be read and applied in conjunction with this policy sub-section are as follows:

(e) Austroads
Guide to Road Design Part 3 – Geometric Design
Guide to Road Design Part 4 - Intersections and Crossing - General

(2) Terminology

Driveway	unless stated otherwise, the term driveway in this sub-section refers to the access between the road and the property boundary; ie. on council-controlled land. This sub-section does not provide advice on the vehicular movement area within the private property.
Crossover	the part of a driveway that is located crossing the kerb and channel.

Local Road	a road under the control of a Local Government.
Property owner	entity, applicant, developer or owner/s who is responsible for the driveway at the time.
Queuing area	the area of a circulation roadway between the property boundary and the vehicle control point, available for the queuing of vehicles.
Regulated parking	parking controlled by traffic signs or line marking.
Rural area	an area where the urban criteria are not met as specified in the Townsville City Plan.
Road corridor permit	a permit issued by the Department of Transport and Main Roads authorising works on a State-controlled Road.
Road works permit	a permit issued by council authorising works within the road reserve on a Local Road; the area of land under the council's control, dedicated, notified or declared to be a road for public use.
Sight stopping distance	means the distance to enable a normally alert driver, travelling at the design speed on wet pavement, to perceive, react and brake to a stop before reaching a hazard on the road ahead. Refer to the *Austroads Guide to Road Design Part 3 – Geometric Design*.
State-controlled road	means a road under the control of the Department of Transport and Main Roads, including national highways.
Urban area	an area where the urban criteria are met in accordance with SC6.4.3.13.

Note—types of driveways include:
New driveways - must comply with the requirements of council's standard drawings. Works are at the property owner's cost and to the satisfaction of council.

Non-conforming driveways - existing driveways which do not meet council requirements that must be reassessed in the event of a redevelopment of the site. Works are at the property owner's cost and to the satisfaction of council.

Redundant driveways – existing driveways that are no longer in use and must be removed. Works are at the property owner's cost and to the satisfaction of council.

Unapproved driveways - driveways that have not been approved by council. Council may require these driveways to be removed or modified. Such works are at the property owner's cost and to the satisfaction of council.

Modified driveways - modifications to existing driveways must comply with the requirements of council's standard drawings. Works are at the property owner's cost and to the satisfaction of council.

Temporary driveways - Temporary property access during construction. Works are at the property owner's cost and to the satisfaction of council.

SC6.4.3.17.2 Responsibility

(1) The driveway is the responsibility of the property owner to construct and maintain. A Road Works Permit is required for all works within the road reserve under council control.

(2) Costs

The property owner is responsible for the cost to:

(a) prepare and obtain the appropriate permit(s);

(b) design and construct the driveway and associated works; and

(c) maintain the driveway.

SC6.4.3.17.3 Location

The location and layout of a driveway must consider the type of frontage road, land use of the property, and the type and volume of vehicles likely to use the access. It must be located to avoid being a hazard to any pedestrian and cyclist, through movement of traffic, and to minimise damage to the verge and vegetation/ landscaping. A separate, clearly distinguishable access for pedestrians and cyclists is to be provided.

The property owner must ensure that there are no impacts on stormwater, upstream or downstream, due to the driveway (refer to SC6.4.3.8 Stormwater) being constructed.

Rural driveway location and layout must also consider the through traffic volume, turning volume, vehicle type,speed environment, road layout, land use and general topography. It may be necessary to widen the shoulder or provide a turning lane to enhance safety for turning vehicle and through traffic.

(1) For all driveways, the location of the driveway should be:

(a) as far as practical from intersections to minimise points of conflict and confusion, and to improve safety. Driveways should not be situated within the functional area of at-grade intersections;

(b) to a road of a lower hierarchy where reasonable access can be provided;

(c) at least 6m from the tangent point, or where no tangent point exists, at least 12m from the intersection of two street property boundaries; and

(d) positioned to achieve adequate sight distance for all traffic movements associated with property accesses. Desirably, a driver has at least stopping sight distance available to react to a potential conflict and come to a stop.

Editor's note—refer to *AS2890.1 Off street car parking.*

(2) All driveways should avoid being located:

(a) opposite the terminating road of a T-junction on non-residential streets;

(b) within the signalised area (defined by extension of the signal stop lines to the road boundaries), within 25m of a signalised intersection, and not adjacent to auxiliary lanes, depending on the property frontage width. Access may be permitted if it can be demonstrated to council that the location of the driveway will be safe;

(c) within a roundabout area, nor desirably within 25m of the roundabout entrances or exits. Access may be permitted if it can be demonstrated to council that the location of the driveway will be safe;

(d) opposite or within 6m of a median opening in a major road; and

(e) within the bus stop boarding area and on the downstream side of the bus stop.

Note—on-site parking bays must be located clear of queuing areas. This allows vehicles to drive completely onto the property without having to stop for other vehicles to complete on-site parking manoeuvres.

(3) Driveways must be constructed at a right angle to the kerb line/road centreline unless demonstrated that it is not safe to have the driveway at a right angle.

(4) Driver visibility at the property line to pedestrians, cyclists and other vehicles must be clear of obstruction (e.g. fencing and landscaping), and should account for changes in grades or curves in road alignment.

Note—if sight distance is not adequate then a mirror, or other approved device, will be required to be installed at the property owner's cost.

SC6.4.3.17.4 Amenity

(1) The driveway should not adversely affect, impede or cause a nuisance to neighbouring properties.

(2) The driveway crossover of one property should not encroach onto the frontage of any adjacent property, except where it is required to achieve the desired outcome and has received approval from council.

(3) The driveway should minimise the vehicle headlight impact on the adjacent neighbourhood.

SC6.4.3.17.5 Materials

The driveway must be constructed in accordance with SC6.4.4.8 Standard drawings.

SC6.4.3.17.6 Clearances

The driveway must be constructed in accordance with SC6.4.4.8 Standard drawings.

SC6.4.3.17.7 Gradient

The driveway must be constructed in accordance with SC6.4.4.8 Standard drawings.

Note—this may not be practicable in some particularly hilly residential locations. Driveways with higher gradients can be constructed by using the expertise of a professionally qualified engineer and with the approval of council.

SC6.4.3.17.8 Number of driveways

(1) The number of driveways will be one per lot.

(2) Two may be permitted where:

(a) there will be more than ten metres or less than four metres between the driveways; and/or

(b) the property has two street frontages; and

(c) an analysis of on-street parking demonstrates that on-street parking will continue to be adequate even if a second driveway is constructed.

Where parking bays are marked on the street including service bays and bus stops and alteration to these bays is required to accommodate the second driveway, there is to be no loss of use. Displaced bays can be included in the off street parking component of a commercial development where considered appropriate. The applicant is responsible for the alterations to the line marking and signage.

(3) Commercial and industrial properties with separate entry and exit points or two or more entry levels or multiple ramps can have more than two driveways. Where two or more access driveways are permitted for industrial or commercial sites, the two access driveways must be separated by a minimum spacing of ten metres from the edge of the driveway at the kerb and channel.

SC6.4.3.17.9 Stormwater

(1) The property owner must ensure that there are no impacts upstream or downstream as a result of the works.

(2) In rural areas in particular, the driveway must not block or significantly impede stormwater flow along the road table drain.

(3) Where a box culvert is installed under the access, the minimum clearance below the level at the property boundary or the edge of the bitumen roadway (whichever is the lower) to the top of the access is provided in accordance withSC6.4.4.8 Standard drawings. This clearance must be achieved to allow water flowing in the drain to surcharge over the access before entering onto the roadway or the adjacent property.

SC6.4.3.18 Geotechnical investigations

SC6.4.3.18.1 Introduction

(1) Purpose

This policy sub-section provides advice and guidance and assist applications

(a) on the preparation and assessment of geotechnical investigation reports;

(b) on the expected level of geotechnical investigation required for development based on the level risk or hazard identified; and

(c) information council may request for a development application.

(2) Background

Development on steep lands presents a unique set of design and engineering challenges, often requiring a greater degree of detail in the design and approval of allotments, earthworks, roads, services and built form.

There is a growing awareness of the risks, environmental values, and ongoing costs associated with development on steep slopes, which has resulted in an expectation of an improved standard of design in these environmentally and geologically sensitive areas. This is supplemented by an increased mindfulness of the risks and financial cost to construct and maintain the servicing in these areas and the need to consider these factors in the assessment of applications involving a landslide hazard.

Editor's note—certain existing steep land or hillside developments have demonstrated how inappropriate forms of land use and servicing can permanently damage local environmental features and diminish valued natural assets, particularly scenic qualities. In addition, it has been noted how the costs to maintain associated infrastructure can become a burden on the wider community due to the specialist nature of this infrastructure and the generally lower density in these areas. Whilst these areas do contribute to the diversity of housing choice, the pricing of lot and housing prices usually exceed the ability for the local economy to include these as affordable housing options.

(3) Application

This sub-section applies to development affected by the Landslide hazard overlay maps OM-07.1 and OM-07.2.

(4) Reference and source documents

Australian Geomechanics Society (AGS), *Australian Geomechanics*, Volume 42 No 1 March 2007.

Fell, R., Hungr, O., Leroueil, S. Riemer, W., 2000: *Keynote Lecture – Geotechnical engineering of the stability of natural slopes*, *and cuts and fills in soil*, GeoEng2000, 1, 21-120. Invited Papers, Technomic Publishing, Lancaster, ISBN: 1-58716-067-7, November 2000.

SC6.4.3.18.2 Geotechnical investigations

(1) Requirement of a site-specific geotechnical investigation report.

(a) Where development is subject to assessment against Part 8.2.7 Landslide hazard overlay code, an applicant will be required to undertake a geotechnical investigation of the likely impacts of the proposed development and to determine the measures to avoid or mitigate unacceptable risk and other adverse impacts.

(b) Table SC6.4.3.18.1 Guidelines for applicability of geotechnical assessment techniques in landslide hazard categories specifies the level of investigation required for the particular hazard level affecting the subject land. Where the subject land has more than one hazard level mapped, the assessment technique shall be for the higher hazard level mapped. Table SC6.4.3.18.2 Applicability of site investigation methods to slope classes should be considered in conjunction with Table SC6.4.3.18.1.

(c) The planning and design of future development should consider the level of professional geotechnical input commensurate to the landslide hazard category which the development is subject to. In general, it is appropriate that geotechnical input for development be carried out in accordance with the reporting standards proposed by the AGS, 2007c Landslide Risk Management (Reference 8). This requires the

practitioner to consider not only the issues surrounding the landslide hazard (if one exists) but also the consequences if a landslide were to occur (i.e. the assessment need to be couched in a risk assessment context).

(d) The extent and detail of the investigation will vary dependent upon the level of hazard identified on the Landslide hazard overlay maps OM-07.1 and OM-07.2 and the nature of the development being proposed. Council will require each report to demonstrate a scope and depth of investigation appropriate to the level of hazard identified, for the specific site characteristics and the proposed development and works.

(e) Geotechnical reporting needs to clearly indicate whether the risk assessment is based on existing slope conditions or with risk treatment measures implemented (or both).

(2) Preparation of a site-specific geotechnical investigation report

(a) A geotechnical investigation report must document the following:

(i) introduction to the proposal including a description of the subject land, locality and proposed development;

(ii) description and investigation of existing conditions of the development site, including assessment of land stability and geotechnical constraints to development (see SC6.4.3.18.2(3) Investigation information requirements);

(iii) assessment of the suitability of the site for the development. This should include an assessment of the likely effects and impacts of the development upon slope stability or landslide hazard (see SC6.4.3.18.2(3) Investigation information requirements);

Editor's note— assessments should be undertaken and give sufficient consideration of the final intended development outcomes for the subject site, including staging of development and associated works.

(iv) measures recommended to mitigate impacts including siting, design, engineering, and any other necessary mitigation measures; and

(v) conclusion and recommendations (see SC6.4.3.18.2(3) Investigation information requirements).

(b) Geotechnical investigation reports are to reference Australian Geomechanics Society (AGS) Volume 42 No 1 March 2007, or any later guideline of the AGS as agreed by council.

(c) Geotechnical investigations are to be undertaken and certified by an appropriately qualified and experienced engineering geologist, geotechnical engineer or registered professional engineer appropriately experienced in slope stability investigations in accordance with Australian Geomechanics Society Volume 42 No 1 March 2007.

(d) The findings, recommendations and specific works of the geotechnical investigation report must be implemented and complied with to ensure that the risk level for the development will be no more than "low". If the engineer's assessment report finds that the site will be "low risk" after development without the need for specific works to achieve this, certification need not be required.

(e) Laboratory testing is required to be undertaken by a National Association of Testing Authority (NATA) certificated laboratory. All investigations, testing and design should be undertaken in accordance with industry practice and the provisions of relevant Australian Standards.

(3) Investigation information requirements

(a) Geotechnical investigations should cover the matters set out below, and may include, but need not be limited to:

(i) review of existing data sources including regional geology, topographic maps and geotechnical reports;

Editor's note— applicants may also refer to SC6.4.3.7 Steep land development design guidelines for further information.

Note—where a geotechnical investigation has been previously undertaken and the report provided as supporting documentation to council for a previous application over the subject land, these documents must be clearly referenced in the report prepared for the subsequent application. Such supporting documentation must be made available to council and be current and specifically relevant to the proposed development.

(ii) stereoscopic viewing of vertical air photo pairs to facilitate terrain mapping;

(iii) preparation of site plan showing results of geomorphic and engineering geological mapping (to scale);

(iv) subsurface investigations including drill holes, auger holes, shafts and test pits with locations shown on to scale site plan;

(v) results of laboratory testing of samples recovered from the subsurface investigation;

Note—the results of all laboratory tests must be included in the geotechnical report, including the location and level (including datum).

(vi) groundwater and surface water studies including recording of groundwater conditions in sub surface investigation and mapping of surface seepages;

(vii) preparation of cross section(s) showing interpreted geotechnical and groundwater conditions with cross section location identified on site plan;

(viii) evidence of past slope stability performance;

(ix) evidence of history of slope instability with assessed trigger events, including in relation to adjoining land;

(x) identification of landslides, shown in plan and on section, and discussed in terms of the site geomorphology and slope forming process;

(xi) assessment of consequences to property and life for each landslide and or type of landslide with basis therefore;

(xii) assessment of risk for each landslide and or type of landslide;

(xiii) assessment of landslide frequency (probability) and or type of landslide;

(xiv) risk assessment in relation to tolerable risk criteria (e.g. published criteria where appropriate); and

(xv) risk mitigation measures and options, including revised risk assessment following implementation.

(4) Guidelines for applicability of geotechnical assessment techniques in landslide hazard categories
Table SC6.4.3.18.1 has been prepared for the standard geotechnical techniques identified in AGS, 2007c which are applicable for the assessment of landslide risk. The various investigation techniques have different levels of applicability for the different hazard categories shown on the Development constraints overlay map – Landslide hazard OM-07.1 and OM-07.2. Table SC6.4.3.18.1 should therefore be considered as a guideline as to the applicability of professional geotechnical input for any hazard category.

Table SC6.4.3.18.1 Guidelines for applicability of geotechnical assessment techniques in landslide hazard categories

Investigation techniques	Landslide hazard

SC6.4.3.19 Road and street naming

SC6.4.3.19.1 Introduction

(1) Objectives

The objectives of this sub-section are to:

(a) provide a consistent procedure and setting of standards for road and street naming within the Townsville City Council Local Government Area to contribute towards a legible road and street network;

(b) ensure urban and rural addressing are simple as possible, unique and clearly identifiable;

(c) identify the information council may request for a development application or as a condition of approved; and

(d) provide guidance or advice about satisfying an assessment criteria.

(2) Terminology

Estate	an Estate is a group of homes and other buildings built together as a single development (e.g. housing development).
Roadway	is considered to be any public or private land- based thoroughfare or course navigable by vehicle or foot that can be used for assigning addresses or allowing access between points or to a feature. Examples of roadways include alleyways, roads, streets, highways, laneways, fire tracks, bike paths and walking tracks.
Roads	are generally through routes for the movement of vehicular traffic.
Streets	are generally for providing property access, pedestrian and cycle movement with more localised vehicular traffic.

(3) Reference and source documents

(a) Australian standards
AS/NZS 4819 – *Rural and urban addressing*

(b) SC6.4.4.8 Standard drawings
SD065 Street Name Sign and Installation Details
SC6.4.6.2 Minor concrete works
SC6.4.6.24 Signposting

SC6.4.3.19.2 Information requirements

(1) In order for council to consider a name for a new road or street, the following information is required, in support of the request:

Note—an application for road/street name approval must be submitted to and approved by council prior to the submission of any operational works application.

Editor's note— fees are to be paid in accordance with the *Planning and Development Schedule of Fees and Charges* for formal applications for road and street naming approval. *Planning and Development Schedule of Fees and Charges* – Schedule 1 can be found on council's website.

(a) for new developments not associated with an Estate, three proposed names for each proposed road/street;

(b) for a new Estate, a list of proposed names to be used within the Estate; and

(c) the origin of each name should be clearly stated on the submitted proposal for consideration. Requests

for roads/streets to be named after significant individuals are to be accompanied by a summarised autobiography of each individual to be recognised. For groups of names with similar origins, a bulk explanation is acceptable if the theme generated is from the same source.

Editor's note - For roads/streets that are existing gazetted roads, whether constructed or not, names must be submitted to council for approval

Editor's note - The approved road/street names as well as the road/street type must be shown on the engineering drawings submitted for subsequent operational works approval.

SC6.4.3.19.3 Criteria for the naming of roads and streets

The following criteria will be used in assessing requests for road and street naming:

(1) Australian standard (AS/NZS 4819 – *Rural and urban addressing*)

This sub-section adopts the parts of AS/NZS 4819 – *Rural and urban addressing* identified below, for use in the naming of roads and streets:

(a) **Section 1** – Scope and General;

(b) **Section 4** – Road definition and naming; and

(c) **Appendix A** – Road types – Australia.

Where this sub-section is silent on a matter, Sections 1, 4 and Appendix A of AS/NZS 4819 shall apply and, further, they will prevail to the extent of any inconsistency with this sub-subsection.

(2) Name duplication

Name duplication (both existing names and approved names) within the Townsville City Council Local Government Area will not be approved. This requirement is to ensure consistency and to avoid confusion and misunderstanding in the delivery of goods or services or in the dispatch of emergency vehicles.

(3) Sources

(a) The preferred sources for road and street names include:

(i) indigenous names of significance to the area, subject to prior approval of the relevant local Aboriginal or Torres Strait Islander Land Council via council's Aboriginal and Torres Strait Islander Advisory Committee;

Note—the relevant local Aboriginal or Torres Strait Islander Land Council should be consulted via council's Aboriginal and Torres Strait Islander Advisory Committee when choosing Aboriginal or Torres Strait Islander names, unless council already has an agreed list of appropriate names.

(ii) flora and fauna, generally using the common name and excluding lengthy or complex scientific names;

(iii) names of founding mothers and fathers, prominent citizens or identities, excluding living persons;

(iv) war casualty lists;

(v) local heritage values; and

(vi) existing road/street naming themes in the suburb or area.

(b) Names should be appropriate to the physical, historical or cultural character of the area concerned.

(c) The origin of each name should be clearly stated on the submitted proposal for consideration. Requests for roads/streets to be named after significant individuals are to be accompanied by a summarised autobiography of each individual to be recognised. For groups of names with similar origins, a bulk explanation is acceptable if the theme generated is from the same source.

(d) A variation to these sources will be considered on the individual merits of the proposal.

Note—all proposed names will be considered on their individual merit.

(4) Communication

(a) Names should be reasonably short, easy to read, spell and pronounce in order to assist service providers, emergency services and the travelling public. Proposed names should not be similar in spelling or sound to existing names.

(b) Names must not be offensive or discriminatory.

(c) Unduly long names and names composed of two or more words should be avoided:

(i) a given name should only be included with a family name where it is essential to identify an individual or where it is necessary to avoid ambiguity, e.g. Angus Smith Drive, John Melton Black Drive, Sir Leslie Thiess Drive etc. The use of given names should generally be avoided; and

(ii) whilst street and cul-de-sac names should have only one word it is recognised that some roads require a two word name because of their geographic relationship e.g. Old Common Road, Ross River Road etc.

(5) Spelling

(a) Where it is intended that a road/street have the same name as a place or feature with an approved geographical name, then particular care should be taken to ensure that the correct spelling is adopted.

(b) Where names have been changed or corrupted by long established local usage, it is not usually advisable to attempt to restore the original form; that spelling which is sanctioned by general usage should be adopted.

(c) Generally, road/street names proposed or approved should not contain abbreviations. For example, the "Creek" in "Wallaby Creek Road" must not be abbreviated. There is, however, one exception: "ST" should always be used in place of Saint.

(6) Form

(a) "The" must not be used in place of a name followed by a road type for example, "The Boulevard".

(b) Prepositions in road names should not be used, for example, "Hampton on Boulevard".

(c) No directional indicators are to be used, for example, "Gold Road West" and "Gold Road East".

(d) Prefixes such as "Upper", "New", "North" or "South" must not be used unless the name has been specifically derived from a name that includes these.

(e) The apostrophe mark must be omitted in the possessive case, e.g. ‘Smith’s Road’ should be "Smiths Road".

(f) Hyphens are not to be used.

(g) Full stops are not to be used.

(h) No symbols, diacritical marks or special characters are to be used. The exception is macrons for Maori names.

(i) Numerals are not to be used. Any numbers in a name must be written in full. Only standard A to Z alphabet characters may be used.

(7) Road types

(a) Particular attention should be paid to the use of street, road, court, crescent, drive etc., to ensure that the road type is representative of the road being described. Road/Street types are to be in accordance with AS 4819 Appendix A and read in conjunction with section 4.3 of AS 4819.

(b) The road/street type/s is required to be submitted to council as part of the application for consideration of road/street names. The road/street type/s is to be submitted for checking by council on plans associated with operational works approval. The road/street type must be appropriate for the road layout.

(8) Holding of approved names

Approved names remain valid for the following periods:

(a) 5 years for developments not associated with Estates; and

(b) for Estates, the applicant is to advise council at the time of the request for approval of names, the proposed, estimated time period for the completion of the Estate. Approved names will be held for this time period.

SC6.4.3.19.4 Street name signs

The street name signage must be in accordance with standard drawing SD065 Street Name Sign and Installation Details and installed and constructed in accordance with SC6.4.6.28 Minor concrete works and SC6.4.6.24 Signposting.

SC6.4.3.20 Public lighting and utility services

SC6.4.3.20.1 Introduction

(1) Purpose

The purpose of the Public lighting and utility services sub-section is to provide standards, advice and guidelines for the design, installation and construction of public lighting and utility services.

(a) Public lighting is provided to:

(i) allow for the use of and safe movement in public spaces;

(ii) provide improved safety and security for the community at night; and

(iii) enhance the public amenity.

Council encourages the design and use of efficient lighting systems that support council's commitment to sustainability and meet the requirements of AS/NZS 1158 *Lighting for roads and public spaces*.

(b) Utility services

A purpose of a road reserve is to provide a corridor for the delivery of utility services such as water supply, sewerage, gas, telecommunications (including future telecommunications) and electricity to all properties fronting the road, street or rear lane. The verge or footpath area between the road reserve boundary and the edge of the roadway provides the space for these service corridors and these guidelines are designed to achieve the following aims:

(i) provide a convenient location for the installation and safe access to all utility services for maintenance and retrofitting purposes;

(ii) provide a corridor for street furniture including road lighting poles;

(iii) minimise possible conflict with other underground services; and

(iv) provide an opportunity for street landscaping.

Council standard drawings (SC6.4.4.8 Standard drawings) for service corridors provide details of utility alignments within the footpath/verge and should be read in conjunction with SC6.4.4.1 Geometric road design

(2) Scope

(a) Public lighting includes:

(i) road lighting (urban and rural);

(ii) lighting for footpaths and cycle paths;

(iii) lighting for parks;

(iv) lighting for sports grounds and sports complexes;

(v) lighting for public buildings;

(vi) lighting for off-street car parks; and

(vii) feature lighting which may include bollards and in ground lighting.

(b) Utility services include (but are not limited to):

(i) reticulated water supply;

(ii) reticulated sewerage supply;

(iii) reticulated gas supply and its supporting infrastructure;

(iv) reticulated telecommunications network, including future services (fibre optic);

(v) reticulated electricity, both underground and overhead supply; and

(vi) lighting networks, including road, open space, community facilities and off-street parking.

(3) Consultation

Developers and sporting groups are encouraged to consult with council and the relevant servicing authority and determine any requirements these authorities may have before undertaking any detailed design.

Developers should obtain service plans from all relevant public utility authorities and organisations whose services may exist within the area of the proposed development. These services are to be plotted on the relevant drawings including the plan and cross-sectional views.

If there is an expectation that an application may have higher servicing demands, details of these additional demands should be provided to council and the servicing authority.

(4) Reference and source documents

(a) Council specifications and drawings
SC6.4 Development manual planning scheme policy - all specifications and drawings for design and construction.

(b) Australian Standards, in particular
AS/NZS 1158 - *Lighting for roads and public spaces*
AS/NZS 1596 - *The storage and handling of LP gas*

(c) Other
Australian Government, *Disability Standards for Accessible Public Transport 2002*
Electricity Act 1994
Electrical Safety Act 2002
Energy Queensland, *Developer's Tool Kit* (web-based)

Editor's note—the *Developer's Tool Kit* can be found on the Energy Queensland website.

SC6.4.3.20.2 Public lighting (urban and rural)

(1) Public lighting general
There are a number of types of public lighting infrastructure which meet a range of different needs. Infrastructure associated with public lighting generally consists of poles, outreach arms, lamps, luminaires, photoelectric cells, switch gear, footings and connections to a supply. The size and type of lighting infrastructure will be determined by the size and type of the use, the intensity of lighting required, remoteness from supply and the time of operation.

All lighting designs must be prepared and certified by an appropriately qualified Registered Professional Engineer of Queensland prior to submission to council with a development application.

Road and public space lighting must be designed in accordance with AS/NZS 1158 and Energy Queensland's requirements.

(2) Road lighting general
Lighting infrastructure must be chosen from the list of products supported by Energy Queensland, unless specifically otherwise agreed by council. Road lighting chosen from the list of products supported by Energy Queensland will become infrastructure owned by Energy Queensland, on a Rate 2 Tariff.

All Category P lighting in new residential areas must be LED lights as approved by Ergon Energy.

If other road lighting infrastructure is preferred by a developer for aesthetic or other reasons including for environmental protection, which the developer expects to hand to council for ongoing maintenance, justification must be provided on how this will fit into any lighting master plans for the area. Without approval council gives no guarantee that this infrastructure will be adopted by council, and if it is adopted, that it will be maintained in that form. Any "non standard" road lighting would be on a Rate 3 Tariff.

Editor's note—council does not support shading of lights on the basis that it would be a penalty to road users, particularly cyclists and pedestrians.

(a) Road lighting in rural residential areas
Flag lighting is to be provided at:

(i) all intersections on roads;

(ii) on curves where the advisory speed through the curve is 15 km/h lower than the gazetted speed limit of the road; and

(iii) at the ends of cul-de-sacs.

A maximum 150W luminaire should be used at a mounting height of 10.5m.

Lighting on roads under the control of the Department of Transport and Main Roads must be designed to meet their requirements.

(b) Road lighting in urban areas
Lighting must be provided in accordance with the relevant sections of AS 1158 and the following:

(i) Category V3 Lighting on arterial and sub-arterial roads;.

(ii) Category V5 Lighting on major collector streets;

(iii) Category P4 Lighting on, access Streets, access Places, industrial streets, and commercial precincts unless otherwise determined by council, e.g. higher lighting levels to assist with CCTV surveillance; and

(iv) lighting in public transport infrastructure (compliance to the *Disability Standards for Accessible Public Transport 2002*).

(c) Lighting for bicycle, pedestrian and shared paths
Lighting Category P1 – P4 for bicycle, pedestrian and shared paths as advised by council after consideration of location, hours of use and risk to the public.

(d) Lighting for parks
Lighting requirements for parks will be determined by council based on where the park fits into the hierarchical structure. A point of supply is required to most parks and where required, the precise location of the supply will be advised by council. This lighting may have a sub-metered supply.

(e) Lighting for sports grounds and sports complexes
Lighting requirements for sports grounds and sports complexes will be determined by council based on where the park fits into the hierarchical structure.

A point of supply is required to most parks and where required, the precise location of the supply will be advised by council.

(f) Lighting for public buildings and spaces
Lighting requirements for public buildings and spaces will be determined based on a risk assessment considering location, time of use, number of people, relevant building codes and AS/NZS 1158.

(g) Lighting for off-street car parks.
Lighting must be provided in accordance with the relevant sections of AS 1158. A point of supply is required to most off-street car parks. Lighting shall be provided in accordance with the lighting master plan for the area, unless otherwise approved by council. This lighting must have its own separate metered point of supply.

(3) New subdivision marketing banners on light poles

It is common practice for developers to place marketing banners on light poles along local roads within the boundary of the new subdivision. Banners are lightweight and made of a non-rigid material.

The developer must obtain approval from Ergon Energy to erect marketing banners on light poles and comply with all Ergon Energy conditions. Banners on light poles must not be a driver distraction on the road or at an intersection. Banners must not interfere with an official traffic sign, distract a drivers attention at a critical time, obscure the drivers view of a road hazard, give instructions to stop, imitate an official traffic sign, nor be an obstruction to the road or a hazard to all other road users. A high level of safety for road users must be maintained.

At the time of on maintenance council may accept the marketing banners on light poles, but the developer must indemnify council for all matters arising from the banners erected on light poles. The banners may remain on the light poles for twelve (12) months. If banners are required beyond this time then the developer must

submit a request to council for a twelve (12) month extension of time. Council may request the developer to remove any marketing banner on any light poles at any time.

Editor's note – there may be additional related requirements in Subordinate Local Law No. 1.4 (Installation of Advertising Devices) 2011.

Council will not give consent for advertising banners to be placed on street lights that are owned and maintained by council.

SC6.4.3.20.3 Utility services

(1) All utility services are to be underground.
All services to new developments must be constructed underground unless otherwise approved by council.
Layout plans for all service installations must be submitted to council as part of the developmentapplication.

(2) Alterations to existing services
Care should be taken during the design to avoid other existing underground services, and where this is unavoidable it will be the developer's responsibility to undertake the necessary alterations to the satisfaction of the asset owner at the developer's cost.

Where it is necessary to install conduits under existing roads, this installation must be undertaken by boring unless otherwise approved by council.

Telecommunication cabinets and electricity supply pillars
The proposed location of on street telecommunication cabinets and electricity supply pillars must be shown on plans and be located clear of access driveways to properties, and clear of any water and gas services in accordance with any requirements of the relevant authority.

(4) Electricity supply general
An overhead supply approved by the relevant energy authority where in the rural residential zone, special purpose zone or high impact industry zone or where on a lot of less than 2,500 m^2 within an area where the existing supply is overhead is acceptable.

In exceptional circumstances, remote access properties in the rural zone may be permitted provide an electricity supply that is not connected to the grid. It shall be demonstrated by the applicant that an adequate and reliable supply that maintains standards for safety, environmental, health and amenity is achievable. Acceptable alternatives may include solar or other similar self-generating system.

Electricity and/or telecommunications services must be designed in accordance with the relevant utility provider's guidelines. Electricity design plans submitted to council with an RPEQ certification are only accepted by council to permit the utility provider (e.g. Energy Queensland) to formally approve the design.

In the construction phase only conduits for both electricity and telecommunications utilities are installed, with the relevant utility provider installing the actual service after the works are complete.

(5) Gas supply
Where it is proposed to provide a reticulated gas supply to a development, the gas service pipe must be installed in the verge or footpath on the alignment shown on SC6.4.4.8 Standard drawings.

If a storage cylinder is proposed as part of the development, the cylinder must be installed and maintained on a separate freehold parcel of land in accordance with all safety regulations contained in the AS/NZS 1596 *The storage and handling of LP gas*. Details for servicing the gas cylinder must be provided to council as part of the development application.

SC6.4.3.21 Townsville Water planning and design guidelines

SC6.4.3.21.1 Introduction

(1) General

This sub-section has been developed by the Programs and Technical Support (PATS) department within Townsville Water and Waste, to document the procedures undertaken during the delivery of their services.

(2) Intent of the sub-section

This sub-section has been developed to detail relevant information pertaining to planning and design projects and to collate Townsville Water and Waste practices not documented elsewhere. Its intended use is as a reference manual for:

(a) internal Townsville City Council staff including Townsville Water and Waste and Planning and Development (Infrastructure Planning Unit and Development Assessment);

(b) external consultants engaged to perform specific commissions; and

(c) developments that include water and wastewater infrastructure.

(3) Application

These guidelines shall apply to sewerage and water supply distribution, collection, pumping and treatment and effluent reuse in the areas of:

(a) planning;

(b) design;

(c) technical specifications for approval;

(d) preparation of technical contract documentation; and

(e) collection and submission of as-constructed details.

It excludes: information on the presentation of drawings.

(4) Purpose

The purpose of these guidelines is to ensure that:

(a) all water supply, sewerage and effluent reuse works are designed and constructed to common standards throughout Townsville city, and comply with codes and standards established by the relevant government authorities;

(b) the reticulation and pumping systems provided are hydraulically adequate for the demands from the currently planned stage of development within any particular Water Supply/Sewerage Scheme at any point in time;

(c) the total system of reticulation pumping and treatment is progressively developed with adequate capacity to meet the ultimate requirements of the particular Water Supply/Sewerage Scheme; and

(d) the quality of water supplied and the quality of effluent disposed by Townsville Water and Waste meets acceptable minimum standards established by the relevant government authorities.

(5) Triple bottom line

Any new works undertaken by Townsville Water and Waste and development must meet the requirements of a triple bottom line approach to sustainable development, and be economically, environmentally and socially viable.

(6) Acceptance of designs and documentation

The design of infrastructure shall comply with the requirements that are detailed in Townsville Water and Waste's Total Management Plans where relevant.

Externally produced designs and documentation including drawings shall be certified by a Registered Professional Engineer of Queensland (RPEQ).

SC6.4.3.21.2 Water supply design

(1) Introduction

(a) Scope

The work to be carried out under SC6.4.3.21.2 includes the design of a water supply system either as a stand-alone project or as part of a development.

(i) Inclusions

SC6.4.3.21.2 covers the design of:

(A) pump stations;

(B) storage reservoirs;

(C) water mains – including trunk and reticulation mains; and

(D) property connections.

(ii) Exclusions

SC6.4.3.21.2 does not cover requirements for:

(A) bulk water storage – dams etc.; and

(B) water treatment plant design considerations.

Bulk water supply infrastructure will be planned and designed by council in conjunction with experienced specialist consultants.

(b) Documents

(i) Reference and source documents

SC6.4.3.21.2 is to be read in conjunction with the current version of the following documents.
Australian Drinking Water Guidelines (National Health and Medical Research Council)
Planning Guidelines for Water Supply and Sewerage, Department of Energy and Water Supply (*DEWS Guidelines*)
(WSA 03) Water Supply Code of Australia
Workplace Health and Safety Queensland, *Safe Design of Structures – Code of Practice*

(ii) Document precedence

The order of precedence (highest to lowest) of documents shall be:

(A) SC6.4.4.8 Standard drawings;

(B) this sub-section;

(C) WSA 03; and

(D) DEWS Guidelines.

(c) Standard drawings

SC6.4.4.8 Standard drawings shall be read in conjunction with this sub-section. Standard drawings other than water and sewerage (such as road crossings) also contain information on water and sewerage infrastructure and shall also be referred to.

(i) Amendments to WSA 03

The design of water supply systems shall comply with *WSA 03 Water Supply Code of Australia* unless otherwise specified herein, and shall be constructed in accordance with *WSA 03 Water Code of Australia Construction Specification.* Amendments required by Townsville Water and Waste to WSA 03:2011 are included in Table SC6.4.3.21.1. Any conflicting information in later codes shall be referred to Townsville Water and Waste for clarification.

Table SC6.4.3.21.1 Amendments to WSA 03:2011 – Water Supply Code of Australia

WSA 03 Section	Amendments to WSA 03 – Water Supply Code of Australia:
2.3	Demand parameters are set in SC6.4.3.21.2(2). Variations from these parameters are to be approved by Townsville Water and Waste.
Figures 2.1(a) and 2.1(b)	Dead end mains are not permitted.
2.4	Minimum mains sizing – DN100 (with fire service provision) on one side of the street, in conjunction with DN63 (rider main) to the other side.
2.5.3	Minimum service pressure shall be 22 m at the service connection under peak flow conditions, with a minimum service flow rate of 30 L/minute.
2.9	Storage reservoirs shall be sized to not empty under 7 consecutive days of 95% peak day demands.
3.1.5	Water supply systems shall be designed for fire fighting capability in accordance with parameters set out in Table SC6.4.3.21.3.
3.3 and 3.8	Minimum Class of pipe shall be PN16.
4.7	GRP pipe is not permitted.
5.6	Shared Trenching is not permitted without prior written approval.
5.10	Dead end mains are not permitted.
5.11 and 15.8	Property Service and Water Meters shall only be installed by Townsville Water and Waste upon application.
9.2.2	Longitudinal section drawings shall be provided for water mains DN200 and above.
14.2, 16.0	Pipe embedment and support: For flexible pipes refer to AS2566.2, Tables G1, G2 and G3 for suitable material types.
15.20.1	An access hatch is required on the steel main to reinstate cement mortar lining.

(2) Water supply planning

(a) Scope

Water supply system planning covers the requirements of the water distribution and reticulation system from the bulk supply system to the service connections. This includes pump stations, storage reservoirs, trunk water mains, and reticulation mains.

(b) Hydraulic loading assessment

(i) General

Hydraulic loadings shall be determined in terms of equivalent persons (EP) and developed into flows using the unit loading factors and peaking factors detailed in the following sections.

(ii) Equivalent population estimations

The ultimate equivalent population (EP) used to determine design flows shall be determined from the following:

(A) designated value of EP per hectare for each zone type provided in Section 4.2.11 of Part 4 of Townsville City Plan;

(B) the location of various zone types as specified in Townsville City Plan;

(C) an assessment of the ultimate population, including the expected peak occupancy rates and the quantity of undeveloped land for each zone type listed in Townsville City Plan; and

(D) estimation of contributing loads for “Special Purpose” zonings (university, refineries, hospitals, etc.) shall be determined by an analysis of historic consumption and consultation with the institution regarding future development.

Editor's note - Where staging of the works is necessary, the planner is to consider the expected growth rate for the area to develop loadings for intermediate planning horizons. This shall be based on the Townsville City Council Growth Model which is available from Planning and Development (Infrastructure Planning Unit). This model is based on population projection information available from the Planning Information Forecasting Unit (PIFU), Office of Economic and Statistical Research within the Queensland Government, Department of Treasury and Trade.

(iii) Design flows

Peak demands are to be calculated from Table SC6.4.3.21.2.

Table SC6.4.3.21.2 Water supply unit demand parameters

Parameter	Unit Demand	Peaking Factor
Average Day (AD)	600 L/day/EP	
Mean Day Max Month (MDMM)	900 L/day/EP	1.5 AD
Peak Day (PD)	1125 L/day/EP	1.25 MDMM
Peak Hour (PH)	0.033 L/s/EP	2.56 PD

In addition to the residential demand, the AD irrigation demand is 60L/EP.

(iv) Design criteria

Water supply systems shall be sized in accordance with the requirements of:

- *Planning Guidelines for Water Supply and Sewerage.*

The design criteria for water supply infrastructure are summarised in Table SC6.4.3.21.3.

Table SC6.4.3.21.3 Water supply infrastructure design criteria

Design Criteria	Value
System Pressure NB: measured immediately upstream of the customer's water meter not downstream of water meter. Max Head loss through a water meter is 25kPa i.e. 2.5 m (AS3565.1)	
Minimum Operating Pressure	22 m to the meter
Maximum Operating Pressure	80 m to the meter
Fire Fighting Requirements	
System Pressure	12 m minimum at the property boundary and any point within the system
Fire Flow	Rural Residential (Zone 1 or 2) – 7.5L/s Residential – 15 L/s Commercial and industrial – 30 L/s
Background Demand	PH > 3,000 person communities 2/3 PH < 2,000 person communities Linear interpolation between 2/3PH and PH for 2000 and 3000 persons communities
Reservoir level	Mid-water level
Reservoir Storage	
Ground Level Storage	7 days of 95% PD Demand; Cases where inflow is MDMM Demand this equates to:- 7*(0.95*1.2*MDMM-MDMM) = 1.31 MDMM
Elevated Storages	6*(PH-1/12 MDMM) + Fire fighting reserve (150 kL)
Pumping Capacity	
Duty Pump Capacity	Sized for MDMM flows with 20 hours operation
Pumps serving Elevated reservoirs	(6*PH-Operating Volume)/(6*3600)
Standby pump capacity	To match the capacity of the largest pump in the station

Design Criteria	Value
Pipeline Design	
Pipe Capacity - Distribution Mains	Sized for MDMM flows.
Pipe Capacity - Reticulation	Based on peak instantaneous demands; of PH and Fire Flow.
Fire Services Pumps	TWW preference is for pumped fire services to be connected downstream of a fire tank. If fire pump is directly connected to the water reticulation main applicant must provide evidence that the selected pumps will not have adverse impact on the surrounding network.

Friction factors to be adopted for the pipe network modelling are detailed in Table SC6.4.3.21.4.

Table SC6.4.3.21.4 Hazen Williams pipe friction coefficients

Mains	Diameter (mm)	Adopted "C" Values	
		Cement Lined Pipe	Plastic Pipe
Distribution	< 300 300-600 > 600	110 120 125	130 140 150
Reticulation	<= 150 225 – 300 > 300	100 110 120	120 130 140

(c) Network planning

(i) Purpose

The purpose of network planning is to determine the most effective means of providing a service to an area through analysis of both infrastructure and non-infrastructure based solutions. The determination of the most effective solution should be made through analysis of whole of life costs and consideration of non-financial aspects such as operations, maintenance, and environmental obligations.

Section SC 6.4.3.21.2(2)(c) details the circumstances under which a network plan should be prepared.

When preparing planning reports for both water and sewerage assets, the author shall refer to Section 6 of the DEWS *Planning Guidelines for Water and Sewerage.*

(ii) Network modelling

A water network model is required for all code or impact assessable material change of use (MCU) and reconfiguring a lot (RoL) applications where:

(A) new trunk and/or reticulation mains are to be constructed as part of a development;

(B) the development requires trunk infrastructure identified in council's Plans for Trunk Infrastructure to be constructed ahead of its planned date, or out of sequence identified in master planning;

(C) the proposed land use results in an increase in demand greater than what is presently allowed for Townsville City Plan; or

(D) water mains are required to be relocated or reconfigured as part of the proposed works, and these works are expected to change the hydraulics of the existing supply.

TCC also requires the development of a network model for:

- the preparation of Infrastructure Master Plans; and
- the preparation of Priority Infrastructure Plans (and Plans for Trunk Infrastructure).

Network modelling shall be undertaken in accordance with SC6.4.3.23 Water and sewerage network modelling guidelines.

(iii) Levels of assessment

Depending on the type of works in question, simplified or detailed modelling may be required to demonstrate compliance with these guidelines. Simplified or detailed assessments are defined below:

(A) "Simplified Assessment" – an assessment that demonstrates network capacity through manual calculations, or through the use of simplified network models (schematic style models); and

(B) "Detailed Assessment" – an assessment involving the preparation of detailed network models based on proposed design and/or development layouts.

SC6.4.3.23 Water and sewerage network modelling guidelines outline the process to be followed to obtain council advice as to what level of assessment is required.

(iv) Timeframes

Master planning shall be undertaken over a 30 year timeframe. The capacity of the existing network to service ultimate demand should be assessed and any system augmentations to service ultimate requirements identified. The staging of infrastructure works is an essential consideration and should be incorporated into the planning and design process. Staging of infrastructure works should be also considered at no greater than 10 year intervals until the ultimate horizon.

For developments being completed in less than a 5 year timeframe, network modelling shall be undertaken for existing case, and full development.

Council may request that master planning consider provision to adjacent developments to enable an efficient trunk network.

Net present value cost analysis should be undertaken using a range of interest rates (typically 3%, 5% and 7%), as well as the rate for weighted annual cost of capital (WACC) which can be sourced from council. Timeframes of 10, 20, and 30 years shall be applied.

Longer timeframes will enable assessment of the impacts of major replacement and upgrade works on the viability of the system. Council may require longer timeframes for analysis.

Cost assessments should only consider an engineering cost assessment, with loan interest and depreciation considered separately by council when considering a business case for a particular project. The following on-cost allowances should be made:

Establishment	2%
Project management/engineering design/council management costs	15%
Contingency	30%

(3) Bulk water storage and water treatment

(a) General

New bulk water storages and storage upgrades, new water treatment process design and upgrades are complex and site specific, and are typically undertaken as one-off projects and performed by experienced designers/consultants with the necessary qualifications, specialist skills and experience to carry out the planning, assessment, design and delivery processes for the project.

Generally, Townsville Water and Waste will prepare a detailed design brief and requirements for the engagement of specialist consultants suitable to carry out the project.

(b) Re-chlorination

At locations within the distribution system it may be necessary to re-chlorinate the water supply to maintain the free chlorine residual within the target range of 0.5 – 1.5 mg/L.

Re-chlorination stations should be located either at pump stations or at reservoir sites.

For safety, re-chlorination stations are to be fitted with appropriate signage and alarms to comply with

work, health and safety codes and requirements.

(4) Pump stations

(a) General

This section covers the design of:

(i) bulk water supply pump stations to service reservoirs; and

(ii) smaller booster pump stations to boost pressure in the distribution system. Booster pump stations should be avoided wherever practical by appropriate reticulation design, and will only be permitted with written approval by Townsville Water and Waste.

(b) Capacity and pump sizing

(i) Pump station capacity

Pump stations shall be sized to meet the system requirements for the planning horizon. Multiple pump units can be used to achieve the required pump duty.

(ii) Booster pump stations

Pump stations acting as reticulation boosters will supply the range of flow and head duties from Minimum Flow to Peak Hour conditions.

(iii) Hydraulic analysis

Hydraulic analysis is to be used to determine the flow and head requirements for the pump station.

(iv) Pump and rising main sizing

Pump size in combination with the delivery main size is to be designed to minimise whole of life costs covering capital, operating and maintenance costs.

(v) System resistance curves

System Resistance Curves covering all expected duties of the pumps, including maximum and minimum head cases shall be prepared. A net positive suction head available (NPSHA) curve shall also be prepared.

(vi) Pump selection

Pump selection shall achieve all expected duties as per the system resistance curves.

Redundant (standby) pump capacity shall be provided. Standby pump capacity shall be at least equal to the capacity of the largest pump unit.

(c) Building structure and general arrangement issues

(i) Materials

Pump stations shall be contained in above ground structures, constructed from reinforced masonry block and/or reinforced concrete walls with concrete or metal (Colourbond) roofs.

In undeveloped areas metal clad buildings may be acceptable subject to suitable compliance with noise emission requirements and adequate site security/vandalism restraint, and with approval from Townsville Water and Waste (See SC6.4.3.21 Attachment C).

(ii) Buildings general

(A) Permits – a development permit is required for building work (IDAS Form 2) for permanent pump station buildings.

(B) Location - pump station location and visual appearance shall be approved by Townsville Water and Waste, and shall generally complement the amenity of the local area. Pump stations in built-up areas should have appropriate external appearance to match the surrounds.

(C) Security – pump station shall be secure, and protected against vandalism, vermin and birds. Buildings shall be designed for Importance Level 3 (minimum) in accordance with the *Building Code of Australia* Table B1.2a as well as with designs shown in SC6.4.3.21 Attachment C.

(D) Level – pump station floor to be located a minimum of 300 mm above 1% AEP flood level,

be subject to a flood risk assessment, and shall be approved by Townsville Water and Waste.

(E) Noise management – pump stations shall be designed to comply with the relevant noise emission legislation, regulations and policies.

(F) Ventilation – ventilation or air-conditioning where required shall be provided as necessary to control heat from equipment within the building. Independent ventilation of chlorinator rooms shall be provided to meet work, health and safety requirements.

(G) Internal drainage – provision shall be made to drain leakage/flows from pumps/pipework away from the building without flooding of switchboards and electrical components.

(H) Safety – Pump station structures shall be designed in accordance with Safe Design of Structures – Code of Practice.

(iii) Structure sizing
Pump stations structures shall be sized to:

(A) provide adequate access around all pumps and associated pipework, generally 1 m minimum clearance and for maintenance access to pumps, pipework, valves etc.;

(B) house the pump station electrical switchboard and telemetry;

(C) house necessary cranage (see also (v);

(D) house chlorination systems (where required) – a separate room is generally required for chlorination systems, independently ventilated; and

(E) wherever practical the pump station structure shall be sized to accommodate the pumps and equipment necessary to achieve the proposed ultimate pump station capacity.

(iv) Site access
All weather sealed access for maintenance vehicles shall be provided, including:

(A) sealed asphalt access road, minimum pavement width 4 m;

(B) provide access during a minimum 1% AEP flood event; and subject to a flood risk assessment;

(C) on-site turn-around for maintenance vehicle; and

(D) road geometry suitable for use by light vehicles and single axle trucks.

(v) Lifting requirements
Design of the building shall enable the use of mobile cranes for lifting of pump units, motors and other equipment.

Where this is not possible, permanent cranage is to be provided within pump stations to allow maintenance of equipment, consisting of a minimum of a monorail crane accessing the pumps and motors. Set-down areas shall be provided:

(A) within the pump station adjacent to large maintenance doors where the area can be accessed externally by a crane truck; or

(B) externally by extending the monorail outside the building to allow loading onto the back of flat bed vehicle (bed height 1.2 m).

(d) Pipework

(i) Each pump shall be provided with suction and discharge isolation valves and a non-slam non-return valve on the pump discharge.

(ii) At least one easily removable piece of pipework is required on each pump to enable efficient removal and replacement.

(iii) Steps and walkways in accordance with AS1657 Fixed platforms, walkways, stairways and ladders - Design, construction and installation shall be provided over pipework such that access is readily available to both sides of each pump.

(e) Disinfection system

(i) Chlorine residual booster stations shall be provided when required.

(ii) Chlorine dosing will be by the use of sodium hypochlorite solution or chlorine gas. Dosing control (either flow paced, fixed rate or other) is to be approved by Townsville Water and Waste.

(iii) Sodium hypochlorite or chlorine gas storage and dosing equipment shall be housed in a separate room, independently ventilated. The chemical unloading, storage and dosing facility should comply with the handling and safety requirements for the chemical.

(iv) Chlorine dosing should be into the pump station discharge pipework.

(v) A safety shower and eyewash facility and appropriate signage is to be provided to meet work, health and safety requirements.

(f) Power supply and telemetry/instrumentation

(i) Power supply for the site shall be provided in accordance with the requirements of SC6.4.3.21.4.

(ii) Backup power is not normally provided within water pump stations. Where deemed necessary emergency power shall be provided in accordance with SC6.4.3.21.4.

(iii) Telemetry/instrumentation - All pump stations shall be provided with telemetry monitoring. Reticulation system booster pump stations typically are controlled to maintain a constant pressure at the pump station discharge. Pump stations are normally monitored but not controlled by the Telemetry system. Control of the pumps is performed locally.

(g) Land tenure

The required land tenure for a pump station site is council-owned freehold title.
The land tenure for access to the pump station in order of suitability is:

(i) public road; or

(ii) council-owned freehold land; or

(iii) water supply easement in the name of Townsville City Council.

(5) Storage reservoirs

(a) Scope

This section covers the design of water supply reservoirs, including the requirements for on-ground storages and elevated tanks on steel tank stands.

Refer to SC6.4.3.21.2(5)(c) for structural design of reservoirs.

Editor's note–Townsville Water's Program and Technical Support maintains a set of internally used Standard Drawings for Reservoirs, which can be made available on request.

(b) Site

(i) Location selection

Selection of reservoir site shall be approved by Townsville Water and Waste and shall consider the following:

(A) proximity to the area(s) to be served and length of mains necessary to supply into the reservoir and distribute to the service area;

(B) elevation of land to achieve required top water level (TWL) and bottom water level (BWL), and minimum operation level for the reservoir;

(C) environmental impacts, including visual impact;

(D) access to site;

(E) ability to achieve required land tenure;

(F) geotechnical issues;

(G) impacts on other services and infrastructure;

(H) landscaping of the site should be provided where necessary to minimise the visual impact of the facility; and

(I) where the reservoir is not readily accessible from a public road, particular attention to the

following criteria is required:

- vehicle access and site manoeuvrability;
- access road cross section and drainage; and
- width of land required for access road.

(ii) Visual appearance

The location and visual appearance shall complement the amenity of the local area.

If deemed necessary, a landscape architect shall be engaged to design fast growth plantings to provide a visual screen.

(c) Reservoir tank design

(i) Size and design life

The reservoir and associated inlet and outlet pipes shall be sized in accordance with the planning requirements of this section.

The reservoir design life shall be 80 years minimum.

(ii) General arrangement

Reservoirs shall be circular where possible to provide the most economic construction.

Foundations – the entire tank structure shall be founded on undisturbed parent material. Founding on fill material is not permitted.

The reservoir shall include, but not be limited to:

(A) steel floor, walls and roof support columns:

- a zincalume (or Colourbond Ultra) double sided coated roof on zincalume coated steel purlins (with down-turned lip on bottom flange) and beams;
- inlet and outlet pipework with valves;
- scour pipework with valve;
- overflow pipe;
- lockable access ladders (external only);
- fall arrest system for safe roof access in form of a permanent static line from roof access hatch platform to centre of reservoir;
- davit arm provision for vacuum cleaning by divers;
- telemetry control and monitoring;
- flow meter;
- level sensor;
- natural vermin proof roof ventilation; and
- telemetry control on inlet valve.

(B) all reservoirs shall be roofed and made vermin and bird proof. Drainage from the roof shall not enter the tank; and

(C) personnel access – access shall be provided into the reservoir:

- external access consisting of a galvanised steel ladder to AS 1657;
- lockable roof access opening minimum dimensions 1 m x 1 m;
- minimum one wall access hatches with sampling tap; and
- external accesses shall incorporate features to prevent use by unauthorised persons.

(iii) Materials

The following applies:

(A) the reservoir shall be constructed from plate steel;

(B) steel reservoirs shall be cathodically protected; and

(C) painting – the interior and exterior of the reservoir shall be painted with an approved epoxy paint system, approved for immersion in potable water supply. Colours will be advised by Townsville Water and Waste.

(iv) Pipework

The following applies:

(A) reservoirs shall be provided with separate inlet and outlet pipes, on opposite sides of the reservoir tank to achieve circulation. the inlet shall have a bend to facilitate circulation;

(B) a control valve shall be provided on the inlet pipework where specified by Townsville Water and Waste;

(C) a non-return valve shall be provided on the outlet pipework only where specified by Townsville Water and Waste;

(D) scours shall be sized to enable the reservoir to be completely drained from full within 24 hours. Scours are to be specified to stormwater; and

(E) an overflow capable of carrying the ultimate design inflow shall be provided, with connection to scour pipework.

(d) Geotechnical

Geotechnical investigations shall be undertaken for reservoir sites to ascertain sub-surface conditions for the tank design and for stability of batter slopes. Founding must be on undisturbed ground. Construction on fill is not permitted. The following must be taken into consideration:

(i) slope stability for the reservoir site;

(ii) site excavation;

(iii) stability of excavation batters; and

(iv) design parameters for the access road pavement.

(e) Security

Fencing is required around reservoir sides. Refer to SC6.4.3.21.5(4) for details.

(f) Telemetry/instrumentation

Minimum telemetry monitoring requirements for reservoirs should be reservoir level by submersible pressure transducer.

(g) Land tenure

The required land tenure for reservoir sites is council-owned freehold title.

The land tenure for access to the reservoir site in order of suitability is:

(i) public road; or

(ii) council-owned freehold land; or

(iii) reserve for water supply purposes; or

(iv) water supply easement in the name of Townsville City Council.

(6) Water mains

(a) General

(i) Scope

This section covers the design of distribution and water supply reticulation mains:

(A) distribution mains – provide for the transfer of bulk water between treatment and storages infrastructure within the water supply network; and

(B) reticulation mains – provided for supply from the bulk water system to consumers through the reticulation network.

(ii) Extent

Mains shall be provided to service all properties within the development and where relevant also include bulk mains to service the declared water service area.

(b) Water main sizing

(i) Demands

Mains shall be sized to meet demands (including fire flows).

(ii) Network modelling and whole of life costs

Where specified by Townsville Water and Waste, appropriate network modelling shall be

undertaken to determine mains sizes within the development.
Where distribution mains are pumped, the main size is to be determined in conjunction with the pump size to minimise whole of life costs for the system including capital, operating and maintenance costs.

(c) Mains layouts and general arrangements

(i) Configuration

(A) Distribution mains shall comply with the following:

- configuration and extent of the main is to be determined to suit the requirements of the ultimate development to the approval of Townsville Water and Waste; and
- connections to reticulation mains network and consumers are not permitted, unless required under the project and approved by Townsville Water and Waste.

(B) Water reticulation mains layout shall comply with the following requirements:

- water mains are required down both sides of roads where service connections are provided. Cross-road service connections are not permitted, except in the Rural residential zone where a main on one side of the roadway is acceptable;
- Low density residential zone and Character residential zone streets shall have a minimum of DN 100 (with fire hydrants) on one side of the street and a minimum of DN 63 PE service main on the other;
- water mains (DN100 minimum with fire hydrants) are to be provided on both sides of the road in the cases of divided carriageways, centre, industrial, and medium or high density residential zones. In centre, industrial or high-rise building areas, one of the mains in the street shall be DN150 minimum; and
- permanent dead end mains are not permitted.

(ii) Temporary dead ends are not permitted for more than 12 month defect liability period, temporary loops are to be installed prior to end of defect liability period. Temporary ends/loops are to be design to allow for future connection without shutdown to existing residents, which may include in-line thrust block, valve and FH.

The location for water mains in order of preference is in:

(A) council controlled roads; or

(B) main roads controlled by State or Federal Governments; or

(C) reserves and unallocated state land; or

(D) council owned freehold land; or

(E) easements in privately owned freehold land.

Distribution mains alignment shall be as follows:

- the alignment of distribution mains is to be resolved with the appropriate control authority for the road, land or easement, and approved by Townsville Water and Waste.

Reticulation mains alignment shall be as follows:

- the alignment within a road reserve shall be in accordance with SC6.4.4.8 Standard drawings SD-015 Verge Service Corridors, General Type, Sections.

(iii) Cover requirements

Cover requirements shall comply with WSA 03 (Section 5.4.2) plus:

(A) distribution mains – minimum cover is to provide for the structural integrity of the pipe, meet the requirements of the appropriate control authority for the road, land or easement; and

(B) reticulation mains:

- minimum pipeline cover requirements for water mains shall be in accordance with standard drawing SD-325 Embedment and Trench Fill, Typical Arrangement; and
- maximum cover for maintenance purposes – 1.5 m.

(iv) Services and alignments

Consideration is to be given to other services in the area when selecting alignments.

Refer to WSA 03 Table 5.5 and SC6.4.4.8 for minimum clearance requirements from other services.

Minimum clearance requirements and/or conditions may be imposed by the service owner. Specific conditions apply to construction near services including:

(A) fibre optic cables;

(B) high pressure gas or oil mains;

(C) underground power; and

(D) overhead power - consider overhead power when selecting pipeline alignments for:

- safety and clearance issues with construction under or near overhead power lines; and
- the designer should avoid locating continuously welded steel pipelines in parallel to high voltage power lines (WSA 03, Section 5.4.12).

(v) Shared trenches

Shared trenching of water mains with other services will not be permitted without approval from Townsville Water and Waste.

(vi) Easements

Easements shall be taken over water mains constructed in private property.

The easement width shall be a minimum 3 m. For >DN375 mains, easement width shall be approved by Townsville Water and Waste.

Easement corridor widths shall be suitable to accommodate all water mains for the ultimate development, and approved by Townsville Water and Waste.

(d) Pipe

(i) Materials

Allowable pipe materials include:

(A) PVC-U, PVC-O, PVC-M (OD compatible with DICL fittings);

(B) ductile iron cement lined (DICL);

(C) mild steel cement lined (MSCL);

(D) ABS;

(E) polyethylene (PE);

(F) copper; and

(G) stainless steel.

Pipeline materials shall be in accordance with WSA 03.
Pipe shall be minimum pressure class of PN16 for all pipe sizes.

(ii) Pipe design

Pipeline material structural design shall be undertaken in accordance with WSA 03 for all internal and external loads applied to the pipeline.
The “PN” rating shall be selected to suit the pipeline design pressures.

In selecting the PN rating for plastic pipes, pressure de-rating for transient loads (water hammer) and temperature shall be taken into account (refer to WSA 03*).*

(iii) Pipe jointing

Pipelines should generally be rubber ring jointed. Mild steel cement lined pipes will normally be rubber ring jointed unless there are specific reasons for installation of continuously welded pipe segments. PE pipe shall be connected by butt thermal fusion or by electrofusion couplings. Up to 50 mm ID PE pipe may use compression fitting connections.

The following applies for flanged Joints:

(A) Flanged pipework shall be used where necessary at connections, to transfer thrust, or provide beam action for the pipeline to span;

(B) Flange classes shall be selected to suit the pipeline design pressures; and

(C) Flange classes shall be to AS/NZS 4087 *Metallic flanges for waterworks purposes* except where connecting to existing flanges from a different standard. Minimum flange classes shall be:

- Class 14 for Steel Cast Iron; and
- Class 16 for DICL.

(iv) Pipe anchorage

Water mains with unrestrained flexible joints shall be designed to resist the total unbalanced thrust and transmit all thrust loads to the adjacent native soil or rock.

Pipe anchorage and thrust blocks shall be provided in accordance with WSA 03.

Alternatively, TYTON-LOK joints or similar may be approved by Townsville Water and Waste in special circumstances. Marker tape shall be provided above the pipe to clearly show the extent of the restrained jointing.

(v) Concrete encasement

Concrete encasement of pressure mains is not permitted without written approval of Townsville Water and Waste.

(vi) Above ground water mains

Above ground construction is to be approved by Townsville Water and Waste.

Where a section of water main is to be laid above ground, the pipe materials, support and restraint for the pipes and fittings shall be in accordance with WSA 03, and the pipe manufacturer's recommendations.

(vii) Cathodic protection

Cathodic protection (CP) for steel mains laid through corrosive environments may be required if specified by Townsville Water and Waste.

CP shall be designed by an experienced specialist in accordance with WSA 03.

(viii) Pipe bedding

Pipe bedding for water mains shall be in accordance with WSA 03.

(ix) Restoration

Refer to WSA 03 for construction specification.
For restoration under roadways refer to standard drawing SD-055 Road Crossing and Footpath Reinstatement for Trench Laid Services.

(x) Geotechnical

Geotechnical matters shall be considered in accordance with WSA 03.

(xi) Trenchless construction

Where specified by other infrastructure owners or Townsville Water and Waste, trenchless construction methods may be required. Circumstances requiring trenchless construction methods may include:

(A) crossing of major roads;

(B) where the land controller specifies (e.g. rail and main roads); and

(C) crossing environmentally sensitive areas.

The designer is to provide the details of trenchless construction techniques proposed.
QR National requires compliance with their Specification: *MCE-SR-16 Requirements for Services under the Railway Corridor (Non-QR Services)*. Common forms of trenchless pipeline construction include:

- pipe jacking;
- horizontal direction drilling; and
- micro tunnelling.

The designer shall identify where trenchless construction techniques are necessary or economical during the design process.

(xii) Road and rail crossings of existing pipes

Road crossings for existing above ground pipes shall comply with the requirements of the standard road crossing drawing provided in SC6.4.3.21 Attachment B. Rail crossings will be designed on a case by case basis.

For existing underground pipes where road/rail upgrades or new roads/rails are proposed protection or relocation may be required. Concrete encasement may be approved on a case by case basis, preference however is for envelopers. This often is required at major road crossings, at rail crossings and sometimes at waterway crossings. Enveloper designs for road and rail crossings shall be undertaken in accordance with the Land Corridor controller's requirements. Where no specific requirements are provided refer to the standard drawings of WSA 03 and Townsville Water and Waste for further details.

The void between enveloper and carrier pipe shall be grouted at each end using low strength grout on completion of the pipe installation unless other arrangements are required by the Land Corridor controller.

(xiii) Disinfection

The designer shall specify the disinfection of all water mains after satisfactory testing in accordance with *WSA 03*.

(xiv) Pipeline drawings

Drawings shall include a Plan (1:500) for all mains, and Longitudinal Sections (1:1000 (H); 1:100(V)) for mains DN200 or greater.

(e) Pipeline appurtenances

(i) Hydrants

Hydrants shall be located such that:

(A) existing and future development lots are or will be within 40 m of the nearest hydrant;

(B) the spacing between hydrants does not exceed 80 m;

(C) hydrants are also provided at all high and low points of distribution mains and at (temporary) dead ends; and

(D) hydrants shall be located in accordance with SC6.4.4.8 Standard drawings SD-305 Street Positioning of Mains, Valves, Hydrants and Domestic Water Service connections and SD-355 Typical Valve and Hydrant Installation – Hydrants and Air relief Valves.

Hydrants may not be located within 10m of pole/pad mounted transformer.

Hydrants located within mixed commercial/residential zones must be installed on a tee with a valve to allow maintenance of hydrant without shutdown of the water main.

(ii) Stop valves

The following applies:

(A) stop valves for reticulation shall be provided in accordance with the requirements of WSA 03;

(B) stop valves shall be provided so that a maximum of ten dwellings are isolated for maintenance purposes, and a maximum of four valves to be closed to isolate any section of reticulation main (maximum of one block to be shutdown within the ten dwellings);

(C) valves shall be located to avoid conflicts with driveways, telephone house service pits, and underground electrical boxes;

(D) stop valves shall be anti-clockwise closing;

(E) maximum of 200m between valves; and

(F) stop valves are to be located on either side of a road crossing.

(iii) Valve and hydrant installation

Valve and hydrant installation shall be in accordance with the following standard drawings:

(A) SD-305 Street Positioning of Mains, Valves, Hydrants and Domestic Service Connections;

(B) SD-345 Valve and Hydrant Identification – Identification Markers and Marker Posts;

(C) SD-350 Typical Valve and Hydrant Installation – Valve Arrangement; and

(D) SD-355 Typical Valve and Hydrant Installation – Hydrants and Air Relief Valves.

(iv) Air valves

Air valves are to be provided at high points in distribution water mains. It is not normal practice to provide air valves in reticulation mains as air can be exhausted through hydrants and property connections.

Air valves shall be designed in accordance with WSA 03 and SC6.4.4.8 Standard drawings SD-355 Typical Valve and Hydrant Installation – Hydrants and Air Relief Valves.

(v) Scours

Scours shall be provided at low points in distribution mains and larger reticulation mains for maintenance purposes.

Scours are not normally provided in smaller reticulation systems. This function is performed using hydrants.

Scour design will be in accordance with WSA 03 and SC6.4.4.8 Standard drawings SD-360 Typical Appurtenance Installation – Scour Arrangement.

(vi) Pressure and flow control devices

The detailed design of a water reticulation system shall identify the need for pressure and flow control devices.

The designer shall specify, for ease of valve maintenance, fittings located within concrete valve chambers. Valve types shall be selected such that, wherever possible, servicing of the valve can be effected without its removal.

Pressure and flow control valve design shall be in accordance with WSA 03.

The designer is to refer to WSA 03 for detailing requirements for valves chambers.

(vii) Envelopers

Enveloper pipes shall be used where necessary, and as required by Townsville Water and Waste.

Enveloper designs for road and rail crossing shall be performed in accordance with the land corridor controller's requirements. Where no specific requirements are provided, refer to the standard drawings of WSA 03.

QR National requires compliance with their Specification: *MCE-SR-16 Requirements for Services under the Railway Corridor (Non-QR Services)*.
Suitable casing spacers/insulators shall be fitted to the pipe to ensure adequate spacing from the enveloper. The void at each end between enveloper and carrier pipe shall be grouted on completion of the pipe installation in accordance with SC6.4.4.8 Standard drawings SD-376 Buried crossings, Bored and jacked encasing detail.

(7) Property connections

(a) General

In most circumstances property service connections are not provided by the developer as part of the development, but are installed by Townsville Water and Waste on application from the property owner. Where small and/or narrow lots are created, and there is only one option for service connection location; or council has agreed to service connections within the road reserve or under concrete footpaths or driveways, they must be provided by the developer and located within a valve box to protect the service and to provide easy access.

(b) Property service mains

The following applies:

(i) distribution mains – Property connections from distribution mains are not permitted; and

(ii) reticulation mains – Property connections not permitted from reticulation mains > DN225. A smaller service main shall be provided for property service connections where necessary.

(c) Sub-metering

Sub-metering shall be in accordance with WSA 10 and subject to Townsville Water and Waste approval.

Point of supply for properties with sub-meters will be the master meter. Any equipment between the master and sub-meters is the responsibility of the property owner.

SC6.4.3.21.3 Sewerage system design

(1) Introduction

(a) Scope

The work to be undertaken in SC6.4.3.21.3 includes the design of a sewerage system either as a stand-alone project of as part of a development.

(i) Inclusions

SC6.4.3.21.3 covers the design of:

(A) property connections;

(B) gravity sewers;

(C) sewage pump stations;

(D) pressure mains; and

(E) reuse systems.

(ii) Exclusions

SC6.4.3.21.3 does not cover requirements for sewage treatment plant design considerations. Bulk sewerage infrastructure will be planned and designed by Townsville Water and Waste in conjunction with experienced specialist consultants.

(b) Documents

(i) Reference and source documents

This section is to be read in conjunction with the current version of the following documents.
Department of Energy and Water Supply *Planning Guidelines for Water Supply and Sewerage (*DEWS Guidelines*)*
Department of Energy and Water Supply, *Water Quality Guidelines for Recycled Water Schemes,* November 2008
National Water Quality Management Strategy, *Australian Guidelines for Water Recycling: Managing Health and Environmental Risks (Phase 1),* 2006
National Water Quality Management Strategy, *Australian Guidelines for Water Recycling: Treated sewage and stormwater to augment drinking water (Phase 2)* 2008
Public Health Regulation 2005
Workplace Health and Safety Queensland, *Safe Design of Structures – Code of Practice*
WSA 02 *Sewerage Code of Australia*
WSA 03 *Water Supply Code of Australia* (as referenced by WSA 02)
WSA 04 *Sewerage Pumping Station Code of Australia*
WSA 07 *Pressure Sewerage Code of Australia*

(ii) Document precedence

The order of precedence of documents shall be:

(A) SC6.4.4.8 Standard drawings;

(B) this sub-section;

(C) All WSA codes; and

(D) DEWS Guidelines.

(c) Standard drawings

SC6.4.4.8 Standard drawings shall be read in conjunction with this sub-section. Standard drawings other than water and sewerage (such as road crossings) also contain information on water and sewerage infrastructure shall also be referred to.

(i) Amendments to WSA 02

The design of sewerage systems shall comply with *WSA 02 Sewerage Code of Australia* unless otherwise specified herein, and shall be constructed in accordance with *WSA 02 Sewerage Code of Australia Construction Specification*.

Amendments required by Townsville Water and Waste to WSA 02:2014 are included in Table SC6.4.3.21.5. Any conflicting information in later codes shall be referred to Townsville Water and Waste for clarification.

Table SC6.4.3.21.5 Amendments to WSA 02:2014 Sewerage Code of Australia and WSA 04:2005 Sewage Pump Station Code

WSA 02 Section	**Amendments to WSA 02 – Sewerage Code of Australia:**
2.3	A sewerage Master Plan is to be submitted by the Developer for approval at the discretion of Townsville Water and Waste.
2.4.2	Townsville Water and Waste requirement is ADWF of 230 L/EP/day.
5.2.8	Easements over gravity sewers are not required in Queensland. Easements over pressure sewers may be required in certain situations. Refer to Townsville Water and Waste.
Table 7.6.5	Maximum of four internal drops into a manhole.
7.0	Maintenance Structures (Manholes (MH), maintenance holes, maintenance chambers) required at a maximum spacing of 90 m (industrial zones 40m). Maintenance Shafts (MS and TMS), are not permitted except those approved by Townsville Water and Waste.
6.4.2	Multiple property connections (i.e. combine house drains) are not lawful in Queensland
7.6.9	Ladders, step irons and landings are not permitted.
8.2	Water seals are not permitted.
8.6	Inverted Siphons are not permitted.
8.9	Wet weather storage is not required, as it is impractical in tropical conditions. However, it may be considered upon written application to Townsville Water and Waste.
4.6.2	PVC Sewer Pipe – minimum SN10 for DN100 and SN8 for other sizes is required.
Construction Section	*Internal Epoxy Coating of Manholes – normally only required at Pressure Main receiving manholes.*
Construction Section	*Pipe embedment and support – For flexible pipes refer to AS2566.2 Tables G1, G2 and G3 for suitable material types.*
Appendix B	*Estimation of EP Flows – Townsville Water and Waste's alternative method is to apply EP densities from Townsville City Council Headworks Policy (* EP per hectare for each zone type provided in Section 4.2.11 of Part 4 of the Townsville City Plan)
Appendix C	*Refer to comments above.*
General	Townsville Water and Waste's preference is to convey sewage by gravity systems only. Therefore, Townsville Water and Waste's written approval is required for a Pumping Station proposal, and its particular requirements including current electrical and telemetry standards, overflow and emergency arrangements, and compliance with Townsville Water and Waste's current Licence conditions.
WSA 04 Section	**Amendments to WSA 04-2005, Sewage Pump Station Code**
9.1.2	Minimum size of discharge pipework is DN100.
10.5.4	In selecting the PN rating, pressure de-rating for transient loads (water hammer) and temperature shall be taken into account (refer WSA 03 Planning and Design).
WSA Drawing	**Comments/Amendments to WSA Drawings**
All	These drawings shall be read in conjunction with SC6.4.4.8 Standard drawings: Where there is a conflict, the standard drawings take precedence.

(2) Sewage collection system planning

(a) Scope

Sewage collection system planning covers the requirements of the sewage collection system from service connection to treatment facility. This includes collection sewers, trunk sewers, pump stations and pressure mains.

(b) Hydraulic loading assessment

(i) General

Hydraulic loading shall be determined for all catchments being assessed. Loadings shall be determined in terms of equivalent persons (EP) and developed into flows using the unit loading factors and peaking factors detailed in the following sections.

(ii) Equivalent population estimations

The ultimate equivalent population (EP) used to determine design flows shall be determined from the following:

(A) designated value of EP per hectare for each zone type provided in Section 4.2.11 of Part 4 of Townsville City Plan;

(B) the location of various zone types as specified in Townsville City Plan;

(C) an assessment of the ultimate population, including the expected peak occupancy rates and the quantity of undeveloped land for each zone type listed in Townsville City Plan; and

(D) estimation of contributing loads for “Special Purpose” zonings (university, refineries, hospitals, etc.) shall be determined by analysis of historic consumption and consultation with the institution regarding future development.

Where staging of the works is necessary, the planner is to consider the expected growth rate for the area to develop loadings for intermediate planning horizons. This shall be based on the Townsville City Council Growth Model which is available from the Infrastructure Planning Unit. This model is based on population projection information available from the Planning Information Forecasting Unit (PIFU), Office of Economic and Statistical Research within the Queensland Government, Department of Treasury and Trade.

(iii) Design flows

The flow in a sewer comprises domestic sewage, industrial wastes, groundwater infiltration, stormwater inflows and rainfall dependent infiltration.
Design sewage flow shall be calculated in accordance with WSA 02 with the following amendments:

Design Flow(PWWF)	=5 * ADWF
	PDWF = C2 x ADWF
Where	ADWF = Average Dry Weather Flow = 230L/EP/day; PDWF = Peak Dry Weather Flow
	$C2=4.7 \times (EP)^{-0.105}$

(iv) Sewage pump station design flows

Design flows for sewage pumps stations shall be determined in accordance with SC6.4.3.23 Water and sewer network modelling guidelines.

(c) Network planning

(i) Purpose

The purpose of network planning is to determine the most effective means of providing a service to an area through analysis of both infrastructure and non-infrastructure based solutions. The determination of the most effective solution should be made through analysis of whole of life costs and consideration of non-financial aspects such as operations, maintenance, and environmental obligations.

Section 6.4.3.21.3 (2)(c)(ii) Network modelling details the circumstances under which a network plan should be prepared.

When preparing planning reports for both water and sewerage assets, the author shall refer to Section 6 of the DEWS *Planning Guidelines for Water and Sewerage.*

(ii) Network modelling

A sewer network model is required for code and impact assessable material change of use (MCU) and reconfiguring a lot (RoL) applications where:

(A) the proposed land use results in an increase in load greater than what is presently allowed for in the planning scheme; or

(B) the development requires trunk infrastructure identified in council's Plans for Trunk Infrastructure to be constructed ahead of its planned date, or out of sequence identified in master planning;or

(C) the development requires the construction of new trunk infrastructure not already identified on council's Plans for Trunk Infrastructure; or

(D) existing sewer infrastructure is required to be relocated as part of the development, and such relocation may impact the hydraulics or operational functionality of the system. End of line works are excluded from this requirement.

TCC also requires the development of a network model for:

- the preparation of Infrastructure Master Plans; and
- the preparation of Priority Infrastructure Plans (and Plans for Trunk Infrastructure).

Network modelling shall be undertaken in accordance with SC6.4.3.23 Water and sewer network modelling guidelines.

(iii) Levels of assessment

Depending on the type of works in question, simplified or detailed modelling may be required to demonstrate compliance with these guidelines. Simplified or Detailed assessments are defined below:

(A) "Simplified assessment" – an assessment that demonstrates network capacity through manual calculations, or through the use of simplified network models (schematic style models); and

(B) "Detailed assessment" – an assessment involving the preparation of detailed network models based on proposed design and/or development layouts.

SC6.4.3.23 Water and sewer network modelling guidelines outline the process to be followed to obtain council advice as to what level of assessment is required.

(iv) Timeframes

Master Planning shall be undertaken over a 30 year timeframe. The capacity of the existing network to service ultimate demand should be assessed and any system augmentations to service ultimate requirements identified. The staging of infrastructure works is an essential consideration and should be incorporated into the planning and design process. Staging of infrastructure works should be also considered at no greater than 10 year intervals until the ultimate horizon.

Council may request that master planning consider provision to adjacent developments to enable an efficient trunk network.
For developments being completed over a shorter timeframe, network modelling shall be undertaken for existing case, full development.

Net present value cost analysis should be undertaken using a range of interest rates (typically 3%, 5% and 7%), as well as the rate for weighted annual cost of capital (WACC) which can be sourced from council. Timeframes of 10, 20, and 30 years shall be applied. Longer timeframes will enable assessment of the impacts of major replacement and upgrade works on the viability of the system.

Council may require longer timeframes for analysis.

Cost assessments should only consider an engineering cost assessment, with loan interest and depreciation considered separately by council when considering a business case for a particular project. The following on-cost allowances should be made:

Establishment	2%
Project Management/Engineering Design/Council Management Costs	15%
Contingency	30%

(d) Sewerage systems

(i) General

Where possible the sewer system shall be designed to use gravity to convey the sewage.

Proposals for systems including pumping stations and rising mains require Townsville Water and Waste's written approval, including particular requirements for current electrical and telemetry standards, overflow and emergency arrangements, and compliance with Townsville Water and Waste's current Licence conditions. Undulating terrain or other economic considerations may preclude the viability of a purely gravitational system.

As such, Townsville Water and Waste may opt for sewage pumping stations and pressure mains to transport wastewater into an adjacent catchment or direct to the WWTP and will be at the approval of Townsville Water and Waste.

(ii) Alternative sewer systems

Alternative sewer systems (e.g. common effluent drains, vacuum sewerage, pressure sewer systems, etc.) will only be considered with an analysis showing the benefits of such systems using a triple bottom line approach, and require Townsville Water and Waste's written approval.

(iii) Sewers

Sewer layouts, pipe sizing and grading shall be determined in accordance with WSA 02, unless detailed elsewhere in this guideline.

(iv) Sewage pump stations and pressure mains

Sewage pump stations are to be provided where gravity systems cannot be utilised or sewers become uneconomically deep (usually > 5m).
Sewage pump stations are to be provided where approved in writing by Townsville Water and Waste.

Pump stations shall be planned and designed to optimise construction, operation and maintenance costs for the total-life cycle of the infrastructure and equipment. This shall include the pump station along with the discharge pressure main.

Pump station and pressure main planning shall be undertaken in accordance with WSA 02 and WSA 04 and as amended by this guideline. Unless detailed elsewhere in this guideline.

(3) Property connections

(a) Scope

SC6.4.3.21.3(3) covers the design of property connection sewers (PCS).

(b) Location

Location of property connection points shall generally be in accordance with WSA 02 and the following constraints:

(i) to connect directly to maintenance holes where possible Industrial/Commercial properties connections must be to maintenance holes;

(ii) the property connection jump-up must be 1.5 m from the property boundary, unless council has agreed to the service connection being located within the road reserve, in which case the jump up must be located within a valve box that is easily identifiable and located for access and maintenance;

(iii) combined sanitary (house) drains are not permitted; and

(iv) dual connections to a single jump-up are not permitted permitted and no property connections are allowed to trunk mains.

(c) Maximum depth

The depth at the property connection shall not exceed 1.5 m.
Property connections shall not be made into sewers >3 m deep. In cases of deep sewers private connections must be
MHs or construct a shallow sewer.

(d) Type

Property connections shall be buried interface method in accordance with WSA 02 (Type 2 and 4 Appendix H).
Water Seals on property connections are not permitted.

(e) Size

Minimum size shall be DN100.

(residential) or DN150
(commercial/industrial).

(f) Length

The maximum length of property connection sewers shall be:

(i) DN100 – 10 m

(4) Gravity sewer design

(a) Scope

SC6.4.3.21(4) covers the design of gravity sewers.

(b) Sewer layout

(i) Extent

Sewer layouts shall be prepared to demonstrate drainage of the specified catchment, including the "most disadvantaged lot".

The sewer configuration is to be developed to minimise the overall length of sewers.

Sewers are to be designed to control the whole of the area of each allotment being sewered, except in industrial areas where a lesser area of control can apply if approved by Townsville Water and Waste.

Sewers are to be extended to the boundaries of the site to serve existing lots and potential upstream development sites where specified by Townsville Water and Waste.

(ii) Configuration

The sewers shall comply with the following additional requirements:

(A) be a minimum of DN150 (except property connections);

(B) located at the rear of allotments, except

- in areas where safe work area for staff and equipment, including access from the road frontage to the infrastructure (in particular the maintenance structures) cannot be achieved, sewers may be located in the front clearance area of the lot.
- in small and narrow lots where the alignment is within the road reserve at an alignment agreed to by council and in accordance with the considerations in WSA02
- in industrial and commercial developments where the alignment is within the property 1.5 m back from street frontage; and

(C) alignment is 1.5 m from property boundary. Environmental considerations are must be taken into account when selecting sewer alignments.

The designer must refer to WSA 02 for additional considerations such as alignment with road reserves and pathways. Sewers in road reserves are only permitted when:

- environmental considerations preclude alignments within the properties; and
- approved by Townsville Water and Waste.

(c) Sewers

(i) Sewer loading

Sewer loading shall be determined in accordance with this sub-section.

(ii) Sizing and grading

Sewers shall be sized to carry the design flow with the depth of flow no greater than 70% of internal diameter for initial and any future conditions (WSA 02).

The design flow shall be calculated by the method nominated in this sub-section.

Refer to WSA 02 for minimum sewer sizes and grades to meet required pipe capacities.

(iii) Minimum cover and services clearance requirements

Refer to WSA 02 for minimum cover requirements over sewer mains and requirements for minimum clearance from other services.

(iv) Above ground sewers

The following applies:

(A) above ground sewers are to be avoided where possible;

(B) above ground sewers are to be constructed from DICL or MSCL pipe unless otherwise approved by Townsville Water and Waste; and

(C) the designer of an above ground sewer shall take into account the considerations listed in WSA 02.

(v) Pipe material

The following applies:

(A) pipeline materials shall be in accordance with WSA 02;

(B) PVC pipe shall be a minimum of SN10 for DN100 and SN8 for other sizes;

(C) DICL and MSCL sewers shall be Cement Mortar Lined

(D) FRC and concrete pipes are not permitted; and

(vi) Pipe jointing

Pipelines shall be rubber ring jointed or butt welded in the case of PE pipe.
If flanged pipe is required, minimum flange classes shall be AS4087 Class 14 for Steel pipes and Class 16 for DICL.

(vii) Concrete encasement

Concrete encasement of sewers is not permitted except with the approval of Townsville Water and Waste.

(d) Maintenance structures

(i) Maintenance holes

The design and location of maintenance structures shall be in accordance with *WSA 02.*
Requirements include:

(A) maximum spacing between MHs is 90 m;

(B) a MH is required at the end of all sewers (except PCS see *WSA 02*);

(C) MHs are to be provided at all sewer changes of directions or grade;

(D) MHs on sewers within industrial subdivisions are to be either at 40 m maximum centres or on every second property;

(E) MH may have up to 4 internal drops;

(F) the top of a standard MH must be 150 mm higher than the finished surface level or known flood level (100 year ARI);

(G) MHs may be constructed from pre-cast concrete or cast in-situ concrete;

(H) full depth cylindrical MHs shall be used in lieu of a taper tops;

(I) step irons, ladders or landings are not permitted within MHs for safety considerations; and

(J) internal epoxy coating of MHs is not normally required (except at pressure main receiving MHs).

(ii) Maintenance chamber

(A) Maintenance chamber will only be permitted with the approval of Townsville Water and Waste.

(B) The use of terminal maintenance chamber will not be approved. Maintenance Shafts (as per WSA02-2014) will not be permitted.

(iii) Pressure main discharge maintenance hole

(A) Pressure main discharge MHs shall be in accordance with SC6.4.4.8 Standard drawings SD440A Pressure Main Discharge to Manhole.

(B) Discharge MHs shall be internally epoxy coated.

(C) Discharge MHs shall be vented in accordance with SC6.4.4.8 Standard drawings SD-450 Vents at Sewerage Rising Main Receiving Inspection Chambers and Pump Stations.

(e) Pipe bedding

Pipe bedding for sewers shall be in accordance with WSA 02.
For flexible pipes refer to AS 2566.2 *Buried flexible pipelines - Installation*, Table G1, G2 and G3 for suitable material types.

(f) Restoration

Refer to WSA 02 for construction specification.
For restoration under roadways refer to SC6.4.4.8 Standard drawings SD-055. For state controlled road restoration should be design and constructed in accordance with their standards and requirements.

(g) Geotechnical

For geotechnical matters that should be considered refer to WSA 02.

(h) Envelopers

Enveloper pipes shall be used where necessary at major road crossings, at rail crossing and at major waterway crossings.

Enveloper designs for road and rail crossing are to be undertaken in accordance with the requirements of the Land Corridor controller's requirements. Where no specific requirements are provided refer to the standard drawings of WSA 02.

QR National requires compliance with their specification: MCE-SR-16 Requirements for Services under the Railway Corridor (Non-QR Services).

Suitable casing spacers/insulators shall be fitted to the pipe to ensure adequate spacing from the enveloper. At each end of the void between enveloper and carrier pipe is to be grouted on completion of the pipe installation.

(i) Land tenure

Easements are not required over gravity sewers.

(j) Emergency relief structures

All pumped catchments shall be provided with an "Emergency Relief Structure" in accordance with SC6.4.4.8 Standard drawing SD-445 Overflow Maintenance Hole Arrangement.

(k) Inverted syphons or water seals

Inverted syphons or water seals are not permitted.

(l) Colour coding pipes

Where sewer pipes are to be located in close proximity to other services pipes or where there is the likelihood of the pipes not being recognised as sewerage pipe the designer shall provide for the pipes to be colour coded (in accordance with WSA02 Table 4.1) and shown on the drawings accordingly.

(5) Sewage pump station design

(a) Scope

This section covers the design of sewage pump stations within the sewerage collection system, and also incorporates the requirements for the sizing of sewage pressure mains.

(b) Pump station design

(i) Pump station types

(A) Type 1 - Low lift pump stations
Low lift pump stations are characterised by short pressure mains with the ability of sewage to overflow into the downstream sewer;

(B) Type 2 - Small submersible pump stations (up to 30 L/s)
Small submersible pump stations consist of a single circular 1.8 - 2.3 m diameter wet well containing two submersible pump units;

(C) Type 3 – Medium size submersible pump stations (30 L/s to 200 L/s)
Medium size pump stations consist of a submersible type pump station with total pumping capacity of up to 200 L/s. They may consist of one single large diameter pump well housing multiple pumps or multiple smaller diameter wells housing individual or multiple pumps; and

(D) Type 4 – Large pump stations (>200 L/s)
Large pump stations are the major pump stations often delivering to the sewage treatment works. These stations may be wet well or wet/dry well configuration.

(ii) Design guidance

The *WSA 04 Sewerage Pump Station Code* and DEWS Guidelines shall be consulted in conjunction with this sub-section for Pump Stations Types 1, 2 and 3. These guidelines are based on twin pump submersible configurations in a duty/stand-by arrangement.

Type 4 pump stations require specialist input and shall be designed by experienced pump station design engineers.

Pump stations shall be designed to comply with the Code of Environmental Compliance, ERA 63(3) - Sewage Treatment (EHP) as applicable.

However refer to Townsville Water and Waste for the latest agreement with EHP for this guideline as some sections are not regarded as appropriate.

(iii) Importance level

Buildings shall be designed for Importance Level 3 (minimum) in accordance with the *Building Code of Australia* Table B1.2a.

(c) Pump system design

(i) General

The design of the pressure main and pump station should be considered together.

Pump system design requires the consideration of the interaction of the pump station and pressure main. The design principle is to determine the whole-of-life least cost solution for the pump station and pressure main considering both initial construction costs and on-going operating costs.

The sewage pressure main system within Townsville City consists of two general configurations:

(A) pressure mains that discharge into gravity systems or other sewerage pump stations; and

(B) pressure mains that connect into combined pressure main systems from a collection of pump stations.

The major sewage transport systems within Townsville City are characterised by combined pressure mains. The combined pressure main systems tend to consist of a major trunk pressure main with individual pump stations mains delivering to the trunk main through separate pressure mains up to several kilometres in length.

These combined systems can result in very significant variations in the operating head requirements of the pump depending upon the instantaneous flows from other stations within the combined system.

To service the wide variation in pressure head requirements for the differing conditions it may be

necessary to have several different capacity pumps to cover all conditions.

(ii) Design loading

Design loading for the pump station shall be determined in accordance with this sub-section.

(iii) Design flow

The design flow for the pump station shall be determined for both dry weather and wet weather (peak flow) conditions.

Dry weather flow:

(A) peak dry weather flow (PDWF) shall be based on 2*ADWF unless better information is available.

Wet weather flow:

(B) the peak wet weather flow factor (PWWFF) is defined by:

Peak wet weather flow (PWWF) = PWWFF * ADWF.

The PWWFF shall be determined based on an analysis of the existing pump station flows but in no case should PWWFF be less than 5.

(iv) Pump and pressure main sizing

Pump units shall be sized for the full range of operating conditions that the pump delivery system will be exposed to. This includes initial and long term operational conditions.

Pump units and pressure main sizing shall be:

- optimised for normal ADWF conditions; and
- be capable of performing under PWWF conditions.

For Type 2, 3 and 4 pump stations it may be necessary to provide for each duty.

Pump and pressure main sizing shall be performed in accordance with WSA 04 with the following additional conditions:

(A) a minimum of two pumps shall be provided in a duty/standby arrangement;

(B) pump stations may utilise all pumps within the station to achieve PWWF;

(C) if different size pump units are provided within the station, an environmental assessment shall be performed on the consequences of overflow to determine if a redundant (standby) unit is required for the large pump, and is subject to written approval from Townsville Water and Waste. If the consequences are acceptable Type 2 and 3 pump stations may use a single pump unit for PDWF and a single pump unit for PWWF conditions; and

(D) pumps are able to operate within their safe operating range under all conditions. VSD, high speed and grinder types may be considered, subject to written approval from Townsville Water and Waste.

Pump size in combination with the delivery main size is to be designed to minimise whole of life costs covering capital, operating and maintenance costs.

(v) System resistance

System resistance curves shall be developed for the pump station covering the full range of pump operating conditions. System curves shall be developed in accordance with WSA 04 with the following additional requirements:

(A) separate system curve bounds are to be developed for PDWF conditions and PWWF conditions;

(B) upper and lower bound curves shall be prepared for each case;

(C) upper bound curves are to be based on:

- minimum Hazen “C” value;
- well at pump stop level; and
- in the case of a combined rising main, with all contributing pumps operating; and

(D) lower bound curves are to be based on:

- maximum Hazen “C” value;
- well at pump start level; and

- in the case of a combined rising main, with no other contributing pumps operating.

For Hazen "C" values actual figures shall be derived from calibration data where possible. Where data is not available the values in Table SC6.4.3.21.6 may be used.

Table SC6.4.3.21.6 Range of Hazen C Values

Material	Min C	Max C
Cement Lined and FRC	100	150
Plastic pipes	110	160

Complex pressure main systems will require pipe network analysis packages to assist with the development of the curves.

A net positive suction head available (NPSHA) curve shall also be prepared.

(vi) Pressure mains

Pressure mains shall be sized in conjunction with the pump stations to optimise overall whole-of-life costs.

(vii) Pressure main velocity

The minimum velocity for pressure mains should comply with the requirements of *DEWS Guidelines*. The target velocity at the duty point of the pump is 1.0 m/s with a range of 0.75 m/s to 1.5 m/s.

The minimum velocity in pressure mains is to be 0.75 m/s. Where a small and large pump combination is proposed, 0.5 m/s for the smaller pump may be permissible if the larger pump flushes the main regular intervals of no greater than weekly. Acceptance by Townsville Water and Waste will be based on the individual merits of the design. Pump operation is described in TCC24, Standard Specification for Electrical Switchboards, clause 18.2.

The maximum velocity in pressure mains shall not exceed 1.5 m/s (single) and 2.5 m/s (all pumps).

(viii) Pressure main hydraulic models

Wherever possible pump and pressure main system hydraulics shall be performed using calibrated hydraulic models.
Townsville Water and Waste has a number of network models for the complex pressure main system. These hydraulic models have been developed in SewerGEMS modelling software.

These models shall be used for the analysis of pumping system that is part of the pressure main network system in conjunction with Townsville Water and Waste.

(d) Pump well sizing

Pump well sizing shall be performed in accordance with WSA 04.

The required pump operating volume shall be calculated as follows:
$V = 900 \times Q^P/S$
where:
V = cut-in/cut-out volume (L);
Q^P = pump capacity (L/s); and
S = allowable number of starts per hour.

The maximum number of starts per hour shall be:

(i) Motors <= 50 kW: 12 Starts per hr; and

(ii) Motors > 50 kW: 5 Starts per hr.

For fixed speed pumps, the pump capacity shall be based on the capacity of the largest pump unit within the well.

For variable speed pumps, the pump capacity should be based on the flow rate associated with the minimum velocity requirements of the pressure main.

Operating and control levels within the well shall be in accordance with WSA 04.

(e) Overflow management

(i) General

Systems shall be designed to minimise overflow of sewage to the environment.

All pumped catchments shall be provided with an emergency relief structure accordance with SC6.4.4.8 Standard drawing SD-445. Refer to other sections of this sub-section and ERA 63(3), Code of Environmental Compliance, on requirements for pump station failure or overload management.

An environmental assessment shall be performed to determine the most appropriate overflow location.

The system shall provide, as a minimum, 6 hours of ADWF flow as emergency storage. For remote sites this may need to be increased dependent upon emergency response times.

Methods for limiting the risk of sewage overflows include:

(A) emergency storage;

(B) provision of emergency power at the site; and

(C) inter-catchment overflows.

Pump stations shall be fitted with telemetry monitoring to communicate alarms of system failures to emergency operations personnel.

(ii) Level and location of relief structures

The level of relief structures shall be designed to prevent sewage from exiting through disconnector gullies or maintenance hole lids. Relief structures shall be located as close as practical to pump station.

(iii) Emergency storage

Emergency storages shall be provided in accordance with the requirements of WSA 04.

(iv) Emergency power

Stand-by generators are required at all Type 2, 3 and 4 pump stations.

Sufficient fuel shall be stored to operate the pump station at full capacity for 24 hours.

The electrical system shall be equipped with an automatic change-over switch and start system for the stand-by generator in the event of mains power failure.

(f) General arrangement and site infrastructure

(i) Location and layout

Issues to be considered when sighting a pump station are discussed in WSA 04.

(ii) Standard drawings

Type 2 pump stations shall be in accordance with standard drawing SD-420 Small Sewerage Pump Stations Typical Plans, Sections and Details

(iii) Flood level

Pump stations are to be constructed 300 mm above 1% AEP flood level (refer WSA–04).

(iv) Site fencing

Security fencing is not normally required.
In urban areas where site fencing is deemed to be necessary, fencing shall be in accordance with SC6.4.3.21.5(4).

(v) Landscaping

Sites shall be landscaped to minimise visual impact whilst not compromising access to the pump station and equipment. For landscaping requirements refer to WSA 04.

(vi) Water supply

Water supply shall be provided to all pump stations for wash-down purposes and general amenity. Backflow prevention is required on the water supply service.

Water services shall be provided in accordance with WSA 04.

(vii) Power supply

The power supply connection to the pump station site shall be underground.

Refer to other sections of this guideline for the provision of power for the site.

(viii) Site buildings

If specified by Townsville Water and Waste, site buildings shall be provided for pump stations to house large switchboards and other associated equipment.

Buildings shall be architecturally designed.

A Development Permit is required for buildings.

(ix) Lifting requirments

Permanent cranage or davits are not normally required. Exceptions to this are where equipment is located within buildings and require removal on a basis of more than once every 10 years.

If specified by Townsville Water and Waste, permanent cranage or davits shall be incorporated into the design of the pump station or building. The design shall be approved by Townsville Water and Waste.

Set-down points of the cranage equipment shall be:

(A) in an area able to be reached by a crane truck where the mass and reach are within the crane truck capacity;

(B) paved access is provided for the crane truck to reach the necessary position;

(C) on back of flat bed vehicle (bed height 1.2 m) elsewhere; and

(D) if these requirements are impractical, other lifting arrangements may be considered such as removable roof or local lifting equipment with provision for trolleying to a suitable crane pick-up point.

(x) Valve pits

Valve non-return and isolation pits shall be provided and be in accordance with the general concepts detailed in *WSA 04:2005.*

(xi) Ventilation pole

Ventilation poles are required.

(g) Vehicular access

(i) Access road

Sealed access road shall be provided to pump stations to enable all-weather access for maintenance vehicles. Access requirements shall be in accordance with WSA 04 with the following additional requirements:

(A) sealed asphalt access road;

(B) provide access during 1% AEP flood event;

(C) minimum road width of 4 m;

(D) on-site turn-around for maintenance vehicle; and

(E) parking area provided adjacent to all equipment to be lifted for a crane truck maintenance vehicle. Parking is only required for a single vehicle.

Design of access is to be approved by Townsville Water and Waste.

(ii) Maintenance vehicle reconfiguration

Allowance shall be made for maintenance vehicles that are 10 t (8.8 m long) crane-trucks Medium Rigid Vehicles (AS 2890.2 *Parking facilities - Off-street commercial vehicle facilities*) with

mounted crane positioned centrally on the rear end of the vehicle.

(h) Odour control and septicity control

(i) General

If directed by Townsville Water and Waste, odour and septicity control shall be incorporated into the design of the pump station, and the design shall be approved by Townsville Water and Waste.

The generation and release of hydrogen sulphides can result in odours as well as increasing the corrosiveness of the environment within and around the pump station.

The extent of hydrogen sulphide generation is related to the age and retention time of the sewage, and the turbulence generated when discharged from pressure mains.

For further readings on the generation and management of odours, refer to:

(A) WSA 04*;*

(B) *Hydrogen Sulphide Control Manual;* Volumes 1 and 2, Technological Standing Committee on Hydrogen Sulphide Corrosion in Sewerage Works (1989); and

(C) DEWS Guidelines.

(ii) Management

On-site odour management shall be designed. Options management in order of preference include:

(A) passive control of odour release from sewage (by appropriate pump station design);

(B) odour scrubbing with activated carbon; and

(C) chemical masking.

Air and oxygen injection are not preferred.

(i) Durability

(i) General

The following applies:

(A) pump station structures and equipment shall be designed for the design lives set out in accordance to other sections of this sub-section;

(B) all metalwork within the wells shall be grade 316 stainless steel. Connections to concrete shall be by stainless steel chemical anchors;

(C) all pipework within the wells shall be coated with a fusion bonded coating or high build epoxy coating system that provides long term protection;

(D) submersible pumps shall be provided with stainless steel lifting chains;

(E) guide rails shall be in accordance within other sections of this sub-section; and

(F) covers for wells and pits shall be fabricated from aluminium.

(ii) Well type

Refer to SC6.4.3.21.5(3)(g) Pump stations and wet well materials

(j) Safety

The following applies:

(i) ladders shall not be provided into confined spaces. This includes the pump well and valve pits;

(ii) pits and wells shall be designed for confined space entry access of a person lowered from a tripod system;

(iii) forced ventilation shall be provided for all pump station dry wells;

(iv) the designer shall make provision for temporary fencing around well openings, and permanent grates for times when the covers are open; and

(v) signage shall be provided in accordance with the work, health and safety regulations identifying confined space areas and appropriate actions for entry.

(k) Flotation

Structures shall be designed to resist flotation in accordance with AS/NZS 1170 *Structural design*

actions.

(l) Instrumentation requirements

Control level probes shall be provided in accordance with other sections of this sub section.

Type 3 and 4 pump stations shall be provided with electromagnetic flow meters to measure the entire pump station outflow. Selected Type 2 pump stations may require electromagnetic flow meters – consult with TWW.

(m) Land tenure

The land tenure for the pump station and any associated infrastructure including valve pits, vent poles, etc., is in order of preference:

(i) council owned freehold land; or

(ii) council controlled road or reserve; or

(iii) easement over freehold land.

(n) Documentation

All new pump stations, and any modification works to existing pump stations, require a comprehensive documentation suite including: design and as constructed drawings, equipment operation and maintenance manuals and initial procurement and logistics data.

(o) Operations and Maintenance Manual (O&M Manual)

TheOperationsandMaintenanceManualcomprisesallrelevantdocumentsforthepumpstation. The document structure for the O&M manual shall be adhered to and not altered unless approved by TWW.

Where modifications are being undertaken to an existing pump station, TWW shall provide any existing available O&M manual or relevant documentation to the designer for update.

(p) Document Requirements Schedule (DRS)

The DRS is a control document summarising all documents required in the O&M manual, quantities of each document to be provided at completion of commissioning (Practical Completion, or date of “On Maintenance”).

The DRS lists up to 4 hold points during the design and construction process where TWW require review of documentation. Some elements of documentation may be deleted from the DRS/O&M Manual at the discretion of TWW. The DRS, including necessary documentation and hold points shall be discussed and agreed with TWW prior to commencing detailed design. Hold points shall be adhered to through the design and construction process.

The baseline DRS schedule to be used as a starting point for development of sewage pump station documentation can be made available on request.

(q) Process and Instrumentation Diagram (P&ID)

A Plant and Instrument Diagram (P&ID) is to be delivered with each new pump station and existing P&ID are to be revised by any project modifying or upgrading a pump station.

The P&ID provides the standard symbols and naming/tagging conventions for all equipment delivered. This includes piping, Instrumentation and Mechanical process equipment.

The TWW Process and Instrumentation Sheet includes relevant symbols to be applied to P&IDs. This information can be provided on request.

Unique Tag numbers developed in accordance with the Tagging conventions are to be allocated to each equipment item delivered and included on the P&ID. The tag numbers are to be used as the reference for each document delivered for that specific equipment item. Tag numbers should be used to refer to equipment in Inspection and Test Plans (ITP’s) and as much design documentation as is practical.

(r) TWW Sewage Pump Station Equipment Schedule (TWW SPS Equip Schedule)

An equipment schedule is to be prepared for each new pump station and existing equipment schedules are to be revised for any project modifying or upgrading a pump station. The document is referenced by Tag number and lists, in summary, critical design and performance data for mechanical, electrical, radio and telemetry, and instrumentation and control equipment. The schedule is a required document in all O&M manuals.

The schedule is the cross reference document between the tag number and the actual equipment item delivered. The schedule is a useful tool when selecting equipment as it contains relevant process parameters for each equipment item. The sample Equipment Schedule to be used and can be provided on request.

(6) Pressure main design

(a) Scope

SC6.4.3.21.3(6) covers the design of sewage pressure mains.

(b) Pressure main sizing

Pressure mains shall be sized in association with the pump stations. Refer to SC6.4.3.21.3(5)(c) for guidance on sizing.

(c) Alignment

(i) Location

The location for pressure mains in order of preference is in:

(A) council controlled road; or

(B) council owned freehold land; or

(C) easement in privately owned freehold land.

The alignment within the Road shall be in accordance with SC6.4.4.8 Standard drawings SD 015.

(ii) Service allocations

The designer is referred to the sub-section SC6.4.3.2 Building over or adjacent to services in selecting alignments in other areas:

(iii) Minimum cover

Minimum pipeline cover is 600 mm in accordance with SC6.4.4.8 Standard drawings SD-325 and WSA codes.

(iv) Services and alignments

Refer to WSA 04 for minimum clearance requirements from other services.

Minimum clearance requirements and conditions imposed by other services owners shall be complied with. Minimum clearance requirements may be imposed by the service owner. Specific conditions apply to construction near:

(A) fibre optic cables;

(B) high pressure gas mains; and

(C) underground power.

Refer to the service owner for conditions on clearances.

Consider overhead power when selecting pipeline alignments. Construction with excavation equipment under or near overhead power lines has difficulties with monitoring and clearance requirements.

(d) Pipe

(i) Materials

Allowable pipe materials are:

(A) PVC-U, PVC-O, PVC-M

(B) DICL;

(C) mild steel cement lined; and

(D) polyethylene.

Pipeline materials shall be in accordance with WSA.

Pressure mains shall be a minimum of PN12.

In selecting the PN rating for plastic pipes, pressure de-rating for transient loads (water hammer) and temperature shall be taken into account (refer to WSA 03).

(ii) Pipeline material structural design shall be carried out in accordance with WSA 03.

(iii) Pipe jointing

Pipelines shall be rubber ring jointed or butt welded in the case of polythene pipe.

Flange classes shall be selected to suit the pipeline design pressures. Flange classes should be AS/NZS 4087 *Metallic flanges for waterworks purposes* except where connecting to existing flanges from a different standard.

Minimum flange classes shall be Class 14 for Steel and Cast Iron and Class 16 for DICL.

(iv) Concrete encasement

Concrete encasement of pressure mains are not permitted, unless approved by Townsville Water and Waste.

(v) Above ground pressure mains

The design of above ground pressure mains will be in accordance with WSA 03.

(e) Appurtenances

(i) Air releases

Air releases shall be provided on all high points along the pipeline, unless specifically omitted by Townville Water.

Air release shall be avoided wherever possible by maintaining a continuous rising grade away from the pump station.

Manual air releases shall be used where the release is located in developed residential areas where odours will be noticed. Automatic air valves can be used at other locations. Automatic air valves shall be suitable for use with sewage.

(ii) Scours

To the greatest reasonable extent, a designer shall avoid the occurrences of low points within a pressure system to prevent the use of scours. If a low point is unavoidable, a scour shall be used to assist with clearing of accumulated solids.

Scours shall be directed back into the pump station or adjacent sewer where possible. Where not possible, the scour shall be directed into a manhole designed to allow pump-out into a tanker.

(iii) Isolation valving

Isolation valves shall be provided at the following locations:

(A) outside of pump station;

(B) on the branch of any tees;

(C) at 500 m maximum spacing;

(D) either side of significant waterways; and

(E) either side of major road crossings.

(f) Colour coding of pipes

Where pressure mains are to be located in close proximity to other services pipes or where there is the likelihood of the pipes not being recognised as sewerage pipe the designer shall provide for the pipes to be colour coded to Australian Standard and shown on the drawings accordingly.

(g) Pipe bedding

Pipe bedding for pressure mains shall be in accordance with:

(i) WSA 02 for sewers; and

(ii) WSA 04 for pressure mains.

For flexible pipes refer to AS/NZS 2566.2 *Buried flexible pipelines - Installation*, Table G1, G2 and G3 for suitable material types.

(h) Restoration

Refer to WSA 02 for construction specification.

For restoration under roadways refer to SC6.4.4.8 Standard drawings SD-055.

(i) Geotechnical

Refer to the following for geotechnical matters:

(i) WSA 02, Section 8.6 for sewers; and

(ii) WSA 03, Section 5 for pressure mains.

(j) Marker tape

Detectable marker tape is required on non-metallic pressure mains(refer to SC6.4.4.8 Standard drawings SD325) and shall be in accordance with WSA PS-3.18 Marking Tape, Detectable.

(7) Scope

Wastewater treatment process design is complex and site specific.

New plants and plant upgrades are typically undertaken as one-off projects and performed by experienced wastewater treatment plant designers/consultants with the necessary qualifications, specialist skills and experience to carry out the planning, assessment, design and delivery processes for the project.

Generally, Townsville Water and Waste will prepare a detailed design brief and requirements for the engagement of suitable specialist consultants to undertake the project.

(8) Recycled water systems

(a) General

(i) Scope

SC6.4.3.21.3(8) covers the design of recycled water distribution infrastructure.

(ii) Design citeria

Design of a recycled water scheme shall comply with the requirements of the documents referenced in SC6.4.3.21.3(1)(b).

The design of a proposed recycled water project shall address, as a minimum, the following issues:

(A) be consistent with council's latest practices

(B) quality of treated water appropriate to proposed usage;

(C) maintenance of treated water quality standards within the storage and distribution system; and

(D) distribution system infrastructure including, storage, pumping and mains distribution network and irrigation networks.

Details of the proposed design are to be submitted to Townsville Water and Waste for review and approval.

(b) Infrastructure

(i) Sizing

The methodologies used for the sizing of water supply infrastructure of mains, pump stations and reservoirs can be applied to recycled water.

Reservoirs, pump stations, and mains are required to be sized to maintain the desired flow and minimum pressure at the property connection.

Refer to SC6.4.3.21.2 Water supply design for design requirements, and SC6.4.3.21.3(2) Sewage collection system planning for guidance on sizing requirements.

(ii) Colour coding

All recycled mains and connections and outlets shall be colour coded to AS 2700 *Colour standards for general purposes* to differentiate from other infrastructure.

Mains, taps and meters shall be coloured Lilac P23.

(c) Reticulation mains layout

(i) Extent

Mains shall be provided to service intended connections within the area being serviced.

(ii) Mains

Mains shall be designed with isolating valves, pressure and control regulating valves (as required), air valves and scours to *WSA 03*.

(iii) Scours

Scours from recycled water mains shall be directed into sewers where possible.

(iv) Meters

Water meters are to be provided on all service connections. Left-hand threads shall be used on all fittings to prevent accidental cross connection to potable water.

SC6.4.3.21.4 Electrical and mechanical

(1) Introduction

(a) Scope

SC6.4.3.21.4 addresses the electrical and mechanical design considerations applicable generally to water and sewerage pump stations but can extend to treatment plants.

(b) Treatment plants

New treatment plants and plant upgrades are typically undertaken as one-off projects and performed by experienced treatment plant designers/consultants with the necessary qualifications, specialist skills and experience to carry out the planning, assessment, design and delivery processes for the project.

Generally, Townsville Water and Waste will prepare a detailed design brief and requirements for the engagement of specialist consultants suitable to carry out the electrical aspects of the project including issues of supply, transformers, HV, plant and motor control and monitoring.

(c) Legislative requirements

Electrical designs and works shall consider relevant legislative requirements including:

(i) *Electrical Safety Act 2002* including associated regulations and Codes of Practice;

(ii) *Electricity Act 1994* and associated regulations;

(iii) *Electricity National Scheme (Queensland) Act 1997;*

(iv) *Building Act 1975* and associated regulations; and

(v) *National Electricity Rules.*

(d) Reference and source documents

The following documents shall be referred to.
TCC – 24 *Townsville City Council Standard Specification for Electrical Switchboards*
WSA 02 *Sewerage Code of Australia*
WSA 03 *Water Code of Australia*
WSA 04 *Sewerage Pump Station Code of Australia*
Townsville City Council Standard Specification for Standby Generators

(e) Standards

In general the following standards, codes and manuals are applicable to the design and documentation of typical pumping stations.

Workmanship and design:

Standard	Name
Australian Standards	All relevant Australian Standards
IEC and British Standards	Relevant International Electrotechnical Commission (IEC) and British Standards where no Australian Standard exist.
BCA	Building Code of Australia
NER	National Electricity Rules
ECMM	Queensland Electrical Connection and Metering Manual

Preparation of electrical drawings:

Standard	Name
AS1100	Technical Drawings
AS1102	Graphical Symbols for Electro-technology
AS3702	Item Designation in Electro-technology
TCC24	Townsville City Council Standard Specification for Electrical Switchboards

(2) Electrical supply requirements

(a) General

(i) Provision of power supply

Energy Queensland is the electrical distribution entity responsible for the connection of power supplies to all Townsville Water and Waste infrastructure assets.

The designer shall where possible, commence discussions with the electrical distribution entity at an early stage as part of the overall planning process for the proposed construction of new water and sewerage infrastructure or for the augmentation of existing water and sewerage infrastructure. Early involvement of the distribution entity shall be sought in order to resolve network considerations and availability to meet the anticipated electrical loads. Budget costs where possible shall be obtained from the distribution entity for any required upgrading of the existing power supply network, and provided to Townsville Water and Waste for inclusion in project budgets. The current distribution entity policy is that no cost estimates are provided unless the full application process is completed with a detailed design. This shall be considered in the design program.

The designer shall obtain plans of existing infrastructure in the vicinity from the Dial Before You Dig service of the existing and proposed electricity supply network in the vicinity of the proposed infrastructure. The location of the existing network will have a bearing on the proposed locations of the infrastructure, and electrical “point of supply”. The optimum location for the electrical “point of supply” should be as near as practicable to either the largest electrical loads or the proposed location of the electrical main switchboard and/or motor control centre.

The designer shall seek advice from suitably experienced people where information from the distribution entity is not forthcoming as to potential electrical supply issues.

Electrical power supply connections shall comply with the requirements of the *Queensland Electrical Connection and Metering Manual* available from their web site.

(ii) Energy retailer

The energy retailer may not necessarily be the energy supplier to the infrastructure asset. As the Queensland electricity market is a contestable market, Townsville Water and Waste may decide to obtain electrical energy from another Energy Retailer. The designer shall consult with Townsville Water and Waste to determine current Townsville Water and Waste commercial agreements in regard to energy retailer contracts to be applied to the new infrastructure.

(iii) Clearances

The location of water and sewerage structures such as treatment plant and pump station buildings shall be such that minimum clearances are maintained from overhead and underground electrical cables. These clearance distances are contained within the *Electrical Safety Act 2002* and AS/NZS 3000 *Electrical installations (Australian and New Zealand Wiring Rules)* and are dependent upon variables including the voltage of the overhead power lines. Guidance shall be sought from the distribution entity regarding the voltages of overhead power lines to ensure adequate clearance distances are maintained. The supply authority normally prohibits the construction of structures beneath overhead power lines. The designer shall also consider clearance distances for cranage during construction maintenance and demolition of these structures.

(iv) Ownership of HV infrastructure

Townsville Water and Waste's preference is for ownership and on-going maintenance of high voltage transformers and switchgear to remain with the distribution entity.

Where the designer seeks to have Townsville Water and Waste retains ownership and on-going maintenance of the high voltage supply assets, a detailed financial breakdown of the cost of ownership including initial capital cost and on-going maintenance costs shall be undertaken.

(v) Connection of power supply

It is Townsville Water and Waste's practice that costs associated with the connection of the required power supply to each location (including the distribution entity capital contribution) is normally included in the contract price by the Contractor performing the works. Tender documentation shall state this requirement.

All forms required to be submitted for the connection of the power supply shall be completed by the Contractor and forwarded to Townsville Water and Waste for signature. Submission of the forms shall be by the Contractor. However, circumstances may arise where the arrangements for power connection may be excluded from the contract and undertaken by Townsville Water and Waste directly with the distribution entity, including:

(A) requirements for a capital contribution by the distribution entity; and

(B) extended application timeframes within Energy Queensland and design program requirements where costs may not be known at the time of tendering the works.

(b) Submission of application to distribution entity

The designer shall be responsible for the calculation of the electrical loads for the proposed infrastructure or the additional electrical loads where existing infrastructure is proposed for augmentation. These shall be submitted with the application in the format required by the distribution entity.

(c) Fault levels

In order to determine the applicable fault level for the installation, particularly for HV connections, advice will be required from the distribution entity as to the applicable fault levels at the site connection. This information can then be used during the design process to calculate the fault levels throughout the site and to enable equipment selection.

In practice, this information, particularly for LV connections, is generally not forth coming from the distribution entity within typical project design time frames. To enable design progression, suitable experienced designers shall by site inspection determine as far as possible the existing LV networks configuration and based on anticipated works determine the most likely fault level for the site.

Suitable allowance for future augmentation of the proposed infrastructure shall be taken into account when calculating the prospective fault levels. The designer shall seek advice from Townsville Water and Waste to determine any proposed future upgrading at the facility.

(d) Retail energy metering

All retailer energy metering shall be designed, installed and connected in accordance with the relevant retailer requirements.

Metering locations shall be accessible to the retailer's meter reading personnel during normal working hours. Typically for new installations, the metering panel is not located within a building or locked compound. Where old facilities are being refurbished, the designer shall relocate the meters to an accessible location.

Phone line connections etc. should be provided at each metering location in accordance with the requirements of the distribution entity. Where the installation of GSM modems for remote downloading of energy readings is required, the location of the meter panel shall be such that adequate mobile telephone coverage is achieved.

(e) Energy tariff

(i) Tariff selection

Should it be determined that the site will be connected as a regulated energy tariff connection

rather than as a contestable site then:

(A) the designer shall provide a detailed analysis of energy consumption at the site, taking account of equipment run times and hours of operation. The analysis shall provide indicative comparison; and

(B) submit details of the energy consumption along with monthly metering charges and all other additional costs payable to Townsville Water and Waste, and seek their approval prior to the installation and connection of energy meeting.

(ii) Energy cost minimisation

The electrical design shall encompass all energy cost savings applicable due to off-peak electrical consumption. Where pumps and other large electric motors are installed, control systems shall be configured to only operate pumps within high energy cost periods to maintain minimum levels in reservoirs and pump stations where possible. Major pumping shall occur during periods of off-peak low energy costs. These tariff control measures shall be provided with manual override facilities both locally and as part of any SCADA based control system.

Other constraints particularly in the sewerage network (e.g. pump station storage, or peak flows into sewerage treatment plants) may prevent the use of “off-peak”, for example the storage then delivery of large quantities of raw sewerage to biological treatment plant processes.

Retailer energy charges are in Queensland presently based on real energy measurement with regulated limits on the amount of reactive power that may be produced or consumed at each site.

Some other states in Australia also charge for reactive power consumption, the rate for reactive power is generally higher than real power providing ability to determine a return on investment for power factor correction devices (other than by simple regulatory compliance).

Given potential for Queensland to alter present charging strategies in regard to reactive power design consideration should be given to provision of space for future ability to retrofit power factor correction equipment to the site. This provision may include space, switchgear, and busbar extension, and so on as required.

(3) Emergency power supply

(a) General

(i) Generator requirements

Each water and sewerage site shall have provision for either the permanent connection of a standby diesel generating set, or as a minimum be provided with facilities for the connection of a portable generating set as required by TCC24.

A formal risk assessment of the criticality of a particular infrastructure asset shall be made by the Designer in order to assess whether the standby generating set shall be permanently located and connected or provision made for connection of a portable generating set.

For sewerage pump stations the following general guidelines apply for the provision of standby generating sets:

(A) where a sewerage pump station has inter-area overflow capabilities, the installation of a manual transfer switching arrangement and plug-in type connection socket as a minimum is required; and

(B) where the sewerage pump station does not have inter-area overflow capability, a permanently connected standby generating set with automatic changeover facilities mounted within the electrical switchboard is required.

For water pump stations, it is not normal practice to provide permanent standby generators as water is normally continued to be supplied by gravity from reservoirs during power failures. The exception is where supply to consumers will fail during power outages. In such cases permanent generators are required.

Standby generating sets shall be sized to ensure that the largest pump load combination required at the site can be successfully started and run. Manual transfer switching arrangements shall also be sized for the largest electrical pump load combination required at the site.

Generators shall be fitted with protective circuit breakers on the supply cables.

Technical requirements for the generator are provided in the council's *Standard Specification for Standby Generators*.

(ii) Site location

The generator set shall be located on the site to allow for easy and safe access for servicing and maintenance (including removal from the site where necessary). This may require a suitable hardstand area.

Access shall allow all panels on the generating set to be easily opened without hindering access to the electrical switchboard or pump station.
Vandal proofing shall be to TCC24 minimum requirements.

(iii) Fuel storage requirements and alarms

The generator set shall have a fuel capacity for a minimum of 24 hours operation based on 100% of the rated load of the generating set.

The designer shall also take into account the reliability of fuel supplies to specific locations after severe storm and cyclone events which may prevent access to the sites for re-fuelling. Where the designer determines unacceptable risk to the supply of fuel to a critical site, additional fuel storage shall be provided to Townsville Water and Waste's satisfaction.

Remote locations (e.g. Magnetic Island, rural areas) shall be considered as special cases and the availability of fuel supplies at the site after severe weather events shall be a consideration in resolving the quantity of fuel stored on-site.

A low fuel alarm from fuel storage tanks shall be connected to the telemetry and SCADA systems. The alarm shall operate when the fuel level in the tank has fallen to a level which only provides two hours of remaining operation of the standby generating set at full load.

(iv) Environmental considerations – generating sets

Fuel containment - The generating set shall be located within a bunded area which provides drainage to a low point. A lockable draw-off valve shall be provided for discharge of liquid from the bunded area. Alternatively, suitable fuel containment and drip trays shall be provided within the emergency generator set base frame.

Noise - The generator shall be fitted with sound attenuation systems to meet the environmental requirements for allowable noise emissions.

(v) Battery charging

Each generating set shall have a battery charger powered from a dedicated circuit from the main sites switchboard or distribution board.

(b) Indoor standby generating sets

Where the electrical main switchboard and/or motor control centre are contained within a building structure, the standby generating set shall also be located within the same building structure.

The generating set shall be contained within a fire rated sound attenuated room that provides adequate airflow for cooling purposes. Airflow requirements shall be based upon the individual generating set manufacturer's recommendations.

Bulk fuel storage shall be located externally to the building. The bulk fuel storage shall have a lockable fuel cap.

A smaller day storage tank may be provided within the room. Automatic transfer of fuel between the

external bulk fuel storage tank and the smaller day tank shall be provided.

The location of the refuelling point and ability to access safely shall be considered for each site such that it allows accessibility for the delivery of fuel by the selected method.

(c) External standby generating sets

Where the electrical switchboard is either plinth or pole mounted externally, the generating set shall also be located externally provided requirements such as noise attenuation can be met.

Permanently connected standby diesel generating sets shall be fully enclosed and sound attenuated. Generating set enclosures shall offer easy access to all maintainable parts for maintenance personnel.

Externally installed generator installations shall be vandal resistant. No glass or plastic panels are to be provided on the generator exterior housing. All covers (including radiator and fuel caps) are to be pad-lockable. No controls (eg emergency stop) are to be external or accessible without opening a locked door or cover.

There should be no exposed “hot” parts, such as exhausts. It should not be possible to drop items down the exhaust pipe.

Surface treatment of the generator and acoustic enclosure and other exposed parts shall be selected for the environment at the site, and to provide a 15 year minimum design life.

(4) Determining electrical site loads

(a) General

The designer shall determine the site loading in accordance with AS/NZS 3000 *Electrical installations* requirements, and with consideration of the proposed pump/equipment operation combinations and sequencing. Load calculations shall be approved by Townsville Water and Waste prior to being forwarded to the electrical distribution entity.

The designer shall be responsible for the early submission of electrical load calculations to the electrical distribution entity to minimise delays with electrical connection works.

The designer shall ensure that the calculated motor drive sizing can be achieved by a recognised pump manufacturer selected from Townsville Water and Waste’s preferred equipment lists.

The electrical load calculations shall take into account Townsville Water and Waste’s planned future augmentation of the infrastructure. Where no future augmentation is planned, the electrical loads shall be calculated on the anticipated connected loads plus 25% extra.

(b) Pump stations

Electrical load calculations shall be based on the method of operation of the pumps to be supplied and installed e.g. Duty-Duty, Duty-Standby, Duty1-Duty2-Standby etc. The proposed method of operation shall also be discussed with the distribution entity to determine any potential network issues with the proposed arrangements. The design for motor starting shall meet the requirements of the distribution entity and TCC24.

(5) Electricity point of supply

The preferred method for the connection to the point of supply shall be by underground cabling.

The final location for the point of supply shall be agreed between the distribution entity and Townsville Water and Waste and shall be compatible with access to the site. Parts of the overall area serviced by Townsville Water and Waste are prone to flooding. All electrical infrastructure susceptible to flood damage shall be located above the design inundation levels adopted for the proposed site. Flood inundation level information is available from Townsville Water and Waste to assist in the location of electrical infrastructure above predicted inundation levels.

The point of supply within residential locations shall be via a galvanised steel property pole or underground URD

pillar. Where galvanised steel property poles are used, the pole location shall be such that the final consumer's mains cabling length is kept to a minimum. No aerial cables are permitted to cross over infrastructure or vehicle working areas.

All connectivity at points of supply shall be accessible for maintenance purposes.

(6) Cabling

(a) Consumer's mains cabling

The consumer's mains cabling shall be sized by the designer in accordance with the calculated electrical load at the particular site and the requirements of AS/NZS 3000 *Electrical Installations*.

Cabling shall generally be Cu PVC/PVC/XLPE installed underground in HD uPVC conduits run between the nominated point of supply and the site electrical Main Switchboard.

Where external cabling enters a building, the cabling may be installed on cable ladder or cable tray with mechanical protection as required under AS/NZS3000.

Where underground HD uPVC electrical conduits are installed, the designer shall provide for spare conduits, generally in the ratio of one spare conduit of the same diameter of the conduit installed for each conduit containing electrical cables.

(b) Sub-mains cabling

Sub-mains cabling shall be sized by the designer in accordance with the calculated electrical load at the particular location and the requirements of AS/NZS 3000.

Cabling shall consist of single or multi-core copper PVC/PVC or PVC/XLPE conductors generally installed underground where run external of structures in suitably sized cable ducts or within cable trays where run internally of building structures.

(c) Power and control cables

Power and control cables shall be circular type cabling to facilitate ease of waterproofing cable entries. Consideration shall be given to use of flexible type cabling to pumps to facilitate ease of removal and installation.

Power cables shall be a minimum of 2.5 mm². Control cables shall be a minimum of 1.5 mm². A minimum of two spare cores shall be provided for all control cables following installation. Only one control voltage shall be contained within any control cable.

Where the designer has deemed a higher risk of further mechanical damage, Steel Wired Armoured (SWA) cabling or other protection method shall be provided.

(d) Variable frequency drive cables

Cables run to motors driven by VFDs shall be flexible type cabling to facilitate ease of termination and removal from pumping equipment. Cabling type, length and installation method shall be selected to meet the applicable Electromagnetic Compliance (EMC) requirements. Typically a screened cable would be used with screen continuous from the motor terminal box to the VFD terminals.

(e) Instrumentation cables

Instrumentation wiring and cabling required to carry signals to the PLC or process instrumentation shall be selected to suit the intended application.
Generally, overall screened cables shall be used for digital signal while overall and individually screened pairs shall be used for analogue signals. Analogue and digital signals shall not be provided within the same cable.

Cables shall generally be Dekoron or approved equivalent of minimum conductor size of 0.75 mm². Adequate separation shall be provided between instrumentation cables and other cabling to ensure non-interference from AC power and control cables. As a minimum, cable trays shall have adequate partitions and instrumentation cabling not in trays shall be run in separate conduits.

Provision of surge suppressing transient barriers shall be provided for all instrumentation cabling run external of buildings.

(f) Control systems networks

Control system networks shall be designed to suit specific application by a control system specialist.

(g) Pump power cable connection

Power cable termination for pump units shall be determined in consultation with Townsville Water and Waste. The following applies:

(i) typical all electrical equipment shall be hardwired; and

(ii) remote sites or high maintenance sites shall be connected by decontactor style plug and socket connections.

Where plug-in connections are used, the designer shall ensure that cableways from the plug to the motor are sized to permit plugs to be withdrawn with all other cables in place.

(h) Lighting and power sub-circuits

Cabling for lighting and power circuits shall be sized in accordance with the requirements of AS/NZS 3000 *Electrical installations.*
Generally, sub-circuit cabling shall be circular multiple stranded 0.6/1kV Copper PVC/PVC insulated and sheathed conductors where not enclosed in ducting and single insulated where enclosed by ducting.

The following minimum cable cross sectional areas shall apply:

Lighting sub circuit cabling	1.5 mm²
Power sub circuit cabling	2.5 mm²

(i) Cable identification

All cables shall have an identification number engraved on a non-corrodible metallic tag secured by a non-corrodible metallic tie. Tags shall be fitted to both ends of every cable.

(7) Wiring enclosures

(a) General

Cables shall be installed within wiring enclosures to provide the required degree of mechanical protection in accordance with AS/NZS 3013 *Electrical installations - Classification of the fire and mechanical performance of wiring system elements*. The wiring enclosures shall typically consist of cable ladder or conduits.

Wiring System Classification (AS3013)	Conduit Type
WSX1	Light Duty uPVC or equivalent
WSX2	Heavy Duty uPVC or equivalent
WSX3	Metallic Rigid Conduit or equivalent

(b) Cable ladder

Cable ladders shall typically be a heavy-duty aluminium type conforming to NEMA20B. In wet or corrosive areas stainless steel ladder may be required. Cable ladder shall be the primary method of support for surface run cables. Ladder support systems shall be designed such that loadings on ladders shall not cause deflection in excess of 1:200 of span length. Typically supports for horizontal ladders shall not exceed 3000 mm spacing and for vertical ladders, 1500 mm. In no case shall manufactures guidelines be exceeded. Ladders installed external to buildings shall be fitted with covers – horizontal ladders shall have peaked covers; vertical ladders shall have flat covers. Cables on ladders shall not be exposed to direct sunlight. It may be necessary to fit covers to the underside of some ladders. Bends, Tees and other fittings shall be of the same manufacture as the cable ladder. All fixings shall be stainless steel. Cables shall be secured in ladders utilising ties or clamps. Where external to a building, the ties/clamps shall be a non-corrodible metallic type.

(c) Conduit

Conduits shall have a minimum diameter of 20 mm and shall be run as directly as practical with a minimum number of bends or sets. Surface run conduits are to be as inconspicuous as possible and shall be run parallel to walls, floors and ceilings where ever practical. Conduit fittings shall be of the same manufacture and be compatible with the conduit. Elbows and Tee type fittings shall not be used. Long radius bends/sets or suitably sized junction boxes shall be used. Metallic conduits installed in wet or

corrosive environments shall be stainless steel or aluminium. Corrugated PVC conduit shall not be acceptable.

Underground conduits shall typically be installed to a Category A system as classified in AS 3000. The depth of burial shall be selected to suit the site environment. Sand shall be used as a bedding material – the type and grade selected to provide the required thermal properties for the installation.

Underground cable systems shall use cable pits at each change of direction and every 50 m on straight runs. The pits, lids and method of installation shall be suitable for the maximum wheel loads that may occur in the area in which they are installed. Typically “plastic” pits shall never be used where they might be subject to vehicle traffic. The pits shall be sized to suit the number of conduit entries and size/type of cables to be installed. Ensure that cable manufacturer’s minimum bending radius is never compromised. All conduit entries shall be bell-mouthed.

Underground cable routes shall be identified at each end, each change of direction, each pit entry and every 30 m along straight runs by a non-corrodible metallic plate with direction arrow, set in a concrete block.

(d) Flexible conduit

Flexible conduit shall be used to make the final connection to an item of plant. The flexible conduit shall typically be a PVC sheathed metallic liquid tight type, though in certain environments other materials may be more suitable, e.g. in wet, chemical or hazardous area environments. The flexible conduit shall be terminated with correct fittings from the same manufacturer as the conduit. The length of flexible conduit shall be kept to the minimum required to make a final termination to an item of plant. Corrugated PVC conduit shall not be acceptable.

(8) Switchboard design guidelines

(a) General

The following applies:

(i) electrical switchboards including motor control centres, distribution boards etc. shall be constructed in accordance with the requirements of the TCC specification TCC24 and accompanying standard drawings;

(ii) these typical drawings shall be adapted to suit the application and the proposed switchboard general arrangement;

(iii) the switchboard main switch shall be rated for 125% of the current rating of the consumer mains cabling;

(iv) generator control and/or connectivity shall be included;

(v) switchboard design shall include shrouding of live terminals to prevent inadvertent contact;

(vi) sections of switchboards required to be accessed by non-electrical personnel shall be physically segregated from other sections of the switchboard and be supplied by extra low voltage 24VDC power supplies. Where this requirement is not achievable, lockable hinged escutcheons shall be provided to prevent access to electrical equipment by unauthorised persons;

(vii) where the electrical energy metering is included in the overall switchboard design, a separate compartment with pad-lockable access door shall be provided in where required by the energy retailer;

(viii) switchboards located adjacent to sewerage pump stations shall be mounted on a concrete plinth to the side of the well;

(ix) sufficient concrete hardstand area shall be provided for maintenance personnel servicing the switchboard. Switchboards shall be located such that the access doors do not open towards an access road or the actual pump well; and

(x) galvanised steel bollards filled with concrete shall be erected in the vicinity of external electrical switchboards to minimise accidental vehicular damage to the switchboard and to protect maintenance personnel.

(b) Design documentation

The following list contains the minimum design documentation required for switchboard and electrical design to be submitted to Townsville Water and Waste for approval:

(i) Detailed electrical drawings including but not limited to the following:

(A) power single line diagrams;

(B) control circuit drawings;

(C) PLC control and network drawings;

(D) switchboard general arrangement drawings; and

(E) layout drawings.

(ii) Detailed electrical calculations including but not limited to the following:

(A) electrical maximum demand calculations;

(B) fault level calculations;

(C) cable calculations; and

(D) earth fault loop impedance.

(iii) Detailed electrical schedules including but not limited to the following:

(A) cable schedules;

(B) I/O schedules;

(C) single line diagrams;

(D) electrical equipment lists; and

(E) technical data sheets.

(c) Switchboard construction

Switchboard construction and equipment shall be in accordance with TCC24 specification, including:

(i) construction from 316 grade brushed stainless steel (the use of zinc anneal switchboard enclosures may be considered in internal locations with air-conditioned switch room);

(ii) all switchboard hardware, including, but not limited to, hinges, locking devices etc. shall also be manufactured from 316 grade stainless steel;

(iii) padlockable, vandal resistant swing handle type locking mechanisms are preferred for enclosures to suit the standard keying system. The overall number of lockable compartments shall be kept to a minimum; and

(iv) ventilation/cooling requirements to ensure internal temperatures do not exceed manufacturer's recommendations for any equipment contained in the switchboard.

External switchboards shall be painted colours that provide reflection of direct sunlight to minimise heat build-up within the switchboards, and shall be orientated to minimise risks of direct sunlight affecting internal electronic components.

Externally mounted switchboards and control panels shall be provided with sunhoods to minimise heat build-up within the control panels and to provide cover to maintenance personnel when working on the switchboards in rain.

- separate compartments to locate electronic soft starters > 22kW;
- separate compartments for PLC and telemetry hardware, with associated cabling terminated on suitably rated terminal strips; and
- VFD equipment in external boards may require suitable mechanical refrigeration/cooling systems to extend equipment life.

Motor starters, motor protection, and switchboard instrumentation shall be in accordance with the requirements of TCC specification TCC 24.

Major main switchboards and distribution boards shall include arc detection and VESDA protection.

(d) Electrical switchrooms

Dedicated electrical switchrooms shall be provided for large scale pump stations, treatment plants or where required to suit equipment types or the application.

Switchrooms shall conform to the requirements of AS/NZS 3000, the Building Code of Australia (BCA), and Townsville Water and Waste's operational requirements. Emergency lighting and fire extinguishers shall be provided at each Main Switchboard located within a dedicated switchroom as a minimum.

(e) Lightning and surge protection measures

Transient and surge projection devices shall be provided as recommended by the relevant Australian Standards including:

(i) AS 1768 *Lightning protection*; and

(ii) AS 4070 *Recommended practices for protection of low-voltage electrical installations and equipment in MEN systems from transient over-voltages*.

(9) Monitoring/control guidelines

(a) Design outputs

Control loop and P and ID drawings shall be provided for all major infrastructure including treatment plants and large pump stations.

Functional specifications shall be produced for proposed PLC and SCADA based control systems. Integration works are to be approved by Townsville Water and Waste.

For design and construct works, control loop and P and ID drawings shall be provided as part of the evaluation phase.

(b) Monitoring/control methodology - pump stations

Pump stations shall generally be controlled as per TCC-24 including local automatic / local manual and system control mechanisms.
All pump stations are to be remotely monitored by the telemetry and SCADA system.

(c) Monitoring methodology - reservoirs

Reservoir level monitoring shall be performed using submersible pressure transducers or external differential pressure transmitters.
Where flow to the reservoir is controlled by a pump or control valves, the pressure transducer shall be used for pump and/or valve control.

(d) Monitoring/control methodology - treatment plants

Treatment plants shall be controlled by PLC and SCADA based control systems, utilising optical fibre communication cabling.

Systems shall be to Townsville Water and Waste's current requirements, and systems for plant augmentations shall be compatible with existing systems. SCADA system shall be Citect or ClearSCADA (Townsville Water and Waste to confirm). PLC equipment shall be Siemens S7 series.

A functional specification for the monitoring/control of treatment plant systems including design and redundancy is to be included in the detailed design brief for each project.

(e) Float switches

Encapsulated float switches are to be provided in sewerage pump stations to indicate high level alarms. The installation of float switches must allow for the float to be accessed from the top of the pump well without the need to enter the well.

(10) Field equipment installation, wiring and terminations

(a) General

Field equipment installation, wiring and terminations shall generally encompass all electrical works external to the switchboards and motor control centres including but not limited to the installation of field cabling and cable support systems, local control stations, marshalling boxes, motor and equipment isolation and field instrumentation.
Important considerations include:

(i) preferred method of support and environmental conditions - includes consideration of flood levels, UV and damage by insects or vermin;

(ii) segregation of cabling - separation of differing cable types;

(iii) cable carrier capacity - capacity for present and planned expansion;

(iv) cable bend limitations;

(v) cable labelling requirements; and

(vi) cable mechanical protection.

(b) Field instrumentation and installation

(i) General

Field instrumentation shall be supplied and installed in accordance with the process requirements and the manufacturers' recommendations. The location and height of each instrument shall be shown on the relevant "Layout" drawings.

Field instruments shall be located as close to their primary connection to ensure instrument accessibility while still facilitating ease of access for operation, inspection and maintenance.

An optimum working and/or viewing height for each instrument shall be 1500 mm above grade or finished surface level.

No LCD screens for instrumentation or other plastic components that may be susceptible to damage from UV radiation shall be exposed to direct sunlight and potential vandalism shall be considered when locating equipment.

Where process instrumentation is installed on process pipework, suitable isolation devices shall be provided to allow for instrument removal.

All power supplies to instrumentation shall be surge protected and filtered.

(ii) Installation

Instrument enclosures suitable for the prevailing environment and any potential hazardous area classification of the area shall be provided for all field instrumentation and shall be installed in safe accessible locations.

Transmitters shall be enclosed in their own weatherproof enclosure and in addition, those mounted outdoors shall be shaded by 316 stainless steel covers with sides, drip hood and back as a minimum. All brackets and mounting bolts etc. for sensors and transmitters shall be 316 grade stainless steel.

Instrumentation shall not be supported from handrails or from steel work or plant which may be subject to vibration. All brackets and supports shall be constructed of 316 grade stainless steel and be constructed so that vibration from wind, operation of surrounding equipment, etc. is negligible.

(iii) Specific instrument requirements

Pressure transmitters where installed shall be fitted with valve manifold blocks.

Hydrostatic type level sensors shall be installed such that they are not affected by turbulence by the use of either stainless steel weighted cables or stilling tubes.

Impulse lines shall be fitted with valves and strainers. Lines shall be constructed of either copper or stainless steel and be provided with draining facilities for cleaning and maintenance. Cables shall be identified by an engraved metallic tag with SS fixings.

(c) Labelling of equipment

Equipment labels in the form of "traffolyte" labels shall be provided at each field mounted instrument to identify the instrument and at each local isolator or stop/start station to identify the item of plant that the isolator or control stations controls. Labels shall be fixed to equipment with stainless steel screws.

(11) Radio telemetry and SCADA system

(a) General

Townsville Water and Waste operates a telemetry system to monitor and/or control sewage pump stations, water supply pump stations and reservoirs. The system is based on Schneider Scadapack Hardware Controls (previously Serck/Hunter Watertech) PDS and Enet hardware connected by narrow band analogue and digital UHF radio networks. Human machine interface is provided by various SCADA software.

Automated and manual alarm dial outs are provided from SCADA alarms.

(b) New facilities

All new sewerage pump stations, water supply pump stations and reservoirs are required to be connected to the Telemetry system for the purposes of monitoring and control as required in TCC 24.

Functional system requirements such as network and repeater interfaces for the site and frequency details shall be determined during the design in consultation with council's electrical systems engineer.

(12) Mechanical services

(a) Pump design - general guidlines

(i) Pump selection

Pump selection shall be based on the following criteria:

(A) Townsville Water and Waste preferred equipment lists;

(B) system resistance curves (refer SC6.4.3.21.2 Water supply design; and SC6.4.3.21.3 Sewerage system design [SC6.4.3.21.3(5) Sewage pump station design]). Pump selection shall achieve all expected duties as per the system resistance curves;

(C) redundant (standby) pump capacity shall always be provided. Standby pump capacity should be at least equal to the capacity of the largest pump unit;

(D) availability of local product support for maintenance purposes; and

(E) whole of life costs.

For all pumps supplied as part of contracted works, the NPV shall be based on a 15-year design life and 8% real discount rate.

(ii) Motors

All pump motors shall be afforded a minimum of IP56 and be tropic proofed.

(iii) Water void protection

Water void protection shall be provided for all water pumping applications. Water void protection on large installations shall typically consist of limit switches mounted on an extended shaft of the non-return valve.
On smaller applications, flow switches may be used for water void protection.

(iv) Document requirments

The following documentation shall be provided as a minimum by the Contractor and/or pump supplier:

(A) details of all recommended spare parts and servicing tools including a priced list of the costs for each individual item;

(B) operations and maintenance manuals which adequately detail servicing intervals and requirements, dismantling instructions, itemised parts lists;

(C) pump performance – pump/motor factory test curves;

(D) the results of specific pump/motor performance testing to AS2417, showing flow rate, pressure, current, efficiency, and NPSH as a minimum; and

(E) pump/motor specification plates – shall be fixed to the pump and motor. Two additional sets of specification plates shall be supplied, one for inclusion into the switchboard.

(b) Pumping applications

Types of pumps for typical applications shall generally be as follows:

(i) sewage pump stations shall be provided with wet well submersible centrifugal pumps for all new

locations. Existing pump stations that are planned for upgrades shall be converted to dry well mounted submersible centrifugal type pumps. Grinder style pumps may also be offered where conditions exist that may prevent an 80 mm sphere being passed through the pump and discharge pipework;

(ii) water pumping stations shall generally be centrifugal pumps, with the number of pump stages to suit the duty point required;

(iii) RAS and WAS pumps at Sewage Treatment Plants shall generally be centrifugal submersible type controlled by VVVF Drives; and

(iv) positive displacement type pumps shall generally be installed for sludge handling applications.

Where sand infiltration causes excessive abrasion at pump stations, wear rings with increased hardness shall be fitted to the pumps and consideration given to ceramic coatings on the wearing surfaces.

Where pumps are provided with a double mechanical seal, a barrier fluid conductivity probe shall also be provided. This type of system shall be capable of producing an alarm which will be registered in the pump's switchboard and possibly the telemetry system when a change in conductivity is sensed. It is assumed that this will alarm due to a mechanical seal fault.

(c) Chemical dosing pumps

Dosing pumps shall generally be small diaphragm type pumps with either electronic or manual stroke adjustment depending on the application. Pump type and material is to be suitable for the chemical to be dosed.

Critical dosing pumps may require installation with automatic alarm considerations and feedback signals to the telemetry or PLC. These dosing pumps will generally be installed with means of electronically recording/confirming the flow in the dosing line and a means by which the flow in the dosing lines can be diverted back to the dosed fluid reservoir.

Dosing pumps may be required to be flow paced. Flow pace settings shall be manually adjustable.

Larger dosing pumps for dosing rates of between 5 and 50 L/hr shall generally consist of centrifugal pumps with magnetic drive. In this instance fluid void protection is to be provided.

Mass balance dosing systems are not desirable.

Generally Sodium Hypochlorite tank levels shall only be monitored in treatment plant applications.

Townsville Water and Waste's standard P and ID control and pipework drawing shall be used for all dosing pump installations.

(d) Pumping equipment

(i) Motor cable
The designer is to consider the future application of the pump, including if future conversion to VVVFD operation is required. Pumps with present or future VVVF Drive requirements shall be fitted with screened flexible cable.

(ii) Guide rails
Guide rails for removal of submersible pumps shall generally be stainless steel pipe, SCH 40 or better and shall be a minimum of 40 mm diameter.

(iii) Lifting chains
Lifting chains shall be provided at each submersible sewage pump station. Lifting chains shall be selected to be suitable tensile strength to lift the attached pump and shall be manufactured from coated or galvanised steel.

(iv) Pressure gauges
Pumps for water pumping applications shall be supplied with suction and discharge pressure gauges.

(e) Vibration monitoring

Pumps shall generally be provided with the following vibration monitoring devices in three axis locations.

Motor Size	Vibration Monitoring Requirements
10 kW and under	No requirement for vibration monitoring devices
Over 10 kW and up to 99 kW	Vibration monitoring pads
100 kW and above	Inbuilt vibration monitoring devices

Inbuilt vibration monitoring devices shall have all alarms connected to the telemetry and/or SCADA-based monitoring system.

(f) Pump work testing

Works testing of pumps shall be performed for units rated at 5 kW and above. All other pumps shall be provided with a Type Test Certification from the pump manufacturer.

Works testing shall be performed to AS 2417 *Rotodynamic pumps - Hydraulic performance acceptance tests - Grades 1 and 2:*

(i) Class 1 for water supply pumps greater than 20 kW; and

(ii) Class 2 otherwise.

The pump supplier shall provide copies of all test certification prior to the pump being dispatched from the manufacturer's factory.

Works testing will normally negate the requirement for a draw-down test to be conducted at each individual site. Where specified draw-down tests may be used to judge the performance of the pumps installed.

(g) Mixers

Mixers shall be either of the submerged type or stool mixers.

(h) Manual valves

Pressure reducing valves shall generally be Derot 300 series (or approved equivalent) with throttling plugs. Vee Port valves shall only be used with the permission of Townsville Water and Waste.

(i) Actuated valves

Actuated valves shall generally be installed with AUMA or Rotork electric actuators (or approved equivalent), in accordance with Townsville Water and Waste's preferred equipment lists.

Electrically actuated valves shall be three phase 415 V rated.

Pneumatically actuated valves shall generally be installed with Tyco Keystone pneumatic actuators, limit switches and/or positioners. In general, "spring close" is required for this type of installation.

All actuated control valves shall have analogue 4-20 mA signal position feedback into PLC and SCADA based monitoring and control systems. Where the actuated valve is not a control valve, limit switches may suffice for positioning.

(j) Air supply blowers

Air supply blowers for treatment plant applications shall generally be lobe type or roots blowers. Townsville Water and Waste's preference is for Robuschi manufactured blowers (or approved equivalent) of the positive displacement rotary type.

Blowers shall be provided with sound attenuation devices to limit the operating noise to levels that are within the limits that provide a safe working environment without the need for ear protection and are in accordance with the relevant local laws and environmental requirements.

(13) Equipment manuals

When purchasing equipment the designer shall specify that, detailed operations and maintenance manuals are to be provided.

As a minimum operation and maintenance manuals shall contain details of:

(a) general description of systems and equipment;

(b) operation and maintenance of systems and equipment instructions which adequately detail servicing

intervals and requirements, dismantling instructions, itemised parts lists Maintenance of Systems and Equipment Instructions;

(c) equipment schedules;

(d) manufacturer's literature;

(e) as-constructed equipment drawings; and

(f) commissioning and test data.

The following copies of the manual shall be provided:

- three hard copies of the manuals; and
- one PDF copy of all documentation.

Specific requirements for sewerage Pump Stations shall refer to SC6.4.3.21.3(5)(n).

SC6.4.3.21.5 Structural and civil design

(1) Introduction

(a) General

SC6.4.3.21.5 sets out the minimum requirements for:

(i) the design of new steel and reinforced concrete structures;

(ii) modifications to existing Townsville Water and Waste steel and reinforced concrete structures; and

(iii) design of civil works including fencing and security, roads and access, site works and landscaping for Townsville Water and Waste infrastructure.

(b) Reference and source documents

SC6.4.3.21.5 is to be read in conjunction with the following documents.
WSA 02 *Sewerage Code of Australia*
WSA 03 *Water Supply Code of Australia*
WSA 04 *Sewerage Pumping Station Code of Australia*
Workplace Health and Safety Queensland – *Safe Design of Structures – Code of Practise*

(c) Codes and standards

All designs and materials shall conform to these guidelines, the relevant current versions of the following general codes and standards in Table SC6.4.3.21.7, and also to the standards referred to within following Sections (2) to (6).

Table SC6.4.3.21.7 Townsville Water and Waste general codes and standards

Code/Standard	Description:
General	
Building Code of Australia (BCA)	Structures shall be designed for a minimum Importance Level of 3 according to the Building Code of Australia Table B1.2a
AS/NZS 1170.0	Structural design actions; Part 0: General principles
AS/NZS 1170.1	Structural design actions; Part 1: Permanent, imposed and other actions
AS/NZS 1170.2	Structural design actions; Part 2: Wind actions
AS/NZS 1170.4	Minimum design loads on structures; Part 4: Earthquake loads
AS 1657	Fixed platforms, walkways, stairways and ladders – design, construction and installation
AS 1418.1	Cranes (including hoists and winches); Part 1: General requirements
Structural Steelwork	
AS 1210	Pressure vessels
AS 4100	Steel structures
AS 4600	Cold formed steel structures
AS 1163	Structural steel hollow sections
AS/NZS 1594	Hot-rolled steel flat products
AS/NZS 3678	Structural steel – hot-rolled plates, floorplates and slabs
AS/NZS 3679.1	Structural steel – Part 1: Hot-rolled bars and sections
AS/NZS 3679.2	Structural steel – Part 2: Welded I sections
AS 3828	Guidelines for the erection of building steelwork

Code/Standard	Description:
AS/NZS 1554.1	Welding of steel structures
AS/NZS 1554.5	Welding of steel structures subject to high levels of fatigue loading
AS/NZS 2312	Guide to the protection of iron and steel against exterior atmospheric corrosion
AS 1627	Metal finishing – Preparation and pretreatment of surfaces; Part 0 to Part 9
AS/NZS 2311	Guide to the painting of buildings
AS 4020	Products for use in contact with Drinking Water
AS/NZS 4680	Hot-Dip Galvanised (Zinc) Coatings on Fabricated Ferrous Articles
AS/NZS 4791	Hot-Dip Galvanised (Zinc) Coatings on Ferrous Open Sections, Applied by an In Line Process
AS/NZS 4792	Hot-Dip Galvanized (Zinc) Coatings on Ferrous Hollow Sections Applied by a Continuous or Specialised Process
AS 2832.4	Cathodic Protection of Metals – Internal Surfaces
AS 3774	Loads on Bulk Solids Containers
Australian Institute of Steel Construction.	Structural Design of Steel Bins for Bulk Solids
API 650	Welded steel tanks for liquid storage
AWWA D100	Welded carbon steel tanks for water storage
Concrete Design	
AS 2870	Residential slabs and footings
AS 3600	Concrete structures
AS 3610	Formwork for concrete
AS 3700	Masonry structures
AS 3735	Concrete structures retaining liquids
AS 2159	Piling design and installation
AS 5100	Bridge design
AS/NZS 4671	Steel reinforcing materials
AS 1379	The specification and manufacture of concrete
AS 1478	Chemical admixtures for concrete
AS 1012	Methods of testing concrete

Where a discrepancy exists between this sub-section and the documents referenced herein, this sub-section shall take precedence.

(d) Certification

All designs shall be certified by a Registered Professional Engineer of Queensland (RPEQ).

Designs shall require a structural design certificate signed by an RPEQ prior to acceptance by Townsville Water and Waste. Acceptance of the design by Townsville Water and Waste does not relieve the designer of their legal or contractual obligations.

(2) Structural steelwork design

(a) General

(i) Scope

This section sets out the minimum requirements for the design of new steel structures and modifications to existing Townsville Water and Waste steel structures.
Typical Townsville Water and Waste steel structures include:

(A) reservoir tanks;

(B) monorails

(C) walkways / platforms and ladders; and

(D) buildings and sheds.

These guidelines do not apply to the design of other types of structures or the following materials:

- aluminium structures (except aluminium walkways/platforms and ladders);
- stainless steel; and
- composite structures.

Design incorporating these materials or relating to other structures shall be performed by suitably

experienced and competent persons.

(ii) Design and materials

All steelwork designs and materials shall conform to these guidelines, the relevant current versions of the standards listed in Table SC6.4.3.21.7 and the standards referred to within them.

(iii) Connections

The following applies:

(A) minimum design actions for connections shall be as per the relevant loading codes;

(B) generally bolted connections shall be designed to be a minimum of 2 x M20 8.8S bolts through 10mm thick cleats. Generally weld sizing shall be designed by using GP welds using E48XX welding electrodes;

(C) seal plates, where required, shall be a minimum of 6 mm thick;

(D) cast in bolts for structural purposes shall be galvanised and at least M12 diameter. Structural fixings to insitu concrete or masonry shall be a minimum of 2 x M12 bolts; and

(E) base plates shall be a minimum of 10 mm thick and grout shall be a minimum of 35 mm thick.

(iv) Protective coating systems

The following applies:

(A) generally, the protective coating system of the steelwork shall conform with current version of AS/NZS 2312 and Standards and documents referred to therein;

(B) painting where adopted shall conform with the current version of AS 1627 and AS/NZS 2311, and standards and documents referred to therein;

(C) all painting on the internal surface of water storage structures shall conform with the requirements of AS 4020 *Products for use in contact with Drinking Water;*

(D) galvanising, where required, shall conform with the current version of AS/NZS 4680, AS/NZS 4791, AS/NZS 4792, and standards and documents referred to therein;

(E) the design and detailing of members to be hot dipped galvanised shall take into account the recommendations of the Galvanizers Association of Australia;

(F) protection of steelwork by a protective wrap shall be in accordance with the manufacturer's recommendations and specifications and to the satisfaction of the designer; and

(G) protection of internal surfaces of water storage tanks by cathodic protection shall be in accordance with the current version of AS 2832.4 and standards and documents referred to therein.

(b) Reservoirs

Reservoir structures shall be designed for a minimum importance level of 3 according to the *Building Code of Australia* Table B1.2a.

Townsville Water and Waste has a preference for circular steel reservoirs, with a steel floor and roof structure. Typical "standard" reservoir details can be made available by Townsville Water and Waste, on request.

"Non-standard" reservoirs shall be designed using the principles outlined in AS 3774 *Loads on Bulk Solids Containers and Structural Design of Steel Bins for Bulk Solids* published by the Australian Institute of Steel Construction.

Reservoir Design criteria shall incorporate:

(i) bird and vermin proofing;

(ii) the roof shall ensure adequate ventilation and sufficient fall to ensure adequate drainage for the adopted roof sheeting;

(iii) steel purlins shall have downturned lips to the bottom flange and be oriented to prevent ponding of moisture;

(iv) roof falls shall allow for rafter and purlin deflections. The exposure of the site will determine the roof

sheeting finish and type;

(v) a lockable access cover shall be provided through the roof to allow access for internal cleaning. No permanent access to the interior of the reservoir shall be provided. Access shall be via temporary means only;

(vi) the design of the reservoir shall incorporate an access ladder or stairway from ground level to roof level, with lockable cage to restrict unauthorised access;

(vii) the roof design shall incorporate sufficient fall arrest restraints or hand railing around the perimeter;

(viii) the design of the floor shall consider cleaning and maintenance required in the future; and

(ix) the foundations of the entire tank structure shall be founded on undisturbed parent material. Founding on fill material is not permitted.

(c) Monorails

The following applies:

(i) monorail beams and supports shall be designed in accordance with AS 4100 and AS 1418.1;

(ii) the safe working load (SWL) shall be clearly and permanently marked (not painted) on all monorails beams;

(iii) the minimum SWL shall be determined by the functional requirements of the monorail, but shall not be less than a minimum lift weight of 1000 kg;

(iv) unless known otherwise, monorail beams shall be designed based on the assumption that the centre of bearing of the trolley wheels is on the edge of the beam flange;

(v) deflections of monorails beams and supports shall not impair the functioning of the monorail but in no instances shall exceed the span/500;

(vi) the number of load cycles shall be calculated for each individual monorail based on a minimum design life of 50 years;

(vii) all monorail beams shall be load tested after erection; and

(viii) the design of the monorail beam shall consider future maintenance requirements.

(d) Walkways/Platforms and Ladders

The following applies:

(i) walkways, platforms and ladders shall be designed in accordance with AS 1657;

(ii) generic products conforming with the above Standard may be utilised;

(iii) all ladders greater than 2.5 m high shall be provided with a cage complying with AS 1657;

(iv) walkways, platforms and ladders may be galvanised, stainless steel or aluminium;

(v) where possible riser and going dimensions on stairs shall conform with both AS 1657 and the BCA; and

(vi) no ladders or stairs shall be designed for access to confined spaces as defined by workplace health and safety unless approved by council.

(e) Sheds

Typically, design of sheds will be outsourced to suitably experienced and competent persons.

(3) Concrete design

(a) General

(i) Scope

This section sets out the minimum structural requirements for the design of reinforced and plain concrete members, and reinforced concrete masonry block work for Townsville Water and Waste. Specifically, this section provides guidelines for the design of the following types of structures:

(A) thrust blocks, valve and fittings pits associated with pipelines;

(B) bored piers;

(C) slabs on ground;

(D) concrete pavements

(E) manholes;

(F) pump stations and wet walls; and

(G) retaining walls.

These guidelines do not apply to the design of post tensioned concrete. Design incorporating post tensioned concrete or relating to other structures shall be performed by suitably experienced and competent persons.

(ii) Design and materials

All concrete and false work designs and materials shall conform to these guidelines, the current relevant versions of the standards listed in Table SC6.4.3.21.8 and standards referred to within them.

All reinforcement and concrete materials shall be sourced from a quality assured manufacturer of such products.

Splicing and lapping of reinforcement shall be as per the requirements of AS 3600. All exposed corners shall be designed for a 25 x 25 chamfer.

The use of low ductility mesh as reinforcement in suspended concrete should be avoided.

(iii) Minimum concrete requirements

Concrete grades and cover for reinforcement shall be in accordance with the appropriate exposure classification in AS 3600 and AS 3735 with minimum values as set out in Table SC6.4.3.21.8.

Table SC6.4.3.21.8 Minimum concrete strengths

Construction Element	Minimum Concrete Strength
Access cover (sewer and stormwater)	N32
Thrust blocks	N20
Concrete surrounds for sewerage house connection branches	N20
Bored pier footings	N25
Pump stations and wet wells	N40
General concrete works (sign post bases, bases for post and rail fences etc.)	N20

Minimum reinforcement in reinforced concrete members shall conform with the requirements of AS 3600, AS 3735, AS 5100 or AS 2159.

(b) Thrust blocks and valve pits

Thrust blocks shall be sized in accordance with SC6.4.4.8 Standard drawings SD-371 Thrust Block Details – Concrete Blocks.

Valve pits shall be sized to provide adequate clearance around valves, pipes and fittings to allow for operations, maintenance and repair of the equipment. Pits required to provide in-line thrust shall be designed accordingly, taking into account the allowing bearing capacity of the soils. Pits shall be provided with lockable aluminium lids; and the designer is to refer to WSA-03 for detailing requirements for valve chambers.

(c) Bored piers

Bored pier design shall take into account the design loads and soil parameters. Soil parameters for the design of piers may be assessed visually by suitably experienced and competent persons if deemed suitable for the application.

Typically bored piers for building applications shall be a minimum size of 450 mm diameter by 900 mm deep in undisturbed ground. When steelwork is cast into piers the top surface of the concrete pier shall be worked to provide a positive fall away from the steelwork to the outside of the pier.

(d) Slab on ground

Slabs and footings for habitable buildings shall be generally designed and constructed in accordance with AS 2870. Assessment of site reactivity shall be in accordance with requirements of AS 2870. Beam

layouts and depths shall be as per AS 2870 except that all footings shall be continuous at re-entrant corners.

Non habitable buildings shall be designed using the guidelines in *Guide to Industrial Floors and Pavements* published by the Cement, Concrete and Aggregates Australia. The possible future uses of the building should be considered in determining the appropriate design for the slab and footings.

Minimum slab thickness shall be 100 mm and minimum reinforcement shall be SL72. Slab thicknesses and reinforcement shall be sufficient to support any loads from plant and maintenance equipment and sufficient to provide adequate cover to any slab fixings.

(e) Concrete pavement

Concrete pavement shall only be designed by suitably experienced and competent persons. Concrete pavement shall be designed in accordance with sub-section SC6.4.4.2 Pavement design and all standards and documents referred to in them.

(f) Access covers

Access covers shall be circular, and sized in accordance with the current version of the following standard drawings:

(i) SD-510 Maintenance Holes; Typical Manhole Cover Arrangements;

(ii) SD-205 Stormwater Manhole Details;

(iii) SD-210 Precast Stormwater Manhole Slab Top Details; and

(iv) SD-475 Typical MH Cover Arrangements.

(g) Pump stations and wet well materials

Pump station buildings shall be constructed from reinforced concrete and/or reinforced masonry block. Wet wells shall be constructed from reinforced concrete. Drainage of below ground structures shall be considered in the design.

Other materials (e.g. GRP) are subject to approval from council.

The structure shall be sized to allow for adequate clearances for maintenance and replacement work, with appropriate clearances for different valves and fittings. No permanent access ways shall be constructed within pump stations or wet wells. The size of the structure shall be the most cost effective combination allowing for concrete, reinforcement and formwork costs.

(4) Fencing and security

Townsville Water and Waste assets will generally require an assessment of fencing and security issues, some security designs are shown in Attachment C: General facility security.

(a) Reference and source documents

The following references shall be consulted.
Disaster Management Act 2003
AS/NZS 4360 *Standard for Risk Management*
Emergency Management Australia - *Critical Infrastructure Emergency Risk Management and Assurance* handbook to support AS/NZS 4360
Queensland Government - *Securing Queensland's Critical Infrastructure: Guideline for Owners/Operators*
LGAQ - *Local Government Counter Terrorism Risk Management Kit*
The National Security Australia web site www.nationalsecurity.gov.au

(b) Minimum fencing requirements

The minimum requirement shall be a 2.8 m high chain mesh fence with 4 barb extensions with top and bottom rails, with double access gates 6 m minimum width determined by site requirements as per SC6.4.3.21 Attachment C.

All gates shall be provided with the standard Townsville Water and Waste padlock.

Some installations may require additional interlocked padlocks for access by other services.

(5) Roads and access

(a) General

This section sets out the minimum requirements for the design of roads and accesses to Townsville Water and Waste facilities.

The facilities typically encountered include pump stations, storage reservoirs and roads, access and parking at treatment plants.

(b) Design standards

All roads, accesses and carparks shall be designed in accordance with the following sub-sections:

(i) SC6.4.4.1 Geometric road design; and

(ii) SC6.4.4.2 Pavement design.

(c) Minimum requirements

All weather sealed access for maintenance vehicles shall be provided including:

(i) sealed asphalt access road, minimum pavement width 4 m (spray sealed access roads may be considered for longer accesses or lower longitudinal grades in areas where vehicles do not manoeuvre);

(ii) special surface treatments e.g. pavers may be required for aesthetic reasons or usage/transport of chemicals at some facilities;

(iii) provide access during a 1% AEP flood event;

(iv) road geometry suitable for use by light vehicles and single axle trucks, including vertical alignment check to ensure vehicle clearance. All turning movements shall be analysed with turning path software. Three point turns are allowed for access at pump stations;

(v) bunding of tanker unloading areas will be necessary as well as associated storage and pump-out facilities; and

(vi) all accesses shall be provided with suitable signage and line marking.

(6) Stormwater drainage

(a) General

This section sets out the minimum requirements for stormwater drainage at Townsville Water and Waste facilities.

(b) Design standards

All stormwater drainage shall be designed in accordance with SC6.4.4.4 Stormwater drainage design.

(c) Minimum design requirements

The following are minimum requirements for consideration during stormwater design:

(i) all Townsville Water and Waste facilities shall be above the 1% AEP flood level plus 300 mm freeboard and above the 0.2% AEP storm surge level;

(ii) all accesses shall be above the 1% AEP flood level, where possible;

(iii) the design shall allow for both primary and secondary drainage paths;

(iv) the issue of contaminated water shall be addressed and pollution traps may be necessary; and

(v) erosion and sediment control plans shall be prepared for all projects.

(7) Site regrading

(a) General

This section sets out the minimum requirements for site regrading at Townsville Water and Waste facilities.

(b) Design standards

(c) All site regrading shall be designed in accordance with SC6.4.4.5 Earthworks. Minimum design requirements.

The following are minimum requirements for consideration during site regrading design:

(i) a geotechnical investigation may be necessary by a suitably qualified consultant;

(ii) excavation may expose acid sulfate soils and this must be addressed in accordance with

legislation;

(iii) excavation may expose hazardous substances and this is to be addressed in accordance with workplace health and safety legislation; and

(iv) if blasting is necessary suitably qualified personnel are to be consulted and all safety approvals and public consultation requirements are to be addressed.

Note—SC6.4.3.24 Geotechnical investigations, specifies requirements for undertaking geotechnical investigation works. Part 9.3.2 Healthy Waters Code of Townsville City Plan has requirements regarding ASS/PASS and accords to State requirements.

(8) Landscaping

Where specified, some Townsville Water installations will require landscaping. Refer to requirements in SC6.4.3.6 Landscaping policy.

(9) Blasting activities

All purposed blasting activities must be designed and certified by an RPEQ and specifically state that there will be no structural impact on council infrastructure. Refer to SC6.4.5 Construction management and SC6.4.6.10.4 Blasting general, for use of explosives during construction.

(10) Drafting deliverables

All drafting shall be to current Australian Standards.

All drawings submitted for approval shall be provided in A3 size paper format or digital PDF format as determined by the Townsville Water and Waste project officer.

Final drawing submission shall comprise the following:

(a) digital DWG file in AutoCAD 2008 format on CD;

(b) digital PDF file on CD; and

(c) one x A3 size paper copy.

SC6.4.3.22 Waste management guidelines

SC6.4.3.22.1 Introduction

(1) Purpose

The purpose of the Waste management guidelines is to:

(a) ensure development provides for the functional management of waste in a manner which is environmentally acceptable, safe and efficient and that does not have adverse amenity impacts on external properties or internal development;

(b) provide general guidelines and advice about achieving waste management outcomes of Townsville City Plan and satisfying any assessment criteria which identifies this planning scheme policy sub-section as providing that guidance or advice;

(c) state standards for waste management, storage and servicing identified in assessment criteria and which identifies this planning scheme policy sub-section as providing the standards; and

(d) provide guidelines about the preparation of a waste management plan.

(2) Reference and source documents

Reference and source documents and other policy sub-sections listed below shall be used, applied and read in conjunction with this planning scheme policy sub-section.

(a) Development manual planning scheme policy sub-sections that are to be read and applied in conjunction with this policy sub-section are as follows:
SC6.4.3.5 Car parking and public transport facilities guidelines
SC6.4.3.6 Landscaping
SC6.4.3.17 Driveways
SC6.4.4.1 Geometric Road Design

(b) Legislation
Environmental Protection Regulation 2008
Environment Protection (Water) Policy 2009
Environmental Protection (Waste Management) Regulation 2000

(c) Townsville City Council
Townsville Waste Services Requirements for Waste Chute Guidelines, 2012
Liquid Trade Waste Policy, 2009

(d) Australian Standards
AS/NZS 3816 - *Management of clinical and related waste*
AS/NZS 2890 - *Parking facilities*
AS 4123 – *Mobile waste containers*

SC6.4.3.22.2 Waste management plans

Where proposed developments are likely to generate unusual or large amounts of waste, a waste management plan (WMP) may be required in demonstration of providing appropriate waste storage and waste servicing.

(1) Council may require submission of a waste management plan for development involving the following development thresholds:

(a) a residential use with more than 10 dwellings;

(b) a business/commercial/industrial use with a gross floor area greater than 500m² or any use likely to generate large or unusual amounts of waste, including educational establishment, rooming accommodation, hotel major sport, recreation and entertainment facility;

(c) an environmentally relevant activity (as defined by Schedule 1 of the *Environmental Protection Regulation 2008)* and/or development involving the use of a hazardous materials or chemicals;

(d) operational works involving substantial waste materials resulting from removal and construction of new infrastructure or demolition and major earthworks; and

(e) another use or activity where identified as having significant waste management requirements.

(2) Where WMPs are required to support a development application, it should be tailored to the needs of the proposal.

(3) Short-term activities or small-scale, uncomplicated developments require relatively simple and short WMPs.

(4) Larger proposals will require detailed plans covering the different stages of the development, operations or works program.

(5) A WMP should be submitted detailing how the proposal will meet the requirements of the Townsville City Plan and consider the following issues:

(a) Residential applications:

(i) types and amounts of waste that may be generated based on number of dwellings;

(ii) how the waste will be disposed including number of mobile storage bins or nomination of a suitable size bulk bin;

Note—all residential waste must be removed by council.

(iii) access and egress for council waste collection vehicles;

Editor's note—applicants should refer to sub-sections SC6.4.3.5 Car parking and public transport facilities guidelines and SC6.4.3.17 Driveways for additional information on design and access requirements.

(iv) screening of waste facilities by landscaping or other suitable means and where required, nomination of separation distances to property boundary or other residential buildings;

Editor's note—applicants should refer to sub-section SC6.4.3.6 Landscaping for additional information regarding landscape treatments.

(v) design of facility incorporating requirements from SC6.4.3.22.3 Waste management for development and Table SC6.4.3.22.1 General requirements;

(vi) sensitivity of the receiving environment and neighbouring residents (adequate setbacks of waste areas from adjoining property boundaries so as to prevent odour, dust or noise nuisance);

(vii) nomination of collection times where bulk refuse containers are required to protect nearby and on-site sensitive land use; and

(viii) designated bin wash down facilities to be identified for the contained cleaning of waste bins.

Note—bin washing water is not to be disposed of into stormwater facilities.

(b) Commercial and industrial applications:

(i) types and amounts of waste that may be generated by the authorised activities;

(ii) how the waste will be dealt with, including a description of the types and amounts of waste that will be dealt with;

(iii) procedures for identifying and implementing opportunities to minimise the amount of waste generated, promote efficiency in the use of resources, and otherwise improve the waste management practices employed, including recycling;

(iv) access and egress for those disposing waste and waste collection vehicles;

Editor's note—applicants should refer to SC6.4.3.5 Car parking and public transport facilities guidelines and SC6.4.3.17 Driveways for additional information on design and access requirements.

Note—if the waste is stored in a secured underground shelter, then the waste must be taken out and presented to Townsville Waste Services on collection day.

(v) noise management for collection (collection methods and times);

(vi) screening of waste facilities by landscaping when used in combination with other suitable means and where required, nomination of separation distances to property boundary or other sensitive land uses;

Editor's note—applicants should refer to sub-section SC6.4.3.6 Landscaping for additional information regarding landscape treatments.

(vii) details of any accredited management system employed, or planned to be employed, to deal with the waste;

(viii) how often the performance of the waste management practices will be assessed;

(ix) the indicators or other criteria on which the performance of the waste management practices will be assessed;

(x) staff training on matters relevant to waste management;

(xi) details of the responsible person for implementing the WMP;

(xii) procedures for dealing with accidents, spills and other incidents;

(xiii) sensitivity of the receiving environment, and neighbouring residents (adequate setbacks of waste areas from adjoining property boundaries so as to prevent odour, dust or noise nuisance);

(xiv) management of odour;

(xv) extent and life of the proposed activities;

(xvi) details of bunding arrangements to contain waste where appropriate; and

(xvii) designated bin wash down facilities to be identified for the contained cleaning of waste bins.

Note—bin washing water is not to be disposed of into stormwater facilities.

(6) Council may request other reasonable management strategies in relation to individual developments.

(7) The WMP must be implemented during construction and at commencement of the use or the signing of the survey plan.

(8) WPMs should take into account any staging of a development.

(9) Consideration of screening treatments will include ensuring structural safety, durability to minimise whole of life costs, and where practical, integration into the building design and constructed from similar materials used in the building design (integration). Screening must be to a minimum of the height of the bins used and should ensure screening addresses adjoining uses and public spaces.

(10) Any amendments to a WMP must not be implemented until approval from council is received.

SC6.4.3.22.3 Waste management for development

(1) The waste management standards for development are identified in the following section and in Table SC6.4.3.22.1 General requirements.

(2) In addition to the requirements of Table SC6.4.3.22.1 General requirements, the following standards shall be considered for development:

(a) access for a refuse collection vehicle to an on-site or kerbside bin or a compactor is maintained at all times; or

(b) "No Standing Any Time" signs are to be installed in designated refuse truck turning areas including residential developments, cul-de-sacs and other locations to enable safe access for waste refuse vehicles; or

(c) a development application is to indicate the days and times that a refuse removal service is to operate. If evidence from a refuse collection contractor indicates that collection will occur outside normal service/delivery or business times, it may be permissible to allow a refuse collection vehicle to utilise

service bays or parking spaces on the site for access; or

(d) where applicable, development is to provide the vertical and horizontal clearances for the service to safely and efficiently operate. Unless otherwise stated in Table SC6.4.22.1 General requirements, the minimum vertical clearance required for movement of a refuse collection vehicle is 6.5m. Larger operational clearance dimensions may be required depending on site specific requirements; or

(e) where applicable, a development that proposes to utilise a waste collection system requiring clearances less than 6.5m for vehicle movement is to include a written confirmation from the proposed waste collection provider giving full details of the proposed system, bin sizes, number of bins, frequency of collection and the refuse collection vehicle size; or

(f) all refuse collection for residential development is to be collected by council, whilst office refuse may be collected by the council or a private operator and retail, shop or industrial refuse collection is to be collected by a private operator; or

(g) whether domestic refuse collection is from a bulk storage area or bins located throughout a unit development, all circulation and access roads utilised by a refuse vehicle are to be a minimum of 6.5m wide; or

(h) where a development has access onto a road, all refuse collection is from within the site. For access to a road the refuse truck is required to enter and leave the site in a forward direction; or

Editors note - Applicants should refer to SC6.4.3.13 Townsville road hierarchy for additional information.

(i) industrial development is to indicate the location of the refuse collection area in the development application and provide an indication of the proposed method of disposal of refuse and waste, including trade waste. Where disposal of industrial or commercial liquid waste by discharge to a road tanker application is necessary, the road tanker is able to stand totally on-site and comply with all other relevant regulations; or

(j) the owner/occupier must keep the bins clean, in good repair and securely covered.

(k) the property must be designed to store the bin/s at ground-level, and generally located towards the rear of the premises or, if not, out of sight of the general public, except when put out for collection (one day maximum); or

(l) where required, the property must be designed to facilitate the placing of the bin/s out (on the specified collection day) as follows:

  (i) on, or as close as possible to, the kerb adjacent to the premises, with the bin axle away from the road;

  (ii) with no structure or obstacle preventing the waste/ recycling crew from picking the bin up; and

  (iii) with at least 500mm spacing between the bins; or

(m) particular serviced premises may be required to keep the bin on an elevated platform or an imperviously paved area, enclosed and/or with drainage; or

(n) council may also instruct certain residential premises to dispose of their waste by an approved environmental licensed authority.

(3) Applications must ensure that adequate unhindered access for waste collection vehicles is possible, ensuring that not only the road reserve widths accommodate a waste collection vehicle, but that vehicles can safely and efficient collect kerb side waste.

(4) Waste collection from properties in cul-de-sac heads or hammer heads may require kerb side concrete hardstand areas to be constructed to ensure that kerb side collection remains possible. SC6.4.3.22.5 Concrete hardstand design for wheelie bins provides the design specification for kerb site domestic wheelie bins.

Editor's note—applicants may be asked to submit a plan demonstrating the location of waste collection points.

(5) Waste collection from a laneway is only permitted when the laneway has through access, sufficient width to accommodate the waste collection vehicle and the identification of wheelie bin collection points. Overhead

services also need to be clear of the waste collection area.

(6) Private access handles where multiple lots may be serviced from are not accessible by a waste collection vehicle. In such instances, a safe designated kerb side collection point is to be nominated. SC6.4.3.22.5 Concrete hardstand design for wheelie bins provides the design specification for kerb side domestic wheelie bins.

Editor's note—applicants may be asked to submit a plan demonstrating the location of waste collection points.

(7) Where waste collection points are nominated away from the property being serviced (cul-de-sacs, laneways, access handles), nominated collection points are not permitted adjacent to a park and are not to compromise the safe use or access to pedestrian or other utility service.

Editor's note—applicants may be asked to submit a plan demonstrating the location of waste collection points.

(8) Where staged residential estates result in temporary no through connection roads (for example, until subsequent stage construction is complete), compacted gravel (or equivalent) is required to be created at the end of a constructed road within a public tenure (i.e. road reserve).

Editor's note—waste collection vehicles will not be permitted to use privately owned land to turnaround.

(9) In instances where roads terminate to adjoining land and adjoining land is in separate/different ownership or not subject to the development application, applicants will need to provide a turnaround area within the development site until future through connection can be established. In this instance, the turnaround area will need to be constructed of durable material.

(10) If a rear lot, the frontage is to include an additional truncated area to provide sufficient space for the servicing of mobile waste containers. These truncated collection points are to avoid obstructing any driveway or encroachment onto neighbouring frontages.

(11) If there are two or more rear lots, no more than two adjoining truncated areas are provided for the servicing of mobile waste containers.

(12) Collection points are not located:

(a) near intersections;
(b) near roundabouts or traffic calming devices (or other traffic management devices);
(c) on arterial road frontages;
(d) in narrow lanes (where refuse collection vehicle access is difficult or impossible); and
(e) near bus stops.

(13) Where on-street (kerbside) waste collection is proposed for standard domestic waste containers sufficient kerbside space is provided adjacent to the frontage of the premises for the required number of bins and such space is:

(a) clearly separated from car parking bays, loading bays and other similar no-standing areas;
(b) clear of overhanging branches, awnings and other such hindrances to servicing by a lifter arm;
(c) clear of footpaths and pedestrian access connections to the road;
(d) not in front of shop entrances or private residential premises;
(e) not blocking the vision of vehicles using the roadway or entering and exiting the property;
(f) capable of being serviced safely without the collection vehicle impeding traffic flow during servicing; and
(g) capable of being serviced while the collection vehicle travels forward (i.e. without the vehicle needing to

reverse).

SC6.4.3.22.4 Regulated waste guidelines

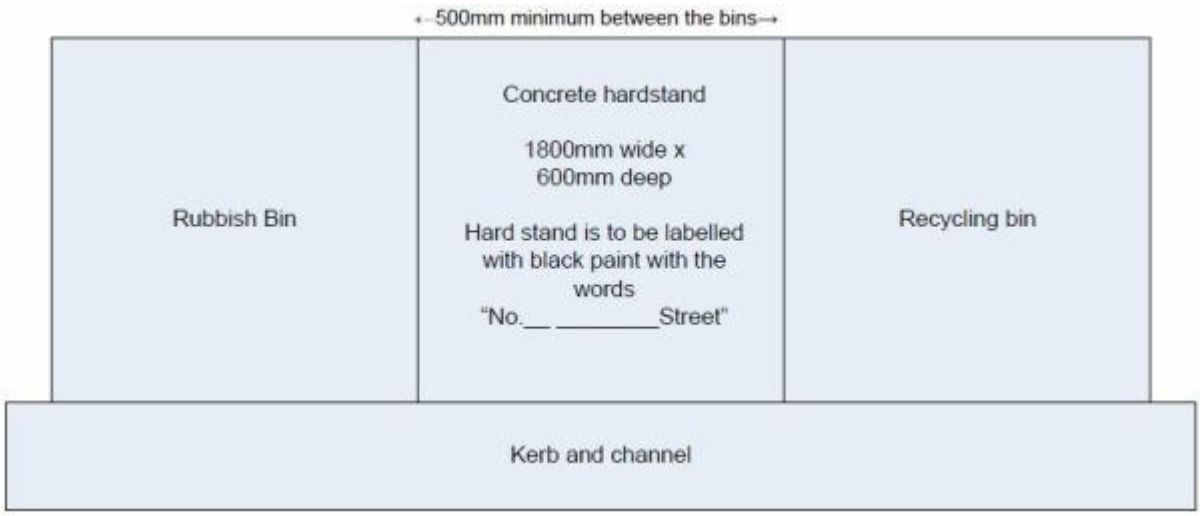
(1) Regulated waste is administered by the Department of Environment and Heritage Protection.

(2) Transport, storage, recycling or disposal of regulated wastes are environmentally relevant activities.

(3) Environmentally relevant activities that are prescribed activities are generally industrial activities but can also include some agricultural activities. A full list of all of the prescribed ERAs can be found in Schedule 2 of the *Environmental Protection Regulation 2008.*

SC6.4.3.22.5 Concrete hardstand design for wheelie bins

Where waste collection vehicles are unable to collect wheelie bins directly in front of a property due to access restrictions, owner/occupiers must take the bin/s to a designated collection point. The diagram below demonstrates the dimensions required for a hardstand for these bins at the designated collection point.



SC6.4.3.22.6 Examples of bin storage area

Figure SC6.4.3.22.1 Concrete hardstand for mobile waste containers or a bulk bin

A: Courtside entrance: The height of the roof is 1m in the middle receding downwards.
B: Interior: The height is 2.5m to the top of the pillar/ gutter level.
C: Exterior entrance: The gate is 1.9m of the total 4m depth and is accessed by a key.
D: Kerbside view.

Figure SC6.4.3.22.2 Enclosed concrete hardstand for bulk waste and recycling mobile waste containers

SC6.4.3.22.7 Bulk bin specifications

Note—refer to AS 4123 for the standard sizing of bulk bins. Bulk bins must be ordered well in advance to ensure availability.

Table SC6.4.3.22.2 Bin dimensions in litres (L) and cubic metres (m^3)

Recycling and Waste bins available for units, multi-dwelling units and commercial units
240 L plastic
360 L plastic (recycling)
Bulk Recycling and Waste bins available for multi-dwelling units and commercial units
660 L plastic/metal
1100 L metal
Bulk Waste bins available for multi-dwelling units and commercial units
0.75 m^3 metal
1 m^3 metal
1.5 m^3 metal
3.0 m^3 metal
Bulk Waste bins available for commercial units
4.0 m^3 metal

Table SC6.4.3.22.3 Weekly bin collections in relation to bulk bin size

Number of units (dwellings)	Bulk bin Size	Collection frequency (per week)
6	0.75 m^3	Twice
6	1 m^3	Twice
6	1.5 m^3	Once
12	1.5 m^3	Twice
12	3 m^3	Once
24	3 m^3	Twice

Table SC6.4.3.22.1 General requirements

	General details	Access and collection	Locality of storage areas/design of facility
Residential (dwelling house dual occupancies)	Mobile waste containers (240 L) are used for both waste collection and recycling. Owner/occupiers may also choose to pay a small additional charge for a 360 L recycling bin.	Where sloping areas exist (≥15%), an adequate level hard stand area with sufficient space to accommodate all bins for collection is to be made available along the street frontage for the collection of mobile waste and recycling containers collected fortnightly. Refer to SC6.4.3.22.5 for an auto court concrete hardstand design for wheelie bins. Other arrangements may be negotiated.	Mobile waste containers must be stored at a location within the property boundary that avoids nuisance to neighbouring properties.

Residential (including multiple dwelling, residential care facility retirement facility and the like)	Developments containing a maximum of 10 dwellings will be issued with new mobile waste containers unless there is insufficient footpath to place the waste and recycling bins for collection. Where on-street access for collection of mobile garbage (wheelie) bins is not available, or multiple dwellings contain more than 10 dwelling (or similar) the developer must provide bulk refuse facilities. Refer to SC6.4.3.22.7 for more information on bulk bin collections. Recycling bins will be allocated at the rate of: 1-4 dwellings 1 bin per dwelling 5-10 dwellings 5 bins More than 10 dwellings 1 bin per 2 dwellings If constructing waste chutes, refer to council's Waste Chute guidelines.	Access roads must be designed and constructed to accept vehicle loadings of not less that G.V.M. 33 tonnes. If the road system is incapable of allowing waste vehicle access, tailored solutions will be negotiated with the developer in association with the Waste Services Division. Vehicles must be capable of exiting the site in a forward gear. A turning circle of 25m is required. Waste collection facilities are to be located within the curtilage of the premises in an accessible location to receive the service. Facilities should be sited in front of any entry gates to the building. Where security gates cross the driveway restricting vehicular access to the site, bin storage areas are to be located within property boundaries on the street side of the gate. A minimum overhead clearance of 6.5m is required (with an additional 2m if located near power lines). This must be unobstructed by anything overhead such as trees, wires, sails, awnings, fascia or other structures. Where sloping areas (≥15%) such as steep road reserves exist, an adequate level hard stand area with sufficient space to accommodate all bins for collection is to be made available along the street frontage for the collection of mobile waste containers (collected weekly), and recycling mobile waste containers (collected fortnightly).	For multiple dwellings where there is sufficient room for each dwelling to store their mobile waste containers; the resident of each dwelling is responsible for the storage of their bins (including recycling bins). Where there is insufficient space for individuals to accommodate their bins, a common waste storage area must be provided of a sufficient size to accommodate all bins (including recycling bins). Storage areas must provide convenient access for owners, tenants and collection vehicles. Refer to SC6.4.3.22.6 for examples of bin storage areas. Facilities must provide a suitable level enclosure with a concrete slab floor, graded and drained through an approved sediment/silt trap to a legal sewer connection. A hose cock and hose must be fitted in close proximity to the enclosure. Enclosure dimensions for bulk bins must exceed the size of the nominated bin size by at least 300mm at the rear and both sides and 600mm at the front; and be oriented to allow convenient access for collection. Where mobile waste containers are in use, an adequate storage area must be provided. Facilities must be enclosed/screened such that they are not visible from any street frontage.

Commercial and business industrial	The proprietor is to arrange for the removal of waste from the premises by a suitably licensed waste transport contractor. Putrescible waste arising from activities undertaken on this development must be collected and removed at periods not exceeding seven days. (a) The collection of waste is to be undertaken to minimise, so far as reasonably practicable, excessive noise to neighbouring occupants. The collection method must ensure that waste is adequately managed to prevent escape or contamination. (b) Where the development has the potential to generate or handle clinical and regulated waste material; clinical and medical related waste is to be handled in accordance with AS/NZS 3816; and the *Environmental Protection (Waste Management) Regulation 2000*. (c) Where practicable, all loading and unloading shall take place within the containment area (storage area). This area is to be constructed in such a way that any spills from loading or unloading are not permitted to escape to areas exposed to storm water. No clinical and related wastes shall be disposed of via the storm water drainage system. (d) Trade Waste is to be managed in accordance with council's Liquid Trade Waste Management Plan 2009.	Access roads and driveways must be designed and constructed to accept vehicle loadings of not less that G.V.M. 33 tonnes. Vehicles must be capable of exiting the site in a forward direction. A turning circle of 25m is required. A minimum overhead clearance of 6.5m is required (with an additional 2m if located near power lines). This must be unobstructed by anything overhead such as trees, wires, sails, awnings, fascia or other structures.	Facilities are to be located within the curtilage of the premises in an accessible location to receive the service. Facilities should be sited in front of any entry gates to the building. Where security gates cross the driveway restricting vehicular access to the site, bin storage areas are to be located within property boundaries on the street side of the gate. Adequate provision must be made for the collection of the waste storage containers within the premises. Storage of waste must not cause odour, dust or noise related nuisance to neighbouring properties. Facilities must provide a suitable level enclosure with a concrete slab floor, graded and drained through an approved sediment/silt trap to a legal sewer connection. A hose cock and hose must be fitted in close proximity to the enclosure. Bulk bin enclosure dimensions must exceed the size of the nominated bin size by at least 300mm at the rear and both sides and 600mm at the front; and be oriented to allow convenient access by the collection vehicle. Where mobile waste containers are in use, an adequate storage area must be provided. Facilities must be enclosed/screened such that they are not visible from any street frontage.

SC6.4.3.23 Water and sewer network modelling guidelines

SC6.4.3.23.1 Introduction

(1) General

Water and sewerage network models are important engineering technical tools that are used to inform both forward infrastructure planning and network design. Where used appropriately as part of the planning and design process, models can assist to achieve the following outcomes:

(a) value for money infrastructure delivery;

(b) utilisation of existing infrastructure to its full capacity; and

(c) provision of accurate information for future infrastructure planning decisions.

(2) Purpose

The purpose of these guidelines is:

(a) to outline an approach to the development of new models to enable a consistent approach to modelling to be followed by both council, external service providers and developers;

(b) to provide guidance regarding modelling approaches to demonstrate compliance of designs with SC6.4.3.21 Townsville Water planning and design guidelines; and

(c) to provide details on reporting requirements to be submitted as part of design reports and planning reports.

(3) Scope

SC6.4.3.23 Water and sewer network modelling guidelines are to be used in conjunction with:

(a) SC6.4.3.21 Townsville Water planning and design guidelines;

(b) Townsville City Plan; and

(c) *Planning Guidelines for Water and Sewerage*, Department of Environment and Water Supply (Latest version).

Editor's note - These guidelines are not intended for use in building hydraulic services or irrigation design.

(4) Terminology

AD	Average Day Demand
ADWF	Average Dry Weather Flow
CSS	Customer Service Standards
DAU	Development Assessment Unit Within TCC
DSS	Design Service Standards
EP	Equivalent Population
FF	Fire Flow Demand
GWI	Groundwater Infiltration
HGL	Hydraulic Grade Line
IP	Infrastructure Planning Unit Within TCC
MDMM	Mean Day Maximum Month
PD	Peak Day Demand
PDWF	Peak Dry Weather Flow
PIA	Priority Infrastructure Area
PIP	Priority Infrastructure Plan
PFTI	Plans For Trunk Infrastructure
PH	Peak Hour Demand
PWWF	Peak Wet Weather Flow
RPEQ	Registered Professional Engineer of Queensland
TCC	Townsville City Council
TWW	Townsville Water and Waste (The Water Service Provider)

SC6.4.3.23.2 Determining when to complete a network modelling analysis

The circumstances under which a network model is required is listed under clauses SC6.4.3.21.2 Water supply design and SC6.4.3.21.3 Sewerage system design of SC6.4.3.21 Townsville Water planning and design guidelines. The process flow chart in SC6.4.3.23 Attachment A demonstrates the decision process that is to be followed when considering the requirement for a network analysis.

(1) Available information

Planning demand and loading rates for water and sewerage infrastructure design are listed in Part 4 Priority infrastructure plan of the Townsville City Plan.

Council has established a number of sewer network models covering service catchments across the city. A map showing sewer catchments, modelling status and latest planning report information can be requested from the Development Assessment Unit (DAU) of council.

A city wide water network model is also available for use.

Editor's note—Access to council's city wide water network model is available to appropriately qualified users approved by the Infrastructure Planning Unit of TCC. Refer to SC6.4.3.23.3 (2).

Plans for Trunk Infrastructure (PFTI) are available and detail trunk infrastructure that is planned for by council to service the Priority Infrastructure Area (PIA). These should also be referred to in order to determine if your development may affect or should take into consideration planned infrastructure in its vicinity.

(2) Preparing a preliminary needs analysis

An applicant for a development must complete a “Preliminary Needs Analysis” form (SC6.4.3.23 Attachment B) for their development which enables identification of any potential impacts on the water and sewer network. Where an impact is anticipated, it is likely that an analysis will be required to demonstrate compliance with design standards. The level of modelling assessment required is dependent on the impact expected.

Editor's note - If your preliminary analysis results in a modelling assessment being required, you should contact the DAU of council to confirm the level of modelling necessary. It is encouraged that this assessment be completed prior to application lodgement to ensure an efficient approval process.

The completed "SC6.4.3.23 - Attachment B - Form M1 - Network model needs analysis form" is required to be included with your analysis and application to justify the level o analysis undertaken.

Editor's note—The "Preliminary Needs Analysis" will determine if:

(a) a network analysis is not required; or

(b) you are required to do a simplified network analysis; or

(c) you are required to do a detailed network analysis, involving establishment of a new model, or use an existing model; or

(d) you need to incorporate a network modification in your application, with details specified by council.

If a network analysis is required, it must be done in accordance with these guidelines

SC6.4.3.23.3 Provision of the TCC Network Model Data

(1) Requesting information to inform your analysis

Modellers may request boundary condition information from council, and/or access to council's network models by submitting a “Request for Network Modelling Information” form included in SC6.4.3.23 Attachment C - Form M2 - Request for network modelling information.

Editor's note—"SC6.4.3.23 Attachment C - Form M2 - Request for network modelling information" is an electronic form.

In most cases it is desired that boundary condition information is sufficient to enable a modeller to prepare their own network model. However, depending on the size or impact of the development being considered, it may be necessary for the modeller to utilise council’s network models to demonstrate:

(a) in the case of the sewer network:

(i) receiving network capacity is sufficient; and

(ii) modified or realigned infrastructure as a result of the development has not adversely affected existing or planned for system hydraulics; and

(b) in the case of the water network:

(i) network supply capacity is sufficient; and

(ii) existing network hydraulic capacity is not adversely affected by any changes to the supply network as a result of the proposed development.

Generally, where trunk infrastructure may be affected by the proposed works, council's network models must be used to verify the impact and identify required mitigation/augmentation options.

(2) Access to council models

Access to council's network model/s is available to appropriately qualified users approved by the Infrastructure Planning Unit of TCC.

Editor's note—For information on the approval process applicants should contact the Infrastructure Planning Unit of TCC.

Council will make available at their offices a computer to enable analysis of a development or for viewing existing network model information. The applicant must apply for access to council's network model/s by submiiting the "SC6.4.3.23 - Attachment C - Form M2 - Request for network modelling information" form. The modeller will need to agree to council's terms of use on this form.

SC6.4.3.23.4 General requirements for network models

(1) Scale and spatial reference

"Simplified Models" may be developed as representative schematics of the proposed network. Manual calculations without the use of network modelling software may be permitted.

"Detailed Models" shall be constructed based on proposed design and/or development layouts. The layouts may be schematic but should remain representative of the proposed development layout. In order to enable import of models into council's existing network models, they shall be developed to the GDA1994 MGA Zone 55 coordinate system unless otherwise notified.

(2) Modelling timeframes

Timeframes for modelling shall be as per clauses SC6.4.3.21.2(2) and SC6.4.3.21.3(2) of SC6.4.3.21 Townsville Water planning and design guidelines.

(3) Model calibration

Where possible, calibrated models shall be used to verify system capacity.

(4) Modeller experience and qualifications

Network modelling must be carried out by professionals suitably experienced and qualified in the undertaking of network modelling analysis and design. Models, associated reports and designs must be certified by the appropriately qualified and experienced RPEQ.

SC6.4.3.23.5 Water network modelling

(1) Scope

A water network model is required where listed under the requirements of SC6.4.3.21.2(2) of SC6.4.3.21 Townsville Water planning and design guidelines.

(2) Model requirements – simplified assessment

A simplified assessment involves the use of manual calculations or simplified network models to demonstrate compliance with design standards. A simplified assessment must include:

(a) assessment of design demands in accordance with SC6.4.3.23.5 (3)(d) of this sub-section;

(b) where necessary, hydraulic calculations based on fixed boundary conditions for both peak hour and fire-fighting demand;

(c) calculations can be undertaken manually, using spread sheets or using network modelling software. Where modelling software is used, the model files shall be provided to council as part of the submission;

and

(d) a brief report covering the requirements of SC6.4.3.23.5 (3)(f) of this sub-section. Sketches of results are to be provided where they make it easier to interpret results.

(3) Model requirements – detailed assessment

(a) Format

Bentley WaterGEMS must be used for the development of new water network models. Models shall be set up such that all scenarios and options considered for the study are incorporated into a single model file. The model file(s) shall be provided to council as part of the submission.

(b) Scenario planning

A scenario plan must be developed by the modeller prior to commencing modelling such that each scenario required for analysis is identified and that differences between scenarios are clearly understood.

The modeller must utilise parent and child scenarios and alternatives such that common information for each scenario is inherited to child scenarios, and that unique changes are clearly identifiable. A “parent” scenario should be applied for each design horizon or stage, and ultimate development. The following model structure provides an example of a model scenario structure.

---Scenario 1000- Existing Peak Day Demand (Extended Period Analysis)
----------Scenario 1100- Existing Peak Hour Demand (Steady State Analysis)
----------e.g. Scenario 1110 - Existing Peak Hour with Infrastructure Option 1
----------e.g.Scenario 1120- Existing Peak Hour with Infrastructure Option 2 (Preferred)
----------Scenario 1121- Existing Fire Fighting Assessment (Steady State analysis, automated)
---Scenario 2000- Ultimate Peak Day Demand (Extended Period Analysis)
----------Scenario 2100- Ultimate Peak Hour Demand (Steady State Analysis)
----------e.g.Scenario 2110- Ultimate Peak Hour with Infrastructure Option 3 (Preferred)
----------Scenario 2111- Ultimate Fire Fighting Assessment (Steady State analysis, automated)

As shown the scenario structure naming should be clear and transparent as to which design case it represents and the preferred option applied for the design should be marked.

(c) Technical specification

(i) Hydraulic method

Modelling must be undertaken using the Hazen Williams hydraulic calculation method, with pipe friction coefficients as listed in Table SC6.4.3.21.4 of SC6.4.3.21 Townsville Water planning and design guidelines.

(ii) Losses across valves

Where control valves are required in the system, the valve should be modelled with appropriate loss factors/curves. The modeller must ensure that loss factors applied for design of a system can be achieved in reality by available products, and where possible apply the loss factor or curve for a design valve.

(iii) Pump curves

A design duty (single point pump curve) may be used initially when designing a pumping system however the modeller is to ensure that the pump duty proposed can be achieved by readily available pumps. Where possible an actual pump curve for a design pump shall be applied for modelling purposes.

(iv) Pump controls

Pumps shall be modelled with simple controls where possible. The modeller must consult with council when applying pump controls to ensure it meets the requirements of Townsville Water operators.

(v) Reticulation

Master Planning Models shall model trunk infrastructure only. Refer to Part 4.7 Definitions of the Townsville City Plan for the definition of trunk infrastructure.

Design Models shall model reticulation down to a DN63 pipe.

(d) Demands

(i) General

Design demands are to be calculated in accordance with SC6.4.3.21.2(2) of SC6.4.3.21 Townsville Water planning and design guidelines.

Demands must be applied as Peak Day demand in litres per second (L/s), with the appropriate diurnal pattern applied for the particular land use.

Demands should be applied at the nearest network node, and within 40 m of the property boundary.

Where a node represents demands generated from different land uses, separate demand entries should be applied to the node to enable quick identification of the source of the demand.

(ii) Use of unit demand factors

WaterGEMS enables unit demand factors to be applied, such that the resultant demand from the unit load, loading rate and peaking factors are calculated as part of the modelling process. The use of this feature is required for master planning models, enabling tracking of design EPs modelled.

(iii) Diurnal patterns

Diurnal patterns represent fluctuations in demand load across a day. Patterns for various land uses are included in SC6.4.3.21 Attachment A of the Townsville Water planning and design guidelines.

(e) Scenarios

(i) Extended period analysis

Extended period analysis is used to demonstrate compliance with SC6.4.3.21 Townsville Water planning and design guidelines. Extended period analysis must be utilised when considering networks that incorporate reservoirs, pump stations or other hydraulic controls.

Extended period analysis enables assessment of the bulk water transportation capacity of the network to ensure that:

(A) reservoirs never empty;

(B) reservoir minimum contingency storage levels are maintained;

(C) the reservoir supply system has a net delivery capacity equal to or greater than Peak Day;

(D) pumping systems are designed within operational limits; and

(E) system pressures are achieved across a day.

(ii) Council requires two scenarios of extended period analysis to be modelled:

3 day extended period analysis

Boundary conditions:

- reservoirs commencing water level 90% capacity;
- pump stations – all pumps in station initially off; and
- demand applied: Peak Day demand.

7 day extended period analysis

Boundary conditions:

- reservoirs commencing water level 90% capacity;
- pump stations – all pumps in station initially OFF; and
- demand applied: 95% of Peak Day demand.

(iii) Steady state analysis

Peak hour

Where a peak day analysis is required for a model, a separate steady state analysis to demonstrate compliance with design standards for Peak Hour is not necessary. Rather, the results at Peak Hour on the Peak Day may be reported at that specific time step.

Peak hour analysis is used to assess network pressures at Peak Hour to ensure the design requirements of SC6.4.3.21 Townsville water planning and design guidelines are met.

Boundary conditions:

(A) demands may be applied directly as Peak Hour demand, or at Peak Day demand with peaking factor to represent Peak Hour.

Fire-fighting analysis

Fire fighting analysis is used to assess network capacity of the network water mains with respect to the design requirements listed the SC6.4.3.21 Townsville water planning and design guidelines.

Use of automated analysis, where fire-fighting conditions are tested at each node/hydrant within the network, should be employed.

Boundary conditions:

(A) reservoirs commencing at mid water level; and

(B) demand applied: Peak Hour unless otherwise advised by council.

(f) Reporting requirements

A water network modelling report must be prepared to document the process, assumptions and analysis employed through modelling to develop the infrastructure design and/or master plan.

The following provides details of sections to be incorporated into the modelling report. The modeller may provide further information as needed to justify decisions made through the modelling and design process.

(i) Introduction:

(A) development locality, lot/plan description, application number (if applicable);

(B) objectives of study – design/master plan; and

(C) brief methodology – describe level of modelling undertaken (simplified/detailed), software used, reference to model overview in appendix.

(ii) Population and demand assessment:

(A) population assessment based on land use categories, site plan showing layout and land use;

(B) demand assessment showing demand calculation and peaking factors applied;

(C) summary table showing total demand, with breakdown for each land use category, Average Day (kL/d), Peak Day demand (kL/d or L/s); and

(D) summary table showing demand breakdown for each service catchment, where applicable.

(iii) Modelling assessment:

(A) modelling method – simplified or detailed assessment;

(B) scenarios analysed, including description or reference to design standards applied;

(C) modelling assumptions;

(D) existing network description, including proposed connection points; and

(E) modelling assessment:

- existing system capacity;
- existing system + ultimate development; and
- augmentations, new infrastructure options analysis including assessment of options at interim stages - 10y/20y/ultimate horizons.

(iv) Options analysis:

(A) triple bottom line analysis; and

(B) net present value assessment.

(v) Summary:

(A) preferred option, justification, capital works program.

(vi) RPEQ Certification statement as detailed in SC6.4.2.

(vii) Appendix:

(A) for detailed models, model overview to be included in appendix (covering scenario structure, options and clearly outlining which scenario represents the design solution);

(B) model map showing model layout (nodes, pipes, labels and any relevant boundary conditions, e.g. reservoirs or head points applied); and

(C) tabulated data and results – to be provided at peak hour analysis and fire fighting analysis:

Nodes	• Element ID • Node Elevation • Peak Hour Demand • Calculated Hydraulic Grade (m) • Calculated Pressure (m) For fire-fighting analysis • Available fire-fighting flow • Available pressure at fire fighting demand
Pipes	• Element ID • Pipe diameter • Material and class • Length • Start node • Stop node • Hazen Williams C value • Flow rate • Velocity • Headloss gradient
Pump Stations	• Element ID • Pump type (fixed, variable speed) • Pump configuration (duty/standby etc.) • Pump curve, if selected
Reservoirs	• Element ID • Reservoir Capacity • Top Water Level • Bottom Water Level

(D) pump stations - system resistance curve with pump curve overlaid. Pump curve may be duty point however the designer shall consider the capability of pumps on the market to meet such a duty (i.e. it needs to be physically achievable).

SC6.4.3.23.6 Sewer network modelling

(1) Scope

A sewer network model is required where listed under the requirements of clause SC6.4.3.21.3 of SC6.4.3.21 Townsville water planning and design guidelines.

(2) Model requirements – simplified assessment

A simplified assessment involves the use of manual calculations to demonstrate compliance with design standards. A simplified assessment must include:

(a) assessment of design loads in accordance with SC6.4.23.6(3)(d) of this sub-section;

(b) where necessary, hydraulic calculations based on fixed boundary conditions for Peak Wet Weather Flow loading;

(c) calculations can be undertaken manually, using spreadsheets or using network modelling software. Where modelling software is used, the model files shall be provided to council as part of the submission; and

(d) a brief report covering the requirements of SC6.4.23.6(3)(f) of this sub-section. Sketches of results are to

be provided where they make it easier to interpret results.

(3) Model requirements – detailed assessment

(a) Format

Bentley SewerGEMS sanitary must be used to undertake detailed assessments of sewer networks. This will enable models to be incorporated into council's existing network models.

Models shall be set up such that all scenarios and options considered for the study are incorporated into a single model file.

(b) Scenario planning

A scenario must be developed by the modeller prior to commencing modelling such that each scenario required for analysis is identified and that differences between scenarios are clearly understood.

The modeller must utilise parent and child scenarios and alternatives such that common information for each scenario is inherited to child scenarios, and that unique changes are clearly identifiable. A "parent" scenario should be applied for each design horizon or stage and ultimate development. The following provides an example of a model scenario structure.

---Scenario 1000- Existing Average Dry Weather Flow
----------Scenario 1100- Existing ADWF Overflow Storage Assessment
----------Scenario 1200- Existing Peak Wet Weather Flow
---Scenario 2000- Ultimate Average Dry Weather Flow
----------Scenario 1100- Ultimate ADWF Overflow Storage Assessment
----------Scenario 1200- Ultimate Peak Wet Weather Flow
----------Scenario 1210- Ultimate PWWF Infrastructure Option 1
----------Scenario 1220- Ultimate PWWF Infrastructure Option 2 (Preferred)

(c) Technical specification

Hydraulic method

Mannings formula must be used for calculation of gravity network hydraulics, in accordance with the requirements of the *Sewerage Code of Australia* (WSA 02-2002).

Hazen-Williams method must be applied for pressure pipe systems in accordance with SC6.4.3.21 Townsville Water planning and design guidelines.

Inflow/Infiltration

Inflow/Infiltration shall be modelled intrinsically as a part of the calculated design loads, in accordance with SC6.4.3.21 Townsville Water planning and design guidelines.

Pump curves

A design duty (single point pump curve) may be used initially when designing a pumping system however the modeller is to ensure that the pump duty proposed can be achieved by readily available pumps. Where possible an actual pump curve for a design pump shall be applied for modelling purposes.

Pump controls

Pumps must be modelled with simple controls where possible. The modeller must consult with council when applying pump controls to ensure it meets the requirements of Townsville Water operators.

(d) Sewage flow calculation

Design loads are to be calculated in accordance with SC6.4.3.21.3(2) of SC6.4.3.21 Townsville Water planning and design guidelines.

Loads must be applied to the model as an Average Dry Weather Flow (ADWF) base demand. A peaking factor multiplier applied as a fixed pattern on the load must be used to generate Peak Wet Weather Flow (PWWF).

Where a manhole represents demands generated from different land uses, separate demand entries must be applied to the node to enable quick identification of the source of the demand.

(e) Scenarios

(i) Static vs. dynamic modelling

Sewer network models should be run dynamically (i.e. over an extended period) to enable:

(A) assessment of system storage prior to overflow;

(B) ensure model stability when system is fully loaded; and

(C) ensure the interaction of pumps on a common system are assessed.

A minimum 24 hr simulation period is therefore recommended. The user should report results at the appropriate timestep (i.e. maximum conditions in system).

(ii) ADWF analysis

ADWF analysis is used to assess basic system performance under dry weather flow conditions. This analysis is also used to assess the amount of system storage available before an overflow is activated within the catchment (being inter-area or environmental).

(iii) PWWF analysis

PWWF analysis is used to assess network performance in respect to the design requirements listed in SC6.4.3.21 Townsville Water planning and design guidelines.

(f) Reporting requirements

A sewer network modelling report must be prepared to document the process, assumptions and analysis employed through modelling to develop the infrastructure design and/or master plan.

The following provides details of sections to be incorporated into the modelling report. The modeller may provide further information as needed to justify decisions made through the modelling and design process.

(i) Introduction:

(A) development locality, lot/plan description, application number (if applicable);

(B) objectives of study – design/master plan; and

(C) brief methodology – describe level of modelling undertaken (simplified/detailed), software used, reference to model overview in appendix.

(ii) Sewage flow/loading assessment:

(A) population assessment based on land use categories, site plan showing layout and land use;

(B) load assessment showing calculation of ADWF and PWWF flows; and

(C) summary table showing total load, with breakdown for each pump station catchment or network subcatchment, average dry weather flow (L/s), (kL/d), peak wet weather flow (L/s), (kL/d).

Where an existing council model is being updated, a table comparing previous catchment loads to updated catchment loads must be provided.

(iii) Modelling assessment

(A) scenarios analysed, including description or reference to design standards applied;

(B) modelling assumptions;

(C) existing network description, including proposed connection points; and

(D) modelling assessment:

- existing system capacity;
- existing system + ultimate development;
- augmentations, new infrastructure options analysis including; and
- assessment of options at interim stages - 10y/20y/ultimate horizons.

(iv) Options analysis:

(A) triple bottom line analysis; and

(B) net present value assessment.

(v) Summary:

(A) Preferred option, justification, capital works program.

(vi) RPEQ Certification statement in accordance with SC6.4.2.

(vii) Appendix:

(A) model overview to be included in appendix (covering scenario structure, options and clearly outlining which scenario represents the design solution);

(B) tabulated results of the manhole, gravity and pressure main outputs:

Manholes	• Element ID • Node Elevation • Design Load
Pipes - gravity and pressure mains	• Element ID • Pipe diameter/material and class • Grade • Upstream manhole • Downstream manhole • Pipe flow depth as percentage of diameter PWWF (gravity mains) • Flow velocity at PWWF (pressure mains) • Flow velocity under single pump operation (pressure mains)
Pump Stations	• Element ID

(viii) pump stations - system resistance curve with pump curve overlaid. Pump curve may be duty point however the designer shall consider the capability of pumps on the market to meet such a duty (i.e. it needs to be physically achievable).

SC6.4.3.23.7 Copyright and ownership of submitted models

When a technical report or study is submitted to council as part of a development application, this report/study, along with all components of the submission, can be made available to the public as part of the notification stage. The report can be provided to anyone seeking the report during this stage and following the approval. Use of the report for any third party use will be at the complete risk of the third party. It should be noted that only the approved report including any council requested amendments, will be referred to in future.

Once a development application is approved council is permitted to use the model for incorporation into its overall city water and sewer models to inform its infrastructure planning.

SC6.4.4 Design specification and standard drawings

SC6.4.4.1 Geometric road design

SC6.4.4.1.1 Introduction

(1) Purpose

(a) This sub-section sets out the specifications developed specifically for the design of roads using principles of street design to ensure safety and improved amenity and to reduce pedestrian/vehicular conflicts.

(b) A fundamental requirement of the design process is for designers to determine the vehicle speed which is deemed acceptable for a particular subdivision or section of road.

(c) All relevant design principles must be integrated in the development of the road network, recognising the primary role of roads for transport function.

(d) The objective of road design is to recognise the carrying of through traffic.

(e) The objectives of street design are to recognise improving safety and security, increase vitality and interaction, reduce private motor vehicle dependence, improve development efficiency, provide valuable community space and retain economic activity in communities.

(2) Scope

(a) This specification must be read in conjunction with the IPWEAQ publication *Complete Streets: Guidelines for Urban Street Design*, with limited adoption in Townsville as follows:

(i) in areas with close nexus to CBD, and in areas where higher densities are encouraged and it can be demonstrated that there is high access and potential use of public transport, then a full adoption of *Complete Streets* while tying into existing road and street networks. For infill development and upgrades in these areas, development is to be in line with *Complete Streets* principles of pedestrian and cyclist friendly environments, encouraging developments that engage with active street frontages;

(ii) new, large, master planned developments are to adopt *Complete Streets*, although they will be required to recognise the particular role of public transport as an alternative to moving people between these sites and other areas of Townsville. Designs should emphasise pedestrian and cyclist movements, and allow for retrofitting of public transport options in the future, if and when they become viable;

(iii) other developments are to adopt updated cross-sections and road hierarchy, and apply priorities in line with *Complete Streets*, but layout is to be adapted to tie into existing road and street networks, recognising high car dependence, and lack of containment opportunities, where commercial centres, schools and retail facilities are not proposed within the development; and

(iv) curvilinear street designs are to be avoided wherever practical, with a focus on the grid structure in accordance with *Complete Streets and requirements of the Townsville City Plan.*

(3) Aims

A road system within a subdivision is to be designed so as to achieve the following aims:

(a) to provide convenient and safe access to all allotments for pedestrians, vehicles and cyclists;

(b) to provide safe, logical and hierarchical transport linkages with existing street system, including consideration of crime prevention in streets, bikeways and pathways;

(c) to provide appropriate access for buses, emergency and service vehicles;

(d) to provide both a permeable and legible street network;

(e) to provide for a quality product that minimises maintenance costs;

(f) to allow for public utilities;

(g) to provide an opportunity for visual amenity, e.g. street landscaping;

(h) to provide convenient parking for visitors;

(i) to provide connecting streets and places through permeable networks without any corresponding increase in vehicle speeds or "rat-runs"; and

(j) to have appropriate regard for the climate, geology and topography of the area.

(4) Terminology

For the purpose of this sub-section the definition of terms used to define the components of the road reserve must be in accordance with these AS 1348 terms.

Carriageway	that portion of the road or bridge devoted particularly to the use of vehicles, inclusive of shoulders and auxiliary lanes.
Footpath	the paved section of a pathway (verge).
Pathway	a public way reserved for the movement of pedestrians and of manually propelled vehicles.
Pavement	that portion of a carriageway placed above the subgrade for the support of, and to form a running surface for, vehicular traffic.
Shoulder	the portion of the carriageway beyond the traffic lanes and contiguous and flush with the surface of the pavement.
Verge	that part of the road reserve between the carriageway and the road reserve boundary. It may accommodate public utilities, footpaths, stormwater flows, street lighting poles and plantings.

SC6.4.4.1.2 Consultation and planning

(1) Consultation

(a) Designers are encouraged to consult with the council and other relevant authorities prior to and during the preparation of the design. Designers should, in addition to requirements of this sub-section, ascertain the specific requirements of these authorities as they relate to the designs in hand.

(b) The designer must obtain service plans from all relevant public utility authorities and organisations whose services may exist within the area of the proposed development. These services are to be plotted on the relevant drawings including the plan and cross-sectional views.

(2) Planning concepts

(a) In new areas (as distinct from established areas with a pre-existing road pattern) each class of route should reflect its role in the street and road hierarchy by its visual appearance and related physical design standards. Routes should differ in alignment and design standard according to the volume of traffic they are intended to carry, the required traffic speed, adjoining land-uses, and other factors. All higher order road networks under Townsville City Council jurisdiction must comply with SC6.4.3.13 Townsville road hierarchy.

(b) The road network for residential developments should have clear legibility for all road users, particularly pedestrians and cyclists.

(c) The road network should reinforce legibility by providing sufficient differentiation between the road functions.

(d) Distinct existing landmark features such as watercourses, mature vegetation or ridge lines should be emphasised within the structural layout so as to enhance their legibility.

(e) Whilst legibility can be enhanced by introduced physical features such as pavement and lighting details, the road network should by its inherent design and functional distinction provide the necessary legibility and place making.

(f) The road network should provide for shortest reasonable access from any lot to the major road system for all pedestrian cyclists and vehicles.

(g) Speed regulation should be built in to the street geometry, to create an environment where drivers are actively discouraged from driving above the legislated/design speed. Speed control devices, often known as Local Area Traffic Management (LATM), are considered unnecessary for appropriately designed new streets and should only be used where no other solution is viable, due both to their capital and maintenance costs and possible intrusive nature. Side friction may be considered to assist with speed regulation where appropriate.

(h) Provide convenient and safe access to all allotments for all road users including pedestrians, cyclists, public transport users, garbage trucks and motorists. Priority of consideration in streets should be as per *Complete Streets.*

(i) Include adequate network considerations in the placement and design of safe pedestrian crossing facilities especially across roads and high volume streets.

SC6.4.4.1.3 Urban design criteria

(1) Road and street hierarchy

(a) A hierarchical road network is essential to maximise road safety, residential amenity and legibility. Each class of road in the network serves a distinct set of functions and is designed accordingly. The design should convey to motorists the predominant function of the road.

(b) Transport routes are divided into two distinct levels (refer to SC6.4.4.8 Standard drawings):

(i) streets; and

(ii) roads

(c) The lowest order of transport route (streets) have as their primary function to facilitate public interaction

and movement through a place, village, town or city.

(i) Streets should be designed in accordance with the adjoining land uses.

(d) The highest order of transport route (Roads) should have as its main function the convenient and safe distribution of traffic and should be designed in accordance with the SC6.4.3.13 Townsville Road Hierarchy, Austroads and Department of Transport and Main Roads standards.

(2) Road network

(a) The design features of each type of road or street convey to the driver its primary functions and encourage appropriate driver behaviour.

(b) Traffic volumes and speeds on any road or street should be compatible with its adjoining land uses and function.

(c) The maximum length of a residential street should ensure its status as a residential place is retained, where the traffic, in terms of speed and volume will enable the integration of pedestrian, bicycle and vehicular movements. This length will also ensure that residential convenience is not unduly impaired as a result of speed restraints.

(d) The distance required for pedestrians, cyclists and drivers to travel between two points within the development should be minimised.

(e) Where local streets form part of a pedestrian or bicycle network, access links should provide suitable connectivity with adjoining local streets or open space systems so as to ensure such pedestrian and bicycle network are functionally efficient and safe.

(f) The road network should ensure that no road intersects with another road which is more than two levels higher or lower in the hierarchy. In exceptional circumstances roads may intersect with others that are more than two levels apart with council approval, however, no local street should have direct connection to an access-controlled arterial road.

(g) The road and street layout should conform to the requirements of the external road network and satisfy the transport provisions of an outline development plan.

(h) The external road network should be designed and located to provide routes which are more convenient for potential through traffic within the network. Major roads should be provided at intervals of no more than 1.5 km and should be complete and of adequate capacity to accommodate through network movements. The internal road system should not provide through routes that are more convenient than the external road network.

(i) The design of sub-arterial roads should achieve a context sensitive design by providing an acceptable balance between the level of service, safety, whole of life costs, flexibility for future upgrading or rehabilitation and environmental impact. Consequently, sub-arterial roads should provide a higher level of efficiency and safety with space for public transport, bicycle lanes and pedestrian facilities.

(j) Operations on sub-arterial roads must be in accordance with Austroads' *Guide to Road Design Part 2: Design Considerations,* taking into account:

(i) intersection spacing and control;

(ii) lane changing;

(iii) weaving;

(iv) merging;

(v) spacing of median openings;

(vi) reverse flow/tidal traffic control;

(vii) pedestrians;

(viii) cyclists;

(ix) parking (if permitted);

(x) transit lanes for buses and high occupancy vehicles (HOV);

(xi) provision for B-doubles and multi-combination vehicles;

(xii) provision for intelligent transport systems (ITS);

(xiii) bus stops;

(xiv) service roads;

(xv) driveway spacing and their distances from intersections (if permitted); and

(xvi) signage and line marking in accordance with Main Roads' *Manual of Uniform Traffic Control Devices* (MUTCD) and *Traffic and Road Use Management Manual* (TRUM).

(3) Design speed

(a) Design speed is generally used as the basic parameter in the specification of design standards, determining the minimum design value for other elements and is the 85th percentile maximum speed of traffic within the street. This is similar to the "Speed Environment" used in Austroads *Guide to Road Design*. Vehicular speeds are also limited by road intersections as well as changes in horizontal and vertical alignment.

(b) Adoption of a low design speed discourages speeding, however, where vertical or horizontal curves of low design speed are located in otherwise high speed sections (tangents) the result is a potentially dangerous section of road. Attention should be given to ensuring that potentially hazardous features are visible to the driver and adopting traffic engineering measures which will help a driver avoid errors of judgement.

(c) Design speed should allow for road characteristics such as:

(i) traffic volume;

(ii) width of carriageway;

(iii) grades; intersections;

(iv) the presence and spacing of consolidated property access;

(v) traffic characteristics; and

(vi) traffic composition (pedestrians, cyclists, public transport, passenger vehicles, heavy vehicles).

(d) The need for road safety barriers must be assessed and designed in accordance with SC6.4.6.25 Non-rigid road safety barrier system and AS/NZS 3845.

(4) Longitudinal gradient

(a) A general minimum gradient of 0.5 % should be adopted. In very flat conditions it may be reduced to 0.3% with council approval. Where underground drainage with gully pits or other special works are used it is preferable to allow near level grades rather than reverting to introduction of artificial undulations. Variable crossfall may be necessary to produce the required grade in the kerb and channel. The maximum longitudinal grade on any street should not exceed 12%, from consideration of pedestrian walking convenience.

(b) Grades over 8% must provide additional considerations for pedestrians, cyclists, public transport and heavy vehicles (e.g. garbage trucks, furniture vehicles) where appropriate. Exceptionally steep terrain may be allowed for very short lengths on steep streets of up to 16%. In these exceptional circumstances, the developer must demonstrate that alternate routes for pedestrians, bicycles and heavy vehicles are available.

(c) The longitudinal grade of the minor street on the approach to an intersection should not exceed 4% with sufficient length to accommodate a stationary single unit truck. Design of the road alignment and the grades used are interrelated. A steep grade on a minor side street is not acceptable if vehicles have to stand waiting for traffic in the major road.

(d) Turning circles in cul-de-sacs on steep grades should have grades less than 5%.

(5) Horizontal curves and tangent lengths

(a) The horizontal alignment of a road or street is normally in a series of tangents (straights) and curves which may be connected by transition curves. The choice of the horizontal alignment should be determined from the design speeds for a particular street, in particular the expected operating speeds and constraints of the developments adjacent to the road in accordance with Austroads' *Guide to Road*

Design Part 3: Geometric Design. Designers should ensure that, for a given design speed, the minimum radius of curvature utilised is such that drivers of all vehicles can safely negotiate the curve. Curves which progressively tighten and sudden reverse curves must be avoided.

(b) While horizontal alignment is one means of limiting vehicle speed, the greater of the following requirements must be complied with:

(i) minimum curve radius for a street - 10 m; or

(ii) minimum curve radius for a road in accordance with DTMR design standards.

(c) Carriageway widening applies to all standard carriageway widths. Widening should be applied to the inside kerb line of the carriageway, in accordance with Austroads' *Guide to Road Design.*

(d) The minimum horizontal sight distance required at any point along the street is the general minimum sight distance for the spot speed relevant at that point. The sight distance is measure along the vehicle path, which may be assumed as the carriageway centreline for streets.

(6) Vertical curves

(a) The design of vertical alignment must reflect the expected operating speeds and constraints of the developments adjacent to the road in accordance with Austroads' *Guide to Road Design Part 3: Geometric Design.*

(b) Vertical curves will be simple parabolas and should be used on all changes of grade exceeding 1%. The length of the crest vertical curve for stopping sight distance is based on speed and should conform with Austroads' *Guide to Road Design Part 3: Geometric Design.*

(c) In addition to the above general minimum sight distance, which is required to be provided at all points along the street, at locations where there may be channelisation or line marking, such as intersections or pedestrian crossings, the driver must be able to see such indications within the stopping distance, i.e. sight distance from 1.15m eye height to zero is not less than single-vehicle stopping distance.

(d) For adequate riding comfort, lengths of sag vertical curves should conform with Austroads' *Guide to Road Design Part 3: Geometric Design.*

(e) Junctions of roads should be located at a safe distance from a crest, determined by visibility from the side road. Location of a side road at a crest should only occur if there is no suitable alternative.

(f) Drainage poses a practical limit to the length of sag curves and a maximum length (in metres) of 15 times the algebraic sum of the intersecting vertical grades (expressed as a percentage) is suggested. To avoid water ponding in excessively flat sections of kerb and gutter, a minimum grade of 0.3% must be maintained in the kerb and channel.

(g) The three dimensional coordination of the horizontal and vertical alignment of a road should be aimed at improved traffic safety and aesthetics. Economic considerations often require a compromise with aesthetic considerations. The following principles should be applied:

(i) the design speed of the road in both horizontal and vertical planes should be of the same order; and

(ii) combined horizontal and vertical stopping sight distance and minimum sight distance should be considered three dimensionally.

(h) Horizontal curves should not be introduced at or near the crest of a vertical curve.

(7) Superelevation

(a) The use of superelevation in association with horizontal curves is an essential aspect of geometric design of roads with design speeds in excess of 60km/h. Streets which are designed for speeds of 40km/h or less and with curves of 60m radius or less generally have the pavement crowned on a curve instead of superelevation.

(b) The maximum superelevation for urban roads of higher design speeds should be 5%. Any increase in the longitudinal grade leading to excessive crossfall at intersections should be considered with caution. While all curves should be superelevated, negative crossfall should be limited to 3%.

(c) In general, curve radii larger than the minimum and superelevation rates less than the maximum should be used where possible. The minimum radius of curves is determined by the design speed, the minimum

superelevation (or maximum adverse crossfall) at any point on the circular portion of the curve, and the maximum coefficient of side friction which allows safe lane changing. Refer to the *Road Planning and Design Manual* Table 11.1.

(d) Recommendations for minimum curve radii (in metres) on major urban roads under varying superelevation/crossfall are as per Austroads' *Guide to Road Design.*

(e) Plan transitions are required on superelevated curves for appearance and to provide a convenient length in which to apply the superelevation. On urban roads, superelevation may be conveniently applied to the road cross section by shifting the crown to 2m from the outer kerb. The axis of rotation of the cross section for urban roads will normally be the kerb grading on either side which best enables access to adjacent properties and intersections.

(f) Rate of Rotation for superelevation refer Austroads' *Guide to Road Design Part 3: Geometric Design* (Section 7.7).

(8) Road reserve characteristics

(a) The cross section of the road reserve must provide for all functions that the road is expected to fulfil, including the safe and efficient movement of all users, provision for parked vehicles, acting as a buffer from traffic nuisance for residents, the provision of public utilities and street scaping. Road reserve widths will depend on verge widths, service roads and pathway requirements, and sub-arterial and arterial roads must also allow for future upgrading.

(b) The carriageway width must allow vehicles to proceed safely at the operating speed intended for that level of road in the network and with only minor delays in the peak period. This must take into consideration the restrictions caused by parked vehicles where it is intended or likely that this will occur on the carriageway. Vehicles include trucks, emergency vehicles and, on some roads, buses. Excessive carriageway widths can be detrimental to safety, amenity, user convenience, capital expenditure and maintenance costs.

For example, for urban residential streets:

(i) narrower urban residential carriageways in accordance with Urban Type A of Standard Drawing SD-001 are allowable for shorter street lengths, with low parking demand, and serving standard residential allotments. This carriageway does not allow for any buses, bike lanes, or indented parking. Frequent staggered parking may occur on both sides of the street where there are less than 150 vehicles per day, otherwise on street parking should be infrequent or along one side of the street only. Generally leg lengths should be kept to a maximum length of 150m. These streets may not function as a through route, and must carry a low traffic volume;

(ii) standard urban residential carriageways in accordance with Urban Type B of Standard Drawing SD-001 are allowable where there is relatively frequent parking on both sides of the street with traffic volumes generally less than 750 vehicles per day;

(iii) wider urban residential carriageways in accordance with Urban Type C of Standard Drawing SD-001 are required where there is a higher density residential area with higher parking demand or higher volume of traffic (less than 3000 vehicles per day in accordance with SC6.4.3.13) and possible bus routes. Indented bus bays may be required, on advice from council;

(c) the safety of pedestrians and cyclists where it is intended they use the carriageway must also be assured by providing sufficient width;

(d) the carriageway width should also provide for unobstructed access to individual allotments. Drivers should be able to comfortably enter or reverse from an allotment in a single movement, taking into consideration the possibility of a vehicle being parked on the carriageway opposite the driveway;

(e) the design of the carriageway should discourage drivers from travelling above the intended speed by reflecting the functions of the road in the network. In particular the width and horizontal and vertical alignment should not be conducive to excessive speeds;

(f) appropriate verge width should be provided to enable the safe location, construction and maintenance of required footpaths and public utility services (above or below ground), with acceptable clearances and to accommodate the desired level of streetscaping. Wherever possible, services should be located in common trenches;

(g) the verge when considered in conjunction with the horizontal alignment and permitted fence and property

frontage treatments should provide appropriate sight distances, taking into account expected speeds and pedestrian and cyclist movements;

(h) stopping sight distances and junction or intersection sight distances, provided by the verge, should be based on the intended speeds for each road type;

(i) safe intersection stopping distance envelopes must be provided to ensure sight distances are achieved in the street layout; and

(j) industrial roads and streets must be designed to allow access for larger vehicles including B-doubles and multi-combination vehicles into these areas, including safe turning manoeuvres at intersections and to and from allotments.

(9) Crossfall

(a) Roads should be crowned in the centre. Typical pavement crossfalls on straight roads are:

Pavement Type	**Crossfall**
Bituminous seal coat	3%
Bituminous concrete pavement	3%
Cement concrete pavement	3%

Source: Austroads, *Guide to Road Design*

(b) There are many factors affecting levels in urban areas which force departures from these crossfalls. Differences in level between road alignments can be taken up by offsetting crown lines or adopting one way crossfalls. Sustained crossfalls should not exceed 4%, although up to 6% may be used where unavoidable with council approval. The rate of change of crossfall should not exceed those adopted in SC6.4.4.1.3(7) Superelevation.

(c) The use of one way crossfalls should be limited taking into consideration overland drainage and the impact on open space, public footpaths and private properties.

(d) The crossfall on a higher order transport route should take precedence over the grade in minor side streets. Standard practice is to maintain the crossfall on the major road and adjust the minor side street levels to suit. The crossfall in side streets should be warped quickly either to a crown or a uniform crossfall depending on the configuration of the side street. A maximum change of grade of 2% in the kerb line of the side street relative to the centre line grading is acceptable.

(10) Verges and property access

(a) A suitable design for the verge will depend on utility services, the width of footpath, access to adjoining properties, likely pedestrian usage and preservation of trees. Low level footpaths may only be used if normal crossfalls are impracticable. Crossfalls in footpath paving should not exceed 2.5%, in accordance with Austroads' *Guide to Road Design - Part 6A: Pedestrian and Cyclist Paths*. Longitudinal grade usually parallels that of the road and this may be steeper than 5%.

(b) Differences in level across the road between road reserve boundaries may be accommodated by:

(i) cutting at the boundary on the high side and providing the verge at normal level and crossfall;

(ii) battering at the boundary over half the verge width with the other half against the kerb constructed at standard crossfall;

(iii) a uniform crossfall across the carriageway; and

(iv) the lower verge being depressed below the gutter level.

(c) The above measures can be used singularly or combined. The verge formation should extend with a 0.5m berm beyond the road reserve boundary.

(d) The designer must design a vehicular driveway centreline profile for the property access and check this design using critical car templates, to ensure that vehicles can use the driveway satisfactorily.

(e) Where commuter pedestrians and cyclist paths are proposed, appropriate shading and rain protection should be provided. An approved landscaping master plan must be provided for approval.

(11) Intersections

(a) The design of intersections or junctions should allow all movements to occur safely without undue delay. Projected traffic volumes should be used in designing all intersections or junctions on major collector streets.

(b) Intersection design for the junction of subdivision roads and streets with existing state rural or urban roads and national highways should generally be in accordance with the publication Austroads' *Guide to Road Design – Part 4, Intersections and Crossings.*

(c) Intersections with state roads or national highways are to be designed, approved and constructed in accordance with the requirements of the Queensland Department of Transport and Main Roads.

(d) Where major intersections are required to serve a development complete reconstruction of the existing road pavements may be necessary.

(e) Intersections should be generally located in such a way that:

(i) the streets intersect preferably at right-angles and not less than 70º;

(ii) the landform allows clear sight distance on each of the approach legs of the intersection;

(iii) the minor street intersects the convex side of the major street;

(iv) the vertical grade lines at the intersection do not impose undue driving difficulties;

(v) the vertical grade lines at the intersection will allow for any direct surface drainage;

(vi) two minor side streets intersecting a major street in a left-right staggered pattern must have a minimum centre-line spacing of 50m to provide for a possible right-turn auxiliary lane on the major street; and

(vii) a right-left manoeuvre between the staggered streets is preferable, avoiding the possibility of queuing in the major street, but only where staggered streets cannot be avoided.

(f) Adequate stopping and sight distances are to be provided for horizontal and vertical curves at all intersections.

(g) Appropriate provision should be made for vehicles to park safely, where required.

(h) Safe intersection sight distance - refer clause SC6.4.4.1.3(8)(i).

(i) The drainage function of the carriageway and/or road reserve must be satisfied by the road reserve cross-section profile.

(j) All vehicle turning movements are accommodated utilising *Design Vehicles and Turning Templates*, as follows:

(i) for intersection turning movements involving low order roads, the "design semi-trailer" with turning path radius 15 m;

(ii) for intersection turning movements involving streets, the "design single unit" bus with turning path radius 13 m; and

(iii) for turning movements at the head of cul-de-sac local streets sufficient area is provided for the "design single unit" truck to make a three-point turn Driveway entrances are not to be used for turning movements. The minimum cul-de-sac head radius is 9m to kerb lip.

(k) Turning radii at intersections or driveways on major collector streets accommodate the intended movements without allowing desired speeds to be exceeded.

(l) On bus routes 3-centred curves with radii 15m, 10m, 30m are to be used at junctions and intersections.

(m) Un-signalised intersections on sub-arterial roads at grade should have a median width of at least five metres to allow for a two stage crossing from the side street.

(n) Design of traffic signals in sub-arterial roads must be in accordance with the Department of Transport and Main Roads' *Road Planning and Design Manual* (RPDM), Chapter 18. Council approval is required for use of equipment that is uniquely associated with traffic signals.

(o) Barrier kerb and channel must be used at intersection kerb turnouts extending to the tangent point. A one metre kerb transition must be used to connect barrier kerb and channel turnout with adjacent layback kerb and channel.

(12) Roundabouts

(a) Roundabouts are to be approved by council.

(b) Roundabouts should generally be designed in accordance with the requirements of *Austroads Guide to Road Design - Part 4B - Roundabouts.* Designs adopting alternative criteria will be considered on their merits. Roundabout design should generally comply with the following:

(i) safe provision for pedestrians, cyclists and public transport movements;

(ii) entry width to provide adequate capacity;

(iii) adequate circulation width, compatible with the entry widths and design vehicles e.g. buses, trucks, cars;

(iv) central islands of diameter sufficient only to give drivers guidance on the manoeuvres expected;

(v) deflection of the traffic to the left on entry to promote gyratory movement;

(vi) adequate deflection of crossing movements to ensure low traffic speeds;

(vii) a simple, clear and conspicuous layout; and

(viii) design to ensure that the speed of all vehicles approaching the intersection will be less than 40 km/h.

(13) Local area traffic management

(a) Local area traffic management (LATM) devices are unnecessary for appropriately designed new streets, but may be used to address speed and safety issues in existing streets, and must be approved by council.

(b) Calming devices such as thresholds, slow points, speed humps, chicanes and splitter islands should be designed in accordance with the requirements of the publication *Guide to Traffic Management Part 8: Local Area Traffic Management (LATM)* and the *Manual of Uniform Traffic Control Devices*. Device designs should generally comply with the following.

(i) Streetscape:

(A) reduce the linearity of the street by segmentation;

(B) avoid continuous long straight lines (e.g. kerb lines);

(C) short straights and short distances between intersections;

(D) enhance existing landscape character;

(E) maximise continuity between existing and new landscape areas;

(F) on-street parking; and

(G) mixed activity precincts.

(ii) Location of devices/changes:

(A) devices other than at intersections should be located to be consistent with streetscape requirements;

(B) existing street lighting, drainage pits, driveways, and services may decide the exact location of devices; and

(C) slowing devices are optimally located at spacings of 100-150m.

(iii) Design vehicles:

(A) emergency vehicles, garbage trucks and furniture vehicles must be able to reach all residences and properties;

(B) local streets with a “feeding” function between arterial roads and streets must be designed for an Austroads Design Single Unit Truck/Bus;

(C) where bus routes are involved, buses should be able to pass without mounting kerbs and with minimised discomfort to passengers; and

(D) in newly developing areas where street systems are being developed in line with LATM principles, building construction traffic must be provided for.

(iv) Control of vehicle speeds:

(A) maximum vehicle speeds can only be reduced by deviation of the travelled path. Pavement narrowings have only minor effects on average speeds, and usually little or no effect on maximum speeds;

(B) speed reduction can be achieved using devices which shift vehicle paths laterally (slow points, roundabouts, corners) or vertically (humps, platform intersections, platform pedestrian/school/bicycle crossings); and

(C) speed reduction can be helped by creating a visual environment conducive to lower speeds. This can be achieved by "segmenting" streets into relatively short lengths (less than 300 m), using appropriate devices, streetscapes, or street alignment to create short sight lines and by inducing in drivers a feeling of constriction through the introduction of side friction.

(v) Visibility requirements (sight distance):

(A) adequate critical sight distances should be provided such that evasive action may be taken by either party in a potential conflict situation. Sight distances should relate to likely operating speeds;

(B) sight distance to be considered include those of and for pedestrians and cyclists, as well as for drivers; and

(C) night time visibility of street features must be adequate. Speed control devices particularly should be located near existing street lighting if practicable, and all street features/furniture should be delineated for night time operation. Additional street lighting must be provided by the developer at proposed new speed control devices located away from existing street lighting.

(vi) Critical dimensions

Many devices will be designed for their normal use by cars, but with provision (such as mountable kerbs) for larger vehicles. Some typical dimensions include:

(A) pavement narrowings in accordance with *Guide to Traffic Management;*

(B) bicycle lanes (including adjacent to pavement narrowings) – 1.5m minimum, 1.2m absolute minimum with council approval (in accordance with *Guide to Traffic Management*, and *Guide to Road Design);*

(C) plateau or platform areas;

(D) 75 mm to 100 mm height maximum, with 1 in 15 ramp slope;

(E) width of clear sight path through slowing devices;

(F) The width of the portion of carriageway which does not have its line of sight through the device blocked by streetscape materials, (usually vegetation);

(G) dimensions of mountable areas required for the passage of large vehicles to be determined by appropriate turning templates; and

(H) on bus routes, devices must allow the full-length of the bus to be contained between ramps.

(14) Road safety audits

(a) Road safety audits (RSA) should be carried out on sub-arterial road projects in accordance with *Guide to Road Safety Part 6: Road Safety Audit*. Confirmation from council is to be sought on which project stages require an RSA. The following stages of the project should be considered for an RSA, as appropriate:

(i) feasibility design;

(ii) completion of design development;

(iii) completion of final design;

(iv) during construction, where temporary traffic management measures are proposed;

(v) two weeks prior to opening to traffic; and

(vi) within one week of opening to traffic.

(15) Parking

(a) The parking requirements for normal levels of activity associated with any land use should be accommodated on-site.

(b) All on-site parking should be located and of dimensions that allow convenient and safe access and usage. All designs must account for a B99 (AS 2890) vehicle as the minimum requirement.

(c) Adequate parking should be provided within the road reserve for visitors, service vehicles and any excess resident parking since a particular use may generate a high demand for parking. Such parking is to be convenient to the use.

(d) The availability of parking should be adequate to minimise the possibility of driveway access being obstructed by cars parked on the opposite side of the street.

(e) On single lane local streets parking spaces should be provided within the verge. Such parking should be well defined and an all-weather surface provided. Such parking may not restrict the safe passage of vehicular and pedestrian traffic.

(f) Parking spaces provided on the verge or carriageway should be of adequate dimensions, convenient and safe to access.

(g) For non-residential land uses the opportunity for joint use of parking should be maximised by being shared by a number of complementing uses.

(h) On single lane carriageways a number of verge spaces are combined to provide for short term truck parking within 40m of any allotment.

(i) All verge spaces and indented parking areas are constructed of concrete, interlocking pavers, bitumen with crushed rock or other council approved base material and are designed to withstand the loads and manoeuvring stresses of vehicles expected to use those spaces.

(j) Right-angled kerbside parking is provided only on streets where posted speeds do not exceed 40 km/h.

(16) Bus routes

(a) It is important that the road hierarchy adequately caters for buses. The main criteria in determining the location of bus routes is that no more than 5% of residents should have to walk in excess of 5 minutes to catch a bus. Sub-section SC6.4.3.5 Car parking and public transport facilities guidelines details minimum criteria for bus route design, though local conditions, including climate and topography should be taken into consideration to demonstrate that bus routes are readily accessible to the majority of residents.

(b) Carriageway widths must comply with sub-sections SC6.4.4.8 Standard drawings, and SC6.4.3.13 Townsville road hierarchy. For indented bus bays on streets identified as bus routes, refer to SC6.4.4.8 Standard drawings. Shelters are subject to council's requirements.

SC6.4.4.1.4 Rural design criteria

(1) General

(a) In addition to the above, SC6.4.4.1.4 specifically applies to all those sites identified as being suited to rural subdivisions inclusive of rural home sites and hobby farms types of developments.

(b) Design speed is to be generally used as the basic parameter of design standards and the determination of the minimum design value for other elements in rural subdivisions is to be based on the concept of a "speed environment" as outlined in *Guide to Road Design.*

(c) Superelevation, widening and centreline shift and their associated transitions are to comply with Austroads Guides, where appropriate.

(d) Where the table drain is likely to scour, a stone pitched or suitably lined dish drain is to be constructed along the invert. For grades of less than 0.5%, the inverts of the drain are to be lined to prevent siltation. Drains with a minimum gradient of 0.25% are to be concrete lined.

(e) All rural subdivisions should be designed to restrict access to major roads.

(f) Access should be limited to one point on to street, major collector or arterial road networks.

(2) Sight distances

(a) Stopping sight distance should be provided at all points on the road.

(b) Stopping sight distance is the sum of the braking distance and the distance the vehicle travels during a reaction time of 2.5 seconds.

(3) Horizontal and vertical alignment

Horizontal and vertical curves are to be designed generally to the requirements of *Guide to Road Design*. These requirements are essential to satisfy the safety and performance of proper road design. Roads having both horizontal and vertical curvature should be designed to conform with the terrain to achieve aesthetic quality and being in harmony with the landform.

(4) Intersections

(a) Intersections should generally be designed in accordance with the publication *Guide to Road Design Part 4: Intersections and Crossings and Guide to Traffic Management Part 6: Intersections, Interchanges and Crossings.* The type of intersection required will depend on existing and planned connecting roads.

(b) Adequate sight distance should be provided at intersections both horizontally and vertically. Each intersection location must be examined for conformance with the criteria for Approach Sight Distance (ASD), Entering Sight Distance (ESD) and Safe Intersection Sight Distance (SISD).

(i) ASD relates to the ability of drivers to observe the roadway layout at an anticipated approach speed.

(ii) ESD relates to the driver entering the intersection from a minor road and ability to observe the roadway layout and assess traffic gaps. SISD relates to an overall check that vehicles utilising the intersection have sufficient visibility to allow reaction and deceleration so as to provide adequate stopping distance in potential collision situations.

(iii) Tabulated speed/sight distance requirements together with detailed explanations for each of the sight distance criteria are given in the relevant sections of the *Austroads Guide to Road Design*. Repositioning of an intersection may be required to obtain conformance with the sight distance criteria.

(iv) Stopping distance envelopes must be provided to ensure sight distances are achieved in the street layout.

(c) Staggered-T arrangements proposed for rural cross-intersections should preferably be of the “right to left” type. This arrangement eliminates traffic queuing in the major road, the need for additional pavement for right turn lanes and greater stagger length associated with “left to right” T-intersections. Figures and discussion on staggered-T treatments are given in the *Austroads Guide to Road Design.*

(5) Carriageways

Carriageway widths for rural roads should generally be as per SC6.4.4.8 Standard drawings SD-010 Typical Road Cross Sections – Rural Roads.

(6) Superelevation

Use of maximum superelevation will be considered where the radius of the curve in approaching the minimum speed environment. Reference should be made to *Austroads Guide to Road Design* for superelevation calculation. At low and intermediate ranges of design speed (i.e. below 80 km/h) all curves should be superelevated to at least a value equal the normal crossfall of straights.

(7) Table drains

Table drains to rural roads must comply with *Guide to Road Design Part 3: Geometric Design*. Minimum longitudinal grade of table drains is 0.50%. Refer to *Guide to Road Design Part 6: Roadside Design, Safety and Barriers for capacity of drains.*

(8) Scour protection

Scour protection of roadside drainage and table drains is required. The level of protection will depend on the

nature of the soils, road gradients and volume of stormwater runoff. Protection works may involve concrete lined channels, turfing, rock pitching, grass seeding, individually or any combination of these. Geotechnical investigations should be carried out of determine the level and extent of any protection works prior to proceeding to final design stage.

SC6.4.4.2 Pavement design

SC6.4.4.2.1 Introduction

(1) Objectives

The objective in the design of the road pavement is to select appropriate pavement and surfacing materials, types, layer thicknesses and configurations to ensure that the pavement performs to its design functions and requires minimal maintenance under the anticipated traffic loading for the design life adopted.

The objective in the design of the subsurface drainage system is to control moisture content fluctuations in the pavement and/or subgrade to within the limits assumed in the pavement design. In areas with a history of salinity problems, subsurface drainage may be prescribed to keep the groundwater table lower in the strata so as to avoid progressive deterioration of the health of topsoil and upper layers due to salinity levels increased by rising and/or fluctuating groundwater tables.

(2) Scope

(a) This sub-section covers the design guidelines for road pavement to meet the required design life, based on the subgrade strength, traffic loading and environmental factors, and including the selection of appropriate materials for select subgrade, subbase, base and wearing surface, and the design of the subsurface drainage system for the road pavement and/or subgrade.

The sub-section contains guidance in the design of the following forms of surfaced road pavement construction types:

(i) flexible pavements consisting of unbound granular materials;

(ii) flexible pavements that contain one or more bound layers, including pavements containing asphalt layers other than thin asphalt wearing surfaces;

(iii) rigid pavements (i.e. cement concrete pavements); and

(iv) concrete or clay segmental pavements.

(b) This sub-section generally sets out procedures in determining the following design criteria:

(i) design traffic;

(ii) design CBR of pavement subgrade (including method of sampling and testing);

(iii) determination of required subgrade treatments;

(iv) design methods for rigid and flexible pavement (pavement thickness);

(v) subsoil and foundation drains;

(vi) sub-pavement drains; and

(vii) drainage mats, including Type A and Type B mats.

(3) Terminology

Foundation drains	are intended for the drainage of seepage, springs and wet areas within and adjacent to the foundations of the road formation.
Sub-pavement drains	are intended for the drainage of the base and subbase pavement layers in flexible pavements. They may also function to drain seepage or groundwater from the subgrade.
Subsoil drains	are intended for the drainage of ground water or seepage from the subgrade and/or the subbase in cuttings and fill areas.
Type A drainage mats	are intended to ensure continuity of a sheet flow of water under fills, to collect seepage from a wet seepage area, or for protection of vegetation or habitat downstream of the road reserve where a fill would otherwise cut the flow of water.

Type B drainage mats are constructed to intercept water which would otherwise enter pavements by capillary action or by other means on fills and to intercept and control seepage water and springs in the floors of cuttings.

(4) Reference and source documents

(a) Development manual planning scheme policy sub-section to be read and applied in conjunction with this sub-section are as follows:

SC6.4.4.1 - Geometric road design
SC6.4.6.8 - Drainage mats
SC6.4.6.12 - Flexible pavements
SC6.4.6.13 - Asphaltic concrete
SC6.4.6.14 - Mass concrete sub base
SC6.4.6.15 - Plain and reinforced concrete base

SC6.4.4.2.2 Pavement design criteria

(1) The design traffic loading must be calculated based on the following minimum design lives of pavement:

Table SC6.4.4.2.1 Design ESAs

Road or street type	Minimum design life
Urban streets and roads	20 years
Rural streets and roads	20 years
Rigid (concrete)	40 years
Segmental block	25 years

Design traffic loading for urban areas must be calculated in equivalent standard axles (ESAs) for the applicable design life of the pavement, taking into account present and predicted commercial traffic volumes, axle loadings and configurations, commercial traffic growth and street capacity.

For new subdivisions, the design traffic loading must take account of the construction traffic associated with the subdivision development, and the in-service traffic for the subdivision and any future developments linked to that subdivision.

When designing staged developments, the number of vehicle trips must take into consideration the ultimate development that will eventually access each segment of the road under consideration with appropriate allowances for bus, garbage, construction and in-service traffic.

For interlocking concrete segmental pavements, the simplification of replacing ESAs with the number of commercial vehicles exceeding 3 tonne gross contained in CMAA-T45 is acceptable up to a design traffic of 10^6ESAs. Beyond this, ESAs should be calculated.

The pavement design must include all traffic data and/or assumptions made in the calculation of the design traffic. The estimated design traffic must generally be made in accordance with G*uide to Pavement Technology* – in particular *Part 2 Pavement Structural Design* for the calculation of design traffic volumes up to and exceeding 10^6ESAs.

In the absence of other traffic data, the following traffic values (in ESAs) may be taken as a guide to the minimum design traffic, but are subject to variation depending on the circumstances for the particular development.

Table 6.4.4.2.2 Design ESAs

Street Type	Design ESAs - 20 year design life (minimum)
Urban Residential	
- Type A	2×10^4
- Type B	1×10^5
- Type C	1×10^6
Major Collector	2×10^6
Commercial and Industrial	5×10^6
Rural Roads	1×10^6

Traffic volume and annual growth rate can be obtained upon request to council as guidance in determining the design traffic loading to be used for pavement design. For roads, the design traffic loading must be determined using a design life as per SC6.4.4.2.2.(1), however, a practical design strategy to allow extensions of the pavement life to 35 years (minimum) must also be submitted.

For new residential developments where traffic data is not readily and accurately available, the design may consider the following data to determine the design traffic loading:

(a) traffic generation – 10 vehicles per day/allotment plus 20 ESAs per equivalent allotment for consideration of construction traffic;

(b) traffic growth rates – 0.5% – 2% for streets. Annual traffic growth rates for roads are subject to

confirmation by council and will be based on available traffic data;

(c) commercial vehicles – 3%-7% for streets. Commercial vehicle percentages for roads are subject to confirmation by council and will be based on available traffic data;

(d) ESA per heavy vehicle (ESA/HVAG) - Urban 0.7, Rural 0.9; and

(e) axle group per heavy vehicle (NHVAG) – Urban 2.5, Rural 2.8.

(2) The calculation of design traffic loading for rural area must adopt a similar approach to the urban areas while the design for industrial roads will require a detailed assessment addressing the following factors and must be designed using a mechanistic approach:

(a) traffic generation, including peak hour traffic volumes and truck volumes;

(b) details of the types of heavy vehicles that are expected to utilise the road; and

(c) predicted route patterns (heavy vehicles).

(3) The calculation of design traffic loading for industrial development must include the following factors:

(a) traffic generation of the proposed industrial development (including peak hour traffic volumes). Refer to *Guide to Pavement Technology Part 2* for the method of calculating load factors for each type of heavy vehicles;

(b) to Austroads Guide to Pavement Technology Part 2 for the method of calculating load factors for each type of heavy vehicles;

(c) details of types of trucks that will utilise the proposed road network with consideration to the proportion of heavy vehicles that will have full load; and

(d) predicted truck usage patterns with consideration to expected land use.

SC6.4.4.2.3 Geotechnical evaluation

(1) General

The designer must arrange a detailed geotechnical investigation of the naturally occurring material along the alignment of the proposed roads. The extent of any areas of filling and cutting must be determined including the strength of the underlying materials and considered in the overall pavement design.

The geotechnical investigation, including both field and laboratory testing must be undertaken in accordance with all relevant Australian Standards (e.g. AS 1289) and *Guide to Road Design* in particular *Part 7 Geotechnical Investigation and Design.*

(2) Subgrade testing

(a) Except where a mechanistic design approach is employed using Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design*, the measure of subgrade support must be the California Bearing Ratio (CBR). Where a mechanistic design approach using linear elastic theory is employed for flexible pavements, the measure of subgrade support must be in terms of the elastic parameters (modulus, Poisson's ratio), e.g. for use in CIRCLY computerised pavement design methods.
In conducting subgrade tests, the following approach must be adopted for new roads:

(i) test pits/holes along the alignment of the road must have a spacing between 60m and 120m as appropriate for each urban residential and industrial street or a minimum of three test locations per street in a stage, whichever is greater;

(ii) test pits/holes along the alignment of a rural area must have a spacing of up to 300m or a minimum of 3 test locations per road whichever is greater;

(iii) test holes must be excavated to a minimum depth of 1 m and must extend a minimum 500mm below the proposed subgrade level;

(iv) if the depth of fill material over the natural subgrade is more than 500mm, then the fill material is considered to be the new subgrade and it must be assessed; and

(v) if the depth of fill is less than 500mm, investigation must assess the natural ground conditions and also the properties of the proposed fill material.

(b) The following factors must be considered in determining the design strength/stiffness of the subgrade:

(i) sequence of earthworks construction;

(ii) the compaction moisture content and field density specified for construction;

(iii) moisture changes during service life;

(iv) subgrade variability; and

(v) the presence or otherwise of weak layers below the design subgrade level.

(3) California Bearing Ratio (CBR)

(a) Notwithstanding the requirements of AS1289.6.1.1, this document specifies additional or differing requirements, including:

(i) CBR tests must be carried out with a maximum of 4.5kg surcharge; and

(ii) maximum correction allowable to the applied force is 0.5mm along the horizontal axis of the penetration curve.

(b) The calculation of the Design CBR must be based on either soaked or unsoaked conditions as appropriate.

(i) For boxed in pavements soaked conditions must be adopted for the calculation of Design CBR and must be based on a minimum of three 4-day soaked CBR laboratory samples for each subgrade area compacted to 97% of maximum dry density, standard compaction at optimum moisture content (OMC).

(ii) If it can be demonstrated that the subgrade is well drained and not less than 300mm above natural surface or table drain, e.g. Rural formation, in free draining material and not influenced by spring/seepage conditions then the unsoaked condition will be considered for design by council. When unsoaked conditions are to be adopted the calculation of Design CBR must be based on a minimum of three laboratory samples for each subgrade area compacted to 97% maximum dry density standard compaction at OMC and corrected to allow for the effects of subsurface drainage (or lack of), climatic zone and soil type if appropriate (as per the guidelines in Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design*) to give an estimate of equilibrium in-situ CBR.

(iii) The Design CBR for each subgrade area is computed by using the appropriate formula as follows:

Design CBR = Least of estimated CBRs, for less than five results

or

Design CBR = 10th percentile of all estimated CBRs, for five or more results

Where practicable, the Design CBR obtained from laboratory testing should be confirmed by testing performed on existing road pavements near to the job site under equivalent conditions and displaying similar subgrades.

The pavement design must include a summary of all laboratory and field test results and assumptions and/or calculations made in the assessment of Design CBR.

(4) Environment

The environmental factors which significantly affect pavement performance are moisture and temperature. Both of these factors must be considered at the design stage of the pavement. Reference should be made to Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design.*

The following factors relating to moisture environment must be considered in determining the design subgrade strength/stiffness and in the choice of pavement and surfacing materials:

(a) rainfall/evaporation pattern;

(b) permeability of wearing surface;

(c) depth of water table and salinity problems;

(d) relative permeability of pavement layers;

(e) whether shoulders are sealed or not; and

(f) pavement type (boxed or full width).

The effect of changes in moisture content on the strength/stiffness of the subgrade must be taken into account by evaluating the design subgrade strength parameters (i.e. CBR or modulus) at the highest moisture content likely to occur during the design life, i.e. the design moisture content. The provision of subsurface drainage may, under certain circumstances, allow a lower design moisture content, and hence generally higher design CBR.

The effect of changes in temperature environment must be considered in the design of pavements with asphalt wearing surfaces, particularly if traffic loading occurs at night when temperatures are low, thus causing a potential reduction in the fatigue life of thin asphalt surfacing. The effect of changes in temperature environment should also be considered for bound or concrete layers.

The pavement design must include all considerations for environmental factors, and any assumptions made that would reduce or increase design subgrade strength, or affect the choice of pavement and surfacing materials.

(5) Expansive soils

Highly expansive materials are classified as highly reactive with high plasticity. Refer to the classification in Table SC6.4.4.2.1 Guide to classification of expansive soils, with prominence give to classification based on the CBR swell. Expansive soilds have the potential to exhibit significant volume changes with the variation in moisture content leading to possible loss of pavement shape and longitudinal cracking in the future pavement. For this reason, if test results indicate highly expansive materials (classified as "High" or "Very High"), the design CBR must be 3% or less. Materials having a measured CBR swell ≥2.5% must incorporate a low permeability treatment layer to minimise significant moisture changes in the underlying subgrade.

Table SC6.4.4.2.3 Guide to classification of highly expansive soils

Expansive Nature	Liquid Limit (%)	Plastic Index	PI x % <0.425mm	Potential Swell (%)*
Very High	>70	>45	>3200	>5.0
High	>70	>45	2200-3200	2.5-5.0
Moderate	50-70	25-45	1200-2200	0.5-2.5
Low	<50	<25	<1200	<0.5

*Swell OMC and 97% MDD using Standard compactive effort; 4 day soak based on 4.5kg surcharge.
(Source: Guide to Pavement Technology – Part 2).

SC6.4.4.2.4 Subgrade treatment

(1) General

Subgrade treatment may be required subject to ground conditions defined in Table SC6.4.4.2.4 Ground conditions for subgrade treatment.

Table SC6.4.4.2.4 Ground conditions for subgrade treatment

Category	Condition	Definition	Treatment Type
A	Excessively wet subgrade anticipated prior to construction and/or excessively wet subgrade encountered once construction commences	“Wet” subgrade	Working Platform
B	Low Design Subgrade Strength *	Soaked CBR ≤ 3%	Capping Layer
C	Highly or very highly expansive subgrade soil #	Swell ≥ 2.5%	Pavement Cover
D	Ground beneath pavement will be exposed to water (due to the effect of capillary rise and/or positive head)	“Water Exposure”	Drainage Layer

* CBR swell at OMC and 97% MDD using Standard Compactive effort; 4 day soak based on 4.5kg surcharge. (Source: Austroads Guide to Pavement Technology – Part 2)

Swell measured in CBR test described in SC6.4.4.2.3 (5)

Design subgrade CBR = 3% must be adopted into the pavement design if the subgrade soaked CBR is > 3% but with CBR swell of ≥ 2.5% (classified as highly or very highly expansive).

This specification does not provide direct criteria for determining the required depth of subgrade treatment in highly or very highly expansive soils (Category C). However, as Category C subgrade will need to be designed with CBR of ≤ 3%, the subgrade treatment of Category B (low design subgrade strength) will ensure that the total "Pavement Cover" is adequate to meet the cover requirements for an expansive subgrade soil. It is noted that the type of subgrade treatment that is acceptable will be depend on the expansive nature of the soil. A subgrade with CBR swell of ≥ 2.5% will require capping material to include a low permeability layer.

Subgrade Treatment selection is outlined in flowchart Figure SC6.4.4.2.1 Guide to determine subgrade treatment. Details for subgrade "Treatment Layer" is described in Table SC6.4.4.2.5 Selection of subgrade treatment type. Subgrade treatment may comprise one or a combination of the alternatives listed.

(2) Subgrade treatment types

(a) In-situ lime stabilisation of the subgrade;

(b) Plant mixed cement stabilised gravel;

(c) Unbound gravel;

(d) Select fill;

(e) Rock fill (geofabric wrapped) + min. 150mm select fill;

(f) Drainage layer material + min. 150mm select fill; and

(g) Geofabric separation layer.

The acceptable types and combinations of treatment are as outlined in SC6.4.4.2.4 (3).

(3) Selection criteria for subgrade treatment type

Figure SC6.4.4.2.1 Guide to determine subgrade treatment outlines subgrade treatment layers, denoted as Treatment L1 to L11. Table SC6.4.4.2.5 Selection of subgrade treatment type details which subgrade treatment options are acceptable for each condition.

Table SC6.4.4.2.6 Thickness of treatment layer outlines procedure for determination of the required thickness of the treatment layer under the pavement. Note that no prescription is given to the required thickness of Working Platform, as this will depend on the specific conditions encountered and the treatment layer selected.

(4) Required thickness of treatment layer

Table SC6.4.4.2.6 Thickness of treatment layer outlines procedure for determination of the required thickness of the treatment layer under the pavement. Note that no prescription is given to the required thickness of Working Platform, as this will depend on the specific conditions encountered and the treatment layer selected.

(5) Working platform

A working platform could comprise of any of the treatment type *(a)* to *(g)* as defined in Table SC6.4.4.2.5 Selection of subgrade treatment type.

(a) Except for treatment type (g) – geofabric separation layer, the working platform is required to meet the following minimum standards necessary for it to function when it becomes part of the subgrade for the operating service life of the pavement structure:

(i) at least 150mm compacted thickness, and as thick as necessary to provide support required;

(ii) have a surface maintained with a geometric tolerance of ± 10mm of the specified height and a maximum deviation from a 3m straight edge of 8mm at all points on the surface; and

(iii) where a treatment type (b) – plant mixed cement stabilised gravel is used, gravel must be of a standard no less than Type 2.3 with a minimum UCS of 0.8 MPa and a maximum UCS of 3.5 MPa at 28 days.

(b) The working platform must be designed by the Contractor to meet the particular requirements of the project including, but not limited to, the following considerations:

(i) the characteristics of the underlying subgrade materials;

(ii) the Contractor's construction traffic and equipment the Contractor intends to use to construct the

pavements and other works;

(iii) the full operating life of the working platform including, but not limited to:

- actual period during which the working platform will be required to provide access for construction traffic;
- actual periods during which the working platform will be required to provide a platform for construction traffic and equipment, including for construction of the pavement layers; and
- actual periods during which it is not in use prior to the construction of the overlying pavement;

(iv) provide protection to the underlying layers, including protection from water and stress;

(v) provide a platform for the construction of the overlying pavement;

(vi) suitability for the Contractor's construction program; and

(vii) be sufficiently stiff to enable the placement and compaction of the overlying pavement layers in accordance with their specified requirements.

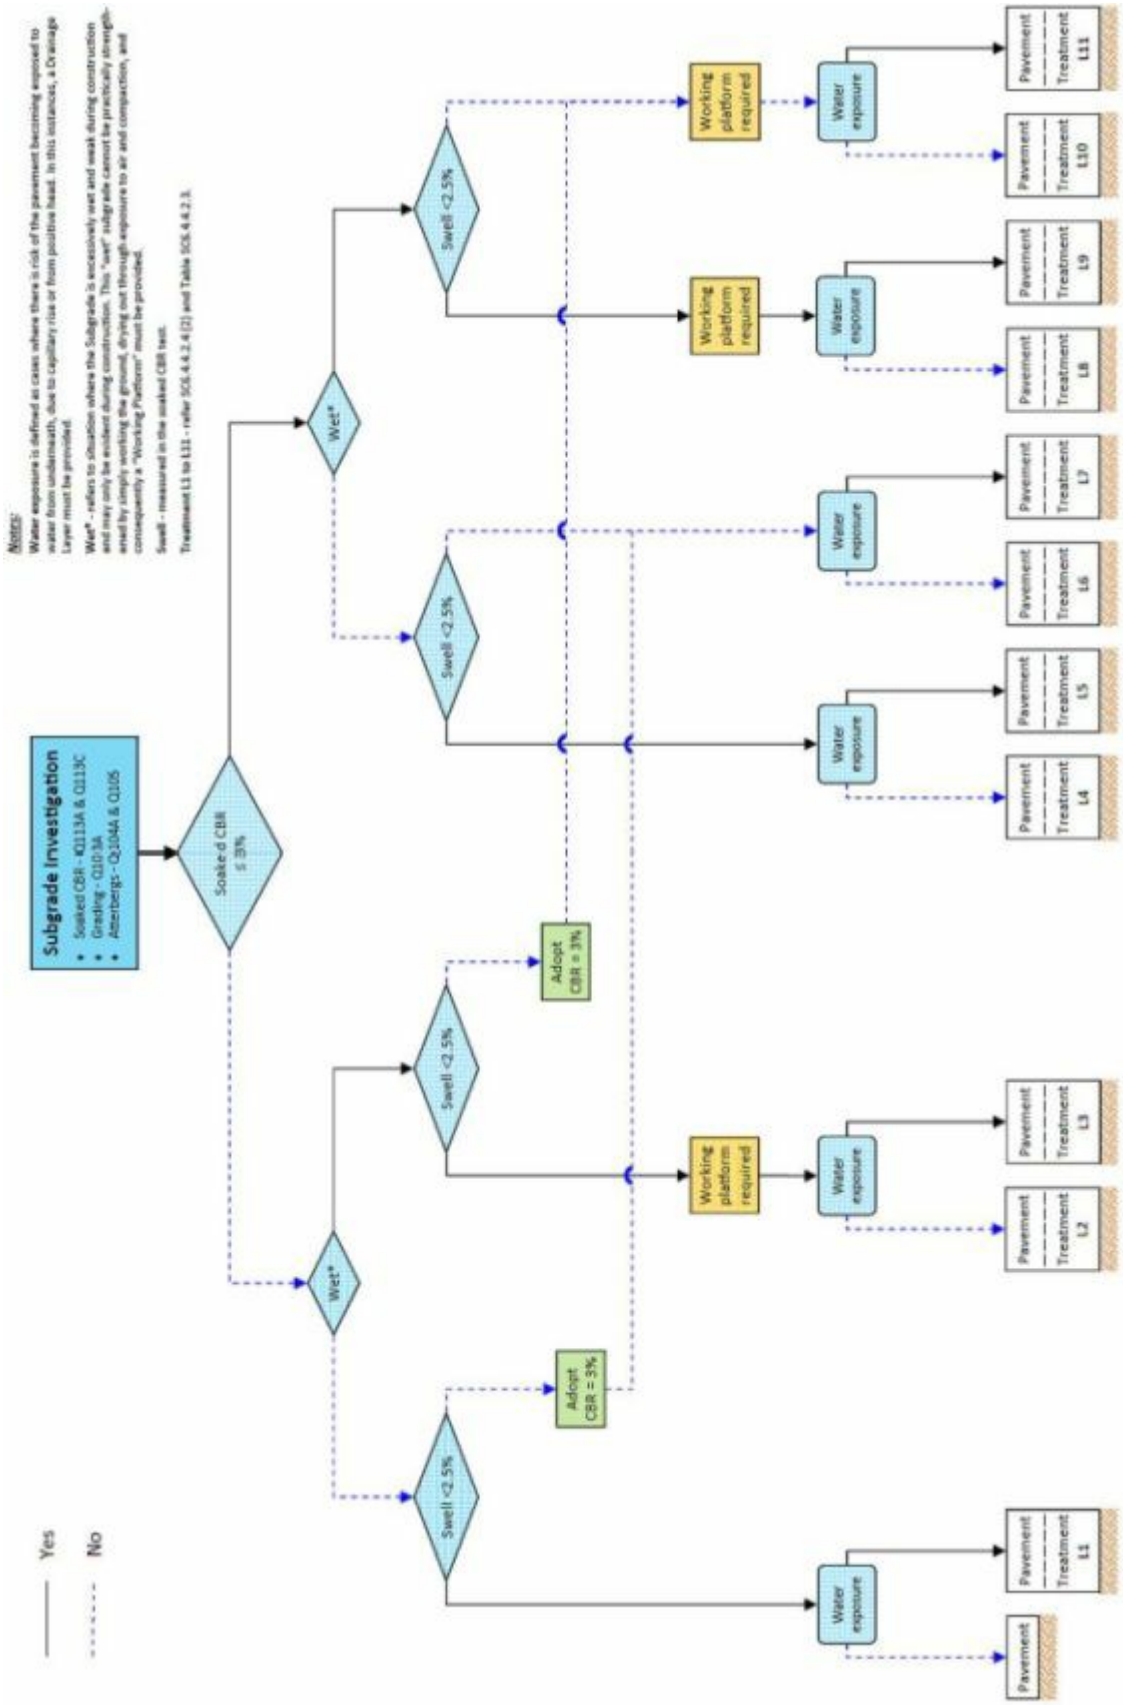

Figure SC6.4.4.2.1 Guide to determine subgrade treatment

Table SC6.4.4.2.5 Selection of subgrade treatment type

Treatment	Soaked CBR ≤ 3%	Wet at construction	Swell < 2.5%	Water Exposure	Acceptable Treatment Types	Treatment Name
-	X	X	✓	X	No treatment required	-
L1	X	X	✓	✓	(e) or *(f)*	Drainage layer
L2	X	✓	✓	X	If "Wet" layer entirely removed & replaced: (b) to (e) & (g)*. If not: (a), (b), (e) or *(g)**.	Working platform
L3	X	✓	✓	✓	(e)	Drainage layer & working platform
L4	✓	X	✓	X	(a) to (d)	Capping layer
L5	✓	X	✓	✓	(e) or (f)	Capping layer & drainage layer
L6	✓	X	X	X	(a), (b) or (d)	Capping layer & pavement cover
L7	✓	X	X	✓	(e) or (f)	Capping layer, pavement cover & drainage layer
L8	✓	✓	✓	X	If "Wet" layer entirely removed and replaced: (b) to (e). If not: (a), (b) or (e)	Capping layer & working platform
L9	✓	✓	✓	✓	(e)	Capping layer, drainage layer & working platform
L10	✓	✓	X	X	(a), (b) or (e)	Capping layer, pavement cover & working platform
L11	✓	✓	X	✓	(e)	Capping layer, pavement cover, drainage layer & working platform

* (g) – geofabric layer may or may not provide adequate as a working platform upon which pavement construction can proceed. This can only be determined by trial and error. If it proves insufficient support, other acceptable treatments will be required.

(6) Capping layer

Capping layer must be provided where the in-situ untreated subgrade has a design CBR ≤ 3%. Treatment types that are suitable for use as a capping layer and a reference to the quality requirements are as follows:

(a) in-situ lime stabilisation of the subgrade – refer SC6.4.4.2.4 (8);

(b) plant mixed cement stabilised gravel – refer SC6.4.6.12 Flexible pavements;

(c) unbound gravel – refer SC6.4.6.12 Flexible pavements;

(d) select fill – refer SC6.4.4.2.4 (7);

(e) rock fill (geofabric wrapped) + min. 150mm *(b)* or *(d)* – refer SC6.4.4.2.4 (9); and

(f) drainage layer material + min. 150mm *(b)* or *(d)* – refer SC6.4.4.2.4 (10).

(7) Select fill

Select fill can be used as part of a subgrade treatment solution when a "capping layer" and/or "pavement cover" is required, and could also be used as a "working platform" to replace a wet layer. Select fill may comprise a naturally occurring material from on site or imported to site, or may comprise a natural material that has its properties improved by addition of cement or lime. The natural material or improved product must meet the minimum requirements in Table SC6.4.4.2.7 Material properties for select fill.

Table SC6.4.4.2.6 Determining thickness of treatment layer

Treatment	Thickness of treatment	Treatment name
L1	Refer SC6.4.6.8 Drainage mats	Drainage layer
L2	Excluding *(g)* "geofabric layer", thickness is as required to successfully achieve compaction on top of the working platform, min. 150mm	Working platform
L3	Refer SC6.4.6.8 Drainage mats. A minimum 150mm thick layer of type *(d)* must be provided on top of the drainage layer	Drainage layer & working platform
L4	Refer SC6.4.4.2.7 (1) and (2)	Capping layer
L5	Refer SC6.4.4.2.7 (1) and (2) and SC6.4.6.8 Drainage mats. A minimum 150mm thick layer of type *(d)* must be provided on top of the drainage layer	Capping layer & drainage layer
L6	Refer SC6.4.4.2.7 (1) and (2)	Capping layer & pavement cover
L7	Refer SC6.4.4.2.7 (1) and (2) and SC6.4.6.8 Drainage mats. A minimum 150mm thick layer of type *(d)* must be provided on top of the drainage layer	Capping layer, pavement cover & drainage layer
L8	Refer SC6.4.4.2.7 (1) and (2). Greater thickness may be required to achieve an adequate working platform	Capping layer & working platform
L9	Refer SC6.4.4.2.7 (1) and (2) and SC6.4.6.8 Drainage mats. A minimum 150mm thick layer of type *(d)* must be provided on top of the drainage layer. Greater thickness may be required to achieve an adequate working platform	Capping layer, drainage layer & working platform
L10	Refer SC6.4.4.2.7 (1) and (2). Only types *(a), (b)* or a combination of a minimum 150mm of *(d)* on top of *(e)*, are acceptable due to expansive subgrade. Greater thickness may be required to achieve an adequate working platform	Capping layer, pavement cover & working platform
L11	150mm of *(d)* is required on *(e).* Thickness of *(e)* determined from SC6.4.6.8 Drainage mats. Combined thickness must also satisfy SC6.4.4.2.7 (1) and (2). Greater thickness may be required to achieve an adequate working platform	Capping layer, pavement cover, drainage layer & working platform

Table SC6.4.4.2.7 Material properties for select fill and treated material

Property	**Depth below Working Platform** [1]	
	≤ 150 mm	**> 150 mm**
Laboratory CBR (%) [1]	≥ 10	≥ 10
Maximum aggregate size (mm)	75	75
Plasticity index	≥7	≥7
Weighted plasticity index (WPI)	< 1200	< 2200
Swell (%) [2]	≤ 0.5	≤ 2.5
% passing 0.075 mm	15–30 inclusive	4–30 inclusive

Note—

(1) material may be chosen with a minimum CBR greater than specified above, ift his is considered to provide a better overall design solution. However, for design purposes, the layer may not be modelled with CBR of greater than1 5%. CBR to be tested in accordance with Q113C (97.0% MDD, OMC, standard compactive effort), 4.5kg surcharge and soaked for a period of four days.

(2) swell determined from CBR test described above.

(8) In-situ lime stabilised subgrade

In-situ lime stabilisation of the subgrade soil is the preferred means of satisfying "Capping Layer" and "Pavement Cover" requirements when the subgrade comprises plastic clay soils.

In-situ treatment of clay subgrades using lime involves mixing lime, which has been either previously hydrated or hydrated on site by adding water (slaking), into a subgrade to increase subgrade strengths. This may be done to modify the subgrade (i.e. usually achieve a temporary strength gain) or it may be added to stabilise it (i.e. achieve a permanent increase in strength). In the case of the latter sufficient lime must be added to ensure that these strength gains are permanent. It is essential that the purpose of the treatment is clearly identified and clear to all concerned.

No design benefit can be adopted if stabilisation is only for the purpose of "modifying" the subgrade soil properties. To qualify for use as a "Capping Layer" and/or "Pavement Cover", full stabilisation as outlined below is required.
Subgrade soil not suitable for lime stabilisation must include:

(a) unbound material with:
  (i) a plasticity index less than 10%; or
  (ii) less than 25% passing the 0.425 mm sieve; or
  (iii) Soluble sulphate > 0.2%

(b) any patch which may include:
  (i) concrete; or
  (ii) cement treated material; or
  (iii) asphalt.

Lime stabilisation of subgrade material must be carried out as a 2 day operation to a minimum depth of 250mm, except for natural subgrades with a representative strength of CBR 0.5% where stabilisation depth must be a minimum of 300mm. The required process is detailed in SC6.4.6.12 Flexible pavements.

(9) Rock fill (geofabric wrapped) + min. 150mm of *(b)* or *(d)*
Rock fill (geofabric wrapped) can be utilised in combination with treatment types *(b)* or *(d)* for application within a capping layer, a working platform and a Drainage Layer.

Rock fill must meet the quality requirements for rock Fill in TMR Specification MRTS04 and the Geofabric must be selected in accordance with TMR Specification MRTS27.

The minimum rock fill layer thickness must be twice the maximum particle size, but not less than 300mm. If a working platform is also required, the thickness must be sufficient to bridge the natural subgrade and provide solid support for the *(b)* or *(d)* overlying layer.

(10) Drainage layer + min. 150mm of *(b)* or *(d)*

A drainage layer must be provided where water exposure occurs, or is likely to occur, from beneath the pavement (due to the effect of capillary rise and/or positive head). The drainage layer must be a minimum 300mm thick (refer SC6.4.6.8 Drainage mats) and covered by a minimum 150mm of type *(b)* or *(d)*.

Treatment type *(f)* must not be used for situation where a working platform is also required due to the insitu material being wet and of low strength (which can be assessed by in situ dynamic cone penetrometer testing), and only treatment type *(e)* is acceptable.

(11) Equivalent subgrade CBR for design
Section SC6.4.4.2.4 (1) to (10) outlines the requirements of subgrade treatment and treatment type options acceptable by Council. Once subgrade treatment has been identified, the equivalent subgrade CBR value for pavement design calculation or modelling must be adopted as per Table SC6.4.4.2.8 Equivalent subgrade CBR.

As a capping layer is compulsory for treatment L4 to L11, there are two design conditions to determine the thickness requirement and equivalent subgrade CBR strength for the capping layer.

(a) Capping layer comprises in-situ lime stabilised subgrade or plant mixed cement stabilised gravel
The pavement above an in-situ lime stabilised subgrade or plant mixed cement stabilised gravel must be designed for an equivalent CBR derived from the natural subgrade CBR and the design traffic load (ESA's) as shown in Figure SC6.4.4.2.2 Design chart: Subgrade CBR equivalent to lime stabilised layer + natural subgrade (M. Matheson).

The capping layer depth required must be 250mm for natural subgrade CBR of > 0.5%, otherwise depth must be 300mm.

(b) Capping layer comprises unbound material

As detailed in section SC6.4.4.2.4 (6), unbound material that are acceptable to be used as capping layer include:

- unbound gravel;
- select fill;
- rock fill (geofabric wrapped) + min. 150mm select fill; and
- drainage layer material + min. 150mm select fill.

The required capping thickness is given in Table SC6.4.4.2.9 Capping thickness for unbound materials. However, for natural subgrade CBR ≤ 1.0%, a specific assessment is required.

Table SC6.4.4.2.8 Equivalent subgrade CBR

Treatment	Natural ground subgrade CBR (%)	Treatment type	Equivalent subgrade CBR
-	> 3	Nil	Use natural ground subgrade CBR
L1	> 3	*(e)* or *(f)*	CBR = 10%
L2	> 3	*(b), (c), (d), (e)* or *(g)**	If wet layer is removed and replaced: Use natural ground subgrade CBR
		(b), (e) or *(g)**	If wet layer remains: CBR = 3%
L3	> 3	*(e)*	CBR = 3%
L4	≤ 3	*(a)* or *(b)*	Refer SC6.4.4.2.4 (11A)
		(c) or *(d)*	CBR = 3%. Refer SC6.4.4.2.4 (11B)
L5	≤ 3	*(e)* or *(f)*	CBR = 3%. Refer SC6.4.4.2.4 (11B)
L6	≤ 3	*(a)* or *(b)*	Refer SC6.4.4.2.4 (11A)
		(d)	CBR = 3%. Refer SC6.4.4.2.4 (11B)
L7	≤ 3	*(e)* or *(f)*	CBR = 3%. Refer SC6.4.4.2.4 (11B)
L8	≤ 3	*(a)* or *(b)*	Refer SC6.4.4.2.4 (11A)
		(e)	CBR = 3%. Refer SC6.4.4.2.4 (11B)
L9	≤ 3	*(e)*	CBR = 3%. Refer SC6.4.4.2.4 (11B)
L10	≤ 3	*(a)* or *(b)*	Refer SC6.4.4.2.4 (11A)
		(e)	CBR = 3%. Refer SC6.4.4.2.4 (11B)
L11	≤ 3	*(e)*	CBR = 3%. Refer SC6.4.4.2.4 (11B)

* (g) – geofabric layer may or may not provide adequate as a working platform upon which pavement construction can proceed. This can only be determined by trial and error. If it proves insufficient support, other acceptable treatments will be required.

Table SC6.4.4.2.9 Capping thickness for unbound material

Natural subgrade CBR	Minimum capping layer thickness (mm)
≥ 2.5% to ≤ 3.0%	150
≥ 2.0% to < 2.5%	200
≥ 1.5% to < 2.0%	300
≥ 1.0% to < 1.5%	400

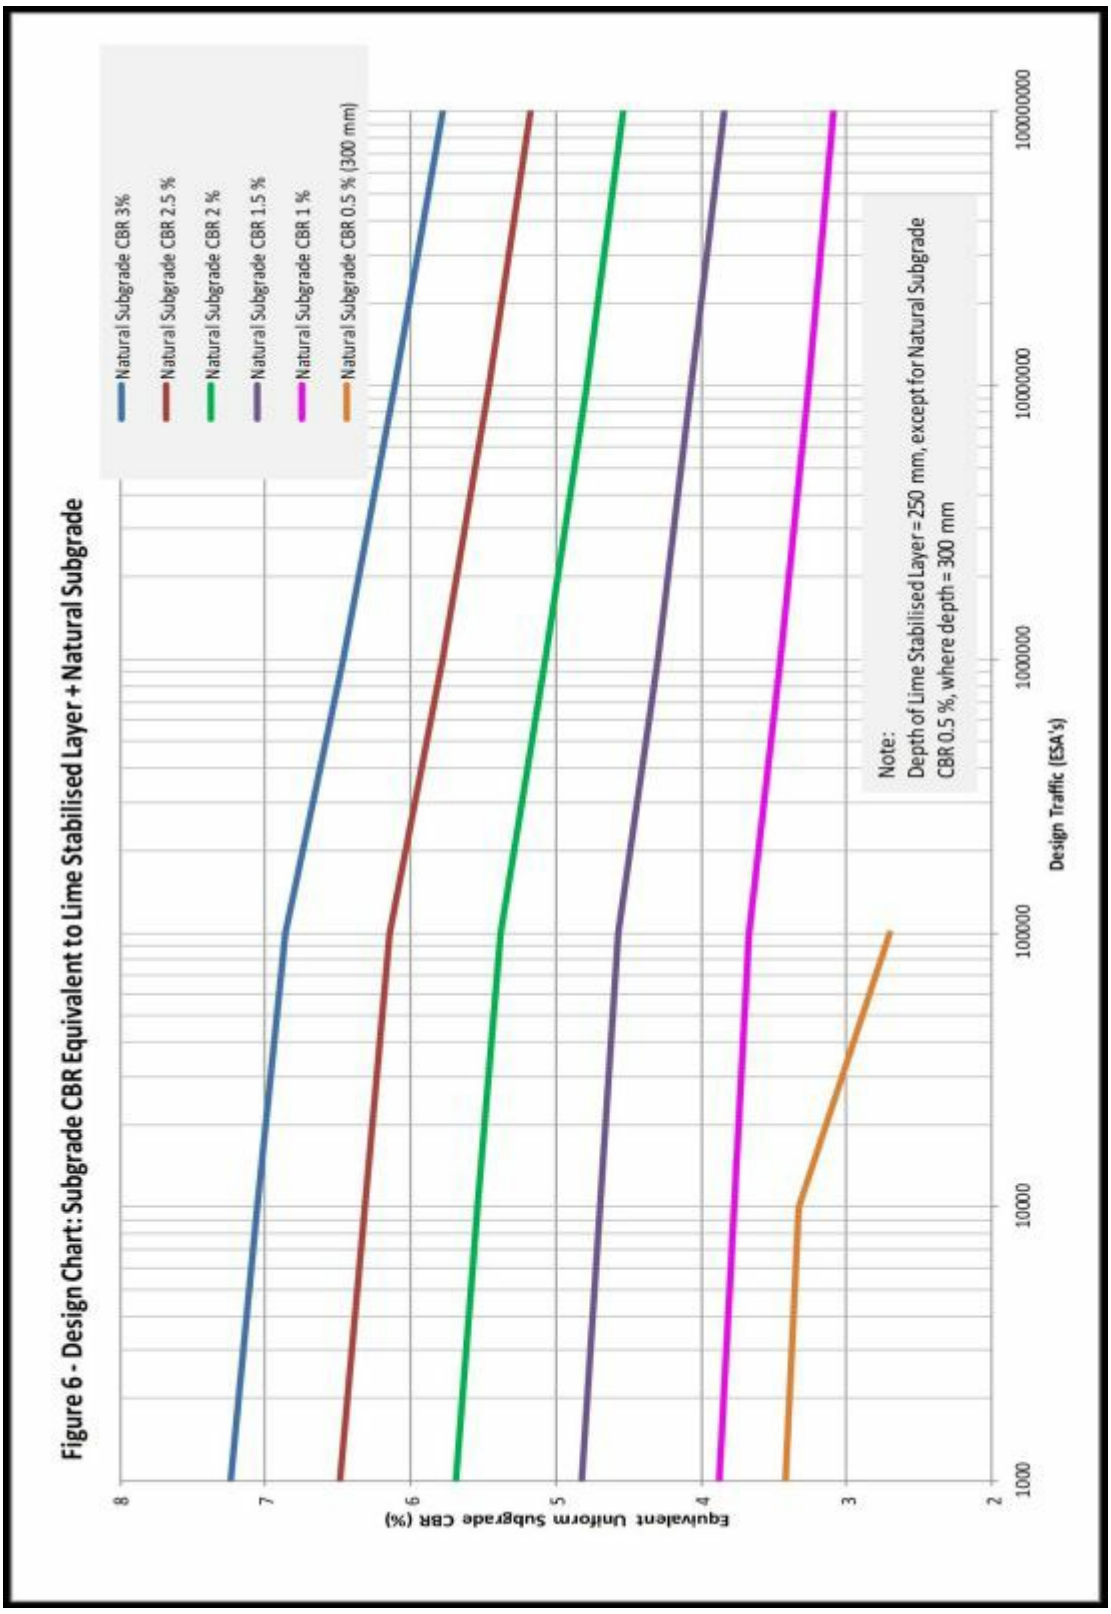

Figure SC6.4.4.2.2 Design chart: subgrade CBR equivalent to lime stabilised layer + natural subgrade (M. Matheson)

SC6.4.4.2.5 Pavement and surfacing materials

(1) Pavement materials can be classified into the following categories according to their fundamental behaviour under the effects of applied loadings:

- unbound granular materials;
- cement modified granular materials, also known as cement modified (0.8 MPa < UCS < 1.5 MPa);
- bound (cemented) granular materials, also known as cement treated (UCS >1.5MPa);
- asphaltic concrete;
- cement concrete; and
- heavy duty asphalt (deep lift asphalt).

(2) Surfacing materials can also be classified into essentially five categories or types:

- sprayed bituminous seals (flush seals);
- asphaltic concrete;
- cement concrete;
- concrete segmental pavers; and
- clay segmental pavers.

(3) Unbound granular materials, including modified granular materials, must satisfy the requirements of SC6.4.6.12 Flexible pavements.

(4) Bound (cemented) granular materials must satisfy the requirements of SC6.4.6.12 Flexible Pavements.

(5) Asphaltic concrete must satisfy the requirements of SC6.4.6.13 Asphaltic concrete.

(6) Cement concrete must satisfy the requirements of SC6.4.6.14 Mass concrete subbase, SC6.4.6.15 Plain and reinforced concrete base, as appropriate.

(7) Sprayed bituminous seals must satisfy the requirements of SC6.4.6.16 Sprayed bitumen surfacing.

(8) Concrete and clay segmental pavers must satisfy the requirements of SC6.4.6.18 Segmental paving.

(9) Heavy duty asphalt pavements must satisfy the requirements of MRTS31.

SC6.4.4.2.6 Construction and maintenance considerations

The type of pavement, choice of base and subbase materials, and the type of surfacing adopted should involve consideration of various construction and maintenance factors as follows:

(1) extent and type of drainage;

(2) use of boxed or full width construction;

(3) available equipment of the Contractor;

(4) use of stabilisation;

(5) aesthetic, environmental and safety requirements;

(6) social considerations;

(7) construction under traffic;

(8) use of staged construction; and

(9) ongoing and long-term maintenance costs

These factors are further discussed in Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design.*

SC6.4.4.2.7 Pavement design

Pavement design must be in accordance with Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design* unless otherwise stated in this document.

(1) Pavement Thickness

Notwithstanding subgrade testing and subsequent pavement thickness design, the minimum pavement thickness on local streets must not be less than 250 mm. This is necessary to ensure that council has sufficient thickness for future insitu stabilisation of pavements (without the risk of mixing the subgrade into the pavement during the process). Additionally, individual compacted layer thickness must be chosen to suit construction process and must be no less than 125 mm nor greater than 250 mm for optimal compaction and to avoid lamination of layers.

(2) Design subgrade CBR

The subgrade Design CBR adopted for the pavement design must consider the effect of moisture changes in the pavement and subgrade during the service life, and hence consideration must be given to the provision of subsurface drainage in the estimation of equilibrium in-situ CBRs, and hence in the design of the pavement structure.

Design CBR of untreated subgrade must be no greater than 3% unless otherwise approved by council who reserves the rights to carryout independent 3rd party geotechnical investigations to confirm adopted design CBR's and respective pavement designs.

Warrants for the provision of subsurface drainage are given in SC6.4.6.21 Subsurface drainage. If subsurface drainage is not provided, then the Design CBR adopted must allow for a greater variability in subgrade moisture content during the service life of the pavement, and hence a design moisture content above the optimum moisture content (OMC).

Subgrade treatment must be carried out in accordance with this document on all natural subgrade CBRs ≤ 3% (97% maximum dry density standard compaction at OMC). The equivalent design subgrade CBR of the treated subgrade must be determined in accordance with this document. Pavement design over treated subgrades may adopt the equivalent CBR determined in accordance with this document.

(3) Pavement structure - general

Unbound granular materials used must comply with the requirements of MRTS05. Bound layers must comply with the requirements under MRTS08.

The subbase layer must extend a minimum of 150 mm behind the rear face of any kerbing and/or guttering. The base and surfacing must extend to the face of any kerbing and/or guttering. Where the top surface of the subbase layer is below the level of the underside of the kerbing and/or guttering, the base layer must also extend a minimum of 150 mm behind the rear face of the kerbing and/or guttering.

For unkerbed roads, the subbase and base layers must extend for the full width of the formation.

The pavement designer must make specific allowance for traffic load concentrations within car park areas (e.g. entrances/exits).

The pavement designer must make provision for pavement layer drainage on the assumption that during the service life of the pavement ingress of water will occur. Compaction of the subbase, including 150mm behind the rear face of the kerb and channel, must be carried out before trenching of the subsoil behind the kerb.

(4) Unbound granular flexible pavements (bituminous surfaced)

Unbound granular flexible pavements with thin bituminous surfacings, including those with cement or lime modified granular materials, with design traffic up to 1 x 10^6 ESAs must be designed in accordance with Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design*.

Residential streets and rural roads with non-fixed level construction (future overlay possible) must be designed in accordance with Austroads Guide to Pavement Technology Part 2: Pavement Structural Design.

For design traffic above 1 x 10^6 ESAs, the design must be in accordance with Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design.*

An unsealed gravel pavement may be acceptable for assigned traffic volumes of less than 100vpd on lightly trafficked roads in rural areas. Where the connecting road to a reconfiguration is also unsealed, it must be upgraded to at least the gravel pavement standard, and, if the assigned traffic volume equals or exceeds 100vpd, it must be fully sealed, from its connection with an existing sealed road to a threshold point where the assigned traffic volume on the connecting road falls below 100vpd. Where an existing rural road is specified as upgraded to gravel pavement standard, the minimum pavement thickness is 100mm.

(5) Flexible pavements containing bound layers (bituminous surfaced)

Flexible pavements containing one or more bound layers, including cement stabilised layers or asphaltic concrete layers other than non-structural asphalt surfacings, must be designed in accordance with Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design.*

(6) Rigid pavements

Rigid (concrete) pavements, with design traffic up to 1 x 10^6 ESAs must be designed in accordance with either CACA -T51 or Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design.*

Rigid (concrete) pavements for design traffic above 1 x 10^6 ESAs, the design must be in accordance with Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design.*

(7) Concrete segmental pavements

Concrete segmental pavements with design traffic up to 1 x 10^6 estimated commercial vehicles exceeding 3T gross must be designed in accordance with CMAA T45.

For design traffic above 1 x 10^6 ERAs estimated commercial vehicles exceeding 3T gross the design must be in accordance with Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design*, with the calculation of design traffic in terms of ESAs.

(8) Clay segmental pavements

Clay segmental pavements with design traffic up to 1 x 10^6 ESAs must be designed in accordance withAustroads *Design Manual 1 - Clay Segmental Pavements.*

For design traffic above 1 x 10^6 ESAs and up to 1 x 10^7 ESAs the design must involve consideration of both *Design Manual 1 - Clay Segmental Pavements* and Austroads *Guide to Pavement Technology Part 2: Pavement Structural Design,* with the thicker and more conservative design of each of the two methods adopted.

For design traffic above 1 x 10^7 ESAs, the pavement must be designed in accordance with *Guide to Pavement Technology Part 2: Pavement Structural Design.*

SC6.4.4.2.8 Surfacing design

(1) Choice of surface type

Except where the pavement is designed for concrete or segmental paver surfacing, the wearing surface must be a bituminous wearing surface as follows:

(a) urban residential streets – urban Type A, B and C, major collector, sub-arterial and arterial roads—prime, plus one coat flush seal, plus asphalt;

(b) rural residential streets—access roads, collector roads, sub-arterial and arterial roads—prime, plus two coats flush seal; and

(c) commercial and industrial streets—prime and one coat flush seal plus asphalt;

In cases where it is required for the road to be opened to traffic upon completion of work, primerseal may be used with prior approval from council.

At intersection approaches and cul-de-sac turning circles on residential streets with flush seals, asphalt surfacing must be provided within the vehicle braking and turning zones.

Variations to these requirements may be approved by council in special circumstances.

(2) Sprayed bituminous seals (flush seals)

The design of sprayed bituminous (flush) seals, including primer seals, must be in accordance with the *Guide to Pavement Technology Part 3: Pavement Surfacings.*

7mm primer seals or prime and seals must be indicated on the Drawings below all flush seals, and asphalt surfacings. Where a 7 mm primer seal is impractical, a 10mm primer seal must be indicated in lieu.

Two-coat flush seals must be double-double seals, comprising a minimum of two coats of binder and two coats of aggregate. The preferred seal types are:

(a) 1st coat 14 mm; and

(b) 2nd coat 10 mm.

Single coat flush seals may be allowable if asphaltic concrete is to be applied as the finished surface. The preferred seal type is either 14mm or 10mm.

(3) Asphaltic concrete

In urban residential roads, medium to heavily trafficked commercial streets and in all industrial roads, the asphalt mix design must be a dense graded mix in accordance with the MRTS 30 06/09.

Asphaltic concrete surfacings must be designed to provide a nominal compacted layer thickness of not less than 30 mm (AC10) on light to medium trafficked residential streets, and 50 mm (AC14) minimum on medium to heavily trafficked residential, commercial roads and on all industrial and classified roads including all roundabouts and all cul-de-sac heads.

As a minimum, a 10mm primer seal or prime and seal must be indicated on the Drawings below the asphalt surfacing. Tack coat is to be used where the asphalt is used as an overlay.

Polymer Modified Bitumen in accordance with MRTS18 must be used in the asphalt in areas of heavy traffic where braking, turning, acceleration is to be experienced.

(4) Segmental pavers

Pavements must be sealed with a minimum of 10 mm primerseal prior to laying segmental pavers. Concrete segmental pavers must be 80mm thick, shape Type A, and designed to be paved in a herringbone pattern.

Clay segmental pavers must be 65mm thick, Class 4, and designed to be paved in a herringbone pattern. The edges of all paving must be designed to be constrained by either kerbing and/or guttering, or by concrete edge strips.

SC6.4.4.2.9 Documentation – pavement design criteria and calculations

All considerations, assumptions, subgrade test results, and calculations and other documentation required under this design specification must be submitted with the pavement design for approval by council.

The Drawings must clearly indicate the structure, material types and layer thicknesses of the proposed pavement and surfacing.

Pavement design criteria must be shown on the pavement drawings and include the ESA, CBR and expected design life.

SC6.4.4.2.10 Subsurface drainage design

(1) Subsoil and sub-pavement drains

(a) Warrants for use

(i) Subsoil drains are designed to drain groundwater or seepage from the subgrade and/or subbase in cuttings and fill areas.

(ii) Sub-pavement drains are designed to drain water from base and subbase pavement layers in flexible pavements, and to drain seepage or groundwater from the subgrade.

(iii) Subsoil or sub-pavement drains must be provided on both sides of the formation in the following locations, unless the geotechnical report indicates the absence of subsurface moisture at the time of investigation and the likelihood that changes in the subsurface moisture environment will not occur within the design life of the pavement and/or the pavement has been specifically designed to

allow for likely variations in subgrade and pavement moisture contents:

(A) cut formations where the depth to finished subgrade level is equal to or greater than 400mm below the natural surface level;

(B) locations of known hillside seepage, high water table, isolated springs or salt affected areas;

(C) irrigated, flood-prone or other poorly drained areas;

(D) highly moisture susceptible subgrades, i.e. commonly displaying high plasticity or low soaked CBRs;

(E) use of moisture susceptible pavement materials;

(F) existing pavements with similar subgrade conditions displaying distress due to excess subsurface moisture; and

(G) at cut to fill transitions.

Where only one side of the formation is in cut, and the other side in fill, it may be sufficient to provide subsoil or sub-pavement drains only along the edge of the formation in cut.

(iv) The need for subsoil and sub-pavement drains may otherwise become apparent during the construction process, due to changes in site moisture conditions or to areas of poorer subgrade being uncovered that were not identified in the geotechnical investigation. The Design Drawings must be suitably annotated to the potential need for subsoil or sub-pavement drains in addition to those shown on the Drawings.

(2) Layout, alignment and grade

Typical cross sections of subsoil drains are shown in SC6.4.4.8 Standard drawing SD-080 – Subsoil Drain. In kerbed roads, the only acceptable location for the line of the trench is directly behind the kerbline. Pavement layers must extend to at least the line of the rear of the trench.

In unkerbed roads, subsoil and sub-pavement drains must be located within the shoulder, preferably at the edge of the pavement layers.

The minimum desirable longitudinal design grade is 1.0%. For non-corrugated pipes, an absolute minimum grade of 0.5% is acceptable.

Trench widths must be a minimum of 300 mm for a 100mm diameter slotted pipe or a minimum of 100mm for strip drains, Outlets must be spaced at maximum intervals of 150m into gully pits or outlet headwalls. As a salinity prevention measure and where practical, discharge must be on the downhill side of the embankment or in the cut-fill area to reduce the risk of recharge to the subsurface water table. Unless otherwise authorised, where subsurface drains outlet through fill batters, unslotted plastic pipe of the same diameter as the main run must be specified. A small precast concrete headwall must be installed at the drain outlet with a marker post to assist maintenance and protect the end of the pipe.

Cleanouts must be provided at the commencement of each run of drain, and at intervals not exceeding 80m. Cleanouts must generally be located directly at the rear of kerb or at the edge of shoulder, as applicable.

In salinity affected areas, the Designer should consider providing a separate drainage system for subsurface drains to discharge to a basin where controlled release or desiccation treatment and removal can be facilitated as a maintenance operation. Saline subsurface drainage should not be routinely discharged directly into natural watercourses. Reference to water quality targets for downstream watercourses is essential and the Designer must provide advice on discharge operations and maintenance compatible with water quality targets and the requirements of the relevant land and water resource or environmental protection authority.

SC6.4.4.2.11 Foundation drains

(1) Warrants for use

Foundation drains are designed to drain excessive ground water areas within the foundation of an embankment or the base of cutting, or to intercept water from entering these areas.

The need to provide foundation drains may be apparent from the results of the geotechnical survey along the proposed road formation alignment, and in this case the location must be shown on the Drawings. However, more commonly, the need to provide foundation drains is determined during construction, and hence in this situation requirements and locations cannot be ascertained at the design stage.

Where the road formation traverses known swampy, flood-prone, salt affected areas or watercharged strata, the Drawings must be suitably annotated for the potential need for foundation drains at various locations, in addition to those shown on the Drawings.

(2) Layout, alignment and grade

Typical cross-sections of foundation drains are shown below in Figure SC6.4.4.2.3.

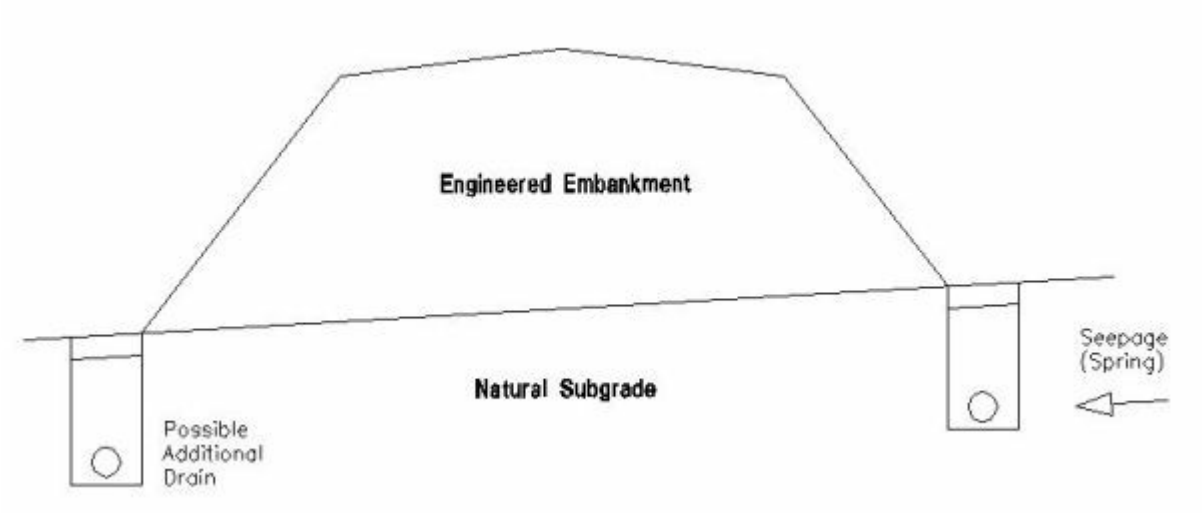

Figure SC6.4.4.2.3 Foundation drains

The minimum desirable design grade is 1%. For non-corrugated pipes an absolute minimum grade of 0.5% is acceptable.

Foundation drains must have a minimum trench width of 300 mm, with a variable trench depth to suit the application and ground conditions on site.

Outlets must be spaced at maximum intervals of 150m.

Where practicable, cleanouts must be provided at the commencement of each run of foundation drain and at intervals not exceeding 60 m. Where not practicable to provide intermediate cleanouts, outlets must be spaced at maximum intervals of 100m.

SC6.4.4.2.12 Drainage mats (blankets)

(1) Warrants for use

Type A drainage mats are designed where there is a need to ensure continuity of a sheet flow of water under fills, to collect surface seepage from a wet seepage area, or for protection of vegetation or habitat downstream of the road reserve where a fill would otherwise cut the flow of water. Type A drainage mats are constructed after the site has been cleared and grubbed and before commencement of embankment construction.

Type B drainage mats are designed where there is a need to intercept water which would otherwise enter pavements by capillary action or by other means on fills and to intercept and control seepage water and springs in the floors of cuttings. Type B drainage mats must be constructed after completion of the subgrade construction and before construction of the pavement.

The need to design for the provision of drainage mats should be apparent from the result of the geotechnical survey along the proposed road formation alignment.

SC6.4.4.2.13 Materials

(1) Subsoil and sub-pavement drain pipe

Pipes designated for subsoil, foundation and sub-pavement drains must be 100mm dia. slotted pipe.

Corrugated plastic pipe must conform with the requirements of AS 2439.1. The appropriate class of pipe must be selected on the basis of expected live loading at the surface. Joints, couplings, elbows, tees and caps must also comply with AS 2439.1.

Slotted rigid UPVC pipe must be of a type and class approved by council.

All pipe must be slotted, and fitted with a suitable geotextile filter tube, except for cleanouts and outlets through fill batters which must be unslotted pipe.

(2) Intra pavement drain pipe

Pipes designated for intra pavement drains with crushed rock subbases having layer thicknesses neither less than 150mm nor more than 200mm must be slotted thick walled UPVC pressure pipe complying with AS/NZS 1477.

Pipes designated for intra pavement drains with crushed rock subbases having layer thicknesses exceeding 200 mm must be slotted pipe of a type and class approved by council.

Pipes for use in Type B drainage mats must be slotted thick walled UPVC pressure pipe complying with AS/NZS 1477.

(3) Filter material

The types of filter material covered by this sub-section must include:

(a) Type A filter material for use in subsoil, foundation, and sub-pavement (trench) drains and for Type B drainage mats;

(b) Type B filter material for use in subsoil, foundation and sub-pavement (trench) drains;

(c) Type C filter material comprising crushed rock for use in Type A drainage mats; and

(d) Type D filter material comprising uncrushed river gravel for use in Type A drainage mats.

Material requirements and gradings for each type of filter material are included in the construction sub-section SC6.4.6.21 Subsurface drainage.

The type of filter material specified to backfill the sub-surface drainage trenches (subsoil, foundation and sub-pavement drains) depends on the permeability of the pavement layers and/or subgrade and the expected flow rate. Generally, Type A filter material is used for the drainage of highly permeable subgrade or pavement layers such as crushed rock or coarse sands, while Type B filter material is used for the drainage of subgrade and pavement layers of lower permeability such as clays, silts or dense graded gravels. Further guidance to the selection of appropriate filter material is contained in *Guide to Pavement Technology.*

(4) Geotextile

To provide separation (i.e. prevent infiltration of fines) between the filter material in the trench and the subgrade or pavement material, geotextile must be designated to encapsulate the filter material. The geotextile must comply with the requirements included in sub-section SC6.4.6.21 Subsurface drainage.

Geotextile must also be designated for both Type A and Type B Drainage Mats.

SC6.4.4.2.14 Documentation – subsurface drainage drawings and calculations

The proposed location of all subsurface drains must be clearly indicated on the Drawings, including the nominal depth and width of the trench, and the location with respect to the line of the kerb/gutter or edge of pavement. The location of outlets and cleanouts must also be indicated on the Drawings.

SC6.4.4.3 Bridges and other structures

SC6.4.4.3.1 Introduction

(1) Objective

This sub-section sets out design considerations to be adopted in the design of structural engineering elements associated with

(a) road traffic bridges;

(b) pedestrian/cyclist bridges;

(c) any structure designed to carry a road or a path over a waterway, depression or obstacle; and

(d) temporary works.

(2) Design considerations

Such structures may be primarily constructed of concrete, timber, steel or other materials appropriate to the application. The design should always have a primary emphasis on safety and whole of life cycle costs. The structure/s should comply with current Safety in Design principles and guidelines.

The design is to be certified that the proposed structure will not become unfit for use during its intended design life. This assessment will have measured regard to all associated issues with the proposed structure including:

(a) consideration of any future infrastructure planning;

(b) economic constraints;

(c) physical or structural constraints;

(d) aesthetic considerations;

(e) flooding or hydraulic capacities (if applicable);

(f) safety in design;

(g) maintenance and repair constraints;

(h) constructability; and

(i) fit for purpose.

(3) Basis of design

(a) The basis of the proposed bridge design is to principally conform to Austroads' road design standards, and AS 5100 as appropriate. The design must be based on sound engineering principles, and certified by a suitably qualified engineer (RPEQ).

(b) The safety and service performance of a structure will depend on the quality control exercised in fabrication, supervision of the site, control of unavoidable imperfections and the experience and skill of the personnel involved. Specific attention must therefore be given to these particular factors.

(c) All design criteria for bridges in the Townsville City Council local government area must be approved by council prior to the design being carried out. The Designer must make reference and address all issues outlined in Appendix A of AS 5100.1.

(d) Adequate management control and supervision by experienced engineers (RPEQ) is required at all stages of the design and construction to prevent the occurrence of any unapproved non-conformances with the plans and specifications.

(e) Specifications must be notated on the Drawings with sufficient details to ensure that the above described strategies are able to be effectively implemented throughout the construction stage.

(4) Reference and source documents

(a) Development manual planning scheme sub-sections to be read and applied in conjunction with this sub-section are as follows:

SC6.4.4.1 - Geometric road design

SC6.4.4.2 - Pavement design

SC6.4.4.4 - Stormwater drainage design

SC6.4.4.7 - Bicycle, pedestrian and shared path design

(b) Australian Standards

AS 1158	*Lighting for roads and public spaces*
AS/NZS 3845	*Road safety barrier systems*
AS 5100	*Bridge Design*
AS1428	Design for access and mobility

Queensland Department of Main Roads, *Road Traffic Noise Management: Code of Practice, 2000*
Queensland Department of Energy and Water Supply, *Queensland Urban Drainage Manual*

SC6.4.4.3.2 Road traffic and pedestrian bridges

(1) Bridge design must only be carried out by properly qualified persons who are Registered Professional Engineers of Queensland (RPEQ) and experienced in structures design. If requested, such designers must submit evidence of these qualifications and experience to council prior to approval of any bridge design.

(2) The *Bridge Design Code* (AS 5100) must be used for all bridge design.

(3) Bridges must have low maintenance finishes. Adequate precautions must be taken for protection of the materials used in the bridge design; for example, timber and steel require special consideration. Heavy debris and bed loads may be characteristic of some streams so that large spans with slender piers are encouraged. If floodwater overtopping is to occur, pedestrian safety rails and road safety barriers could be omitted to reduce debris collection on the roadway. Flood depth indicators and appropriate signposting will be provided in such cases.

(4) Preventative maintenance is a key issue affecting the design life of the structure. The Drawings must specify the design life of the structure together with the relevant maintenance programs to be adopted upon which the design life is based. Parameters used in the design must also be shown on the Drawings.

(5) Hydraulic design of bridge/s must be in accordance with the requirements for major structures in SC6.4.4.4 Stormwater drainage design.

(6) Where structures are designed to be inundated, the effect of the backwater gradient on upstream property must be identified on the Drawings. Detailed consideration of alternate evacuation routes are also to be considered in the event that the bridge structure is to be inundated.

(7) Where no inundation is permitted, appropriate afflux must be adopted together with a 500mm freeboard to the underside of the bridge deck. All road structures with a 1% annual exceedance probability (AEP) designed waterway which is in excess of 5sqm must be modelled using current hydrological modelling practices (software) to determine the upstream impacts over the full range of storm events up to and including the 1% AEP. Impacts of the PMF are also to be assessed on the structure.

(8) The designer is to enquire with the appropriate authority on any current or likely provisions for public utilities or services on bridges. These should be concealed for aesthetic reasons. Consultation with the appropriate utility authority is to be undertaken during the course of the structural design, particularly in regard to the location and placement of existing and future public utilities.

SC6.4.4.3.3 Provision for pedestrians and cyclists on road bridges

(1) Provision for pedestrians and cyclists on bridges is required in rural residential as well as urban areas. The

minimum provision is a 1.5m footpath with a 150mm high kerb at the traffic lane edge. The design is to consider pedestrian on the bridge. A safety railing is to be provided between pedestrians and the trafficable lane together with 1.5m (min) wide shoulder to accommodate on-road cyclists.

(2) Council may require the provision of a combined cycleway and pedestrian footway should the risk to on-road cyclists be too high.

(3) Disability access across the proposed bridge is to be DDA compliant and generally in accordance with AS 1428.

(4) Urban bridge approaches should be lit in accordance with AS 1158.

SC6.4.4.3.4 Structures other than bridges, associated with roads

Public utility structures, major culverts, major sign support structures, retaining walls, and the like will be designed by a competent, practicing engineer (RPEQ certified) who is accredited in the design of such structures. The design must be in accordance with the SC6.4 Development manual planning scheme policy, relevant Austroads codes, all relevant Australian Standards, and the requirements of any utility owners that may be applicable.

SC6.4.4.3.5 Structures used for public safety

(1) Since the requirement of road safety barriers and pedestrian safety rails on bridges are different, the design engineer must consider whether separate traffic and pedestrian barriers can be detailed to satisfy the major functional requirements.

(2) The *Bridge Design Code* (AS 5100.1 Sections 10 - 12) and AS/NZS 3845 are recommended references in this regard.

(3) It is essential that all safety barriers and rails have been fully tested and accredited for the intended use under quality assurance provisions.

(4) Bridge crossings in urban and rural residential areas must be provided with street lighting in accordance with AS 1158. Such requirements will be noted accordingly on the drawings.

SC6.4.4.3.6 Temporary works

Structures which are proposed for the temporary support of roads, services and the like must be designed by a qualified Engineer (RPEQ certified) experienced and accredited in the design of such structures and designed in accordance with the *Bridge Design Code* (AS 5100). A construction programme, indicating the sequence of events leading to the implementation and removal of the temporary structures must be specified on the drawings. The design of such temporary structures is to mandate the safe constructability and use of these structures throughout the term of the construction works.

SC6.4.4.4 Stormwater drainage design

SC6.4.4.4.1 Introduction

(1) Objectives

(a) The objectives of SC6.4.4.4 Stormwater drainage design are as follows:

(i) to ensure that inundation of private and public buildings located in flood-prone areas occurs only on rare occasions and that, in such events, surface flow routes convey floodwaters below the prescribed velocity/depth limits;

(ii) to provide convenience and safety for pedestrians and traffic in frequent stormwater flows by controlling those flows within prescribed limits; and

(iii) retain within each catchment as much incident rainfall and runoff as is possible and appropriate for the planned use and the characteristics of the catchment.

(b) In pursuit of these objectives, the following principles apply:

(i) new developments are to provide a stormwater drainage system in accordance with the "major/minor" system concept set out in QUDM (Third Edition 2013 – provisional or as amended); that is, the "major" system shall provide safe, well-defined overland flow paths for infrequent storm runoff events while the "minor" system shall be capable of carrying and controlling flows from frequent runoff events; and

(ii) redevelopment - where the proposed development replaces an existing development, stormwater must be managed in a way that does not exacerbate flooding, and /or adversely impact on neighbouring land or road. The level of drainage provided must be consistent with new development.

(2) Scope

The work to be executed under this sub-section consists of the design of stormwater drainage systems for urban and rural areas.

(3) Reference and source documents

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with its sub-section are as follows:

SC6.4.6.4 Stormwater Drainage
SC6.4.6.5 Drainage Structures
SC6.4.6.6 Pipe Drainage
SC6.4.6.7 Precast Box Culverts
SC6.4.6.9 Open Drains

SC6.4.4.4.2 Major and minor system design AEPs

(1) The Annual Exceedence Probability(AeP) is the probability of exceedence of a given rainfall intensity or discharge within a period of one year.

(2) The major system design AEP is the Defined Flood Event, being the 1% AEP, unless altered by Table 8.2.6.3(b) of the Flood hazard overlay code.

(3) The Minor system design AEPs must be in accordance with Table SC6.4.4.4.1.

Table SC6.4.4.4.1 Minor System Design AEP and ARI

Development Category	ARI (yrs)	AEP
Residential	2	39%
Commercial - Lower order (district centre and below)	2	39%
Commercial - Other (excluding Lower order commercial and Principal centre)	5	18%
Industrial	5	18%
Principal Centre (CBD)	10	10%
Rural Residential	20	5%
Parks and recreation areas (excluding community facilities)	1	1EY

(4) The Minor system design AEP for streets is as per the adjacent development category listed in Table SC6.4.4.4.1.

SC6.4.4.4.2 Hydrology

(1) Design rainfall data can be obtained from one of the following methods:

(a) Design intensity-frequency-duration (IFD) rainfall - IFD relationships shall be derived in accordance with Volume 1, Book II, of AR&R, 1998 for the particular catchment under consideration;

(b) The nine basic parameters read from Maps 1-9 in Volume 2 of AR&R shall be shown in the calculations submitted to council, except where the Bureau of Meteorology provides a polynomial relationship for the catchment; or

(c) Design IFD rainfalls can be obtained from the Bureau of Meteorology website for specific locations and these are to be submitted to council.

(2) Catchment area

(a) The area of land contributing stormwater runoff to the point under consideration. Consideration must be given to likely changes to individual catchment areas and catchment parameters caused by the full development of the catchment in accordance with the zonings in the Townsville City Plan.

(b) Where no detailed survey of the catchment is available, contour maps produced from council's GIS are to be used to determine the catchments and to measure areas. A suitable scale shall be chosen.

(c) Catchment area land use shall be based on current available zoning information or proposed future zonings, where applicable.

(3) Rational method

(a) Rational method calculations to determine peak flows shall be carried out in accordance with QUDM (Third Edition 2013 – provisional).

(b) All calculations shall be carried out or supervised by a qualified engineer (RPEQ certified) who is experienced in hydrologic and hydraulic design.

(c) Coefficients of discharge shall be calculated as per QUDM (Third Edition 2013 – provisional or as amended) and full details of coefficients utilised shall be provided.

(d) Details of percentage impervious for individual zonings are given in SC6.4.4.4 Attachment A.

(e) The time of concentration of a catchment is defined as the time required for storm run off to flow from the most remote point on the catchment to the outlet of the catchment. Most catchments will have multiple lengths of flow paths and gradients. The longest length flow path may not always govern the critical flow path. The hydrologic design should analyse several paths to assess any sensitivity to the catchment's time of concentration.

(f) Where the flow path is through areas having different flow characteristics or includes property and roadway, then the flow time of each portion of the flow path shall be calculated separately.

(g) The minimum time of concentration shall be taken as 5 minutes urban and 10 minutes rural.

(h) Flow paths to pits must be designed to accommodate the flows from the fully developed catchment and provide for anticipated obstructions such as fences, building pads, buildings and other likely obstructions. Any proposed changes to flow paths must be undertaken on a catchment wide basis to ensure flow paths are not diverted onto other land parcels which may result in damage or loss of enjoyment of the adjoining lands.

(i) Surface retardance "n*" shall generally be derived from information in Volume 1, Book 8 Section 1.5.4 of AR&R 1998. Values applicable to specific zoning types and overland flow path types are given below:

Flow across parks 0.35
Flow across rural residential land (sparse vegetation) 0.30
Flow across park residential (short prairie grass) 0.150
Flow across residential low density 0.21
Flow across residential high density flow across industrial 0.06
Flow across commercial 0.04
Flow across paved areas 0.01
Flow across asphalt roads 0.02

Flow across gravel areas 0.02.

(j) The design and analysis of stormwater drainage is to be based on the peak runoff flows from sub-catchments and from accumulated catchments. Designers are to show, by the assessment of partial catchment areas, that the peak flows have been identified.

(k) The rational method is not appropriate for use in catchments with floodplain storage, timing effects due to multiple flow paths, and detention basins.

(4) Hydrological models

(a) Council has carried out flood modelling for most area across Townsville. Hydrological information from these models such as peak flows should be obtained to assist with the design of the stormwater system.

(b) Other hydrological models may be used as long as the requirements of AR&R are met, summaries of calculations are provided and details are given of all program input and output.

Details on the modelling requirements should be obtained from SC6.7 Flood hazard planning scheme policy.
A sample of a summary sheet for hydrological calculations is given in SC6.4.4.4 Attachment B.

(c) Where computer analysis programs are used, copies of the final data files shall be provided on submission of the design to council and with the final drawings after approval by council.

SC6.4.4.4.3 Hydraulics

(1) Hydraulic grade line

(a) Hydraulic calculations shall generally be carried out in accordance with AR&R and shall be undertaken by a qualified person experienced in hydrologic and hydraulic design. The calculations shall substantiate the hydraulic grade line adopted for design of the system and shown on the drawings. Summaries of calculations are added to the plan and details of all calculations are given including listings of all programme input and output.

(b) The "major" system shall provide a safe, well-defined overland flow path for larger storm events up to the maximum defined flood event. The "minor" system shall be capable of carrying and design flows from the lesser nominated flood events based on the land zoning of the area.

(c) Downstream water surface level are to be obtained from council's current existing flood studies. If flood study information is not available, the most appropriate of the below is to be used:

(i) known hydraulic grade line level from downstream calculations including pit losses at the starting pit in the design event;

(ii) where the downstream starting point is a pit and the hydraulic grade line is unknown, details of the downstream system shall be obtained and further analysis performed to determine the hydraulic grade line;

(iii) where the outlet is an open channel and the design storm is the minor event, details of the downstream system shall be obtained and further analysis performed to determine the hydraulic grade line. The top of the outlet pipe or the hydraulic grade line, or mean high water springs shall be the downstream control, whichever is higher;

(iv) where the outlet is an open channel, the design storm is the major event and downstream flood levels are not known, details of the downstream system shall be obtained and further analysis performed to determine the hydraulic grade line. The top of the outlet pipe or the hydraulic grade line shall be the downstream control whichever is the higher;

(v) where the outlet is an open channel, the design storm is the major event and downstream flood levels are known, the downstream control shall be the highest of all duration events for the defined flood event;

(vi) mean high water springs (MHWS) where discharges are to river or creek systems within the intertidal zone:
In some instances, the downstream water surface level may need to be determined with the

development of a flood study. Details on the flood study requirements should be obtained from SC6.7 Flood hazard planning scheme policy; and

(vii) the downstream water surface level used in the calculations should be provided to council.

(2) Major/minor system

Design of the drainage system should be in accordance with the major/minor flood management concept which recognises the dual requirements of the drainage system to provide for convenience and the protection of life and property for all storm events up to the defined flood event.

All design work undertaken should follow the guidelines set down in the *Queensland Urban Design Manual* (Third edition 2013 - provisional) unless otherwise instructed in this sub-section.

(3) Minor system criteria

(a) Minimum conduit sizes shall be as follows:

(i) pipes 375mm diameter; and

(ii) box culverts 600mm wide x 300mm high.

(b) Maximum velocity of flow in stormwater pipelines shall be 4m/sec. Minimum velocity shall be determined by ensuring self-cleansing velocity is achieved; this requirement shall be deemed to be satisfied if the product of slope and diameter (S x D) is not less than 0.0008m where S = slope (m/m) and D is pipe diameter (m).

(4) Roadway flow width and depth

(a) Flow width and depth criteria for major and minor storm events must comply with QUDM section 7.4.

(5) Inlet pits and Manholes

(a) Inlet pits and manholes must be provided:

(i) to enable access for maintenance;

(ii) at changes in direction, grade, level or class of pipe; and

(iii) at junctions.

(b) The maximum recommended spacing of pits and manholes where flow widths are not critical should be spaced every 80m for ease of maintenance purposes. Kerb inlets shall be constructed in accordance with SC6.4.4.8 Standard drawings SD 200.

(c) Pit entry capacity calculations must be undertaken to provide for adequate spacing of pits, and to ensure flow capture has been adequately analysed. Flow under weirs and/or orifice conditions must be carefully considered. Information on pit entry capacities is available in the following sources:

(i) Queensland Urban Drainage Manual;

(ii) Pit relationships given in Volume 1, Book 7 of AR&R 1998; and

(iii) manufacturers' design specifications.

(f) Blockage factors to be applied to theoretical inflow capacities of inlet pits are given in Table SC6.4.4.4.2:

Tables SC6.4.4.4.2 Allowable pit capacities

Condition	Inlet Type	Blockage factor
Sag	Side entry	20%
Sag	Grated	50%
Sag	Combination	Side inlet capacity only Grate assumed completely blocked
Sag	"Letterbox"	50%
Continuous Grade	Side entry	20%
Continuous Grade	Grated	50%

Continuous Grade	Combination	90%
Field inlet	Flush	80%
Field inlet	Raised grate	50%

(6) Hydraulic losses

(a) Pressure change co-efficient "K" shall be determined from the appropriate charts given in *QUDM* Appendix 2.

(b) Allowable reduction in "K" due to benching is given in *QUDM* section 7.16.8.

(c) Computer program default pressure change co-efficient "K" shall not be acceptable unless they are consistent with those from the charts in *QUDM*. The chart used and relevant co-efficients for determining "K" value from that chart shall be noted on the hydraulic summary sheet provided for plan checking and included on the final design drawings.

(d) Bends may be permissible in certain circumstances and discussions with council regarding their use is required prior to detailed design. Appropriate values of pit pressure change co-efficient at bends are given in *QUDM*.

(e) The design must avoid clashes between services. However, where unavoidable clashes occur within the existing network, then the pressure change co-efficient "Kp" must be determined from the chart given in *QUDM* section 7.16.11.

(f) Requirements for private pipes entering council's system are given below:

(i) all pipe inlets, including subsoil pipes, must where possible, enter the main pipe system at junction pits. These must be finished off flush with and be grouted into the pit wall; and

(ii) if a junction has to be added then a junction pit shall be built at this location in accordance with this sub-section.

(g) Construction of a junction without a structure should be avoided where possible. Permission to do this is required by council prior to detailed design. Where this is unavoidable the pressure change coefficients Ku, for the upstream pipe and Kl, for the lateral pipe, must be determined from the chart given in *QUDM*.

(h) Going from larger upstream to smaller downstream conduits is not permitted without approval of council prior to detailed design. In going from smaller to larger pipes benching must be provided in pits to enable a smooth flow transition. Losses in sudden expansions and contractions are given in *QUDM*.

(i) Underground drainage systems must be designed as an overall system, with due regard to the upstream and downstream system and not as individual pipe lengths. Drainage system designs must clearly show the hydraulic grade line (HGL), especially in systems operation undue pressure.

(7) Major system – minimum freeboard criteria

(a) Where floor levels of adjacent buildings are above road level there must be a minimum freeboard of 300mm to floor level of adjacent buildings.

(b) Where floor levels of existing adjacent buildings are below, or less than 300mm above the top of kerb, and there is at least 100mm fall on the footpath towards the kerb, the maximum flow depth is 50mm above the top of kerb.

(c) Where floor levels of existing adjacent buildings are below, or less than 300mm above the top of kerb, and there is less than 100mm fall on the footpath towards the kerb, the maximum flow depth is at the top of kerb.

(d) Wave action wash that enters properties from passing vehicles must be considered.

(e) Road capacities and major system flood levels are to be determined adopting the roadway as an open channel. Assessment of flood impacts on adjoining properties must consider any effects of backwater from the adjacent waterway using backwater analysis techniques.

(8) Minimum grades

(a) Unlined drains must have a minimum grade of 0.5% and lined drains must have a minimum grade of 0.3%. This includes table drains and kerb and channel.

(b) Pipe and box culverts must have a minimum grade of 0.2%.

(9) Open channels

(a) Generally, open channels and swales must be designed to have smooth transitions with adequate access provisions for maintenance and cleaning. Where council permits the use of an open channel to convey flows from a development site to the receiving water body, such a channel must comply with the requirements of this sub-section.

(b) Design of open channels must be in accordance with Volume 1, Book VIII of AR&R 1998. Open channels must be designed to contain the major system flow.

(c) Friction losses in open channels must be determined using Mannings "n" values. Mannings "n" roughness co-efficients for open channels must generally be derived from information in Chapter 14 of AR&R. Mannings "n" values applicable to specific channel types are given in the table below:

Surface Type	Mannings “n”
Concrete Pipes or Box Sections	0.011
Concrete (trowel finish)	0.014
Concrete (formed without finishing)	0.016
Sprayed Concrete (gunite)	0.018
Bitumen Seal	0.018
Bricks or pavers	0.015
Pitchers or dressed stone on mortar	0.016
Rubble Masonry or Random stone in mortar	0.028
Rock Lining or Rip-Rap	0.028
Corrugated Metal	0.027
Earth (clear of weeds and debris)	0.022
Earth (with weeds and gravel)	0.028
Rock Cut	0.038

For all grass channels refer to the *Road Drainage Manual* (Chapter 8) for grass retardance factors.

(d) Where the product of average Velocity and average flow Depth for the design flow rate is greater than 0.4 m^2/s, the design must specifically provide for the safety of persons who may enter the channel in accordance with Volume 1, Book VIII of AR&R 1998.

(e) Maximum side slopes on grassed lined open channels must be in accordance with section 9.5.3 of *QUDM* (3rd Edition 2013 – provisional, or as amended.).

(f) Low flow provisions in open channels (man-made or altered channels) will require low flows to be contained within a pipe system or concrete lined channel section at the invert of the main channel. The width of the concrete lined channel section must be the width of the drain invert or at least sufficiently wide enough to accommodate the full width of a tractor with an absolute minimum width of 1.5 m.

(g) Open channels should be wide and shallow in preference to narrow and deep in order to maintain natural invert level to reduce the expression of groundwater.

(h) Designers should also ensure that longitudinal grades are sufficient to prevent the ponding of storm water for periods of more than 2 days after a rain event.

(i) Transition in channel slopes is to be designed to avoid or accommodate any hydraulic jumps due to the nature of the transition.

(j) Drop structures must be designed in open channels were the water velocity exceeds 2m/s. The design must address the size and location of the structure as well as details of any stilling basins and revetment works surrounding the structure.

(k) Special consideration must be given to erosion control where sodic soils occur. Details of treatment proposals prepared by a competent person must be provided and approved by council.

(10) Major structures

(a) All major structures in urban areas, including bridges and culverts, must be designed for the 1% AEP storm event with minimal afflux. Some afflux and upstream inundation may be permitted in certain rural and urban areas provided the increased upstream flooding does not inundate private property or critical infrastructure.

(b) A minimum clearance of 0.5m between the 1% AEP flood level and the underside of any structure is required to allow for passage of debris without blockage.

(c) Certified structural design must be provided for bridges and other major culvert structures and may be required on some specialised structures. Structural design must be carried out in accordance with the SC6.4.4.3 Bridges and other structures.

(d) Culverts (either pipe or box section) must be designed in accordance with information and charts provided in QUDM 3rd Edition - provisional (as amended).

(e) Safety limitations – overtopping of roadways. All floodwaters overtopping a major structure such as a culvert or bridge structures within a road are to be checked for safety and stability limitations for both pedestrians and vehicles. Assessment of the waterway crossing safety and stability is to be undertaken based on criteria outlined in *QUDM* 3rd Edition 2013 - provisional (as amended) – Table 7.4.3 and 7.4.4

Detention basins

(a) For each AEP a range of storm events shall be run to determine the peak flood level and discharge from the retarding basin. Storm patterns shall be those given in Volume 1, Book III of AR&R. The critical storm duration with the retarding basin is likely to be longer than without the basin. A graph showing the range of peak flood levels in the basin and peak discharges from the basin shall be provided for the storms examined.

(b) Flood routing should be modelled by methods outlined in AR&R. Rational method approximations of flood hydrographs are unacceptable.

(c) The high level outlet to any retarding basin shall have capacity to contain a minimum of the 1% year AEP flood event. Additional spillway capacity may be required due to the hazard category of the structure. The hazard category should be determined by reference to ANCOLD.

(d) The spillway design shall generally be in accordance with the requirements for Open channel design in SC6.4.4.4.3(7) Open channels and *QUDM* (Chapter 5).

(e) The low flow pipe intake shall be designed in accordance with the requirements of QUDM, Section 5.08.

(f) Freeboard - Minimum floor levels of dwelling shall be 0.3m above the Defined 1% AEP flood level in the basin.

(g) Public safety issues - Basin design is to consider the following aspects relating to public safety:

(i) side slopes are to be a maximum of 1 in 6 to allow easy egress. Side slopes of greater than 1 in 4 may require handrails to assist in egress;

(ii) water depths shall be, where possible, less than 1.5m in the defined AEP flood event. Where neither practical nor economic, greater depths may be acceptable. In that case the provision of safety refuge mounds should be considered;

(iii) the depth indicators should be provided indicating maximum depth in the basin;

(iv) signage of the spillway is necessary to indicate the additional hazard;

(v) basins shall be designed so that no ponding of water occurs on to private property or roads;

(vi) no planting of trees in basin embarkment walls is allowed;

(vii) no basin spillway is to be located directly upstream of urban areas; and

(viii) submission of Drawings to the Dam Safety Committee is required where any of these guidelines are not met or council specifically requires such submission.

(ix) Stepped spillways are used in rare instances for energy dissipation and scour control. Guidance on hydraulic design and analysis of these structures is as per Chanson 1994.

(12) Tidal barriers

The use of tidal barriers on stormwater outlets are required in areas affected by tides. The device used should meet the following criteria:

(a) limited pressure head required to allow the discharge of stormwater from the system without any manual intervention. Specifications of the device used should be supplied to council prior to detailed design;

(b) barriers should not be able to be wedged open to an incoming tide by litter;

(c) council will not accept hinged flap gates as a suitable solution; and

(d) minimal requirements for repairs and maintenance of the device. Any maintenance information for the

device should be supplied to council prior to detailed design.

(13) Barriers at inlet and outlets

Provision shall be made for the safety of the public including children in regards to the inlet and outlet of the stormwater system and should be based on the following criteria:

(a) no opening into an underground system shall be wider than 150mm except at head walls to pipes and box culverts;

(b) headwalls on the inlets and outlets to underground drains in which the drain is longer than 30m and has a cross sectional area greater than 0.5m^2 must be protected with hand rails, guard rails or fencing which restricts easy access to the entry structure;

(c) trash screens or other forms of grates are not favoured across the front of inlets and are unlikely to be approved by council unless there is a tidal barrier on the outlet of the stormwater system – this may be considered by council;

(d) any grates over field inlet pits shall be set above the top of the pit so as to provide a 50mm gap between the top of the pit and the bottom of the grate. In areas of open space, marker posts must be used to identify each corner of the pit; and

(e) under no circumstances, should fixed barriers or grates be placed at the end of stormwater outlet.

SC6.4.4.4.4 Stormwater detention

(1) Installation of stormwater detention is required on all development sites where insufficient capacity in the downstream drainage systems exist and a minimum amount of detention will be that required to ensure no worsening of the flooding situation occurs during the defined flood event.

(2) The requirements for stormwater detention design are outlined in *QUDM.*

(3) The development must limit any increase in discharge rate for all storm events up to and including the defined flood event.

(4) The developed site must not discharge more stormwater than the discharge calculated for pre-development flows.

(5) Combined sedimentation and detention ponds must be designed in accordance with SC6.4.3.9 Water sensitive urban design guidelines so that remobilisation of sediment is minimised.

SC6.4.4.4.5 Interallotment drainage

(1) Interallotment drainage must be avoided wherever possible. Where interallotment drainage is proposed, the developer must demonstrate that no other drainage alternative is possible.

(2) Where interallotment drainage is unavoidable, it must not cover more than 2 allotments and must be contained within an easement not less than 3m wide. The easement must be provided over the entire length of the drainage structure in favour of lots benefiting from and affected by the pipe. All interallotment and allotment drainage, connector pipes and surface water collection infrastructure remains the responsibility of the lot owner.

(3) Where drainage is required over more than two allotments, a drainage easement is required in favour of council. See SC6.4.4.4.8 Drainage easements and drainage reserves.

(4) Interallotment drains must be designed to accept concentrated drainage from buildings and paved areas on each allotment for flow rates having a design AEP the same as the "minor system" per Table SC6.4.4.4.1.

(5) Major system flows within interallotment drains should be avoided where possible. In instances where this is unavoidable, the design of interallotment drainage must make allowance for major system flows, with appropriate freeboard.

(6) In lieu of a more detailed analysis, the fraction impervious for surfaces contributing runoff to the interallotment drain are as per SC6.4.4.4 Attachment A.

(7) Pipes must be designed to flow full at the design discharge without surcharging of inspection pits.

(8) Interallotment drainage pits must be located at all changes of direction. Pits must be constructed of concrete, with 100mm thick walls and floor and have a minimum 600mm x 600mm internal dimensions. Raised grated inlets are required at all locations. (including change in direction).

(9) The interallotment drainage must have a minimum longitudinal gradient of 0.2% or as agreed by council.

(10) The interallotment drainage must be constructed from either fibre reinforced concrete drainage pipe, reinforced

concrete pipe, or UPVC pipe which must conform respectively to the requirements of AS4139, AS/NZS4058 and AS/NZS1254 respectively.

(11) Where interallotment drainage and sewer mains are laid adjacent to each other they must be spaced with 1.5m between pipe centrelines (where the pipe inverts are approximately equal).

(12) Where there is a disparity in level between inverts the spacing must be submitted for approval.

(13) Where sewer mains are in close proximity to interallotment drainage lines they must be shown on the interallotment drainage plan.

SC6.4.4.4.6 Detailed design

(1) Conduits

(a) Pipe bedding and cover requirements for reinforced and fibre reinforced concrete pipes shall be determined from the Concrete Pipe Association's *Concrete Pipe Guide* or AS/NZS 3725. For uPVC pipes, the requirements shall be to AS/NZS 2032.

(b) Conduit jointing shall be in accordance with manufacturer's specifications. S.R.C pipes shall use external band joints.

(c) Drainage lines in road reserves shall generally be located behind the kerb line and parallel to the kerb. Drainage lines in easements shall generally be centrally located within easements. Refer to SC6.4.4.8 Standard drawing SD-015.

(d) Drop structures shall be designed on drainage lines where the pipe gradient exceeds 5 per cent or water velocity exceeds 4m/s. The design details shall address the size, and position in the trench as well as spacing along the line.

Note—Buried flexible drainage pipes
Particular situations may be identified during the design of a development for the use of buried flexible pipes instead of the pipes specified in SC6.4.6.6 Pipe drainage.

In such cases, the design will be required to select the flexible pipe type appropriate for the particular application and prepare the relevant technical specification clauses for the supply and construction with reference to AS/NZS 2566.1, Buried flexible pipelines Part 1: Structural design. The proposed additional clauses would then be submitted, as an addendum to the development consent, for review and approval by council.

(2) Pit design
Pits shall be designed in accordance with SC6.4.4.8 Standard drawings SD-200, SD-205, SD 210 and SD-215. Safety and safe access are important in pit design and grates shall be of "bicycle safe" design.

(3) Stormwater discharge

(a) Scour protection at culvert, pipe system or kerb and channel outlets shall be designed in accordance with the guidelines outlined in *QUDM 3rd Edition - 2013 – provisional*, Section 8.7. Council will discourage the use of any outlet structure that proposes ponding at the outlet

(b) Where a developer proposes to concentrate stormwater onto an adjoining property, council will require the Developer to provide written agreement from the adjoining owner(s) granting permission to the discharge of stormwater through their property and the creation of any necessary easements.

(c) Where it is proposed to discharge runoff to an area under the control of another statutory authority, the design requirements of that statutory authority are also to be met.

(d) Piped stormwater drainage discharging to recreation reserves is to be taken to a point of discharge nominated by council and in the manner nominated by council.

(4) Trench subsoil drainage
Subsoil drainage should be designed and installed as per SC6.4.4.8 Standard drawings SD 080.

SC6.4.4.4.7 Documentation

(1) Drawings

(a) Catchment area plans shall be drawn to scales of 1:500, 1:1000 or 1:5000, unless alternative scales are specifically approved by council and shall show contours, direction of grading of kerb and channel, general layout of the drainage system with pit locations, catchment limits and any other information necessary for the design of the drainage system.

(b) The drainage system layout plan shall be drawn to a scale of 1:500 for urban areas and 1:1000 rural areas and shall show drainage pipeline location, drainage pit location and number and road centreline chainage, size of opening and any other information necessary for the design and construction of the drainage system.

(c) The plan shall also show all drainage easements, reserves and natural water courses. The plan may be combined with the road layout plan.

(d) The drainage system longitudinal section shall be drawn to a scale of 1:500 horizontally and 1:50 vertically and shall show pipe size, class and type, pipe support type in accordance with AS/NZS 3725 or AS/NZS 2032 as appropriate, pipeline and road chainages, pipeline grade, hydraulic grade line and any other information necessary for the design and construction of the drainage system.

(e) Open channel cross sections shall be drawn to a scale of 1:100 natural and shall show the direction in which the cross sections should be viewed. Reduced levels are to be to Australian height datum (AHD), unless otherwise approved by council where AHD is not available.

(f) Details including standard and non-standard pits and structures, pit benching, open channel designs and transitions shall be provided on the drawings to scales appropriate to the type and complexity of the detail being shown.

(g) As constructed drawings shall be submitted to council upon completion of the drainage construction and prior to council's acceptance of completed works. The detailed drawings may form the basis of this information; however, any changes must be noted on these drawings.

(h) The as constructed plans must clearly identify the sections of the drainage system that will be owned by private residents as agreed by council.

(2) Easements and agreements

(a) Evidence of any Deed of Agreement necessary for the diversion of runoff through an adjoining property must be submitted prior to any approval of the engineering drawings required for operational works application. Easements must be created concurrently with the issue of the plan of survey.

(b) Where an agreement is reached with the adjacent landowners to increase flood levels on their property or otherwise adversely affect their property, a letter signed by all the landowners outlining what they have agreed to and witnessed by an independent person shall be submitted prior to any approval of the application.

(3) Summary sheets

A copy of a Hydrological Summary Sheet providing the minimum information set out in SC6.4.4.4 Attachment B.

(4) Computer program files and program output

(a) Computer program output may be provided as long as summary sheets for hydrological and hydraulic calculations in accordance with this design specification are provided with plans submitted for checking and with final drawings.

(b) Copies of final computer data files (electronic and hard copy), for both hydrological and hydraulic models shall be provided for council's data base of flooding and drainage information in formats previously agreed with council.

SC6.4.4.4.8 Drainage easements and drainage reserves

(1) Specifications for new easements and reserves

(a) Easements must be of a size to enable necessary works including, but not limited to, construction, maintenance and inspection, to be carried out.

(b) Easement widths for drainage must be no less than the greater of the criteria in Table SC6.4.4.4.3.

Criteria	Type	Easement/Reserve Width
Pipe/Culvert	Pipe diameter/box culvert width ≤900mm	Minimum 3.0m
	Pipe diameter/box culvert width >900mm	Easement to extend to outside diameter/box culvert width + 1m each side of external edges of pipe/culvert
Channel/Drain	Base width ≤5m	Full bank width of channel/drain + 4m wide access path along one bank
	Base width ≤5m	Full bank width of channel/drain + 4m wide access path along both sides of channel/drain

(c) All drainage easements must be sized and located to ensure that they are not affected by, and do not impact on, an existing building's footing zone of influence, and give consideration to any future building footings on the subject or adjoining land.

(2) Residential, commercial and industrial areas
All major drainage is to be located within a drainage reserve with the minimum widths of that reserve being capable of containing the 1 per cent AEP design flows plus a 4m strip on each side for maintenance access and safety purposes.

(3) Rural residential areas

(a) Easement must be created over all drains and natural water courses through private property. Unless council determines the land is to be set aside for public use and is to be handed to council.

(b) In rural residential areas adjacent to a major watercourse, council may require drainage reserves or easements to be extended to cover identified areas of riparian vegetation, which maybe beyond the strip required for maintenance access and safety purposes.

(4) Rural areas

(a) Easements or reserves are not required over natural watercourses. However easements must be provided over all drains where stormwater is diverted from the natural flow path and be wide enough to contain the flows from the defined flood event plus adequate width for maintenance and safety purposes.

(b) Where the land falls away from the road, easements for drainage are required through private property over formed drains from road culverts and table drains. The location of these easements shall be fixed during design and approval of operational works for the roadworks concerned.

(5) Maintenance of easements

(a) A drainage easement over a property restricts the use of the area of land contained within the easement for drainage purposes. Council's level of service for drainage easements is restricted to ensuring the drainage easement is capable of performing its purpose of carrying stormwater flows through the property. If an owner desires a higher order of maintenance for other reasons, this will be at the owner's ongoing cost and must not compromise the drainage function of the easement. Altering of the drain in the easement by the owner without the approval of council may result in action being undertaken by council to restore the drainage path at the expense of the owner.

(b) Where subdividers are required to provide drainage easements and reserves over approved drainage paths, then these are to be acquired over the entire land at the first stage of subdivision. Where surcharge paths are terminated at the end of stages then drainage easements are required over balance lands, with such easements being released progressively with future stages that provide the surcharge path down the future roads or drainage reserves.

(6) Instruments relating to the terms – easements upon private property

Standard wording for the instruments setting out the terms for the various types of easements that can be acquired for drainage are to be utilised, with each document being cognisant of council's needs for future grading and on-going maintenance. The document is to also ensure that the responsibility and definition of maintenance within drains is clearly defined on the instruments that accompany the easement documents. This is particularly important in the rural residential areas where some residents have an expectation that council will maintain the land (easement) to a much higher standard than is needed for drainage purposes. In particular, in relation to inter-allotment drains that are not a part of the public drainage system, provision is to be made in the easement document to state that all maintenance is the owner's responsibility but with provision being made to enable the council to carry out necessary works at the cost of the defaulting owner.

SC6.4.4.4 Attachment A - Design AEPs and fraction impervious for land use zones

Development Category	Land use	Fraction impervious (fi)
Residential zones category	Low density residential	0.65
	Medium density residential	0.7
	High density residential	0.9
	Rural residential	0.6
	Character residential	0.55
Centre zones category	Neighbourhood centre	0.9
	Local centre	0.9
	District centre	0.9
	Major centre	1
	Principal centre (CBD)	1
	Specialised centre	0.9
	Mixed use	0.9
Community facilities and Open space zone category	Sport & recreation	0.2
	Open Space	0.2
	Community facilities	0.95
	Environmental management & conservation	0.4
Industry zones category	Low impact industry	0.9
	Medium impact industry	0.9
	High impact industry	0.9
Rural zones category	Rural	0.1
Other zones category	Emerging community	-
	Special purpose	-

SC6.4.4.5 Earthworks (design)

SC6.4.4.5.1 Introduction

(1) Objectives

This sub-section provides advice, guidelines and standards for earthworks including to ensure the:

(a) efficient, sustainable and economical design;

(b) enhancement of the environmental character of the site whilst maintaining the natural features of the site;

(c) provision of safe conditions for construction commensurate with the proposed purpose of the development;

(d) equality of building conditions for residential development; and

(e) earthworks does not impact on adjoining properties and developments.

(2) Scope

(a) This sub-section sets out requirements for earthworks involved in land development and subdivision. Conceptual requirements are presented as necessary considerations when preparing designs for earthworks.

(b) The scope of this sub-section assumes that the Designer is familiar with requirements cited in the various construction specifications, specifically those related to earthworks, clearing and grubbing and erosion and sedimentation. Additionally the Designer is required to make reference to the associated design sub-sections related to stormwater drainage design, geometric road design and stormwater quality management, and any other relevant best practice documents.

(3) Reference and source documents

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:

(i) Construction sub-sections
SC6.4.6.1 Water sensitive urban design construction and establishment guidelines
SC6.4.6.11 Clearing and grubbing
SC6.4.6.10 Earthworks (construction)
SC6.4.6.26 Landscaping

(ii) Design sub-sections
SC6.4.3.8 Stormwater quality management plans for development
SC6.4.3.9 Water sensitive urban design guidelines
SC6.4.4.1 Geometric road design
SC6.4.4.4 Stormwater drainage design

(b) Australian Standards
AS3798 *Guidelines on earthworks for commercial and residential developments*
AS2870.1 *Residential slabs and footings - construction.*

(c) Qld Government Legislation
Work Health and Safety Act 2011

SC6.4.4.5.2 Earthworks concept design

(1) Areas of a site proposed for earthworks, building or recreational purposes may not be suitable in their natural state for their intended function without improvement works to:

(a) alleviate flooding of low-lying ground;

(b) fill gullies or create emergency flowpaths after underground stormwater piping has been installed;

(c) allow improved runoff from flat ground;

(d) regrade excessively steep slopes that would preclude economical construction of dwelling foundations; and

(e) allow effective recreational use or give reasonable access.

The Designer must review the natural surface contours as determined and identified on site and where

necessary must design finished surface levels that ensure the land is suitably prepared.

(2) Areas should be regraded to minimise the necessity for underground drainage systems with surface inlet pits, and allow surface water to flow naturally to roads or drainage reserves without excessive concentration.

(3) The Designer must consider the implications of earthworks in relation to the existing natural environment. Generally earthworks must be minimised in heavily treed areas.

(4) Care must be taken to provide depressions for overland flow from low points and over major drainage lines, to direct stormwater for storms up to a 1% annual exceedance probability (AEP).

(5) The design of earthworks areas in conjunction with the design of roadworks must be considered with the objective of balancing cut to fill and achieving both an economical development and minimising haulage of imported fill or spoil to and from the development site. Bulk haulage should always be considered as having an adverse effect on adjacent development and infrastructure.

SC6.4.4.5.3 Special treatment of particular areas

(1) All lots must be regraded to a minimum level at the1% AEP flood level. In doing so, the Designer must ensure that other areas are then not affected by flooding. The site must be identified on the Drawings with appropriate notation of site specific requirements.

(2) In the event that an area is known to be affected by or inundated by local stormwater flows, the Designer must investigate the existing conditions as they relate to the proposed development and advise the Developer in the preliminary design report on all data obtained in the investigation and recommend appropriate contour adjustments. The report should be accompanied by sketch plans to clarify recommendations and any other relevant data.

(3) Site constraints either natural or otherwise may be required to be identified as a burden on developed property. The Designer must take this into account when preparing the design. The property may ultimately be affected by a "restriction as to user", which may be controlled by a legal Instrument placed on title to the land and/or by a message advising prospective purchasers of any restrictions affecting the land.

(4) The finished surface of filled areas must be designed to levels allowing an adequate cover depth over the pipeline (if piped) and permitting surface stormwater flow to be guided to inlet pits if depressions are retained in the finished surface contouring.

(5) The location of such features must be clearly defined on the earthworks plans and defined by distance to corner boundaries etc. for purposes of relocation. A geotechnical report specifying the site specific preparation and compaction requirements must be incorporated in the earthworks plan. A description of the minimum acceptable quality of the fill must also be specified on the plans, supported by geotechnical recommendations. All documentation necessary from various authorities to support the filling of dams and watercourses must be supplied with the Drawings.

(6) The finished level of any building area must be designed to ensure a desirable surface grading of 0.5% minimum oriented in the direction of the drainage system designed to cater for its catchment.

SC6.4.4.5.4 General standard of lot preparation

(1) Special requirements will apply where necessary but generally lots are to be cleared of low scrub, fallen timber, debris, stumps, large rocks and any trees which in the opinion of council are approaching the end of their functional life or are dangerous or will be hazardous to normal use of the development. Prior consultation with council's officer responsible for tree preservation, or other authorised council officer, is necessary. Such requirements must be shown on the Drawings.

(2) All timber and other materials cleared from lots must be removed from the site. All roots, loose timber, etc. which may contribute to drain blockage must be removed. Such requirements must be shown on the Drawings.

(3) In areas to be filled over butts of trees, allowance must be made for clearing of all trees and replanting with a minimum of six advanced suitable species to each lot; planting must to be clear of probable future building location and services and utilities, and not to be commenced until filling has been completed and graded, with provision for watering and maintenance for duration of the contract. These specific requirements must be shown on the Drawings.

(4) Selected trees must be preserved by approved means to prevent destruction normally caused by placement of

conventional filling or other action within the tree drip zone. The Tree Preservation Officer, or other authorised council officer, must be consulted for advice and all specific requirements noted on the Drawings.

SC6.4.4.5.5 Standard of fill for lots

(1) The following notations are to be incorporated in the Drawings. "Filling is to be of sound clean material, reasonable standard and free from large rock, stumps, organic matter and other debris". "Placing of filling on the prepared areas shall not commence until the authority to do so has been obtained from the council".

(2) All work must be in accordance with AS3798. Fill must be placed in layers not exceeding 150mm compacted thickness. All fill must be compacted to 95% standard maximum dry density. Maximum particle size is 2/3 of the layer thickness.

(3) Fill comprising natural sands or industrial wastes or by-products may only be used after the material type and location for its use is approved by council and will be subject to specific requirements determined by prevailing conditions.

(4) It is essential that prior advice be given of intended use of such materials. It should be noted that failure to obtain council's approval may lead to an order for removal of any material considered by council or other relevant authorities as unsuitable or in any way unfit for filling.

(5) All areas where filling has been placed must be dressed with clean arable topsoil, fertilised and sown with suitable grasses. This work must be carried out in accordance with the sub section SC6.4.6.26 Landscaping.

SC6.4.4.5.6 Temporary diversion drains

(1) Where temporary drains are required to divert surface flows away from the earthworks area, the location and silt/erosion control treatment must be clearly identified on the Drawings. The scale of such works must reflect the volume of water to be diverted.

The objective will be to ensure minimal soil disturbances and material loss off the site.

The requirements identified in SC6.4.4.4 Stormwater drainage design, SC6.4.3.8 Stormwater quality management plans for development, and SC6.4.3.9 Water sensitive urban design guidelines must be addressed for technical details and any additional requirements.

SC6.4.4.5.7 Concurrence with the Department of Environment and Heritage Protection

The Designer is recommended to refer to the Department of Environment and Heritage Protection with regard to any items requiring specific consideration when preparing an earthworks plan. Such plans may need to incorporate sediment/siltation/erosion control devices with specific reference to the stage at which these are to be provided. The responsibility rests with the Developer to make enquiries with the Department of Environment and Heritage Protection and subsequently obtain council approval to proposed measures.

SC6.4.4.5.8 As-constructed drawings

The Designer must annotate on the earthworks plan, the site specific detail to be shown on the as-constructed plans. Such detail must include a geotechnical report certifying the works to be suitable for the intended purpose and any other certifications, testing and survey data, as required in this sub-section.

SC6.4.4.5.9 Cartage of soil

(1) The Designer must refer to council for acceptable haul roads with applicable load limits. This detail must be shown on the earthworks plan. The payment of a Bond, as determined by council, may be required by the Developer where council has some concern about the ability of a haul road to sustain the loads without undue damage or maintenance requirements.

(2) Unless specific application is made to council and approval obtained, the plans must be annotated as follows: "All topsoil must be retained on the development site and utilised effectively to encourage appropriate revegetation."

SC6.4.4.5.10 Effect on adjoining properties

(1) Where it is proposed to divert or direct piped stormwater into adjoining properties, drainage easement rights must be created over the adjoining lots in accordance with the SC6.4.4.4 Stormwater drainage design.

(2) A written agreement between the Developer and adjoining property owners to carry out construction work on adjoining properties must to be submitted to council prior to works commencing.

(3) Works must not cause ponding of stormwater on adjacent allotments and no stormwater formerly flowing onto the site may be diverted onto other neighboring allotments or reserves.

(4) Earthworks must be graded so that the new land forms are free draining and all stormwater naturally falling into the site is collected within the property boundaries and discharged to a lawful point of discharge as agreed with council.

SC6.4.4.7 Pathway and Cycleway

SC6.4.4.7.1 Introduction

(1) Purpose

This sub-section aims to set standards and document requirements related to the provision of pathways and cycleways for the use of pedestrians and cyclists, for both on road and off road which encourage pedestrian activities and cycling for transportation and recreational purposes. Pathways and Cycleways are to be safe and convenient and must maintain a satisfactory level of service for path users of all abilities including users with disabilities and/or limited mobility. Pathways and Cycleways should provide a clear and continuous accessible path of travel, void of tripping hazards and unsafe obstacles.

The design of a development must encourage the use of pedestrian and cycle facilities and ensure that priority is given to pedestrians with direct links between a building's main entrance and any adjoining local activities and public transport services and recreational areas.

(2) Scope

(a) This sub-section sets out requirements to be used in the design of various types of pathways and cycleways for the use of pedestrians and cyclists.

(b) All relevant design principles contained in the Austroads' Guides referenced below must be integrated in the design of all pathways and cycleways and their associated infrastructure.

(3) Reference and source documents

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:
9.4.6 Transport impact, access and parking code
SC6.4.4.1 Geometric road design
SC6.4.4.8 Standard drawings
SC6.4.3.3 Footpath Treatment Policy
SC6.4.3.5 Car parking and public transport facilities guidelines
SC6.4.3.6 Landscape Policy

(4) Definitions

Pedestrian	A person walking, and including people in wheelchairs, on roller skates or riding vehicles such as skate boards or other vehicles, other than a bicycle, powered by effort or a motor and with a maximum speed of 7 km/h
Walking	to advance or travel on foot at a moderate speed or pace; proceed by steps; move by advancing the feet alternately to move about or travel on foot for exercise or pleasure.
Cyclist	Rider of a bicycle or human-powered vehicle. On a vehicle with one or more wheels that is built to be propelled by human power through a belt, chain or gears (whether or not it has an auxiliary motor), and includes a pedicab, penny-farthing and unicycle: but not a wheelchair, wheeled toy or pedelec.
Cycling	also called **bicycling** or **biking**, is the use of bicycles for transport, recreation, exercise or sport.[1] Persons engaged in cycling are referred to as "cyclists",[2] "bikers",[3] or less commonly, as "bicyclists".[4] Apart from two-wheeled bicycles, "cycling" also includes the riding of unicycles, tricycles, quadracycles, recumbent and similar human-powered vehicles (HPVs).
Path / Pathway	Series of links along a public way defining the connection between nodes in a network, reserved for the movement of pedestrians, motorised wheelchairs and personal mobility devices, and cyclists to chosen destinations via suitable desire lines.
Cycleway	Portion of a road or path devoted to the use of bicycles.

SC6.4.4.7.2 Consultation

The designer should consult with council, the applicant's landscape consultants and relevant authorities prior to and during the preparation of pathway and cycleway designs.

SC6.4.4.7.3 Design concepts

The Designer should be familiar with the different geometric design requirements for the various types of pathways and cycleways in terms of:

(1) width;

(2) grade;

(3) stopping sight distance;

(4) change in grade;

(5) horizontal curvature;

(6) crossfall and drainage; and

(7) sight distance on horizontal curves.

These requirements are discussed in the Austroads Guides.

SC6.4.4.7.4 Types of Pathways and Cycleways

(1) By definition pedestrian paths are "off road"in that, pedestrian facilities are usually designed adjacent to roadways, and meet the criteria outlined in Austroads Guides, SC6.4.4.8 Standard drawings, and SC6.4.4.1 Geometric road design, and to take into consideration SC6.4.3.3 Footpath treatment policy. Common pathway types include:

(a) foothpath;

(b) shared path; and

(c) separated path.

(2) Cycleways can be provided on road and off road. The Austroads Guides provide detailed descriptions, warrants, widths, pavement marking etc. for the majority of these cycleways. The Austroads Guides provide advice on the suitability of pavement conditions, drainage pit grates etc. for on road cycleways. All cycleways may diverge from the road alignment to provide a safer alternative access.

(3) Common cycleway types include:

(a) On road:

(i) bicycle lane;

(ii) bicycle awareness zone (BAZ);

(iii) cycle route; and

(iv) bicycle/car parking lane; and

(b) Off road:

(i) footpath;

(ii) shared path;

(iii) separated path; and

(iv) bicycle path.

(4) Common pedestrian path types include:

(a) footpath;

(b) shared path; and

(c) separated path.

By definition pedestrian paths are "off road" in that, pedestrian facilities are usually designed adjacent to roadways, and meet the criteria outlined in SC6.4.3.3 Footpath treatment policy and SC6.4.4.8 Standard drawings, and SC6.4.4.1 Geometric road design

All paths may diverge from the road alignment to provide a safer alternative access.

(5) Provisions for pathways and cycleways at structures.

Designers must consider the best way to provide for a safe uninterrupted movement of pedestrians and cyclists.

The reference and source documents provide information on:

(i) acceptable widths and clearances;

(ii) types of pathways and cycleways;

(iii) handrails;

(iv) bridges;

(v) approach ramps;

(vi) safety; and

(vii) crime prevention through environmental design (CPTED) principles.

(6) Developments must make appropriate provision for the safe and convenient movement and provide accessibility of pedestrians and cyclists, both on-site and to and from surrounding networks. Design should include the provision of suitable routes and end-of-trip facilities to encourage and facilitate these forms of movement.

SC6.4.4.7.5 End of trip facilities

(1) Where appropriate, consideration must be given to the provision of adequate facilities at destinations for cyclists and pedestrians, to encourage bicycle path and pedestrian path usage.

(2) Such facilities could include:

(a) seats;

(b) secure bicycle parking;

(c) toilets and showers; and

(d) picnic facilities.

(3) The provision of bicycle parking must meet appropriate criteria discussed in the *Austroads Guide to Traffic Management Part 11: Parking* and in accordance with AS 2890.3.

SC6.4.4.7.6 Signage and pavement marking

(1) Adequate signage design for pathways and cycleways must be provided.

(2) Signs and pavement marking must provide for the safe and convenient use of the facility. The signs and

pavement marking must comply with *MUTCD* and SC6.4.4.8 Standard drawings, SC6.4.6.22 Pavement markings and SC6.4.6.24 Signposting.

SC6.4.4.7.7 Design standards

(1) Notwithstanding the guidelines provided in this sub-section and referenced documents, the following minimum standards have been determined as shown in Table SC6.4.4.7.1. Where these values are less than those in the referenced documents, Table SC6.4.4.7.1 may only be used in special circumstances with separate approval.

Table SC6.4.4.7.1 Minimum design standards

	Footpath	**Shared Path**
Path width	1.5m minimum preferred 1.5m minimum for one wheelchair and pedestrian (people with disabilities) 1.8m desirable minimum for two wheelchairs	2.5m absolute minimum 3m – 4m (3.5m desirable) major recreation paths
Crossfall	2.5% maximum (1 in 40) Aids people with a disability	2.5% maximum (1 in 40)
Gradient	1:33 25 m interval* 1:20 15 m interval* 1:14 9 m interval for ramps*	1:33 25m interval* 1:20 15m interval* 1:14 9m interval for ramps*
* Level rest areas 1.2m long should be provided if length is exceeded, and at each change in direction Intervals between 1:33 and 1:20 should be interpolated		
Lateral clearance beside path	0.3 m absolute minimum	1m desirable (cycling) 0.5m absolute minimum (0.3m absolute minimum fencing smooth features aligned parallel)
Vertical clearance	2.5m (pedestrians)	2.5m (cyclists)

Formation Width: During the design process allow 0.5 m minimum either side of reinstatement works. Ensure design for free draining across surface of the verge so as to not create ponding or tripping hazards.

Alternative situations

	Separated Path			**Bicycle Path**
Path width	**Two-way**			2.5m acceptable minimum 3.0m desirable for high speeds 2.0m absolute minimum very low use at all times
	Bicycle Path 2.5m desirable minimum	**Footpath** 2.0m desirable ≥1.5m absolute minimum	**Total** 4.5m	
	One-way			
	Bicycle Path 1.5m desirable 2.0m maximum	**Footpath** 1.5m	**Total** 3.0m	
Crossfall	2.5% maximum (1 in 40)			2%-4% on sealed surfaces Up to 5% on unsealed surfaces
Gradient	1:33 25m interval* 1:20 15m interval* 1:14 9m interval for ramps*			3% maximum 200m 5% maximum 20m (if 3% cannot be achieved) Steeper gradients should not be provided unless unavoidable
Superelevation for cycling	2.5% maximum			Consider horizontal radii 2.5% desirable Can go greater than or equal to 3% dependent on site and situation
* Level rest areas 1.2m long should be provided if length is exceeded, and at each change in direction intervals between 1:33 and 1:20 should be interpolated				

(2) To assist with the safety of pedestrians and cyclists during night time use, illumination of the off road pathways

and cycleways may be required. The lighting must be designed in accordance with AS/NZS 1158.3.1 Pedestrian area (Category P) lighting – Performance and design requirements and SC6.4.3.20 Public lighting and utilities services

(3) Safety and good alignment should not be compromised by inappropriate landscaping. The principles of crime prevention through environmental design (CPTED) should be a key design focus.

(4) Tactile ground surface indicators (TGSI) where required must be:

(a) standard yellow Polyurethane Tactile Indicator Studs (warning tactiles) and bars (directional tactiles), drill and lock installation; and

(b) supplied and installed in accordance with AS/NZS 1428.4.1, providing correct illuminance contrast; and AS1428.1 and AS4586 Slip Resistance of Pedestrian Surfaces and as per manufacturers specifications and in accordance with AS1884.

(5) Kerb ramps must be:

(a) in accordance with the standard drawings see SC6.4.3.3.3(3)(b) - SD-025: Kerb Ramp;

(b) in accordance with AS1428.1 *Design for Access and Mobility, Part 1: General requirements for access - New Building Works*;

(c) installed facing the direction of travel and aligned parallel and perpendicular with opposite kerb ramp ;

(d) located as per requirements for the flow of pedestrian traffic and the position of the signal button;

(e) constructed of broom finished plain natural concrete;

(f) installed with sharp transitions between adjacent surfaces (top and bottom); and

(g) Installed with Tactile Ground Surface Indicators (TGSI) in accordance wtih AS/NZS 1428.4.1 *Design for Access and Mobility, Part 4.1: Means to assist the orientation of people with vision impairment - Tactile ground surface indicators*.

SC6.4.4.8 Standard drawings

(1) Introduction

This sub-section comprises the current Townsville City Council standard drawings.

Standard drawings show the minimum standard that council has adopted with regard to certain types of work. Standards have been developed for works on drainage, irrigation, roads, sewerage, transport, water and other miscellaneous activities.

(2) List of standard drawings

SC6.4.5 Construction management

(1) This section outlines the standards and provides advice and guidelines for construction management of development and covers pre-construction, construction and quality management systems.

(2) All development works shall be supervised by a Registered Professional Engineer of Queensland with relevant experience. Where the owner or developer does not have such a Professional Engineer in their employ, a Registered Consulting Professional Engineer shall be retained for the purpose of supervising the development works prior to commencement of work.

(3) This section aims to clearly define the role of council, Superintendent, Consultant, Principal Contractor and the Developer. This section seeks to ensure that inherited development works are constructed to achieve a cost effective operation and maintenance asset and perform adequately for their design lives.

(4) Reference and source documents

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.1 Water sensitive urban design construction and establishment guidelines
SC6.4.6.2.5 Pipeline testing and restoration (Water supply sub-section)
SC6.4.6.3.4 Pipeline testing and restoration (Sewerage system sub-section)
SC6.4.6.19 Stabilisation
SC6.4.6.22 Pavement markings
SC6.4.6.29 Boundary fencing
SC6.4.6.30 Control of traffic

SC6.4.5.1 Pre-construction guidelines

SC6.4.5.1.1 Pre-construction steps

The chart presented below indicates the steps required to be undertaken prior to commencement of works.

(1) Notice to commence works

The Developer must give council's Development Assessment Unit (DAU) notification of at least 5 business days (in writing) of their intention to commence construction works. Refer to SC6.4.5.1 Attachment A Development works – notice to commence works. Refer to the Development works - notice to commence works form for a list of requirements to be submitted prior to or at the pre-start meeting.

(2) Pre-start meeting

The nominated Consultant must ensure that a pre-start meeting is conducted on the premises between the contractor, supervising engineer (RPEQ), the design consultant and council representatives. This meeting represents a hold point and works may not proceed until the meeting is held and any further requirements identified during the course of the meeting have been satisfied. The pre-start meeting must be based on an agenda which includes:

(a) introduction of the principal contractor, supervising engineer (RPEQ), design consultant (including any specialist) and council representative. A statement of their respective roles and relevant personnel contact details must also be tabled and distributed at that meeting;

(b) confirmation that all relevant statutory permits/approvals have been obtained;

(c) evidence of current public liability insurance. Refer to SC6.4.5.2(21) Insurance and indemnity;

(d) review and discussion of all relevant conditions of the development approval;

(e) review and confirmation of the site establishment and access arrangements including all necessary site security fencing and signage requirements;

(f) review and discussion of the approved traffic management plan and haulage routes if applicable;

(g) review and discussion on a schedule of "hold-points" to be adopted throughout the construction phase. This schedule of "hold-points" is to be approved by council prior to construction proceeding;

(h) discussion of site specific workplace health and safety issues and an approved work method statement and safety plan in compliance with the *Work Health and Safety Act 2011*;

(i) review of the approved erosion and sediment control plan including site base stormwater management

plans and sediment controls during and post construction. Refer to SC6.4.5.2(11) Erosion and sediment control and SC6.4.3.8 Stormwater quality management plans for further details regarding this requirement;

(j) location confirmation and identification of all existing public utilities, services and council assets if applicable, including any approved demolition/rectification actions if required;

(k) scheduling and identification of all necessary responsible persons to undertake any council required works (e.g. disconnection of irrigation systems, sewer line connections etc.);

(l) review of the vegetation protection plan if applicable and confirmation that any necessary vegetation protection measures are in place;

(m) construction schedule and program and any other details that requires review before construction work commences e.g. work quality plan and/or quality manual review of quality requirements (SC6.4.5.3 Quality management system) and inspection test plan requirements;

(n) if required, a development notice (project sign in accordance with SC6.4.5.2.1(6) Development notice) is to be erected;

(o) confirmation of possession of site by the contractor; and

(p) any other relevant matters specified by the principal contractor, supervising engineer (RPEQ), consultant/s and/or council representative that may be pertinent to the successful completion of the project.

SC6.4.5.1 Attachment A Development works - notice to commence works form

Click here to view SC6.4.5.1 Attachment A Development works - notice to commence works form

Note—this form is to be completed, signed and submitted to council by the developer at least 10 working days prior to commencement of any development works.

SC6.4.5.2 Construction

SC6.4.5.2.1 General standards and guidelines

The following are general standards and guidelines during the construction of development works:

(1) Superintendent

The superintendent is to be nominated or appointed by the supervising engineer (RPEQ) and must be supervised by the RPEQ at all times throughout the construction period. The supervising engineer (RPEQ) is to take full responsibility for all construction work on the development site.

(2) Hours of work

Unless otherwise approved by council (in writing), works involving machinery of any description shall only be carried out on site from 6.30am to 6:30pm Monday to Saturday, subject to legislative requirements. No construction work is to take place on Sundays and public holidays without prior approval. Construction work includes deliveries to the site of the works and the onsite servicing of equipment.

(3) Relocation/alteration and repair to existing utility services

The location and level of all existing public utilities and services and the alignment for any new service utility or service in association are to be identifiedwith the relevant authority or council asset owner. The developer is responsible for any relocation and/or alteration to any public utility installation required as a result of any works carried out in connection with this development at no cost to council.

The contractor is to ensure that utmost care is to be exercised during the progress of the development works to prevent damage to any existing utility or service. Any damage to existing utilities or services directly resulting from the development works shall be the responsibility of the developer.

(4) Provision for traffic management

No works shall be conducted within an existing public road without approval (i.e. Road work permit). Any proposed road closure (partial or full), or traffic diversion is to be presented (with full details of proposed traffic management) for approval. Proposed traffic management is to comply with the relevant sections of SC6.4.6.30 Control of traffic.

The developer is to ensure that all appropriate approvals and permits are obtained from council for work zones, gantries and scaffolding prior to commencement of construction.

The developer shall be held responsible for implementing the approved traffic management plan including the safety of all vehicles, pedestrians and cyclists and must provide all necessary measures to prevent any accident, damage and loss.

(5) Condition of entry to adjoining properties

The developer or its representative must effectively protect all adjoining properties against any loss, damage or injury that may occur as a result of development works.

Works must not be undertaken on adjoining properties without prior written consent of the lawful owner. All adjoining property which has been disturbed as a result of the development shall be reinstated to a finish similar to its pre-development state or to an alternative state agreed to in writing by the affected property owner.

Upon completion of the development works, written approval from any affected property owners will be required by council prior to acceptance of the completed development works.

(6) Development notice

Where required, a project sign is to be erected within the site boundaries on the road frontage of the subject site or any other council approved location that is prominent and visible to the public. The developer is responsible for maintaining the signage for the duration of the construction. The signage shall have the following information (as a minimum):

(a) description of development (include an overall concept plan);

(b) name of developer;

(c) name of project;

(d) street address of the site;

(e) supervising engineer's name and phone number;

(f) consultant's name and phone number;

(g) principal contractor's name and phone number; and

(h) other specialist consultants' names and phone numbers.

(7) Signage and security

All necessary signage and site security shall be provided wholly within the site and in strict accordance with current Workplace Health and Safety (QLD) guidelines and requirements.

(8) Site access

The construction site shall be accessed via one convenient access from a public road. The location and details of this access point is to be approved by council prior to construction commencing. This access point shall be used by all vehicles, equipment and personnel during the approved construction hours of the site. Appropriate vehicle "shake-down" facilities are to be provided at the point of access in accordance with appropriate water quality management objectives for the site. The vehicle shake-down facility is to be a minimum 1.5m long by 3m wide for one-way or 6m wide for two way entrances.

(9) Site fencing

The developer must erect a temporary man-proof fence to restrict unauthorised access into the construction site. The fence is to extend around the entire perimeter of the site with access being provided as outlined above. The developer is to refer to SC6.4.6.29 Boundary fencing for details of the temporary fence.

(10) Site management

The Contractor is responsible for the management of the construction site and control of construction activities throughout the period of works, with particular attention to reducing the impact of the construction work on the public, adjacent and nearby properties and other areas of the site not part of the works. The primary objective is to eliminate the impacts of the temporary and permanent works having regard to:

(a) work health and safety;

(b) erosion control;

(c) acid sulphate soils;

(d) run-off;

(e) traffic management;

(f) disposal of all materials;

(g) gaseous discharges and odour;

(h) noise; and

(i) dust.

Adjacent waterways shall be regularly monitored for turbidity plumes, algal blooms and dead marine life which may be attributable to the construction of the works.

(11) Erosion and sediment control

During the construction phase and up until council accepts the development works or at the end of the defect liability period the contractor shall be responsible for the installation and maintenance of all erosion and sediment control measures on site.

The approved erosion and sediment control plan (ESCP) submitted as part of the operational works or compliance application must be presented during the pre-start meeting. This plan must be presented to council's nominated representative for review and "fit-for-purpose" implementation on the site. If the ESCP requires revision to suit the current conditions of the development site, the plan must be amended to achieve the approved set of water quality outcomes required by council. Upon approval of the ESCP, the procedures

and guidelines outlined in the plan for establishing, managing (inspection and monitoring) and maintaining water quality across the development site shall be the responsibility of the contractor.

At the end of the agreed period of implementation and maintenance, all identified temporary sediment control measures must be removed by the developer and the ground reinstated to council's satisfaction.

(12) Suppression of dust
At all times the Contractor shall ensure that dust resulting from the proposed works, including excavation, backfilling, grading and stockpiles is kept to an absolute minimum and to the satisfaction of council, by approved methods.

(13) Noise control
All construction work is to be undertaken pursuant to the *Environmental Protection (Noise) Policy (EPP (Noise))*. Construction works shall be carried out in accordance with the requirements and restrictions relating to hours of work specified in SC6.4.5.2.1(2); and the *Environmental Protection Act 1994*.

(14) Hazardous material
Hazardous materials are to be stored in a hazardous goods store such that it is free from flood and storm tide inundation. The hazardous goods store must ensure that materials cannot enter the environment or cause a public safety nuisance or hazard. Hazardous goods may only be kept on site for the duration of construction and are to be safely removed from site at completion of works, unless otherwise approved by council.

(15) Machinery refuelling
During construction, fuel and petroleum products shall not be stored on the site nor shall construction equipment and machinery be serviced on the site. Procedures shall be developed and implemented by the contractor for the refuelling of machinery and equipment which will minimise any potential for contamination of the site by way of spillage. The procedures shall ensure that refuelling on the site occurs within a designated area that does not drain directly into adjacent stormwater systems or waterways. Any procedures developed and implemented in this regard must include bunding of the refuelling area.

Any spillage of fuels and petroleum products during construction shall be reported to the superintendent. All steps necessary to rectify the contamination shall be undertaken by the contractor prior to the completion of the works and at no cost to council.

(16) Material storage
Materials shall not be stored on site unless approved in writing by the Superintendent or unless material storage details are shown on the drawings and approved by council.

All necessary measures shall be implemented to reduce the potential for environmental damage, which may arise from the storage of materials.

(17) Stockpiling of materials
Wherever possible, materials shall be installed directly in place or continually removed from site, eliminating the need for stockpiles. In all other cases, stockpiling of materials shall be on a temporary basis at the discretion of superintendent.

The location of approved stockpiles shall be in accordance with the ESCP and as a minimum stockpiles shall:

(a) Remain on site for as little time as practical;

(b) Be limited to a height of 2m;

(c) Not to be located within 10m of a residential boundary;

(d) Have batter slopes, covers and drainage which limit the potential for erosion and/or segregation;

(e) Be managed in accordance with SC6.4.5.2 Attachment B;

(f) The contractor is to erect and maintain a temporary sediment fence around all stockpiles for the duration

of the stockpile being on the site.

(18) Vegetation disposal

Burning or burying of waste vegetation on site is not permitted unless otherwise approved by council. Clearing and grubbing of the development site shall otherwise be undertaken in accordance with SC6.4.6.11 Clearing and grubbing.

(19) Work adjacent to trees and protection of environmentally significant vegetation

(a) Protection of trees and vegetation – general

All existing and newly planted trees and vegetation should be noted on the drawings and protected from damage during construction. The approved vegetation protection plan should be available onsite prior to commencement and during works. The vegetation protection plan will identify key stages where monitoring and certification will be required.

As specified in the vegetation protection plan, a vegetation protection zone must be established on site to ensure the required retention of existing trees and vegetation identified for protection and retention. The vegetation protection zones must be identified as *"no-go"* areas for construction traffic and meet the following requirements:

(i) For trees, the extent of the vegetation protection zone is to be determined in accordance with the tree protection zone (TPZ) requirements of AS 4970 - *Protection of trees on development sites.*

(ii) For areas of vegetation not including trees, other areas of natural heritage or hydrologically sensitive features, the extent of the Vegetation Protection Zone is to be determined by a qualified arborist, ecologist, or other approved officer.

(iii) The Vegetation Protection Zone is to be fenced or barricaded to prevent unauthorised vehicle and machinery access, as per AS4970 *Protection of trees on development sites* and AS4687 *Temporary Fencing and Hoardings*.

(iv) Signage to indicate "Vegetation Protection Zone - No Access" should be installed as per AS4970 *Protection of trees on development sites* and AS1319 *Safety signs for the occupational environment*.

(v) Where required, the tree bark is to be protected by wrapping a triple layer of hessian or rubber matting around the tree trunk.

(vi) Fixing of temporary service wires, nails, screws, stays, guys and or any other fixing device to trees should be avoided.

(vii) No fuel, oil dumps or chemicals are allowed to be used or stored within the Vegetation protection zone and the servicing or re-fuelling of equipment and vehicles must be carried out away from the vegetation protection zones.

(viii) Deposition of wind-blown materials (such as cement) into the protection area should be avoided through the attaching of cloth to the Vegetation Protection Zone fencing.

(ix) Soil compaction and removal of top soil within the Vegetation Protection Zone is to be avoided. Where compaction occurs, hand methods to de-compact the soil should be used.

(x) No vehicles are to access or be parked within the Vegetation Protection Zone. Where traffic is unavoidable within the zone, a 300 mm thick layer of mulch over a geotextile fabric should be placed in the area to protect the trees surface roots and to reduce the risk of soil compaction.

(xi) No storage of material, equipment or temporary building is to take place within the Vegetation Protection Zone, including the placing of spoil from excavation against tree trunks.

(b) Fill and excavation near trees and vegetation

(i) Any underground service installations within the Vegetation protection zone must be bored and the utility authorities must utilise a common trench where possible. Where practical, trenching is to be combined with locations where roots need to be severed for other reasons.

(ii) Within the Vegetation protection zone, all excavation must be carried out by hand digging or with the use of "air-excavation" techniques.

(iii) Where required, trees roots or branches are to be cut cleanly without tearing, with clean, sharp tools (chainsaw, secateurs or hand saw) in accordance with the AS 4373 *Pruning of Amenity Trees* and under the supervision of a qualified arborist with formal qualifications (Level 3 Australian Qualification Framework) or at least 5 years recognised experience in arboriculture.

(iv) Cutting of tree roots exceeding 50 mm in diameter should be avoided. Where roots must be cut, this should not unduly disturb the remaining root system.

(v) Any ripped or torn roots are cleanly re-cut as soon as noted.

(vi) Roots to be left exposed for any period of time are covered with wet hessian and maintained in a moist condition until recovered.

(vii) Immediately after cutting of any roots, Copper Naphthanate or an equivalent alternative solution is to be applied to the cut surface to prevent the incursion of rot or disease - as deemed necessary.

(viii) Backfill to excavations around tree roots should be with a soil mix similar in consistency and pH value to that of the existing soil.

(ix) Backfill should be placed in layers of 300 mm loose depth and be compacted to a dry density similar to that of the original surrounding soil using hand methods or light compaction equipment.

(x) Backfill layers should generally match the soil horizon of the surrounding soil.

(xi) The depth of fill within the vegetation protection zone should not exceed 200 mm from the original surface level. Immediately after placing any fill around a tree, the area should be watered thoroughly.

(c) Trees to be transplanted

(i) Trees to be transplanted shall be noted on the drawings and/or shall be marked on site by the superintendent prior to the commencement of construction.

(ii) Requirements and procedures for transplanting of trees are to be issued by council for each particular species.

(d) Damage to tree or vegetation

(i) Any unauthorised removal, damage or disturbance undertaken prior to the identification of the protected zone/s (without the required approval) or within the identified protected zone/s shall be rehabilitated by the contractor to the satisfaction of council and at no cost to council.

(ii) In the event of an unauthorised removal and that rectification works to damaged tree/s or vegetation is impractical, or the rectification work has been carried out by the contractor and is rejected by council, then council may direct the contractor to remove the trees/vegetation as part of the rectification work. The contractor will:

(A) replace the damaged tree/vegetation with a tree/vegetation of the same species and similar size to council's satisfaction; or

(B) replace the damaged tree/vegetation with a tree/vegetation of a similar size but different species to council's satisfaction; or

(C) pay for the cost of replacing the tree/vegetation with the same size and species to council's satisfaction; or

(D) replace the damaged tree/vegetation with a smaller tree/vegetation of an approved species and pay for the difference in cost between the new replacement and a specimen of the same size and species, to council's satisfaction.

(iii) The replacement value of an existing tree/vegetation will be calculated using the Revised Burnley Method under the Draft Australian Standard DR99307 *Amenity Trees – Guide to Valuation system*.

(20) Stormwater quality

Development works may cause changes to the quality, quantity and flow rate of stormwater discharged from the site. During the construction phase where soil disturbance and construction activity significantly increases the risk of soil erosion or where the development is required to implement a Stormwater Quality Management Plan (SQMP) that has been approved during the operational works approval phase. Council will then require a detailed maintenance regime to control stormwater quality during the construction phase to be presented during the pre-start meeting for review and acceptance by council unless a detailed maintenance regime has

been presented and accepted by council during the design process.

If the development works involves construction of stormwater quality device/s or is part a catchment with an existing stormwater quality device, then the developer and his contractor must ensure that no stormwater discharge will be permitted to enter such device (directly or indirectly) unless otherwise permitted by council. Refer to SC6.4.6.1 Water sensitive urban design construction and establishment guidelines.

Any temporary stormwater quality device proposed as part of the development works is to be removed and any land or existing infrastructure disturbed or damaged during the installation of any temporary stormwater quality device shall be reinstated to its former condition to the satisfaction and at no cost to council.

(21) Insurance and indemnity

From the commencement of construction until council accepts the development works or the commencement of the maintenance period, the developer or contractor must insure the works against public liability ($10 million dollar minimum cover) and other claims arising from the works, and indemnify council against that liability. Council must be included as an interested party to the insurance policy. The developer must provide council with evidence and a certificate of currency for the insurance and indemnification before commencing the construction works.

(22) Dilapidation survey

Where required by council and where development is directly adjacent to existing infrastructure and improvements, it may be prudent for the developer or his contractor to carry out a dilapidation survey of all the existing adjoining structures prior to construction commencing. This may reduce any damage claims during the construction period. Any damages to adjacent structures as a result of the development works shall be the responsibility of the developer.

(23) Fencing

While undertaking development works, and where appropriate, site fencing is to be erected for the duration of construction activities. Fencing is required to restrict unauthorised site access and to ensure the safety of persons from the subject site and any works on the adjoining road reserve and/or premises.

If existing fencing is to be altered or if there is no existing site fencing, temporary fencing, as a minimum, shall be provided and maintained for the duration of the construction to prevent unauthorised entry into the property or work area from any adjoining road reserve or property. The reinstatement of fencing and removal of temporary fencing on completion of the work shall be undertaken.

A construction site may provide any additional amount of security and/or fencing that is considered necessary that will improve the safety of the public or persons working on the site.

(24) Environment

All work shall be carried out in such a manner as to avoid nuisance and/or Environmental Harm. Development shall be planned and executed so that the works undertaken avoid contamination of the site and its surroundings by taking all reasonable and practical measures to prevent or minimise harm (general environmental duty).

Herbicides and other toxic chemicals shall not be used on the site without the prior written approval of the council or other relevant authority.

(25) Lighting

All lighting associated with the construction activity shall be installed and used so that lighting does not adversely affect the adjoining amenity of nearby sensitive uses, sensitive environmental areas or pose a safety hazard on adjacent road networks. All public road/street lighting systems must be designed in accordance with AS 1158 and must be approved by Ergon prior to construction.

(26) Blasting

Blasting will generally not be permitted. If blasting is necessary and there are no alternatives, it shall be carried out strictly in accordance with SC6.4.6.10 Earthworks (construction) and any other relevant construction specifications found in SC6.4.6 of the Development manual.

(27) Vibration

Ground vibration levels, transmitted from the construction works, rock breaking, drilling, and piling, operating items of plant or other noisy activities shall not exceed levels that are close to the lower level of human perception nor is it to cause any unacceptable damage to any adjoining buildings or infrastructure. Acceptable practices and vibration thresholds shall be determined in accordance with current Statutory Regulations.

Acceptable practices and vibration thresholds shall be determined in accordance with current Statutory Regulations.

A complaints management system should be devised which includes corrective and preventative actions. Consultation with and information supplied to nearby residents, workers and any other sensitive noise receptors is to be undertaken when vibration is known to be generated and is considered sufficient to warrant notification.

Editor's note—the results and recommendations of reporting on noise and vibration, as detailed in SC6.4.3.15 Noise and vibration assessment guidelines, associated with a particular development will be required to be implemented.

Editor's note—the Contractor shall be responsible for any damage and compensation payments as a result of vibration.

The control of ground vibration as a result of blasting shall be strictly in accordance with SC6.4.6.10 Earthworks (construction) and any other relevant construction specifications found in SC6.4.6 of the Development manual and will be solely at the risk and responsibility of the developer.

SC6.4.5.3 Quality management system

(1) Townsville City Council requires an emphasis on quality for the development works being delivered by developers. Where a condition for the approval of the development works requires the works to be completed as a "Quality Controlled and Assured Development", the developer must engage consultants and contractors with the necessary level of Quality Assurance accreditation to undertake and certify the development works.

(2) Quality management system – It is a requirement for a "Quality Controlled and Assured Development Contract" that the contractor shall plan, develop and maintain a documented Quality System in accordance with this section and the current requirements of AS/NZS ISO 9001.

(a) Quality manual
This is a document setting out the general quality policies, procedures and practices of an organisation. The development of this document shall cover and include the requirements as specified in the Quality System Documentation section of AS/NZS 3905.12 with guidance to preparation by AS/NZS ISO 10013. Additionally, it must include standard method statements and inspection and test plans for the activities undertaken by the Contractor. The following details shall be provided by appropriate annexures to the Company Quality Manual:

(i) Organisational Structure – this provides information regarding the management structure of the project with details of the specific responsibilities and authorities of the nominated personnel, which includes but is not limited to:

(A) a project quality management representative – is appointed by the Contractor for a specific project with the authority and responsibility for the implementation and operation of the quality plan, to ensure that Quality System requirements are not subordinated to design and productivity. Details of this person's qualifications, technical experience and present position are also to be provided;

(B) the contracted testing organisation – details of the personnel who will be conducting each type of compliance inspection of testing; and

(C) the person authorised to change construction processes on site; and

(ii) Register of Method Statements – the register shall list all Method Statements that are to be included in the project quality plan for the development contract and shall include any suitable method statements already incorporated in the Company Quality Manual.

(b) Project quality plan
The Quality System as expressed in the project quality plan shall be used throughout the course of the construction to ensure that the quality of the Contractor's and any sub contractor's work complies with all the requirements under this section. The Company Quality Manual, method statements and checklists and other project specific components shall make up the Project Quality Plan. The project quality plan must generally conform to the recommendations of AS/NZS ISO 10006. A concept illustration is shown in Figure SC6.4.5.3.1 Project quality management system documentation.

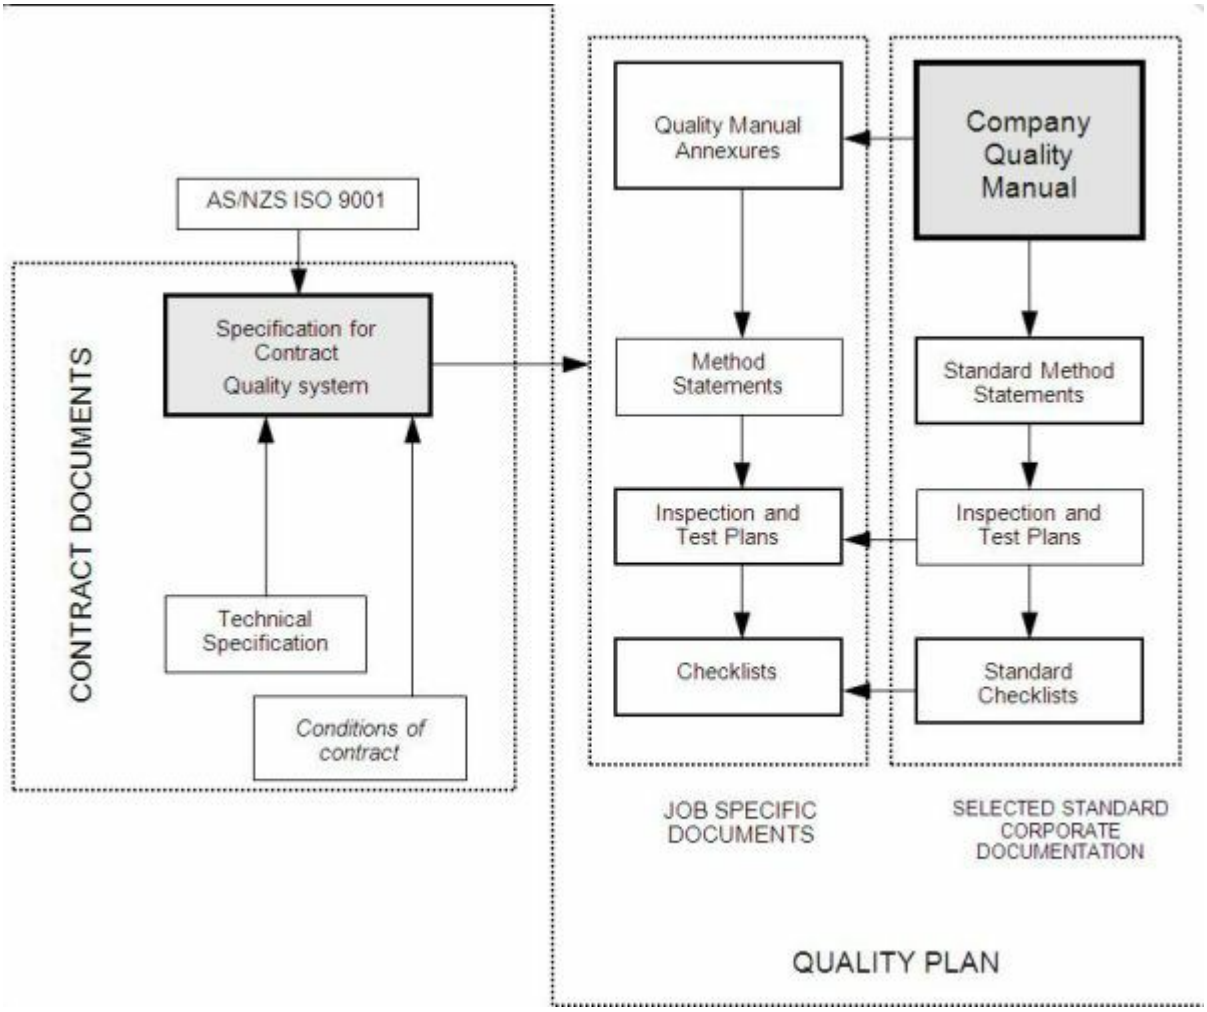

Figure SC6.4.5.3.1 Project quality management system documentation

(3) Where a "Quality Controlled and Assured Development" is not a requirement, a quality plan is not therefore required to be provided but it will be necessary as a minimum requirement that:

(a) the nominated Superintendent or Consultant are suitably and appropriately qualified and experienced;

(b) a work quality plan must be submitted to council for review and acceptance prior the pre-start meeting or commencement of works. The work plan must outline a program of inspection and testing regime that will ensure an adequate control of the progress and correctness of the work in accordance with the accepted design plans and specification;

(c) upon completion of the development works and prior to council accepting the completed development works, all records as required on the work quality plan must be submitted to council to demonstrate compliance with the accepted work quality plan; and

(d) the full cost of all required testing as per the work plan shall be the responsibility of the developer or the contractor. These tests are required to ensure that the materials and the works that were carried out conform to the accepted design specification and standard.

(4) Quality management system procedures

(a) Quality control system

(i) Lots

All items of work shall be subdivided into lots. Each lot shall be given a unique lot number and shall be chosen by the Contractor but must be within the limits given in SC6.4.5.3 Attachment A Maximum lot sizes and minimum test frequencies. In general, the size of the lot shall not exceed one day's output for each work process designated for lot testing.

The lot numbers shall be used as identifiers on all surveys and test results. The Contractor shall determine the bounds of each lot before sampling and shall identify each lot clearly. The

boundaries of a lot may be changed if subsequent events cause the original lot to be no longer essentially homogeneous.

The lot identification system and sample numbering system shall allow test results to be positively identified with material incorporated in the works.

(ii) Sampling and testing
All compliance inspections and tests shall be based on lots. The maximum lot sizes and minimum testing frequencies are listed in the Attachments to the relevant sub-sections and/or in SC6.4.5.3 Attachment A Maximum lot sizes and minimum test frequencies.

Where no minimum frequency of testing, or maximum lot size is stated in the sub-section, the Contractor shall nominate appropriate frequencies for the Superintendent's approval. Sampling shall not be restricted to locations dimensioned or otherwise defined for setting out the works in the drawings or sub-section, but shall be undertaken in a random or unbiased manner, as approved by the Superintendent, at any location within the works to demonstrate its compliance with the sub-section.

Where test methods are nominated in the sub-section, sampling and testing shall be carried out by a (NATA) National Association of Testing Authorities registered laboratory accredited for those test methods and sampling procedures. Sampling shall be conducted by personnel from the NATA registered laboratory which has been accredited for that sampling procedure and shall be supervised by the approved signatory from that laboratory. Test results shall be reported on NATA endorsed test documentation which shall include a statement by the approved signatory certifying that the correct sampling procedures have been followed.

Random sampling techniques shall be used for each lot for the control of compaction of each continuous layer of earthworks, flexible pavement and asphalt. SC6.4.5.3 Attachment B Random sampling defines the method to be used for determining test locations of random sampling in each lot. For quality control of processes other than compaction of layers of earthworks, flexible pavement and asphalt, the sampling locations will be proposed by the Contractor and will require the approval of the Superintendent. All samples shall be each considered to be representative of the lot and all test results will be required to meet the appropriate tolerances for the lot.

The latest NATA advice of the terms of registration and current signatories for the laboratories are to be included within the quality plan shall which will be providing the compliance test reports.

The NATA registered laboratory must provide inspection, testing and measuring equipment capable of producing the precision and/or degree of accuracy specified in the referenced test methods and this shall be made available by providing evidence or records of calibration.

(iii) Surveying
The Contractor shall engage qualified surveyors who are eligible for membership of the Institution of Surveyors, Australia or the Institution of Engineering and Mining Surveyors, Australia to supervise and take responsibility for all Surveying Control.

(iv) Surveying Control shall include all measurement, calculation and record procedures necessary to:

(A) set out the works;

(B) verify conformance to the drawings and sub-section in relation to dimensions, tolerances and three dimensional position; and

(C) determine lengths, areas or volumes of materials or products, where required for measurement of work.

The procedures and equipment used must be capable of attaining the tolerances required in the relevant construction specification. Sampling for conformance verification purposes shall not be restricted to the locations used to set out the Works.

The Contractor shall submit a survey conformance report to the Superintendent for each lot or

component where design levels, position and/or tolerances have been specified. The report shall show “specified vs. actual” for position (defined by co-ordinates or chainage and offset), level and tolerance as appropriate and shall be certified by the qualified surveyor responsible for the verification survey.

(v) Records and quality control documentation
Conformance records shall be stored and maintained such that they are readily retrievable and in facilities that provide a suitable environment to minimise deterioration or damage and to prevent loss.

The Contractor shall submit all conformance records to the Superintendent for inspection and approval. If requested by the Superintendent, the Contractor shall provide copies of the records or test results at no cost to the Developer.

The Contractor shall maintain a quality register which contains all quality control records such as test results, completed check lists, certificates of compliance, and consignment dockets for materials procured.

Prior to achieving practical completion or the commencement of the defects liability period or prior to acceptance of work as “Finally Complete”, the Contractor shall provide council through the Superintendent a copy of the quality register and other required quality control documents as required in this section.

(5) Quality assurance system – is the management of actions covering planning, quality control testing, inspection and verification procedures integrated with production to provide a product fit for the purpose.

(a) Inspection and test plan (ITP) is the document which identifies the specific inspections and tests required to be carried out for on development works including hold points. The ITP is to be prepared by an appropriately experienced consultant identifying specific inspections and tests to be carried out for each item of development works. Refer to council’s minimum ITP requirement on SC6.4.5.3 Attachment D Minimum inspection and test plan.

As a minimum, the inspection and test plans must contain the following information:

- lot references;
- activity description;
- specification requirements (if not provided, referenced specification);
- sampling methodology;
- test frequency and method; and
- identify responsibilities for inspection and testing and approval.

The superintendent shall audit the contractor’s work on a regular basis and provide sufficient site presence and in particular at inspection points identified in the Inspection and testing plan as set out in the construction schedules and agreed to and accepted by council. Inspections by council shall not in any way diminish the responsibility of the consultant and the superintendent to adequately audit the works. Auditing shall include regular site inspections which will be conducted with the presence of the contractor’s representative to confirm acceptability of works as complying with the design intent and other council requirements.

Inspection and test plans will typically have an associated check list which shall require completion for each particular lot. Prior to council’s acceptance of completed development works all documentation relating to compliance to the agreed and accepted ITP are to be submitted by the Contractor and/or the Superintendent which will form part of the Consultants’ certification that the works have been carried out and inspected in accordance with the agreed and accepted ITP.

(A) Inspections
The contractor shall ensure that any particular stage of work to be inspected has been satisfactorily completed before requesting an inspection by the superintendent and/or council. A minimum of 24 hours’ notice (except for off maintenance inspection which requires a minimum of 7 days) is required to enable arrangements to be made for an

inspection. Responses to the requests within the prescribed minimums are not guaranteed, although every effort will be made by council to accommodate request where possible. All council required inspections must be carried out Monday to Friday unless other arrangements have been agreed.

Incoming inspections shall be required for deliveries of materials that will be subsequently included in one or more lots. When completing check lists for particular lots the inspection status shall be cited.

In-process and compliance inspections shall be completed by a responsible officer nominated in the check list and certified by the Contractor's Quality Management Register (QMR) indicating that the work has been completed in accordance with the contract documents.

The Contractor shall establish and maintain a system to ensure and demonstrate that all products or parts of products requiring inspection and/or testing are so inspected and/or tested. The Contractor shall also establish and maintain a system for identifying the inspection status for all lots of work.

(B) Hold points and witness points

To assure compliance with the specified standards and requirements, mandatory hold points shall apply. Hold points are those stages during the construction/manufacturing process where the technical specifications require "approval by the Superintendent" or where a non-conformance report (NCR) or notice of non-conformance (NNC) has been issued. The Contractor shall not proceed past the hold point until approval has been received from the Superintendent to proceed. For ease of identification hold points may also be annotated on the margins of technical specifications.

To obtain the approval to proceed from the Superintendent, the Contractor shall:

- provide the information required by the technical specifications;
- ensure and certify that the particular lot/process is conforming;
- ensure and certify that all underlying and adjacent lots affected by the lot in question are conforming; and
- submit the appropriate form (check list, NCR or NNC) at least 24 hours prior to the time the Contractor wishes to proceed with the placement/construction of the next lot, unless some alternative arrangements have been agreed with the Superintendent.

If the hold point has resulted from a NCR or NNC, the Superintendent's approval may be conditional on a witness point being included.

(b) Quality assurance activities

(A) Document control

In addition to the requirements of AS/NZS ISO 9001 and AS/NZS 3905.2, the quality plan shall specify the method of keeping quality registers, tracking and handling of NCRs, NCC, NNCs and other site correspondence.

(B) Method statements

A document that specifies the key steps and sequence in the manufacture/construction for an activity; what, how and by whom it shall be done; what materials and equipment shall be used to achieve the required quality standards.

Method statements shall be provided for all activities scheduled in SC6.4.5.3 Attachment C Method statement requirements. This requirement applies to both contract and subcontracted work. The documentation shall cover, as applicable, planning, methods, verification and control.

The presentation of method statements may be either descriptive, in the form of flow charts or a combination of both. In either case it must be accompanied by a check list which shall include the

relevant inspection and test points, surveying control points and Hold Points and the officer responsible to verify each check point.

A system audit of each method statement shall be carried out by the Contractor whilst the process is in effect. In the absence of a method statement for activities where it has been specified, this will automatically create a hold point.

(C) Identification of lots and traceability

All items of work shall be subdivided into lots. Lots shall be chosen by the Contractor but shall be within the limits given in SC6.4.5.3 Attachment A. lot numbers are to be used as identifiers on all quality system data. Each lot shall be given a unique lot number. The allocation of lot numbers shall be carried out by the Contractor specific to each item of work and provides a lot numbering system which conforms to these requirements:

The Quality Register must contain records of lot number which provides information such as:

- location of the lot (e.g. start and end chainage, layer and lateral location or a particular structure);
- note regarding conformance/non-conformance (e.g. NCR, CPAR Registers); and
- table of test results (summary) and their respective locations and numerical identification.

In cases where non-conforming lots are identified, a new identification number shall be allocated to the resubmitted documentation, but reference to the original lot number must be included.

The Contractor is responsible in determining the bounds of each lot before sampling and shall physically identify each lot clearly. The physical identification of a lot shall be maintained until the Contractor has ensured that the lot has achieved the specified quality.

To ensure all site personnel can readily identify where the particular lots are in the field, the Contractor shall implement a field identification system which will clearly identify the bounds of each lot and the lot number. This identification system shall be detailed in the quality plan and shall be maintained during all stages of construction of the lot.

The boundaries of a lot may be changed if subsequent events cause the original lot to be no longer essentially homogeneous. This will require appropriate notation in the Quality Register by the QMR.

The lot identification system, site records and sample numbering system shall allow test results to be positively identified with material incorporated in the works. Traceability is required for concrete loads, asphalt loads and steel plate as follows:

- concrete used in bridge components, cast-in-place box culverts, retaining walls, road pavement sub base and base. Asphalt used in wearing courses, intermediate courses and drainage layers;
- the trace shall start at the batch plant and finish at the location where the concrete or asphalt is incorporated in the Works. Records shall be kept of the batch quantities, mix and despatch time, testing details and location of placement; and
- steel plate in bridge girders and bridge columns. The trace shall start at the steelworks and finish at the location of the plate in the girder or column. Records shall be kept of the steel heat number, testing details and location of the plate in the girder or column.

(D) Surveying control

Surveying control shall be treated as a separate system element and shall include all measurement, calculation and record procedures necessary to:

- set out the Works;
- verify conformance to the drawings and specification in relation to dimensions, tolerances and three dimensional position; and
- determine lengths, areas or volumes of materials or products, where required for

measurement of work.

The method statements for surveying control shall address the process control parameters in AS/NZS 3905.2 for special processes which cannot be fully verified by subsequent inspection and test.

The Contractor shall appoint qualified surveyors who are eligible for membership of the Institution of Surveyors, Australia or the Institution of Engineering and Mining Surveyors, Australia to supervise and take responsibility for all surveying control.

The procedures and equipment used must be capable of attaining the tolerances nominated in the specification. Sampling for conformance verification purposes shall not be restricted to the locations used to set out the Works.

The Contractor shall submit a survey conformance report for each lot or component where design levels, position and/or tolerances have been specified.

The survey conformance report shall show “specified vs. actual” for position (defined by co-ordinates or chainage and offset), level and tolerance as appropriate and shall be certified by the qualified surveyor responsible for the verification survey.

Where work is to be covered up after conformance has been achieved, a hold point shall apply until the survey conformance report has been submitted.

All survey records shall be included in the quality records and recorded in the quality register. Verification field book pages shall be clearly labelled, dated and signed by the surveyor with cross indexed references to equipment used lot/component identification and associated survey conformance reports. Where automatic data recording systems are used for verification surveys, a printout of both raw (field) data and reduced data shall be retained in a similar manner as conventional field books.

(E) Sampling and testing

The inspection and test plans shall include details of the sampling methods. Sampling shall not be restricted to locations dimensioned or otherwise defined for setting out the works in the drawings or specification, but shall be undertaken in a random or unbiased manner, as approved by the Superintendent, at any location within the works to demonstrate its compliance with the specification.

The maximum lot sizes and minimum testing frequencies are listed in the attachments to the relevant sub-sections and/or in SC6.4.5.3 Attachment A to this sub-section. Where no minimum frequency of testing, or maximum lot size is stated in the specification, the inspection and test plan(s) shall nominate appropriate frequencies for the Superintendent's approval.

The inspection and test plans shall also uphold any time limits for testing which may be imposed by the specifications. The responsibility for completion of inspections, tests and documentation shall be stated in the quality plan.

Statistical techniques - random sampling techniques shall be used for each lot for the control of compaction of each continuous layer of earthworks, flexible pavement and asphalt. SC6.4.5.3 Attachment B defines the method to be used for determining test locations of random sampling in each lot. SC6.4.5.3 Attachment A lists the maximum lot sizes and minimum test frequencies for the specified activities.

For compaction control of processes other than layers of earthworks, flexible pavement and asphalt, the sampling procedure will be proposed by the Contractor in his method statement and will require the approval of the Superintendent. In such cases the samples shall be each considered to be representative and all test results will be required to meet the appropriate

tolerances for the lot.

Every testing agency or person providing written test reports for any and all testing undertaken shall use unique consecutive project specific serial numbering of the reports for identification and auditing purposes.

The Contractor shall reinstate all core holes, test holes, excavations and any other disturbance resulting from any testing activity. The reinstatement shall be to a standard which is at least equal to the specified requirements for the particular work.

(F) Records and quality assurance documentation

The Contractor shall keep and maintain all Quality System records in a Quality Register as required by AS/NZS ISO 9001, AS/NZS 3905.2 and this sub-section. They shall be systematically recorded, indexed and filed so as to be retrievable and accessible to the Superintendent or an appointed Quality Auditor on a job basis within 1 working day of requisition.

Conformance records shall be stored and maintained such that they are readily retrievable and in facilities that provide a suitable environment to minimise deterioration or damage and to prevent loss.

The Contractor shall make the quality records available to the Superintendent at all reasonable times. If requested by the Superintendent, the Contractor shall provide copies of the records or test results at no cost to the developer.

Prior to achieving practical completion or the commencement of the defects liability period or prior to acceptance of work as “Finally Complete”, the Contractor shall provide council, through the Superintendent, a copy of the quality register and other required quality assurance documents as required in this section.

(G) Non-conformance

In circumstances where there is a concern about workmanship, construction methodology or materials (e.g. variation to the approved work specification), council’s representative and/or Superintendent may require the Consultant and/ or contractor respectively to provide a non-conformance certificate (NCC) (template provided at SC6.4.5.3 Attachment E Non-conformance certificate template). The NCC will be required to be endorsed by the relevant design Consultant. A non-conformance report (NCR) (template provided at SC6.4.5.3 Attachment F Non-conformance report template) is required to be issued by the Contractor addressing intended variations to approved specifications, work method statements or standards by providing proposed disposition.

In the event that the above has not been satisfied and to ensure compliance with the required standards, Superintendent and/or council may issue a Notice of Non-Conformance (NNC) (template provided at SC6.4.5.3 Attachment G Notice of non-conformance template) to the Contractor. The NNC shall be issued within 1 working day of the non-conformance being identified during an inspection or during scheduled audit inspections, i.e. hold points and witness points. Upon issuance of the NNC, the Contractor must not continue the particular work in question unless an appropriate disposition (to be provided within five working days from issuance of the corrective and preventive action request (CPAR)) has been provided and agreed in accordance with the CPAR (template provided on SC6.4.5.3 Attachment H Corrective and preventative action request template). This is to be undertaken by the Contractor if the NNC identifies non-conforming work which has been provided by the relevant design or construction consultant (Superintendent). Similarly, for council initiated NNC, work shall commence upon council’s acceptance of the proposed disposition in accordance with the CPAR. To avoid recurrence of non-conformance issues, all CPARs shall require joint sign off by the Contractor and Superintendent, and council for a council issued NNC. This procedure will require the Contractor to record the CPAR on the relevant issued NNC. Under no circumstances will the deliberation on the disposition of a non-conformance issue be used to justify delays to the construction schedule/period.

The Contractor shall advise the Superintendent in the NCR of the proposed disposition of the particular non-conformance. This proposed disposition will constitute corrective action for the lot or lots referred to in the NCR and may comprise one of the following:

- propose additional works to bring the lot up to the specified standard; or
- replace all or part of the lot to bring it up to the specified standard; or
- request utilisation of a lot for a reduced level of service if such a clause exists in the relevant technical specification; or
- for incidental defects, request that the Superintendent accept the lot without alteration as an exception with or without alteration to the respective unit rates.

Any proposed disposition shall be subject to the approval of the Superintendent. Reworked/replaced lots shall be verified to conform to the specified requirements.

The contractor shall establish a suitable numbering and registration system for all NCRs and NNCs. All non-conformance reports and relevant documentation are required to be submitted to council prior acceptance of development works, to ensure that all departure from the originally accepted requirement and appropriate disposition has been done in accordance with the agreed CPAR.

A process flow diagram of the above processes is shown on Figure SC6.4.5.3.2.

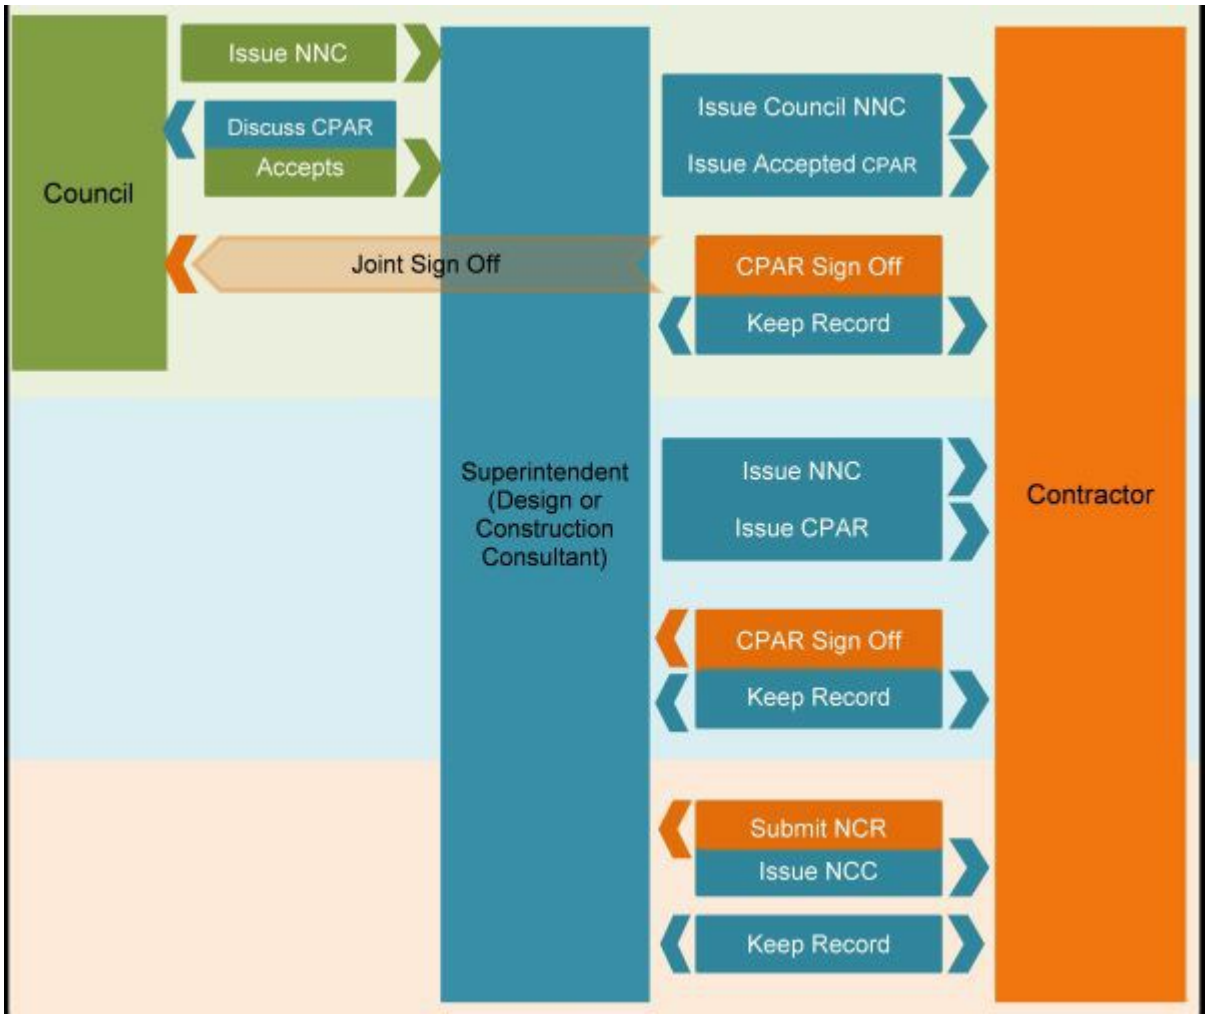

Figure SC6.4.5.3.2 Non-conformance flow diagram

(H) Inspection fees

A works inspection fee (at the rate applicable at the time of payment) must be paid prior to the development works being accepted by council at on maintenance or final completion.

SC6.4.5.3 Attachment A Maximum lot sizes and minimum test frequencies

General

Where material/product quality certification can be obtained from the supplier, tests listed per contract/separable part need not be repeated and where no Queensland Department of Transport and Main Roads (DTMR) Test Methods are available, Australian Standards or NSW Roads and Traffic Authority (RTA) Test Methods are specified.

SC6.4.5.3 Attachment B Random sampling

(1) General

Random sampling of test locations shall be used to control relative compaction of each layer of (which are generally rectangular in area):

(a) earthworks;

(b) selected material zone; and

(c) stormwater drainage.

The number of samples (n) per lot shall be as indicated in the specific sub-sections which are summarised in SC6.4.5.3 Attachment A.

(2) Locations

Sampling locations within a lot for the control of relative compaction shall be determined as follows:

(a) representing the lot as a rectangle, sub-divide the lot lengthwise into equi-area sub-lots in accordance with the number of samples selected (n) in accordance with Table SC6.4.5.3.19;

(b) establish six grid lines within the lot, as illustrated in Figure SC6.4.5.3.3;

(c) throw a die to select a number between 1 and 6. This determines which grid line to use for the sample location in sub-lot 1;

(d) throw die to select a group (1-6) in Table SC6.4.5.3.19;

(e) throw die twice to select two random numbers (between 1 and 6) for row and column in Table SC6.4.5.3.19 and obtain random fraction R;

(f) length co-ordinate for sample location in Sub-lot 1 = RL/n; and

(g) for sample location in next sub-lot:

(i) add L/n to previous length co-ordinate; and

(ii) add 1 (on a cycle of 6) to previous grid line.

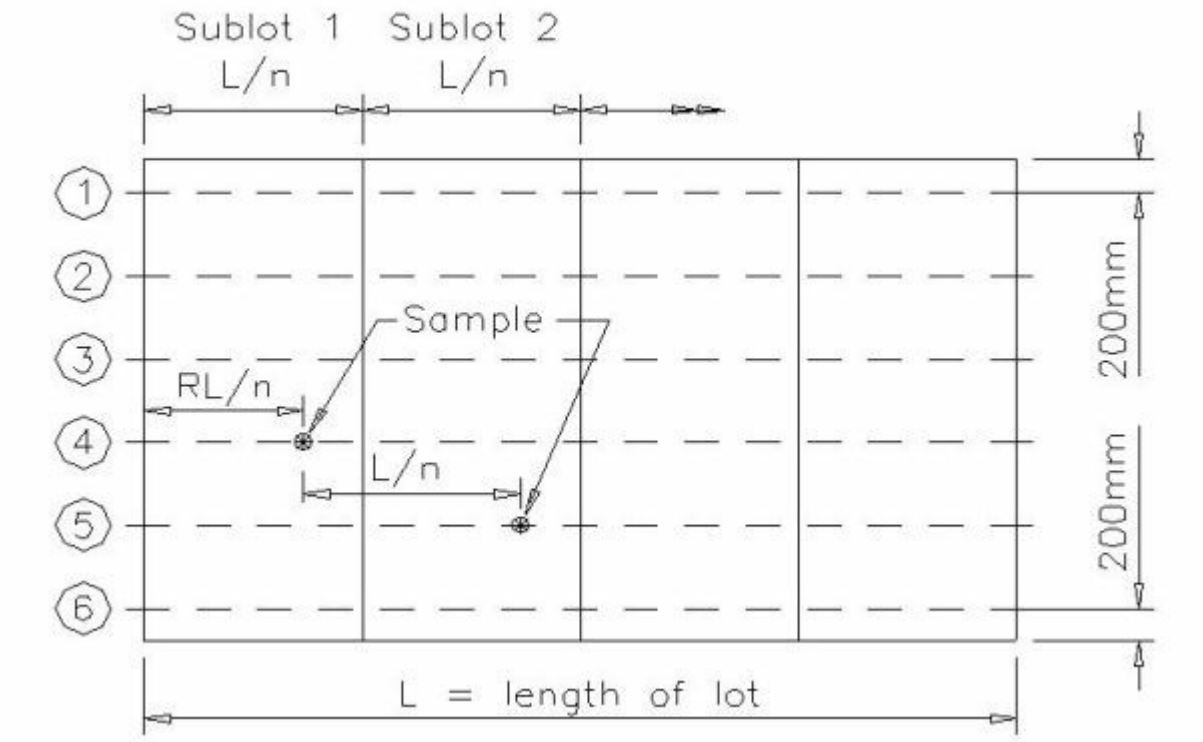

Figure SC6.4.5.3.3 Sampling locations for rectangular lot

SC6.4.5.3 Attachment C Method statement requirements

General

(1) Method statements are required to describe the key steps and sequence in the construction activities, how and by whom each step shall be undertaken and what materials and equipment shall be used. Method statements may include a flow chart to clarify the sequence of key steps. One or more method statements may address a construction activity.

(2) Each method statement will be supported by a check list which shall identify relevant inspections, test points, materials requirements and hold points. Each requirement on the check list will have an officer responsible

identified and will require the nominated officer to sign off the requirement so indicating its satisfactory execution.

(3) Method statements and check lists shall be compatible with the appropriate Inspection and test plan. Check lists will be completed for each lot of work during construction and compiled with other documents to comprise the quality register.

(4) The Contractor shall submit method statements and check lists to describe the key steps in those construction activities listed below that are identified with a preceding asterisk (*).

Item	Enter * here if required	Activity	Sub-section Number
1		Control of Traffic	SC6.4.6.30
2		Temporary Roadways and Detours	SC6.4.6.30
3		Clearing and Grubbing	SC6.4.6.11
4		Earthworks - Cut	SC6.4.6.10
5		Earthworks - Unsuitable Material	SC6.4.6.10
6		Earthworks - Embankment	SC6.4.6.10
7		Compaction and Quality Control	SC6.4.6.10
8		Siting, Excavation, Bedding, Backfilling and Compaction of Stormwater Drainage	SC6.4.6.4
9		Installation of Pipe Drainage	SC6.4.6.6
10		Installation of Precast Box Culverts	SC6.4.6.7
11		Siting and Installation of Drainage Structures	SC6.4.6.5
12		Construction of Lined Open Drains including Kerb and Gutter	SC6.4.6.9
13		Stabilisation of Pavement or Subgrade Materials	SC6.4.6.19
14		Provision of Subsurface Drainage as subsoil drains, pavement drains or free draining layer	SC6.4.6.20-21, SC6.4.6.8
15		Construction of Flexible Pavement Layers	SC6.4.6.12
16		Construction of Concrete Pavement Layers	SC6.4.6.14-15
17		Construction of Asphaltic Concrete Pavement Layers	SC6.4.6.13
18		Sprayed Bituminous Surfacing	SC6.4.6.16
19		Bituminous Microsurfacing	SC6.4.6.17
20		Construction of Segmental Paving	SC6.4.6.18
21		Pavement Marking	SC6.4.6.22
22		Minor Concrete Works	SC6.4.6.28
23		Landscaping	SC6.4.6.28

SC6.4.5.3 Attachment D Minimum inspection and test plan

Table SC6.4.5.3.20 Water supply-hold points

Clause title/ Item	Requirement	Notice for inspection	Release by
Materials			
General	Submit alternative products and materials for approval.	2 weeks before ordering	Council (Water Authority)
Pipeline construction			
General–Work accreditation	Provide proof of accreditation for approval.	1 week prior commencement of work	Superintendent
General–Change of Pipeline Alignment	Approval of the proposed alignment from the Water Authority.	1 week	Council (Water Authority)
Earthworks–Excavation near existing services	Approval from relevant Authority for the excavation.	1 week	Superintendent

Clause title/ Item	Requirement	Notice for inspection	Release by
Minimum Trench Width for Pipelines–Excavation across paved or improved surfaces	Approval from the Authority or Owner prior to commencing any excavation across paved or improved surfaces.	1 week	Superintendent
Pipe Bedding–Trench completed	Present the completed excavated trench prior to pipe laying, jointing and bedding.	2 working days	Superintendent
Laying and Jointing of Pipes–Existing asbestos cement pipe cutting and disposal	Submit method statement for approval.	2 working days	Superintendent
Pipe testing and restoration			
Testing of Pipelines	Conduct pressure testing.	7 days	Superintendent and Council
Testing of Pipelines–unsatisfactory test results, defects and leakage	Conduct pressure testing upon completion of rectification work.	3 days	Superintendent and Council
Backfill and Compaction–Completion of work	Present the laid and jointed pipes for approval prior to the commencement of trench backfilling.	2 working days	Superintendent
Restoration of Surfaces	Restore progressively and as soon as possible after the section of works is completed.	2 working days	Superintendent
Pump stations			
Pumps	Provide written warranty from the manufacturer for approval.	2 weeks before ordering	Superintendent
Electrical Compliance–ompliance with required standard	Supply a proof of compliance**–**Test certificate.	1 week	Superintendent
Electrical Installation–oute of underground cabling	Submit underground cabling requirements and route for approval.	2 weeks	Superintendent
Testing and Commissioning of Pump Station–Compliance with the Specification Requirements	Submit required test results.	1 week	Water Authority and Superintendent
Testing and Commissioning of Pump Station–Commissioning	Give notice of intention to undertake commissioning. Provide pre-commissioning record sheets.	2 weeks	Water Authority and Superintendent
Construction compliance			
Works–as–executed details and Operation and Maintenance Manuals	Submit work-as executed drawing and Operating and Maintenance Manuals.	2 weeks before operating	Water Authority and Superintendent

Table SC6.4.5.3.21 Water supply-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/ Item	Requirement	Notice for inspection
Materials		
General–Compliance with manufacturers recommendations	Contractor to inspect material and products at time of delivery for compliance.	2 working days
General–Certification	Provide product or material certification prior to delivery to the works.	3 working days (Pipes and Fittings) 1 week (Valves and Hydrants)
Pipeline construction		
Location–Set out	Confirm the set out locations prior to construction.	3 working days
Crossings–Crossings authority approvals	Approval from relevant Authority and payment of fees.	2 weeks
Earthworks–Open excavation	Contractor to provide appropriate safety measures for open excavation.	Progressive
Laying and Jointing of Pipes–Inspection prior laying	Contractor to present to the Superintendent materials prior laying (if required).	Progressive
Pipe testing and restoration		
Disinfection and Flushing of Pipelines	Provide evidence of compliance with this requirement.	2 working days upon completion of activity.
Restoration of Surfaces–Disposal of surplus material	Superintendent approval is required prior spreading/disposal.	2 working days progressive

Table SC6.4.5.3.22 Sewerage systems-hold points

Clause title/ Item	Requirement	Notice for inspection	Release by
Materials			
General	Submit alternative products and materials for approval.	2 weeks before ordering	Superintendent
Pipeline construction			
General–Work accreditation	Provide proof of accreditation for approval.	1 week prior commencement of work	Superintendent
General–Change of Pipeline Alignment	Approval of the proposed alignment from the Sewer Authority.	1 week	Superintendent and Council (Sewer Authority)
Earthworks–Prior Excavation	Approval from relevant Authority for the excavation.	1 week	Superintendent
Excavation near underground services–Protection of other services	Submit for approval give notice of any interference to the works caused by an existing service and submit a proposed work method statement.	1 week	Superintendent
Pipe Bedding–Foundation Condition/Water Charged Ground	Notify Superintendent and confirm method of foundation support from the designer.	Progressive	Superintendent
Wrapping Pipelines–Damage to sleeving	Rectify any damage to sleeving before backfilling trench.	Progressive	Superintendent

Clause title/ Item	Requirement	Notice for inspection	Release by
Bedding and Backfill Compaction Requirements–Notification of pipeline laid and jointed.	Present the laid and jointed pipes for approval before the trench backfilling.	Progressive	Superintendent
Bedding and Backfill Compaction Requirements–Embankment	Submit proposal for construction of embankments.	1 week	Superintendent
Pipeline testing and restoration			
Acceptance Test of Gravitation Sewers and Maintenance Holes– acceptance Testing	Present all sewers and maintenance holes for acceptance testing.	1 week	Superintendent and Sewer Authority
Acceptance Test of Gravitation Sewers and Maintenance Holes–Hydrostatic testing	Submit proposed alternative testing regime for approval.	1 week	Superintendent and Sewer Authority
Connection to Existing Sewers	Submit request to connect to the existing sewer and give notice of works including any affected occupants.	3 weeks before connection	Superintendent and Sewer Authority
Testing of Rising Mains–Pressure Test	Present rising main for acceptance testing.	1 week	Superintendent and Sewer Authority
Restoration of Surfaces– Original condition requirement	Restore progressively and as soon as possible after the section of works is completed.	2 working days	Superintendent
Pump stations			
General–Authorised products and materials	Submit alternative products and materials for approval.	2 weeks before ordering	Superintendent
Pumps	Provide written warranty of the equipment.	Upon delivery on site	Superintendent
Electrical Compliance– Compliance with required standard	Supply a proof of compliance – Test certificate.	1 week	Superintendent
Electrical Installation–Route of underground cabling	Submit underground cabling requirements and route for approval.	2 weeks	Superintendent
Testing and Commissioning of Pump Station–Compliance with the Specification Requirements	Submit required test results.	1 week	Sewer Authority and Superintendent
Testing and Commissioning of Pump Station–Commissioning	Give notice of intention to undertake commissioning. Provide pre-commissioning record sheets.	2 weeks	Sewer Authority and Superintendent
Practical Completion of Pump Station	Fulfil all the requirements for issuance of Certificate of Practical Completion.	2 weeks	Superintendent
Construction compliance			
Works–as–executed details and Operation and Maintenance Manuals	Submit work-as executed drawing and Operating and Maintenance Manuals.	1 week before operating	Sewer Authority and Superintendent

Table SC6.4.5.3.23 Sewerage systems-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/item	Requirement	Notice for inspection
Materials		
General–Compliance with Manufacturer's recommendations	Contractor to Inspect material and products at time of delivery for compliance.	2 working days
General–Certification	Provide product or material certification prior to delivery to the works.	3 working days (Pipes and Fittings) 1 week (Valves)
Pipeline construction		
Crossings–Crossings Authority approvals	Approval from relevant Authority and payment of fees.	2 weeks
Earthworks–Open excavation	Contractor to provide appropriate safety measures for open excavation	Progressive
Bedding and Backfill Compaction Requirements–NATA	Provide NATA certified test results for all testing.	2 working days progressive
Thrust and Anchor Blocks for Rising Main–Verification of Bearing Pressures	Give notice if the allowable bearing pressure of the ground and the design pressure of the pipeline differ from actual pressures on site.	1 week
Pipeline testing and restoration		
General–Initial Tests (Sewers and Maintenance Holes)	Give notice prior commencement of initial testing.	2 days progressive
Ovality Test and CCTV Inspection–Deflection testing and pipeline verification	Submit proposal for deflection testing (Ovality Test). Submit CCTV Results.	1 week (Ovality Test) 2 days upon completion of inspection
Acceptance Test of Gravitation Sewers and Maintenance Holes	Submit acceptance test results.	Progressive
Visual Inspection and Measurement of Infiltration–Infiltration testing	Submit method of infiltration testing.	1 week
Testing of Rising Main	Submit acceptance test results.	Progressive
Restoration of Surfaces–Disposal of surplus material	Superintendent approval is required prior to spreading/disposal.	2 working days progressive
Pump stations		
General - Conformance with manufacturers recommendations	Inspect material and products at time of delivery.	2 working days
Electrical Compliance–approval of all design and materials	Submit all design drawings and materials to each Authority having jurisdiction for approval.	2 weeks before ordering

Table SC6.4.5.3.24 Stormwater drainage-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Construction			
Temporary drainage–Erosion and Sediment Control	Confirmation of accepted project ESCP and completion of erosion and sedimentation control measures.	1 week prior to site commencement	Superintendent and Council
Siting of Culverts–Survey set-out	Submit survey set-out of culvert inlets and outlets for approval.	1 week prior to proceeding	Superintendent
Siting of Culverts–Changes by Contractor	Submit proposed changes for approval.	1 week prior to proceeding	Superintendent
Excavation–Public utilities	Obtain approval for adjacent excavation with relevant authorities.	1 week prior to proceeding	Superintendent
Construction traffic–Protection measures	Submit certification and verification of protection measures.	3 working days	Superintendent

Table SC6.4.5.3.25 Stormwater drainage-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Construction		
Excavation–Notice	Identify unsuitable materials and inadequate support material for removal and disposal at the foundation level of the structure.	progressive
Backfilling–In situ concrete structures	Do not backfill against in situ concrete structures within 14 days of concrete placement.	progressive
Backfilling–Tolerance	Check shape of culvert during backfilling.	progressive
Compaction adjacent to culverts or drainage structures	Inform the Superintendent prior rectification any damage.	2 working days before proceeding

Table SC6.4.5.3.26 Drainage structures-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Construction			
Precast Units–Product drawings and Quality	Submit details of precast or proprietary items for approval and Submit quality test results.	1 working day and 3 working days before delivery respectively	Superintendent
Excavation	Excavation and compaction of foundation as documented.	1 working day	Superintendent
Backfill–Commencement	Obtain approval for commencement.	1 workday day	Superintendent

Table SC6.4.5.3.27 Drainage structures-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Construction		
Headwalls and Wingwalls – Batter retention	If dimensions on drawings are unable to satisfy batter retention, notify the Superintendent.	3 working days
Precast units	Give notice of installation of precast pits and junction boxes.	1 week
Construction	Submit for approval part omission of concrete lining.	3 working days

Table SC6.4.5.3.28 Pipe drainage-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Common requirements			
General–Material Certification	Submit conformance certificate and other relevant manufacturer quality documentation.	24 hours in advance of dispatch to site	Superintendent
General–Alternative materials	Submit full product details in accordance with AS/NZS 2566.1.	4 weeks prior to commencing work	Superintendent and Council
General–Backfilling	Present the completed installation and jointed pipes for inspection.	Progressive before backfilling	Superintendent and Council
General–Protection of structures	Submit design proposal for protective measures for approval.	3 days prior	Superintendent and Council
Steel pipes and pipe arches			
Materials and Surface Treatment	Engineer's certification for the pipe materials and surface treatments.	Prior to practical completion	Superintendent
UPVC pipes			
Materials–Proprietary product with external diameter of ≥450mm	Submit for approval prior to construction.	4 weeks	Superintendent and Council

Table SC6.4.5.3.29 Pipe drainage-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Precast reinforced concrete and fibre reinforced concrete pipes		
Excavation–Wide Trench Condition	If deemed as a wide trench, confirm appropriate pipe strength/trench support.	Progressive
Bedding	Source of bedding material -advise Superintendent.	Progressive
Bedding–Cementitious stabilisation	Provide if erosion of bedding material may occur.	1 week

Table SC6.4.5.3.30 Precast box culverts-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Materials			
Culvert Units, Link and Base Slabs	Submit certificate of conformance.	3 working days prior to dispatch	Superintendent
Proof load testing	Submit certificate and test results.	3 working days prior to dispatch	Superintendent
Construction			
Construction of coffer dams	Submit construction details for approval.	1 week prior to construction	Superintendent
Prior placement of bedding	Inspection of foundation and approval of proposed bedding.	2 days before placing material	Superintendent
Backfill—Inspection of seals	Present joints and seals for before backfilling.	1 working day	Superintendent
Construction loading on culvert —Constraint	Do not load base slab until strength has reached 20 MPa.	1 working day	Superintendent

Table SC6.4.5.3.31 Precast box culverts-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Materials		
Handling, Delivery and Storage	Inspect box culvert units for conformance.	1 week prior to installation
Construction		
Coffer Dams—Timber or bracing removal	Inspect removal of bracing materials.	1 working day
Installation of Precast in situ base slabs	Attainment of concrete minimum compressive strength.	1 working day

Table SC6.4.5.3.32 Drainage mats-hold points

Item/Clause title	Requirement	Notice for inspection	Release by
Type A mats / Type B mats			
Geotextile, Damaged geotextile	Approval of condition or repair of geotextile.	1 working day before next activity	Superintendent
Filter material, Thickness	Approval of thickness and layers of filter material.	3 working days before placing filters	Superintendent

Table SC6.4.5.3.33 Drainage mats-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Item	Requirement	Notice for inspection
Type A mats /Type B mats		
Filter material, Protective layer	Inspection of placement of protective layer over mat extension.	3 working days before placing materials
Discharge, Outlets	Inspection of outlet proposals.	7 days before set-out of layers

Table SC6.4.5.3.34 Open drains-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Pre-construction planning			
Provision for traffic	Submit Traffic Guidance Scheme for approval.	2 weeks prior to site commencement	Superintendent
Temporary drainage	Submit details of procedures/devices for approval.	2 weeks prior to site commencement	Superintendent
Materials			
Proprietary Products	Submit proprietary products and manufacturer's instructions.	7 days prior to commencement on site	Superintendent
Gabions/Wire mattresses	NATA compliance certificates for proposed Gabions.	7 days prior to commencement on site	Superintendent
Rock fill material	NATA compliance certificates for proposed rock fill material.	7 days prior to commencement on site	Superintendent
Geotextile	NATA compliance certificates for proposed Geotextile material.	7 days prior to commencement on site	Superintendent
Open drains			
Excavation	Approval to divert drain to avoid trees and/or rocks.	1 working day before set-out.	Superintendent.
Excavation	Location and construction of drains to prevent salination.	1 working day before set-out.	Superintendent.
Kerb and channel (gutter)			
Foundation	Approval for shape and compaction of foundation material.	1 working day before forming	Superintendent

Table SC6.4.5.3.35 Open drains-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Open drains		
Excavation	Unsuitable material removal and disposal.	Progressive
Excavation	Spoil site locations.	Prior to placement
Embankment	Embankment compaction and revegetation.	Progressive
Construction	Grade and compaction of open drains.	Progressive
Construction	Proprietary items installed to manufacturers recommendations.	Progressive
Types	Maintain catch drains.	Progressive
Types	Construct minor diversion and contour drains, table drains, swales and depressed medians.	Progressive
Types	Channels preserving the existing stream bed.	Progressive
Lining		
Concrete lining	Instruction on weephole location.	1 working day before concreting.
Concrete lining	Joints and tolerances.	1 working day before concreting.
Stone pitching	Bedding material and placement.	1 working day before concreting.
Kerb and channel (gutter)		
Stormwater outlets	Positive drainage to channel.	Progressive
Vehicular or pedestrian access	Siting, location and bedding compaction.	Progressive
Backfilling and reinstatement		
Backfill behind kerbs	Backfilling timing, material and compaction.	1 working day prior to backfilling
Pavement backfill	Backfill adjacent new gutter material and location.	1 working day prior to backfilling
Rock filled wire mattresses and gabion– Completion	Inspection of rockfill material and filling method.	On completion of works

Table SC6.4.5.3.36 Earthworks-hold points

Clause/subclause	Requirement	Notice for inspection	Release by
Stockpile Sites	Approval to use any stockpile site not shown on the Drawings.	3 working days before stockpiling	Superintendent
Treatment of Floors of Cuttings–Prior ripping floors of cuttings	Present in situ material for inspection to determine suitability of pavement support.	Before ripping commences	Superintendent
Treatment of Floors of Cuttings–Compacting floors of cuttings	Inspection of compacted cutting floor.	Prior to placing any subsequent layers over the completed cutting floor	Superintendent and Council
Unsuitable material–Floor inspection	Re-present the floor of the excavation after the removal of unsuitable material.	Prior to backfilling with replacement material	Superintendent
Foundations for Embankments	Inspection of the embankment foundation area.	1 working day prior to next activity	Superintendent
Foundation for Embankments–Other Embankments (Bridging layer)	Inspection and direction for bridging layer where required	3 working days before proceeding	Superintendent
Trimming tops of embankments	Inspection of the completed surface to receive subsequent pavement layers.	Prior to placing any subsequent pavement layers	Superintendent
Selected material zone	Inspection of the completed select material zone surface prior to placing any subsequent pavement layers.	1 working day before proceeding	Superintendent
Fill adjacent to structures–General	Concrete strength required for early filling to structures.	3 working days prior to fill placement	Superintendent
Deflection monitoring or proof rolling	Present the completed work for deflection monitoring or proof rolling.	2 working days before next activity	Superintendent and Council

Table SC6.4.5.3.37 Earthworks-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause/subclause	Requirement	Notice for inspection
Natural Surface and Earthworks Materials	Survey method and results, including any discrepancies.	At least 7 days notice
Cuttings–Floors of cuttings	Floors to be no more than 50 mm above or below the designed floor and provide suitable support.	1 working day before next activity
Batters–Excavation beyond the batter line	Minor change in the general slope of the batter to suit the site conditions.	1 working day before next activity
Transition from cut to fill–Terrace	Excavate a terrace for the width of the selected material zone to a depth of 900 mm below and parallel to the cutting floor.	1 working day before excavating terrace
Unsuitable Material	Material deemed unsuitable for embankment or pavement support in its present position.	Progressive
Placing Fill for Embankment Construction–Rock material	Modify grading of fill material to achieve compaction.	Progressive
Fill adjacent to structures–Treatment at weepholes	Proposal to use synthetic membrane geotextile.	3 working days before proposed use
Spoil–Haulage disposal	Obtain planning approval and any permits.	3 working days before commencing activity
Borrow–Requirement	Obtain planning approval and any permits.	3 working days before commencing activity

Table SC6.4.5.3.38 Clearing and grubbing-hold points

Clause/subclause	Requirement	Notice for inspection	Release by
Limits of clearing			
Survey	Decision on the removal of miscellaneous items.	7 days before proposed removal	Superintendent
Extent of clearing	Submit peg out and extent of clearing survey.	7 days before proposed commencement of clearing	Superintendent and Council
Clearing Operations			
Tagging	Confirm clearing perimeters and mark trees to be preserved.	7 days before proposed site clearing	Superintendent and Authorised Council Officer
Work near trees noted for protection	Work method statement for works within the exclusion zone.	7 days before proposed works	Superintendent
Excavation within 4m of tree trunks	Develop appropriate work methods to avoid damage to the tree for approval.	7 days before proposed excavation	Superintendent
Trees within proposed embankment areas	Direction to remove or protect trees within proposed embankments.	7 days before proposed site clearing	Superintendent
Unsound trees in road reserve	Direction on removal of trees or branches not within the clearing limits.	7 days before proposed site clearing	Superintendent
Timber falling on private property	Written consent of owner to leave in place or to enter property to remove.	Prior to carrying out works	Superintendent
Damage	Approval for any rehabilitation of vegetation or fauna habitat.	3 working days prior to carrying out works	Superintendent and Authorised Council Officer
Grubbing			
Blasting	Explosives not permitted without prior approval.	Progressive	Superintendent
Disposal of materials			
Burning of material	Approval prior to disposal of timber and other combustible materials by burning.	Prior to burning	Superintendent

Table SC6.4.5.3.39 Clearing and grubbing-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause/subclause	Requirement	Notice for inspection
Existing Utility services–Marking	Locate all underground pipe and cables.	Before commencing any earthworks
Trees to be preserved–Work near trees noted for protection	Exclusion zone around protected trees.	Progressive
Trees to be preserved–Tree protection	Trees and roots not to be cut or damaged.	Progressive
Grubbing–Backfill	Backfill and compact grub holes.	Progressive
Chipping of cleared vegetation–Stockpiling	Stockpile location approval.	Prior to stockpiling

Table SC6.4.5.3.40 Flexible pavements-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Activity plan			
Pavement construction plan	Prepare and submit pavement plan.	4 weeks before commencing site work	Superintendent
Inspection, sampling and testing			
Notification	Written notice for testing times and provide test results.	3 working days prior to testing or inspection	Superintendent
Materials			
Proposed materials	Prepare and submit schedule detailing material properties including NATA test results and certificate.	2 weeks before ordering materials	Superintendent
Bound or modified materials	Complete and submit (SC6.4.6.19 Attachment A).	2 weeks before ordering materials	Superintendent
Variations to approved materials	Submit details of changes to approved materials.	1 week before use in works	Superintendent
Lime modified base and subbase materials			
Lime modification	Submit proposals to modify materials.	2 weeks before placing	Superintendent
Stationary Plant or In-situ lime modification	Submit proposals for the in-situ use of hydrated lime or quicklime.	2 weeks before activity	Superintendent
Spreading			
Underlying layer	Inspection to determine suitability of underlying layer.	1 working day before placing next layer	Superintendent
Temperature	Submit proposal to proceed outside allowable conditions.	1 working day before placement	Superintendent
Trimming, compaction and curing			
Plant	Submit details of proposed hand operated plant.	1 week before use	Superintendent
Subsequent layers	Submit completed test results of previous layer.	1 working day before placing next layer	Superintendent
Acceptance of compaction			
Lots for acceptance	Submit compaction test results.	1 working day after testing	Superintendent
Compaction requirements and acceptance	Submit evidence that compaction is within tolerances.	1 working day after test results	Superintendent
Tolerances			
General	Submit lot survey reports.	1 working day before next activity	Superintendent
Action on rejection			
Corrective action–rejected unbound layers	Submit proposal for corrective action.	1 working day before next activity	Superintendent
Corrective action–rejected bound layers	Submit proposal for corrective action.	3 working days before next activity	Superintendent
Removal and replacement of rejected course			
Extent of removal	Submit proposal to remove less than full width.	1 working day before next activity	Superintendent

Clause title/Item	Requirement	Notice for inspection	Release by
Prior to replacement	Give notice for inspection of underlying material.	1 working day before next activity	Superintendent
Replacement	Submit proposed methods to make good.	1 working day before next activity	Superintendent
Maintenance before completion of wearing course			
Pavement condition before primerseal	Dry-back, re-prepare and give notice for inspection.	3 working days before next activity	Superintendent and Council
Opening bound pavement to traffic	Give notice of proposed opening to traffic.	3 working days before proposed opening	Superintendent

Table SC6.4.5.3.41 Flexible pavements-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Delivery to site		
Delivered materials	Give notice for inspection.	Progressive
Delivery of modified or bound materials		
Delivery of materials	Provide delivery dockets at point of delivery.	Progressive
Stockpiling of unbound materials		
Location	Give notice of proposed alternative locations.	2 weeks before stockpiling
Trimming, compaction and curing		
Compaction	Give notice of proposal to use alternative layer thickness.	2 weeks before activity
Rework	Give notice for inspection of reworked wetted up layer.	Progressive
Curing of bound materials	Give notice of water curing activities.	Progressive
Acceptance of compaction		
Nuclear density Meter testing	Give notice of proposal to use Nuclear density meter.	1 working day before use
Tolerances		
Layer width	Give notice of completion of layer width.	Progressive
Levels and Surface Trims	Give notice of completed surface layer.	Progressive

Table SC6.4.5.3.42 Asphaltic concrete-hold points

Clause/subclause	Requirement	Notice for inspection	Release by
Plant	Evidence that plant is registered and insured.	2 weeks before using plant	Superintendent
Delivery—work records	Submission for counter signing.	Each day for daily completion	Superintendent
Asphalt mix design			
Approved Mix	Submit approved mix design for Superintendent confirmation.	7 days before using mix	Superintendent
Production Mix— Production Sampling and Testing	Submission of all documented test results.	Within 7 days of delivery of material	Superintendent
Asphalt mixes incorporating RAP	Mixes containing more than 20% RAP to be submitted for assessment.	7 days before using mix	Superintendent
Placing	Present surface prior spreading.		Superintendent
Joints—General	Submit plan of joints location for approval.	7 days before commencing	Superintendent
Preparation of Pavement — Rectification of Pavement Surface	Prepare surface to the satisfaction of the Superintendent.		Superintendent
Laying—Paver	Provide notice of proposed pavers.		Superintendent
Removal and Replacement of Rejected Material	Present surface after removal of the rejected material.		Superintendent

Table SC6.4.5.3.43 Asphaltic concrete-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause/subclause	Requirement	Notice for inspection
Plant	Superintendent to assess faulty plant.	Progressive
Production	Superintendent to access the mixing plant to verify production procedures and the supplier's compliance with the Contractor's Project Quality Manual and Quality Plan.	Progressive
Aggregate—General	Source subject to inspection and approval of Superintendent.	3 weeks before importing aggregate

Table SC6.4.5.3.44 Mass concrete subbase-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Materials for concrete			
Materials	Submit details of concrete mix and materials.	Submit as part of confirmation of nominated mix	Superintendent
Design and control of concrete mixes			
Nominated mix	Submit details of concrete mix and materials including NATA certificates and test results.	21 working days before using the nominated mix (Progressive)	Superintendent and Council
Variations to nominated mix and materials	Submit details of any change to nominated mix and materials.	21 working days before implementing change	Superintendent
Conformance for concrete strength and thickness			
Sampling, curing and testing of fresh concrete	Inspection of sampling procedure.	Progressive	Superintendent
Acceptance criteria	Submit test results.	Progressive	Superintendent
Acceptance criteria for cored concrete (non-conformance)	Submit test results.	Progressive	Superintendent
Production, transport and consistency of concrete			
Concrete production and transport	Submit proposed work methods.	At least 21 working days before starting	Superintendent
Placing and finishing concrete subbase			
Subbase Paving plan	Submit as part of Quality plan.	21 working days before starting	Superintendent
Construction—Placing	Written notice to commence (including trial section).	7 days before starting	Superintendent
Trial Concrete Subbase —Construction	Inspection of the trial concrete subbase.	1 working day after placing trial section	Superintendent
Trial Concrete Subbase —Deficient trial section	Provide justification of the methods used in producing deficient work for assessment.	1 working day after deficiency identified	Superintendent

Table SC6.4.5.3.45 Mass concrete subbase-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Conformance for concrete strength and thickness		
Testing by specimens cut from the work	Coring witnessed by Superintendent	3 working days
Restoration after coring	Inspection of restoration work	3 working days after cutting
Placing and finishing concrete subbase		
Curing – Efficiency Index	Submit certificate of compliance for the curing compound	Progressive
Average application rate	Average rate checked by the Contractor and certified by the Superintendent	Progressive
Bond breaker and spall treatment		
Treatment of Unplanned Cracks	Check for cracks and repair/reject	Progressive

Table SC6.4.5.3.46 Plain and reinforced concrete base-hold points

Clause title / Item	Requirement	Notice of inspection	Release by
Design and control of concrete mix			
Nominated mix	Submit details and certificates for nominated concrete mix and material constituents including NATA certificates and test results	21 working days before using the nominated mix	Superintendent
Variations to nominated mix and materials	Submit details of any change to nominated mix and materials	21 working days before implementing change	Superintendent
Steel reinforcement			
Placing and cover requirements	Approval of placement and fastening of reinforcing steel	4 working hours before concrete placement	Superintendent
Production, transport and consistency of concrete			
Concrete production and transport	Submit proposed methods and equipment	4 weeks before starting	Superintendent
Placing and finishing concrete base			
Subbase survey	Work-as-executed survey of the subbase.	7 days before starting any works	Superintendent
Surface texture	Submit details of proposed texturing device and method of texturing	Before texturing	Superintendent
Trial of Concrete Base Construction	Obtain approval for the trial section	5 working days before main works	Superintendent
Trial of Concrete Base—Deficient trial section	Provide justification of the methods used in producing deficient work for assessment	2 working days after construction	Superintendent
Joints			
Permanent sealing—General	Submit proposed method for permanent joint sealing	4 weeks before installation	Superintendent
Slab anchors			
Excavation	Submit compacted excavated surface	1 working day before concreting	Superintendent
Testing of concrete for compressive strength			
Sampling	Inspection of sampling procedure	Progressive	Superintendent
Acceptance criteria	Submit test results	Progressive	Superintendent
Acceptance criteria for cored concrete	Submit test results	Progressive	Superintendent
Removal and replacement of base			
General	Submit proposed method of removal to preserve adjoining base and underlying subbase	7 working days before replacement works	Superintendent

Table SC6.4.5.3.47 Plain and reinforced concrete base-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Witness Points Off Site		
Clause/ subclause	**Requirement**	**Notice of inspection**
Materials for concrete		
Aggregates - Storage	Storage and handling to preserve quality of aggregate	Progressive
Steel reinforcement		
General	Provide NATA certificates and manufacturer's information.	Before delivering to site
Bar chairs	Demonstrate load bearing capacity	Before delivering to site
Joints		
Silicone Sealant	Provide NATA certificate and manufacturer's information	4 weeks before joint work
Witness Points On Site		
Joints		
Permanent Sealant	Locations as shown on drawings and change to spacing	Progressive
Placing and finishing concrete base		
Consistency	Provide slump check test results	Progressive
Protection of Work - Ambient conditions	Provide details of protection methods for cold or hot weather and rain	Progressive
Traffic considerations	Provide traffic management measures	Progressive
Rate of Evaporation and moisture loss	Provide details of precautionary measures to prevent moisture loss when evaporation rate exceeds prescribed limits	Progressive
Paving (Mechanical and Hand Paving)	Construction joint if hand or mechanical paving is disrupted	Progressive
Alignment and Surface Tolerances - Assessment of base thickness	Survey of base surface, edge alignment and thickness	Progressive
Curing – Efficiency Index	Submit certificate of compliance for the curing compound	Progressive
Testing of concrete for compressive strength		
Testing of specimens cut from the work	Carry out coring in presence of the Superintendent	
Repair and Restore work after coring	Restore holes with non-shrink cementitious concrete	After coring
Conformance of concrete strength, compaction and thickness		
Relative Compaction	Testing conformance of required relative compaction	Progressive

Table SC6.4.5.3.48 Sprayed bitumen surfacing-hold points

Clause title/Item	**Requirement**	**Notice for inspection**	**Release by**
Design of bituminous surfacing			
Confirmation of Design and Materials Compliance	Submit the sprayed seal design and additional details for approval	2 weeks before commencing work	Superintendent
Plant	Evidence that plant is registered and insured	2 weeks before using plant	Superintendent

Table SC6.4.5.3.49 Sprayed bitumen surfacing-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Application and rolling of aggregate		
Removal of loose aggregate, Loose aggregate particles	Completion within specified time	Various to allow inspection of performance in conformance with Tables of time limits
Removal of surplus and waste material	Demonstrate that materials are properly disposed	Progressive
Protection - New work	Demonstrate that line marking and warning signs are in place to protect new work	Progressive

Table SC6.4.5.3.50 Bituminous microsurfacing-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Mix design			
Nominated Mix—Design and control of bituminous mix	Submit details of nominated mix with NATA Certification	7 days before commencing	Superintendent
Production and paving			
Production mix Bituminous —microsurfacing	Target application rate and nominal layer thickness for approval	7 days before commencing	Superintendent
Sampling and testing of production mix	Compliance with maximum permitted variations from approved mix	During mixing	Superintendent
Weather limitations	Cease works if weather conditions are not appropriate	Progressive	Superintendent
Paving unit calibration	Documentation for detailed calibration	7 days before using paving unit	Superintendent
Preparation of Pavement	Provide cleaned surface for inspection	1 working day prior to spreading works	Superintendent
Spreading—Traffic	Capable of carring traffic in short period after slurry surfacing to the approval of Superintendent	One hour after spreading	Superintendent
Surface texture—Test run	Demonstrate surface texture	1 working day before commencing	Superintendent
Non-conformance—Materials and finished surfacing	Approval for correction or replacement	1 working day before corrective action	Superintendent

Table SC6.4.5.3.51 Bituminous microsurfacing-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/Item	Requirement	Notice for inspection
Witness Points Off Site		
Materials		
Binder—Compliance	Submit NATA test results for the nominated binder	7 days prior to commencing works
Mineral Aggregates—Quality	Submit NATA test results for the nominated mineral aggregates	7 days prior to commencing works
Mineral Filler—Quality Compliance	Submit NATA test results for the nominated binder	7 days prior to commencing works
Witness Point On Site		
Spreading—Clean up	Leave road fixtures in clean and satisfactory condition	Progressive

Table SC6.4.5.3.52 Segmental paving-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
Materials			
General—Nominated materials	Submit segmental paving materials and supplier.	2 weeks before ordering	Superintendent
Construction			
Subgrade Preparation—Dimensions and specification	Present the finished subgrade for approval	1 working day before proceeding	Superintendent
Subbase—Dimensions and specification	Present finished subbase for approval	1 working day before proceeding	Superintendent
Base—Dimensions and specification	Present the finished base for approval	2 working days before proceeding	Superintendent

Table SC6.4.5.3.53 Segmental paving-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Item	Requirement	Notice for inspection
Construction		
Opening to Traffic—Inspection	Regularly inspect joints after completion	Progressive

Table SC6.4.5.3.54 Stabilisation-hold points

Clause/subclause	Requirement	Notice for inspection	Release by
Materials proposed for use in the work	Submit NATA certificate of compliance	14 days prior to commencement of works	Superintendent
Field Working Period —Laboratory	Nominate the specific field working period specified in the Stabilisation Mix Design	14 days prior to commencement of works	Superintendent
Materials			
Cement—Storage	Re-test cement stored in excess of 3 months	2 working days prior to usage	Superintendent
Stabilisation Process —Proposed equipment and procedures	Submit a Work Plan nominating proposed plant and work sequence	14 days prior to commencement	Superintendent
Application of stabilising agent—In situ application	Proposals for special processes of supply of stabilising agent into the mixing bowl	7 days prior to mixing	Superintendent
Mixing—In situ mixing process	Demonstration of equipment mixing efficiency in trial section	7 days prior to production stabilisation	Superintendent
Trimming and Compaction—Trimming	Work methods to exclude laminations and slurrying	3 working days prior to production stabilisation	Superintendent
Trimming and Compaction—Survey control methods	Use of trimmed material as fill or spoil	3 working days prior to disposition	Superintendent
Curing—Method statement	Submit details of proposed curing method	As directed	Superintendent
Trial section of stabilised earthworks			
General	Submit a trial section of stabilised earthworks	5 working days prior to commencement of works	Superintendent and Council
General	Any deficient sections will require to be investigated and may be directed to remove	Progressive	Superintendent and Council

Table SC6.4.5.3.55 Stabilisation-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause/subclause	Requirement	Notice for inspection
Witness Points Off Site		
Materials		
Cement	Proof of quality and source	Progressive
Quicklime	Proof of quality and source	Progressive
Hydrated lime	Proof of quality and source	Progressive
Ground granulated blast furnace slag	Proof of quality and source	Progressive
Flyash	Proof of quality and source	Progressive
Blended stabilising agent		
Blended stabilising agent —Standard	Proof of quality and source	Progressive
Blended stabilising agent —Handling and storage	Comply with supplier's handling and storage requirements and arrange sampling of agent	Progressive
Witness Points On Site		
Quality Requirements—Compaction	Adjustment of Field Working Period for site conditions	Progressive
Application of stabilising agent —Stationary mixing plant	Monitoring application of stabilising agent at the plant	Progressive
Application of stabilising agent —Stationary mixing plant	Removal of spilled stabilising agent	Immediately upon spillage event
Application of stabilising agent —Spreading out	Actual spread to be recorded and checked	Progressive
Application of stabilising agent —Spreading out	Record average spreading rate using load cells	Progressive
Mixing—Stationary mixing plant	Test unconfined compressive strength	Progressive
Mixing—In situ mixing process	Visual inspection to ensure uniform mixing and record	Progressive
Mixing—In situ mixing process	Additional passes of mixing equipment to improve uniformity	Progressive
Trimming and Compaction—Survey control methods	Survey to confirm pavement layer thickness remains within tolerances after trimming	Progressive
Trimming and Compaction —Straight edge test	Conform to surface tolerances prior to sealing or practical completion of work component	As directed by Superintendent
Dimensions—Width	Random measurement of stabilised layer width	As directed by Superintendent

Table SC6.4.5.3.56 Subsoil, foundation and pavement drains-hold points

Item/Clause title	Requirement	Notice for inspection	Release by
Construction			
Subsoil and Sub-Pavement Drains / Foundation drains—Excavation	Inspect excavated trench	1 working day prior to filling	Superintendent
Subsoil and Sub-Pavement Drains / Foundation drains—Laying of Pipes	Present bedding of compacted filter material laid to line and grade	3 working days before next activity	Superintendent
General—Filter material	Type of filter material	3 working days before ordering material	Superintendent
Intra-pavement drains —Laying of pipe	Provide certification that drain has adequate crushing strength	3 working days before ordering	Superintendent
Intra-pavement drains —Laying of pipe	Submit details of proposed method of securing pipes	7 days before pipe laying	Superintendent
Edge drains—Laying of pipe	Submit details of proposed method of securing pipes	7 days before pipe laying	Superintendent

Table SC6.4.5.3.57 Subsoil, foundation and pavement drains-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Item/Clause title	Requirement	Notice for inspection
Construction		
Subsoil and Sub-Pavement Drains / Foundation drains—Pipes	Lay on compacted bed to documented line and level	1 working day before filling
Subsoil and Sub-Pavement Drains —Backfilling	Backfilling to documented level and relative compaction	1 working day before covering with geotextile
Foundation drains—Backfilling	Backfilling to documented level and relative compaction	1 working day before covering with geotextile
Geotextile—Installation	Placement of fabric conformance	1 working day before filling
Geotextile—Installation	Ensure exposure periods are within the constraints	Progressive
Cleanouts—Field testing	Perform flushing test	Progressive (timing depending on the construction of pavement layers)

Table SC6.4.5.3.58 Subsurface drainage-witness points

Item/Clause title	Requirement	Notice for inspection	Release by
General			
Siting of Work	Submit the proposed set-out in addition to the designed set-out	7 days before planned execution	Superintendent
Siting of Work—Proposed changes	Present the proposed new set-out for approval	3 days before planned execution	Superintendent
Excavation—Existing underground services	Submit evidence of approval of the relevant authorities.	14 days before planned excavation	Superintendent
Excavation—Trenches	Approval of completed trenches required prior to installation of drainage work	1 working day prior to installation of drainage work	Superintendent
Materials			
Subsurface drainage pipes—General	Submit compliance certificates	7 days before proceeding to provide pipes	Superintendent
Other subsurface drainage pipes	Submit details of proposed alternative pipes and evidence of conformity for approval.	7 days before proceeding to provide pipes	Superintendent
Geotextile—General	Provide documentation of conformity of geotextile and installation process	14 days before proceeding to provide geotextile	Superintendent
Recording of drainage			
Recording of subsurface drainage Information	Progressive supply of subsurface drainage details	5 working days after completion of each drain or drainage system	Superintendent

Table SC6.4.5.3.59 Subsurface drainage-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Item/Clause title	Requirement	Notice for inspection
General		
Temporary drainage during construction	Locate materials and equipment clear of water courses	7 days prior to positioning

Table SC6.4.5.3.60 Pavement markings-hold points

Clause title/subclause	Requirement	Notice for inspection	Release by
General			
Material Quality	Submit NATA Test Reports on materials	7 days before work is scheduled to commence	Superintendent
Surface preparation—Wet Weather	Superintendent direction on suspension of work	Progressive	Superintendent
Removal of pavement markings			
General—Removal of redundant markings	Submit method for approval	1 working day before commencement of activity	Superintendent

Table SC6.4.5.3.61 Pavement markings-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause title/subclause	Requirement	Notice for inspection
General		
Setting Out—Net	Set out in accordance with the drawings	Progressive
Pavement marking paint		
Application of Paint Beads—Glass beads applied to other paint markings	Application method to be approved by Superintendent	Progressive
Field testing—Application Rate	Application to be checked for quality	Progressive
Thermoplastic pavement marking material		
Field testing—Application Rate	Application to be checked for quality	Progressive
Pavement marking tape		
Removal of Pavement Marking Tape	Direction to remove pavement marking tape	Progressive
Raised pavement markers		
Installation of Raised Pavement Markers	Installation to be checked for quality (allow adhesive to set)	Progressive

Table SC6.4.5.3.62 Guide posts-hold points

Clause/subclause	Requirement	Notice for inspection	Release by
General			
Materials—Proprietary posts—Proposed supplier	Supply details of the proposed guide posts	Two weeks before manufacture	Superintendent
Construction			
Erection of Guide Posts —Proprietary guideposts	Provide manufacturers anchorage instructions	5 working days	Superintendent
Erection of Guide Posts —Guide posts on concrete pavements	Provide fixing details	5 working days	Superintendent

Table SC6.4.5.3.63 Guide posts-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause/ subclause	Requirement	Notice for inspection
Construction		
General—Location of guide posts and proximity to underground services	Locations shown on drawings or as specified Check for existing underground services	Two weeks before installation
Erection of Guide Posts—Backfilling	Firm embedment in ground	Progressive
Delineators—Fixing	Arrangement of delineators relative to traffic direction	Progressive

Table SC6.4.5.3.64 Signposting-hold points

Clause/subclause	Requirement	Notice for inspection	Release by
Materials			
General—Approved Supplier	Details of proposed suppliers provided to the Superintendent including documentary evidence	1 week prior to ordering	Superintendent
General—Documentary Evidence	Evidence that materials and parts proposed comply with the requirements of this specification	1 week prior to engaging supplier	Superintendent
Retro-Reflective Material for Background and Legend	Details of material and compatibility in application and durability	1 week prior to ordering	Superintendent
Sign Support Structures —Attachment of signs	Details of proposed attachment systems	2 weeks prior to fabricating attachment systems	Superintendent
Erection of new signs			
Setting Out	Approval of the location and alignment of the sign support structure	1 week prior to erection	Superintendent
Setting Out—Existing underground services	Locate services and protect against damage	1 week prior to erection	Superintendent
Special requirements			
Street Name, Service and Tourist Signs	Submit details of manufacturer for approval by council	1 week prior to ordering	Council

Table SC6.4.5.3.65 Signposting-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause/subclause	Requirement	Notice for inspection
Erection of new signs		
Setting Out	Submit details of and set out for each support structure	1 week before installing signs
Clearing	Clear vegetation after set-out on advice from council	3 working days before clearing
Sign Structure Footings —Excavation	Excavation as shown on drawings and as directed, including disposal of material	1 working day before next activity
Erection—Sign Damage	Repair or replace damaged signs	1 week before installing signs
Adjustment of existing signs and support structures		
General	Conform to Drawings and Superintendent direction	1 week before adjusting signs

Table SC6.4.5.3.66 Non rigid road safety barrier system-hold points

Item/Clause title	Requirement	Notice for inspection	Release by
Materials			
Certification—Evidence of Conformance	Provide documentary evidence of conformity of steel components	1 week prior to erection	Superintendent
Construction			
General— Set Out	Set out to drawings or as directed	2 working days prior to erection	Superintendent
End Treatment of Road Safety Barriers—MELT	Submit alternative MELT locations	1 week prior to ordering	Superintendent

Table SC6.4.5.3.67 Non rigid road safety barrier system-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Item	Requirement	Notice for inspection
Construction		
General—Sequence of Construction (pavements)	Erection after pavement activities	1 week before installation – progressive
General—Underground Obstruction	Alternative method due to obstructions	1 week before setting posts
Erection of Steel Posts—Damage to posts	Assessment by Superintendent for replacement	3 working days before removal of damaged post
Erection of Road Safety Barrier Rails—Excessive damage to rails	Assessment and rejection by Superintendent	1 working day after perceived damage

Table SC6.4.5.3.68 Minor concrete works-hold points

Clause/subclause	Requirement	Notice for inspection	Release by
General			
Excavation and Foundation General—Ground preparation—Base preparation	Inspect prepared surface or sand underlay	1 working day prior to covering	Superintendent
Excavation and Foundation General—Ground preparation—Polymeric film underlay installation	Inspect membrane or film underlay installed	1 working days prior to covering	Superintendent
Approval of Formworks Design	Formwork design certificates	3 working days	Superintendent
Erection—Formwork	Certification of installed formwork and inspection	1 working day prior to covering	Superintendent
Materials for concrete			
Nominated Mix	Submit details of nominated mix for approval	7 working days	Superintendent
Reinforcement for concrete			
Steel reinforcement placement—Approval of reinforcement before concrete placement	Inspect reinforcement placement	1 working day prior to covering	Superintendent
Cores, fixings and embedded items—General	Shop drawings for cores, fixings and embedded items	7 working days prior to commencing works	Superintendent

Clause/subclause	Requirement	Notice for inspection	Release by
Loads on minor concrete structures	Approval for early loading of the structure by design strength in situ tests	3 working days	Superintendent
Sprayed concrete general—Method statement	Submit proposal for spraying	14 days prior	Superintendent

Table SC6.4.5.3.69 Minor concrete works-witness points

Clause title/Item	Requirement	Notice for inspection
General		
Ground preparation—Mass concrete bedding on earth foundations	Inspect concrete blinding slab prior to placing forms or materials	1 working day prior to covering
Concrete quality requirements —Formwork	Check erection tolerances	1 working day
Materials for concrete		
Certificate of compliance	NATA certificates for all materials	7 days prior to commencing on site
Handling and treatment of concrete		
Mixing of concrete—Hand Mix On Site	Submit proposal for use	7 days prior
Mixing of concrete—Pre-mixed supply	Submit delivery dockets and subcontractors details	Progressive
Concrete quality requirements —Flatness	Confirm unformed surfaces	1 working day
Concrete quality requirements —Surface quality	Confirm surface quality	1 working day
Concrete curing	Certified test results for curing compound	7 days prior
Joints	Submit proposal for sawn joints	7 days prior
Concrete placing and compaction —Testing	Certified test results for compressive strength	Progressive
Reinforcement for concrete		
Steel reinforcement placement —Delivery and receipt of reinforcement	Submit notice for test inspection	7 days
Steel reinforcement placement —Placing	Submit proposed changes to reinforcement	2 days prior to commencing on site
Steel reinforcement placement —Damaged galvanising	Submit proposed repair method	2 working days prior
Steel reinforcement placement —Provision for concrete placement	Submit proposed changes to spacing, cover, splicing or welding or reinforcement	2 working days prior
Cores, fixings and embedded items—Cutting or coring	Approval for cutting or coring hardened concrete	2 working days prior
Sprayed concrete—Sprayed concrete test panel	Approval of sample panels	7 days

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Table SC6.4.5.3.70 Boundary fencing-hold points

Clause title / item	Requirement	Notice for inspection	Release by
Materials			
General—Material approval	Submit source, type, Certificate of compliance and manufacturer for each type of material	One week before ordering each type	Superintendent
Construction			
General—Clearing and grubbing	Confirm approval for tree removal	One week before next activity	Superintendent
Erection of posts			
Depth of posts	Method of installing and proposed type of posts to be used	One week before manufacture or order	Superintendent
Erection of wires—General	Approval for any proprietary fasteners	One week before manufacture or order	Superintendent
Flood gates—General	Approval to proceed with flood gates and type	One week before fabricating flood gates	Superintendent
Removal and disposal of surplus material and rubbish	Approval required for burn off for combustible materials	Prior to burning	Superintendent
Bedding—Cattle Grids	Approval for bedding requirements	One week before fabricating flood gate	Superintendent

Table SC6.4.5.3.71 Boundary fencing-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Item	Requirement	Notice for inspection
Materials		
Galvanised Posts, Braces and Rails —Welded Joints	Welding sites to be cleaned and painted	Progressive
Gates—Dimensions and Fittings	Fitting alternatives	3 working days before fabrication
Construction		
Stock-Proof Fencing—Erection of posts—Depth of posts	Posts sunk to the required depths	Progressive
Crossing of Watercourses and Depressions	Secure by installing longer posts as directed	Progressive
Flood gates—Small water courses	Provide required waterway area	Progressive
Erection of Gates	Double gates to be directed	One week before ordering
Removal and disposal of surplus material and rubbish	All surplus material to be removed	Progressive

Table SC6.4.5.3.72 Control of traffic-hold points

Clause title/Item	Requirement	Notice for inspection	Release by
General			
Traffic guidance scheme (TGS)—Approval	Approval of Traffic guidance scheme	2 weeks before proposed commencement on site	Superintendent.
Traffic guidance scheme (TGS)—Relevant Authority Approval	Provide evidence of approvals from Council and other Authorities	4 weeks before proposed commencement on site	Superintendent
Traffic Guidance Scheme (TGS)—Non-complex TGS	Carry out a risk assessment for works not involving complex TGS or staged works	4 weeks before proposed commencement on site	Superintendent.
Side Roads and Property Accesses—Proposed access	Provide Proposal for access	5 working days prior to carrying out works	Superintendent.
Side Roads and Property Accesses—Notice to property owners	Approval to deny vehicular access and provide notice to property owners	3 working days prior to carrying out works	Superintendent.
Temporary roadways and detours			
Approval	Submit design of all proposed temporary roadways and detours	5 working days prior to carrying out works	Superintendent.
Opening to Traffic	Present completed temporary roadways and detours to the Superintendent for approval prior allowing traffic	5 working days prior to carrying out works	Superintendent.
Arrangements for traffic			
Construction Under Traffic—Approval	Approval required to construct under traffic	3 working days prior to carrying out works	Superintendent.
Construction Under Traffic—Details	Submit full details of temporary signposting, traffic control devices and traffic control methods for approval	5 working days prior to carrying out works	Superintendent.
Opening Completed Work—Written Notice	Provide written notice to the Superintendent confirming date of opening of completed works.	5 working days prior to opening of completed works	Superintendent.
Traffic control devices			
Adequate Traffic Control Devices—Default by Contractor	Rectify inadequate traffic control devices	1 working day of notice	Superintendent.

Table SC6.4.5.3.73 Control of traffic-witness points

Note—the Contractor must notify the Superintendent and/or council of impeding works, where the option of attendance may be exercised by the Superintendent and council.

Clause/Item	Requirement	Notice for inspection by the Superintendent
General		
Traffic Guidance Scheme (TGS)—Site Copy	A copy of the approved Traffic Guidance Scheme must be kept on site	Progressive
Traffic Guidance Scheme—Safety Audit	For complex traffic arrangements and staged works carry out safety audits	Progressive
Traffic Controllers—Personnel	Submit names and declaration of proposed traffic controllers	Prior to commencing work
Temporary Speed Zoning—Record	Diary and method of works	Progressive
Temporary roadways and detours		
Drainage—Pavements	Pavement designed and constructed not to pond water	Progressive
Surfacing—Extent	Width of wearing surface and position of finish tying into existing works	3 working days prior to carrying out works
Traffic control devices		
Arrangement of traffic control devices	Arrangement and placement as per the approved TGS	Progressive
Temporary markings—Line Marking	Ineffective line marking, remark within 48 hours.	Progressive
Temporary markings—Old Markings Removed	Obliterate or remove old markings.	Progressive
Raised Pavement Markers—Ineffective Markers	Replace ineffective markers within 24 hours.	Progressive

SC6.4.6 Construction standards

SC6.4.6.1 Water sensitive urban design construction and establishment requirements

SC6.4.6.1.1 Introduction

This sub-section is a supporting document to the Water by Design, 2010, *Construction and Establishment Requirements: Swales, Bioretention Systems and Wetlands* (Construction and Establishment Guidelines), South East Queensland Healthy Waterways Partnership, Brisbane. The Construction and Establishment Guidelines are adopted in whole, with the exceptions and additions as noted in this planning scheme policy.

Editor's note—the most up to date version of the Construction and Establishment Guidelines can be purchased from Water by Design.

SC6.4.6.1.2 Irrigation

Supplementary irrigation may be required to maintain system functionality during prolonged periods of dry. Water supply to bioretention and wetland systems is greatly influenced by localised residential runoff; hence council imposed water restrictions or prolonged periods of dry should be met with supplementary irrigation. Irrigation (temporary or permanent) may be requested by council during landscape installation. All irrigation plans are to be approved for use by council.

Editor's note—use Form D: Swales; Form G: Bioretention systems; Form H: Constructed Wetlands from the Construction and Establishment Guidelines.

SC6.4.6.1.3 Vegetation establishment

Throughout the sub-section, reference is made to building phase protection by temporary measures. Where 80-90% of the building phase is referred to in the text the developer should ensure upwards of 90% build out before removal of temporary measures and establishment of the approved vegetation.

SC6.4.6.1.4 Weed management

Typha spp have shown an ability to dominate systems in Townsville and disable their functionality and maintainability. Although some Typha species are native they are considered an environmental weed whose control is recommended (Queensland Government Department of Primary Industries and Fisheries, October 2010). As such Typha spp should be removed from systems early to prevent spread and actively managed to ensure that the system is free of the weed at the point of handover. This will ensure that hydrological functioning is maintained, reduce snake habitat (both real and/or perceived), increase vector control, protect desirable, approved species; and reduce fuel loads when systems dry out.

The Developer is to ensure that all waterways are free of Typha spp at the end of the defects liability period.

SC6.4.6.1.5 Dredge spoil dewatering areas

As council refuse facilities do not accept "wet waste", the developer will need to incorporate dredge spoil dewatering areas for sediment and aquatic weeds removal into their design. Any dewatering area proposed should be suitable for maintenance vehicle access. The area should be positioned as close as practical to the constructed wetland/drainage channel, be an adequate size and designed to contain the excavated material and associated runoff. The dredge spoil area will not only meet the needs of the developer during the construction and operational phases. Dredge spoil areas must be identified and approved by council prior to any excavation.

Dredge spoil areas are to be retained for the duration of the construction and operational phases of the wetland/drainage canal that is being maintained.
The developer must determine dredge spoil area locations based on the following criteria:

(1) Estimated amount and frequency of dredge material to be dewatered;

(2) Proximity to existing residential and commercial properties;

(3) Proximity to proposed wetland/drainage channel; and

(4) Potential for dredge spoil to emit offensive odours (ie high clay/weed content).

Editor's note—use Form A: Swales; Form A: Bioretention Systems; Form C: Constructed Wetlands from the Construction and Establishment Guidelines.

SC6.4.6.1.6 Saltwater intrusion

Section 4.9 of the Construction and Establishment Guidelines lists potential failures. Saltwater intrusion should be considered as an additional defect or failure.

Table SC6.4.6.1.1 Potential failure scenarios for swales and rectification actions

Defect or Failure	Causes	Rectification
Saltwater Intrusion	Physical disturbance/excavation of clay liner during routine maintenance works. Drying/cracking of clay liner during routine maintenance and system resetting works. System overtopping during Highest Astronomical Tide (HAT): (1) System should be designed for highest expected tide over lifespan of asset; and (2) Overtopping in tidal areas during storm surge and heavy rainfall typically appears manageable due to stratification of fresh on salt during high tides. This should be taken into account. Poor design/construction. No liner present. Low lying wetland encroaching water table.	Provide supplementary water to lower salinity of intruded water and/or leach accumulated salts from underlying soils. Review construction designs such as spill weir heights and clay liners for deficiencies/inefficiencies. Engage soil scientist and water sensitive urban design specialist to review soils/clay lining and species compositions if system fails.

SC6.4.6.2 Water supply

SC6.4.6.2.1 Introduction

(1) Scope

This policy sub-section provides standards, advice and guidelines for the construction of water supply infrastructure including:

(a) mains up to DN600 nominal size; and

(b) small pump stations.

This sub-section excludes the construction of:

(a) reservoirs, including repainting of reservoirs;

(b) treatment plants;

(c) dams;

(d) headworks, including bores and weirs;

(e) dosing plant; and

(f) larger pump stations.

The Contractor shall carry out the work, and supply materials meeting the requirements of the reference documents, and, in particular, in accordance with the requirements of the *Water Supply Code of Australia* except as otherwise specified herein.

(2) Reference and source documents

Documents referenced in this sub-section are listed below whilst being cited in the text in the abbreviated form or code indicated. The Contractor shall possess, or have access to, the documents required to comply with this sub-section.

References to the *Water Supply Code of Australia* are made where there are parallel sections or equivalent clauses to those in this sub-section. Where not called up as part of this sub section, these references are identified by part and section numbers and enclosed in brackets thus (WSA Part, Section).

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:

SC6.4.3.21 Townsville Water and Waste planning and design guidelines
SC6.4.4.8 Standard drawings
SC6.4.6.28 Minor concrete works

Note—SC6.4.4.8 Standard drawings shall take precedence over the WSAA standard drawings. Where any standard drawing used in conjunction with this sub-section includes technical requirements that conflict with this sub-section, the requirements of this sub-section shall take precedence.

(b) Australian Standards

Note—references in this sub-section or on the drawings to Australian Standards are noted by their prefix AS or AS/NZS. Where not otherwise specified in this sub-section or the drawings, the Contractor shall use the latest Australian Standard, including amendments and supplements, available within two weeks of close of tenders.

SC6.4.6.2.2 Materials

(1) General

The Contractor shall comply with the requirements of the manufacturer's recommendations regarding the handling, transport and storage of materials and as further specified in this sub-section.

Prior to the delivery of products and materials, the contractor is expected to obtain relevant product or material certification from the manufacturer which shall be presented to the Superintendent if requested.

The Contractor shall not use damaged or defective materials, including coatings and linings, outside the manufacturer's recommended limits.

If the Contractor proposes to use alternative products and materials other than the products and materials authorised by Townsville Water and Waste, the design drawings and this sub-section, an approval from Townsville Water and Waste is required prior to delivery and use of alternative products or materials.

(2) Unplasticised and modified PVC (uPVC and PVC-M)

Unplasticised PVC (uPVC) and modified PVC (PVC-M) pipes and fittings for mains and suction pipes shall comply with AS/NZS1477 and AS/NZS4765, shall be suitable for use with rubber ring (elastomeric) seals complying with AS1646 joints and shall be of the class and size as shown on the Design drawings. (WSA 03 – 2011, Part 1, Section 4.)

PVC pipes and fittings for mains and suction pipes shall be installed in accordance with AS/NZS 2032 and AS/NZS 2566.1.

Pipes and fittings are to be handled and stored protected from sunlight. The Contractor shall provide protection for the pipes and fittings from ultra violet light and damage. The Contractor shall take account of the time for storage and type of shelter.

(3) Acrylonitrile butadine styrene (ABS)

ABS pipes and fittings shall comply with AS/NZS3518 to the class, size, use, shape and colour as shown on the Design drawings and installed in accordance with AS/NZS2566.2 and AS3690.

ABS pipes and fittings shall be joined in accordance with the manufacturer's instructions using solvent cement to AS 3691.

(4) Glass reinforced plastic (GRP)

The use of this material is not permitted by council.

(5) Ductile iron (DI) pipe and fittings

Ductile iron (DI) pipes and fittings shall comply with AS/NZS2280 and shall be of the class, size and lining, as shown on the Design drawings, and installed in accordance with AS/NZS2566.2. Jointing shall be with rubber rings (elastomeric), complying with AS1646, to the class and type as shown on the design drawings.

Flanges shall be to the table shown on the design drawings. Bolts and nuts for flanged joints shall be galvanised, or stainless steel as for the pumps specified herein, unless shown otherwise on the design drawings.

All pipework shall be sleeved externally with polyethylene sleeving in accordance with the requirements of AS3681 unless specified otherwise to be coated and lined. All fittings shall be fusion-bonded coated, in accordance with AS/NZS4321, or wrapped. The Contractor shall wrap all unprotected joints in the trench with a petrolatum tape system approved by the Superintendent.

(6) Steel pipeline and fittings

Steel pipelines and fittings shall comply with AS1579 and AS/NZS1594 and shall be of the class, size, lining and coating as shown on the design drawings. (WSA 03 – 2011, Part 1, Section 4).

The Contractor shall wrap all unprotected joints in the trench with a petrolatum tape system approved by the Superintendent.

The jointing system shall be rubber ring (elastomeric), complying with AS1646, unless shown otherwise on the design drawings.

The Contractor shall not lay continuously welded steel pipelines parallel to, when in close proximity, high voltage power lines.

(7) Copper pipe and fittings

Copper tube and fittings shall comply with AS1432 and shall be of the size and type as shown on the design drawings.

The Contractor shall install copper tube, capillary and compression fittings, insulated from ferrous mains, as shown on the design drawings (WSA 03).

(8) Polyethylene (PE)

Polyethylene pipe shall comply with AS/NZS4129 and AS/NZS4130 and shall be of the class and size as shown on the design drawings and installed in accordance with AS2033 (WSA 03 – 2011, Part 1, Section 4).

Jointing shall be by butt thermal fusion or by electrofusion couplings, or with compression fittings.

Fittings up to 110mm shall comply with AS/NZS4129. Fittings from 110mm to 600mm shall be ductile iron in accordance with AS/NZS2280 and coated internally and externally in polyethylene in accordance with AS/NZS4129.

The Contractor shall provide pipe of the appropriate external diameter consistent with the required internal diameter shown on the design drawings.

(9) Steelwork

Structural steelwork, including ladders, brackets, and covers, complying with AS1657, shall be abrasive blast cleaned to AS1627.4 Class 2.5 and hot dip galvanised to AS/NZS4680. (WSA 03 – 2011, Part 1, Section 4.)

SC6.4.6.2.3 Valves and hydrants

(1) General

The Contractor shall ensure that the valves and hydrants supplied are compatible with the pipework such that proper sealing is provided between the pipe flanges and the valve. The concrete lining in pipework shall not be chipped away or reduced to provide clearance from the working parts of valves.

The Contractor shall ensure that the valves and hydrants are installed so as to facilitate maintenance. The Contractor shall take into account the manufacturer’s recommendations, the requirements shown on the design drawings, the type of connection, lubrication of connecting bolts, and the location of valves within valve chambers or type of backfill material. (WSA 03 – 2011, Part 2, Section 15.13.)

The type of external corrosion protection of buried valves and hydrants shall be fusion-bonded medium density polyethylene coating to AS3862 and AS/NZS4321 or thermal-bonded polymeric coating to AS/NZS4158.

Flanges shall comply with AS2129 and AS4087 and shall be of the class and size shown on the design drawings.

(2) Stop valves

Sluice valves shall be resilient seated valves manufactured in accordance with AS2638. The valves shall be flanged where permitted by the Townsville Water and Waste unless shown otherwise on the Drawings (WSA 03 - 2011 Part 1, Section 8.2).

Ball valves shall be flanged where permitted by the Townsville Water and Waste unless shown otherwise on the Design drawings (WSA 03 - 2011 Part 1, Section 8.2).

Butterfly valves shall be flanged where permitted by the Townsville Water and Waste unless shown otherwise on the Design drawings (WSA 03 - 2011 Part 1, Section 8.2).

Knife Gate valves shall be flanged where permitted by the Townsville Water and Waste unless shown otherwise on the Design drawings (WSA 03 - 2011 Part 1, Section 8.2).

Scour valve assemblies shall be as shown on the Design drawings.

Valves shall be operated by a removable key. The Contractor shall size “Tee Key” valve operators and hand wheels to operate the valves under all operating conditions throughout their full range with no greater than 180 Newtons applied to the ends of the key bar or the rim of the wheel.

Hand wheels, where specified, shall display an embossed or engraved arrow, together with “open” and/or “close” corresponding to the valve operation.

(3) Air valves

Air valves shall be of the double air valve type with integral isolating valve of minimum size DN80, and shall be installed as shown in the Design drawings (WSA 03 – 2011 Part 1, Section 8.4).

Air valves shall be installed such that they can be maintained without affecting supply.

The Contractor shall obtain the consent of Water Authority for the use of other types of air valves.

(4) Non-return valves

Non-return valves shall be of the swing check type to AS3578 or AS4794 of cast iron or steel body, cover and disc with bronze body and disc seat rings. The leaf shall swing clear and provide an unobstructed waterway (WSA 03 – 2011 Part 1, Section 8.5). Wafer style non-return valves shall not be used.

The body cover shall be located and sized to allow the valve flap to be removed and the seat to be inspected without removing the valve body.

Where shown on the design drawings, non-return valves shall have an extended spindle, minimum grade 316 stainless steel complying with AS1449, fitted with an adjustable counterweight, together with a proximity switch to indicate a no-flow condition.

No flow switches shall have the following features:

(a) be of the eccentric cam operated limit switch type.

(b) have a minimum rating of 10 amps, 240 V AC, 50- Hz.

(c) be oil tight and dust proof to IP 65.

(d) be suitable for 25mm conduit entry.

(e) be mounted on rigid stainless steel complying with AS1449 adjustable brackets. The brackets shall be free of sharp edges and exposed corners.

(5) Spring hydrants

Spring hydrant bodies shall be manufactured in accordance with AS3952 and installed in accordance with AS2419.2 except as varied below (WSA 03 - 2011 Part 1, Section 8.8).

The top of spring hydrants shall be between 100mm and 300mm below finished surface level as detailed in SC6.4.4.8 Standard drawings SD-350. If necessary, this shall be achieved by the use of hydrant risers of various heights.

Spring hydrants shall be protected internally and externally with fusion-bonded coating in accordance with AS4158, or equivalent protection approved by the Superintendent.

(6) Pressure reducing valves

Pressure reducing valves shall be of the type as shown on the design drawings.

Pressure reducing valves shall be installed with isolating valves to facilitate maintenance.

SC6.4.6.2.4 Pipeline construction

(1) General

The Contractor, employees, or subcontractors, engaged in excavations, including tunnelling, are to be accredited for the work. Proof of accreditation must be provided to the Superintendent for approval prior to the release of the hold point.

The Contractor shall not change the pipeline alignment without prior concurrence of Townsville Water and Waste. The Contractor shall provide full details, of any proposed changes to the pipeline alignment, to the Superintendent for submission to Townsville Water and Waste. The Superintendent shall obtain the decision of Townsville Water and Waste prior to the release of the hold point.

(2) Location

The location of the mains and pump stations, sizes of mains, types of chambers and covers and the classes of pipes shall be as shown on the design drawings. The pipelines shall be laid to grades and locations shown on the design drawings and to tolerances in the Water Supply Code unless directed otherwise by the Superintendent (WSA 03 – 2011, Part 2, Section 21). The Contractor shall confirm the locations immediately prior to construction (WSA 03 – 2011, Part 2, Section 11).

(3) Cover over pipelines

The minimum depth of cover to be provided for mains, measured vertically from the finished ground level to the top of any socket, shall be in accordance with SC6.4.4.8 Standard drawings SD-325:

Lesser cover may be provided where special protection of the pipelines has been shown on the design drawings or directed by the Superintendent.

The maximum cover shall be 1200mm, however, greater cover may be provided where special situations occur, where there is conflict with other services or to meet grading requirements.

(4) Crossings

Where a pipeline crosses a road, creek or involves features shown on the design drawings, under the control of any Authority, the Contractor shall carry out the work in accordance with the requirements of that Authority. The Contractor shall provide written notification to the Authority of the intention to carry out the work, and pay the appropriate fees. (WSA 03 - 2011 Part 2, Section 15.16.) The Contractor shall obtain the written approval from the Authority prior to commencement of work. Such written approval shall be supplied to the Superintendent if requested. The Superintendent shall advise at the time of notification by the Contractor whether the option to request the written approval is to be exercised.

Where shown on the design drawings, the Contractor shall use trenchless methods for the installation of the mains. The installation of the main by open trenching shall not be permitted over the lengths designated for trenchless installation (WSA 03 – 2011 - Part 2, section 15.15).

The Contractor shall address, in its method statement for trenchless conduit installation, the following:

(a) general description of method and sequence of operation;

(b) size, depth and position of temporary pits required;

(c) use of specialist subcontractors;

(d) specialist equipment to be used; and

(e) grout type and method of injection.

The encasement pipe shall be as detailed on the design drawings. The encasement pipe shall extend 1m behind the back of kerb on either side of the carriageway.

The carrier pipe shall be positioned on support cradles and the carrier pipe shall be centrally located within the encasement pipe.

After installation and pressure testing of the carrier pipe, the Contractor shall fill the annular space between the carrier pipe and the encasement pipe with suitable grout or cementitious grout filler.

Where the carrier pipe is ductile iron cement lined (DICL), any length of pipe which is enclosed within the encasement pipe need not be wrapped in polyethylene tubing.

(5) Earthworks

The Contractor shall carry out all excavations for structures and pipelines to the lines, grades and forms shown on the design drawings or as directed by the Superintendent within the specified tolerances.

With excavation near existing underground services and structures, the Contractor shall be responsible in obtaining approval of the appropriate Authority and comply with all the requirements of the approval including having regard for drainage, dewatering, silt control, noise abatement, proximity to existing buildings and generally for the amenity of adjacent owners (WSA 03- 2011, Part 2, Section 13). The Contractor shall locate, protect and repair, as necessary, all services affected by the Works at the Contractor's expense.

The Contractor shall leave a clear space of 600mm minimum between the edge of any excavation and the inner toe of stockpiles. No excavated materials shall be stockpiled against the walls of any building or fence without the written permission of the owner of such building or fence. Topsoil from excavations shall be stockpiled separately and utilised to restore the surface after backfilling.

At the completion of work each day, the Contractor shall install safety fencing to statutory requirements along the edges of open excavations to isolate them from the public. The Contractor shall provide fenced walkways and vehicular crossings across trenches to maintain access at all times from carriageway to individual properties or within individual properties and advise all affected residents beforehand. All installations shall be of adequate size and strength and shall be illuminated to prevent accidents.

The Contractor shall carry out erosion and sedimentation control at all construction sites in accordance with *Best Practice Erosion and Sediment Control.*

The Contractor shall take account of safety issues and possible wet weather effects to limit the extent of excavation left open. (WSA 03 - 2011 Part 2, Sections 13.1 and 13.2.)

(6) Minimum trench width for pipelines

The minimum clear width of trench (inside internal faces of timbering or sheet piling, if used) to a height of 150mm above the top of the pipe shall be as shown in Table SC6.4.6.2.1.

Table SC6.4.6.2.1 Minimum trench widths

NOMINAL SIZE OF PIPE (DN)	Minimum clear width of trench(mm) (inside timbering or sheet piling, if any)	
	Pipe other than PVC/PE	PVC/PE Pipe
100	450	450
150	450	450
200	500	450
225	550	500
250	550	500
300	600	550
375	700	650
400	700	650
450	750	700
500	850	800
525	850	800
600	950	900

Where the design drawings provide for a trench to be excavated across a paved or improved surface, the width of the trench shall be kept to a minimum. Bitumen and concrete surfaces shall be carefully cut, by sawcutting or other means approved by the Superintendent, so as to provide a neat straight line free from broken ragged edges. The Contractor is responsible in obtaining approval from the relevant Authority and/or owner before starting any excavation across paved or improved surface.

The Contractor shall widen the trench where necessary for the installation of valves and fittings and protective coating systems.

(7) Excavation depth

The Contractor shall excavate trenches to 75mm below the underside of the pipe barrel and socket or coupling except for mains to be laid on other than rock foundations or as otherwise shown on the design drawings.

The excavation shall be carried out such as to ensure solid and uniform support for each pipe over the whole length of barrel with chases provided for joints and wrapping.

(8) Support of excavation

The Contractor shall adequately support all excavations to statutory requirements as the Works proceed. When withdrawing supports, the Contractor shall exercise every precaution against slips or falls (WSA 03 – 2011 Part 2, Section 13.5).

The Contractor shall ensure that timber is left in place where its removal may endanger structures in the vicinity of the excavation.

(9) Pipe bedding

When excavation of the trench has been completed the Contractor shall obtain the Superintendent's approval prior to commencing pipe laying, jointing and bedding. The Superintendent’s approval of the excavated trench is required prior to the release of the hold point.

Crusher screenings shall only be used for pipe bedding where sand or other non-cohesive material is not readily available locally or where the Contractor can demonstrate that its use will not impede repair operations. (WSA 03 – 2011 Part 2, Section 14.)

Pipes (excluding PVC/PE pipes) may be laid directly on other than rock foundation. The Contractor shall provide non-cohesive granular bedding, having a minimum thickness of 100mm below the barrel and socket of the pipe, where rock or other hard material occurs in the bottom of the trench. The bedding material shall conform to the sands classification described in SC6.4.4.8 Standard drawings SD-370, either loose clean sand and /or medium dense clean sand.

For PVC/PE pipes, irrespective of foundation, the material to be used for pipe bedding (underlay a minimum of 75mm below the underside of the pipe barrel and socket, side support and overlay to a depth of 150mm above the top of the pipe) as shown in Figure 5.1 in AS2032 shall be in sand or other non-cohesive granular material, either crushed, natural or blended, and its grading shall fall within the limits in Table SC6.4.6.2.2, except that where the materials cannot be reasonably sourced from within the vicinity, the Contractor may use materials satisfying the classification in the second paragraph above provided also that the material meets the requirements for passing sieve sizes 9.5mm and 6.7mm shown in Table SC6.4.6.2.2:

Table SC6.4.6.2.2 Grading of bedding material for PVC and PE pipes

Sieve size aperture width (AS1152)	Equivalent BS sieve size (BS410)	Percentage passing
9.5 mm	3/8 inch	100
6.7 mm	1/4 inch	90 - 100
425 µm	No. 36	40 - 90
150 µm	No. 100	0 - 10

All mains laid on grades steeper than 50% shall be encased in concrete as detailed on the design drawings.

(10) Laying and jointing of pipes

Unless detailed otherwise in this sub-section, the Contractor shall install pipes in accordance with AS/NZS2032, AS2033, AS/NZS2566.1 or AS3690 as appropriate (WSA 03 - 2011 Part 2, Sections 15, SC6.4.4.8 Standard drawings SD- 315 and SD-320).

Before being laid, all pipes, fittings, valves, and materials to be used shall be cleaned and examined by the Contractor and, if required by the Superintendent, the Contractor shall suspend each one in a sling to enable the Superintendent to inspect it. If directed by the Superintendent, the Contractor shall oil valves and repack valve glands.

The Contractor shall ensure that the interior of the pipeline is clean and free from obstructions. Plugs shall be used to prevent foreign matter entering sections of pipeline which are left uncompleted overnight.

The Contractor shall take all necessary precautions to prevent flotation of pipes during laying, backfilling and initial testing. Any temporary supports shall be removed prior to completion of backfilling.

Except where solvent cement joints are needed to make up or install fittings, joints in pipelines shall be flexible, rubber ring (elastomeric) joints, either roll-on or skid type or, where shown on the Design drawings, mechanical joints, either fixed flange or bolted gland type.

For pipes with rubber ring (elastomeric) joints, only the lubricant specified in writing by the manufacturer shall be applied in making the joint. The Contractor shall make the joint such that the witness mark shall, at no point, be more than 1mm from the end of the socket.

Pipes may be cut as needed or directed by the Superintendent to suit closing lengths, to remove damaged pipe or fittings or to remove sockets if necessary when jointing a socketed fitting.

For field cuts, a mechanical pipe cutter shall be used, except that PVC/PE pipes may be cut using a power saw or a fine toothed hand saw and mitre box. For field cuts of ductile iron or steel, the Contractor shall ensure that fire fighting equipment, in working order, is on the site prior to the field cuts being made. If the Contractor proposes to use a petrol engined pipe cutter in an excavation, the Contractor shall ensure that a safe atmosphere is maintained in the excavation at all times.

The Contractor shall prepare the ends of any pipes cut in the field to the manufacturer’s written instructions, or as directed by the Superintendent.

Where pipes are cut in the field, the Contractor shall make a witness mark on the pipe using a felt-tip marking pen at the length specified by the manufacturer from the end of the pipe. The Contractor shall not use PVC/PE pipes with scored witness marks. Where the same manufacturer does not make spigots and sockets, the

Contractor shall refer to the socket manufacturer for the correct marking depth.

Where PVC/PE pipes are to be joined to ductile iron pipes, the joints shall be made by inserting a PVC/PE spigot into a ductile iron socket. Ductile iron spigots shall not be joined to PVC/PE sockets. Alternatively, multi-fit mechanical couplings or flanged adaptor couplings may be used to join pipes of different materials.

The Contractor shall conform to the relevant statutory and work, health and safety requirements when cutting and disposing of asbestos cement pipes and submit a method statement for approval of the Superintendent.

Flexibly jointed pipelines with gradual changes in alignment or grade shall be laid with the joint being deflected after it has been made. The Contractor shall comply with the manufacturer's written recommendations in respect of maximum deflection for each joint provided that no joint shall be deflected to such an extent as to impair its effectiveness.

The maximum angle of deflection between adjacent pipes shall be limited to 2o or 0.035 radian in areas subject to mine subsidence or slippage.

Unless otherwise directed by the Superintendent, the Contractor shall lay pipes on continuously rising grades from scour valve to air release valve, notwithstanding any minor irregularities in the ground surface. Detectable identification tape shall be laid along the line of non-metallic mains within 150mm of the finished surface (SC6.4.4.8 Standard drawings SD-325).

(11) Trench stops

Where a pipe is laid on bedding at a grade of 5% to 14%, the Contractor shall construct, as below, trench stops consisting of bags filled with clay, or sand or cement stabilised sand and sealed: (SC6.4.4.8 Standard drawings SD-374)

(a) at the socket side of the joint nearest to the position of a stop required in accordance with the formula hereinafter, a recess 100mm deep to suit the width of bag shall be excavated into the bottom of the trench across its full width and into both sidewalls and extend to within 300mm below finished surface level; and

(b) the bags shall be placed around and above the pipe, as in (a) above, so as to give close contact with the pipe and to fill the entire space between the excavated recess and the pipe. Bags shall not be placed onto sand bedding.

The distance between trench stops shall be determined by the following formula:

$$D = \frac{100}{G}$$, whereby

D = Distance between stops in m

G = Grade of pipe expressed in %.

(12) Concrete bulkheads

Where a pipe is installed at a grade of 15% to 29%, the Contractor shall construct concrete bulkheads. Where a pipe is installed at a grade 30% to 50%, the Contractor shall construct concrete bulkheads integral with concrete encasement. Where a pipe is to be installed at a grade of 50% or more the Contractor shall provide a site specific design. Bulkheads shall be of 25MPa concrete complying with SC6.4.6.28 Minor concrete works, 150mm minimum thickness as follows: (SC6.4.4.8 Standard drawings SD-374 and WSA 03 – Part 2, Section 15.10)

(a) Where concrete bedding or encasement to pipe is required, the 150mm thick bulkhead shall be cast integral with the concrete bedding or encasement across the width of trench and shall be keyed into both sidewalls a minimum of 150 mm. The bulkhead shall extend to 300mm below finished surface level or such other level as directed by the Superintendent.

(b) Where other bedding, or no bedding, is applicable, the bulkhead shall also be keyed into the bottom of the trench 150mm for the full width of trench.

(c) A 75mm nominal diameter drain hole shall be provided in the concrete bulkhead immediately above the top of the encasement bedding or foundation and crushed rock or gravel shall be placed in and at the upstream end of the drain hole to act as a filter. The gravel shall be 10 to 20mm in size within 150mm in all directions upstream and above the invert of the drain hole beyond which another 150mm thick

surround of gravel 2 to 10mm in size shall be placed.

The distance between concrete bulkheads shall be determined by the following formula:

Concrete bulkhead (grade of 15% to 29%)

$$D = \frac{L}{G}$$

Concrete encasement (continuous) and concrete bulkhead (grade of 30 per cent to 50 per cent)

$$D = \frac{100}{G}$$, whereby

L = 80 X Pipe length, m

= 450m max

if L> 100m use intermediate trench stops at spacing < 100/G

D = Distance between bulkheads in m

G = Grade of pipe expressed in %

(13) Valve and hydrant chambers

The Contractor shall construct around each valve and hydrant a chamber of the type and to the details shown on the Design drawings (WSA 03 – 2011, Part 2, Section 15.13).

The concrete shall comply with SC6.4.6.28 Minor concrete works.

Valve chamber covers shall be painted with white pavement marking paint while hydrant chamber covers shall be painted with yellow pavement marking paint.

Where the type of valve chamber is such that the body, or part of the body, of the valve is to be backfilled before the valve chamber is constructed, the Contractor shall either wrap the valve using a tape consisting of synthetic fibre open weave cloth impregnated with saturated hydro-carbons, applied in accordance with the valve manufacturer's written instructions, or apply at least one coat of corrosion preventing material to the valve body after the valve has been installed but before backfilling. The coating material shall be compatible with the coating material which has been applied to the valve prior to delivery.

(14) Chamber covers and frames

Covers and frames shall not be warped or twisted. Surfaces shall be finished such that there are no abrupt irregularities and gradual irregularities shall not exceed 3mm. Unformed surfaces shall be finished to produce a surface that is dense, uniform and free from blemishes. Exposed edges shall have a minimum 4mm radius.

Tolerances for the dimensions on the COVER shall be - 3mm + NIL.

Tolerances for the dimensions on the FRAME shall be - 3mm + 3mm.

Covers shall be seated as shown on the design drawings or as directed by the Superintendent.

Covers shall be finished flush with the surface in road pavements, footpaths and other paved surfaces. Elsewhere, covers shall be finished 25mm above the surface of the ground, or such other level as directed by the Superintendent, in a manner designed to avoid as far as possible, the entry of surface water.

Cast iron covers and frames shall be manufactured in accordance with AS3996 and shall be installed and filled with concrete, as necessary, in accordance with the manufacturer's written requirements.

The Contractor shall take care to avoid lateral movement, cracking and subsidence when installing plastic covers and frames.

(15) Service connections

Not applicable.

(16) Thrust and anchor blocks

Thrust and anchor blocks shall be constructed where shown on the design drawings to the dimensions depicted therein or as otherwise directed by the Superintendent. The blocks shall be provided at valves, flexibly jointed bends, tees, enlargers and reducers or any other point where unbalanced forces resulting from internal pressures will occur (SC6.4.4.8 Standard drawings SD-371 and WSA 03 – 2011, Part 2, Section 15.7).

The Contractor shall provide permanent thrust blocks of 20 MPa concrete, complying with sub-section SC6.4.6.28 Minor concrete works, such that the thrust blocks bear against undisturbed material normal to the direction of thrust resulting from internal pressures over the bearing area not less than that directed by the Superintendent.

The Contractor shall provide permanent anchor blocks of 20 MPa concrete, complying with sub-section SC6.4.6.28 Minor concrete works, of a volume not less than that directed by the Superintendent.

The Contractor shall provide temporary anchorages adequate to restrain the pipe when under test.

The Contractor shall obtain the consent of Townsville Water and Waste for the type and use of restrained joints, as an alternative to thrust blocks, in the case of congested service corridors and urgent commissioning.

(17) Concrete encasement

The use of Concrete encasement shall not be permitted unless otherwise approved by the Townsville Water and Waste.

(18) Wrapping of pipelines

Where shown on the design drawings, the Contractor shall enclose a pipeline or a section thereof, in lay-flat polyethylene sleeving (WSA 03 – 2011, Part 2, Section 15.11).

The materials to be used shall be high impact resistance polyethylene sleeving, of minimum thickness 0.2 mm polyethylene film approved by the Superintendent and 50 mm wide plastic adhesive tape.

The width of the sleeving when flat shall be in accordance with the manufacturer's written recommendations for the size and type of the pipeline which is to be encased. Precautions shall be taken so that exposure to direct sunlight does not exceed 48 hours.

For dual trenching, pipelines shall be identified by colour sleeving, blue stripe for potable water and lilac for recycled water, or an appropriate identification tape.

Application of the polyethylene sleeving and plastic adhesive tape shall be in accordance with the pipe manufacturer's written instructions or as directed by the Superintendent. The Contractor shall take due care not to damage the sleeving during its application or during the backfilling of the trench. Each pipe shall be encased in a length of sleeving overlapped for a minimum of 25 0mm at each field joint, and the ends of each length of sleeving shall be held in position with at least three circumferential turns of adhesive tape. As the polyethylene sleeving material covering the pipe will be loose, excess material shall be neatly drawn up around the pipe barrel, folded into an overlap on top of the pipe and held in place by means of strips of plastic tape at approximately 1 metre intervals. Bends, tapers and similar fittings shall be covered by polyethylene sleeving as specified for the pipes. The Contractor shall hand wrap valves, hydrants and irregular shaped fittings and joints using flat polyethylene sheets secured with plastic adhesive tape, or other suitable material, to provide an adequate seal. The flat polyethylene sheets may be obtained by splitting suitable lengths of sleeving.

The Contractor shall rectify any damage done to the polyethylene sleeving before, during or after backfilling of the trench.

(19) Corrosion protection of steel bolts and nuts

The Contractor shall wrap all galvanised steel bolts and nuts, used for installation below ground, of flanges, bolted gland joints, mechanical joints, tapping bands using a tape, approved by the Superintendent, consisting of synthetic fibre open weave cloth impregnated with saturated hydrocarbons applied in accordance with the manufacturer’s recommendations or as directed by the Superintendent. Bolts and nuts shall be dry, clean and

free from rust immediately before wrapping.

SC6.4.6.2.5 Pipeline testing and restoration

(1) Testing of pipelines

The hydrostatic pressure testing shall be conducted in accordance with Section 6 and Appendix M of AS/NZS 2566.2.

The Contractor shall pressure test mains to detect leakage and defects in the pipeline including joints, thrust and anchor blocks. Pipelines shall be tested in sections approved by the Superintendent as soon as practicable after each section has been laid, jointed and backfilled provided that:

(a) if so specified, or if the Contractor so desires, some or all of the pipe joints shall be left uncovered until the whole of the section has been successfully pressure tested to the satisfaction of the Superintendent; and

(b) the pressure testing shall not be commenced earlier than seven days after the last concrete thrust or anchor block in the section has been cast.

For the purpose of this clause, a section shall be defined as a length of pipeline which can be effectively isolated for testing, e.g. by means of main stop valves.

Pressure testing shall not be carried out during wet weather unless otherwise approved by the Superintendent.

During pressure testing, all field joints, which have not been backfilled, shall be clean, dry and accessible for inspection.

During the pressure testing of a pipeline, each stop valve shall sustain at least once, the full test pressure on one side of the valve in closed position with no pressure on the other side for at least 15 minutes.

Before testing a pipeline section, the Contractor shall flush and clean it to the satisfaction of the Superintendent and fill it slowly with water, taking care that all air is expelled. Purging of air from rising mains shall be promoted by opening air valves. In order to achieve conditions as stable as possible for testing by allowing for absorption, movement of the pipeline and escape of entrapped air, the section shall be kept full of water for a period of not less than 24 hours prior to the commencement of the pressure testing.

The hydrostatic test pressure, which shall be applied to each section of the pipeline, shall be 1200 kPa.

The Contractor shall maintain the specified test pressure as long as required by the Superintendent while the Contractor examines the whole section. In any case, the specified test pressure shall be maintained for not less than 4 hours. For the purpose of determining the actual leakage losses, the Contractor shall carefully measure and record the quantity of water added in order to maintain the pressure during the period of testing.

The pressure testing of a section shall be considered to be satisfactory if:

(a) there is no failure of any thrust block, anchor block, pipe, fitting, valve, joint or any other pipeline component;

(b) there is no visible leakage;

(c) the measured leakage rate for pipes other than PE does not exceed the permissible leakage rate as determined by the following formula:

$Q_1 = 0.14DLH$

where:

Q_1 = permissible leakage rate (litres per hour)

D = nominal diameter of pipe (m)

L = length of section tested (km)

H = average test head (m): and

(d) for PE pipes:

$V_2 \leq 0.55V_1 + 0.14DLH$
where:
V_1 = water volume (litres) added between Hour 2 and Hour 3 to maintain test pressure
V_2 = water volume (litres) added between Hour 4 and Hour 5 to maintain test pressure
D = nominal diameter of pipe (m)
L = length of section tested (km)
H = average test head (m)

Any failure, defect, or visible leakage which is detected during the pressure testing of the pipeline or during the defects liability period shall be made good by the Contractor at the Contractor's expense. This constitutes a hold point.

Unless directed by the Superintendent, the maximum test length shall be 1000m.

(2) Connection to existing pipes

Connections to existing pipes carrying water shall be made at such times as will cause the least interference with the supply. The Contractor shall make arrangements with Townsville Water and Waste or other Authority concerned for the timing of the work including the need to isolate the existing mains and notification of affected dwelling occupants. The Superintendent shall be given 5 working days notice of such arrangements (WSA 03 – 2011 Part 2, Section 22.).

(3) Disinfection and flushing of pipelines

The Contractor shall disinfect all water mains after satisfactory testing in accordance with this sub-section (WSA 03 – 2011 Part 2, Section 20). The Contractor shall adopt procedures for the disinfection of the mains with the concurrence of Townsville Water and Waste. All test results submitted are required to be NATA certified.

After disinfection and testing is completed, the Contractor shall flush all water mains to ensure that the disinfected water used in the process do not enter sections of the system already in service. Flushing and disposal of disinfected water shall be in accordance with WSA 03 – 2011 Part 2, Section 20.2.

(4) Bacteriological testing

(a) General

Disinfection of a water main may be required to ensure suitable water quality parameters are maintained. When disinfection of a main is required, bacteriological testing of the disinfected water must be undertaken.

Disinfection may also be required where there is a likelihood of contamination. A bacteriological test must also be undertaken on all new disinfected mains following satisfactory completion of swabbing/flushing and pressure testing of the water main.

(b) Test procedure

Water mains shall be tested as follows:

(i) scour past the sampling point;

(ii) engage a NATA registered laboratory to collect representative water samples from the test section of the water main; and

(iii) dispose of testing water in accordance with the relevant environmental Regulator and/or Water Agency requirements.

(c) Satisfactory bacteriological test

The water main will be deemed compliant if:

(i) the test results fall within the water quality parameter limits specified in the Table SC6.4.6.2.3; or

(ii) the water quality parameter test results in the test section of water main are no worse than the water quality parameter test results measured by testing an influent sample of existing mains water, provided that the influent sample was collected by the NATA registered laboratory at the

same time as water sample from the test section of water main was collected.

Table SC6.4.6.2.3 Water quality parameter limits

Water quality parameter	Unit	Acceptable range
pH	-	6.8–8.5*
Chlorine (free)	mg/L	0.5–2.0
Total Coliform count	cfu/100mL	0
Faecal Coliform count or E.Coli count	cfu/100mL	0
Heterotrophic Plate count	cfu/mL	0–10

* for cement mortar lined mains an upper level pH of 9.2 is acceptable

For failed tests, the water main shall be swabbed, flushed and/or disinfected and then re-tested. This shall be undertaken until all test results are satisfactory.

(5) Backfill and compaction

After laying and jointing of a pipeline has been completed the Contractor shall present the laid and jointed pipes for inspection by the Superintendent prior to the commencement of trench backfilling. The Superintendent's approval to the laid and jointed pipes is required prior to the release of the hold point. Backfill shall not be placed until the Superintendent has given approval.

Material for the side support and overlay of the pipe shall comply with the requirements for pipe bedding specified SC6.4.6.2.4(9) Pipe bedding. The material shall be compacted in layers of not more than 150mm to a Density Index of 70 as determined in accordance with AS1289.5.6.1 and with reference to WSA 03 – 2011, Part 2, Section 16.3.

The Contractor shall backfill the remainder of the excavation and compact the backfill in layers of not more than 150mm thick as follows: (WSA 03 – 2011, Part 2, Section 17).

(a) where the trench is within a roadway, proposed roadway, or footpath area, the remainder of the trench shall be (WSA 03 – 2011, Part 2, Section 17):

(i) backfilled with a non-cohesive granular material, with a grading falling generally within the limits detailed herein for pipe bedding, and compacted to Density Index of 70 when determined in accordance with AS1289.5.6.1 for cohesionless materials:

(A) below 0.3m of the subgrade road surface; and

(B) in the road reserve, up to top of overlay zone;

(ii) backfilled with selected material, and compacted to 100% of the standard maximum dry density of the material when determined in accordance with AS1289.5.4.1, to top of subgrade level of the road surface, but excluding the pavement layers;

(iii) backfilled with selected material, and compacted to 95% of the standard maximum dry density of the material when determined in accordance with AS1289.5.4.1, to finish surface level of the areas of trench outside of roadways; and

(iv) backfilled with road base and sub-base material as per existing or proposed pavement layers and compacted to 100% of the standard maximum dry density of the material when determined in accordance with AS 1289.5.4.1.

(b) elsewhere, unless stated otherwise, the remainder of the trench shall be backfilled with ordinary excavated backfill material. Where suitable material is not available, granular material may be used for the full depth of backfilling. The material shall be compacted to a density Index of 70 when determined in accordance with AS1289.5.6.1 for cohesionless materials or 98% of the standard maximum dry density of the material when determined in accordance with AS1289.5.7.1 for cohesive materials.

The Contractor shall carry out backfilling and compaction without damaging the pipe or its external coating or wrapping or producing any movement of the pipe.

The Contractor shall carry out compaction tests 75mm to 100mm below the level being tested.

Where a roadway is to be sited over existing infrastructure, excavation of trench material down to overlay zone and subsequent backfilling with appropriate select material to the underside of sub-base to the compaction requirements stated above.

The Contractor may compact backfill by trench flooding only where:

(i) the ground and backfill material is cohesionless sand;

(ii) water for flooding has been sourced at the site;

(iii) the process will not create mud which would be moved off site by vehicles or construction plant. The process is closely monitored to ensure adequate volumes are added to sufficiently compact the materials to achieve the compaction requirements as specified in WSA 03 – 2011, Part 2 – Table 19.1; and

(iv) additives are not used.

(6) Valve and hydrant marking

The Contractor shall clearly mark the position of each stop valve, scour valve, air valve and hydrant on completion of backfilling in a manner and position in accordance with SC6.4.4.8 Standard drawings SD-345 and/or shall be consistent with the method(s) in use by Townsville Water and Waste.

Where, in the opinion of the Superintendent, a valve or hydrant is at too great a distance from any existing wall, fence, kerb face, or post, the Contractor shall provide and set in the ground a post with the relevant marking plate fixed at the top of the post, facing the fitting. The distance to the valve or hydrant in metres, to an accuracy of 0.1m, shall be permanently marked on the plate with legible numbers a minimum 80mm high. Wooden posts are not to be used where there is evidence, by rotting or termite activity, that the integrity of the posts will be affected.

The post shall conform to the following requirements:

(a) the post shall be of sufficient length to be set firmly in place under saturated ground conditions;

(b) when installed, the post shall project 1000mm above the ground, provided that where tall grass or crops are likely to obscure the post, its height above the ground shall be increased to 1500mm; and

(c) the post shall be painted with 2 coats of white enamel for exterior use.

The Contractor shall fix marking plates as soon as practicable after each valve or hydrant is installed. However, the Contractor shall temporarily cover marking plates for hydrants using masking tape or other approved cover which the Contractor shall remove on satisfactory completion of the pressure testing of the pipeline.

For hydrants, the Contractor shall affix blue two-way reflective raised pavement markers to the road pavement in accordance withSC6.4.4.8 Standard drawings SD-345.

(7) Restoration of surfaces

The Contractor shall clean pavements, lawns and other improved areas and leave them in the same order as they were at the commencement of the Works. The Contractor shall restore any fencing removed during construction and shall restore lawns with turf cut and set aside from the original surface and with turf imported from a source approved by the Superintendent (WSA 03 – 2011, Part 2, Section 23). The restoration works shall be done progressively and as soon as possible after the section of works is completed.

The Contractor shall maintain all restored surfaces in the condition to which they are restored until the expiry of the defects liability period applicable to those surfaces, notwithstanding that any deterioration of the restored surfaces, and the need for their maintenance may or may not be due to defects which become apparent or arise from events which occur during the defects liability period. The Contractor shall maintain pavements with crushed igneous rock, gravel or other suitable material allowing for consolidation and shall then restore them to a condition equivalent to that of the original pavement.

The Contractor shall maintain all restored surfaces in the condition to which they are restored until the expiry of the defects liability period applicable to those surfaces, notwithstanding that any deterioration of the restored

surfaces, and the need for their maintenance may or may not be due to defects which become apparent or arise from events which occur during the defects liability period. The Contractor shall maintain pavements with crushed igneous rock, gravel, asphaltic concrete or other suitable material allowing for consolidation and shall then restore them to a condition equivalent to that of the original pavement. Final restoration may include, if required by the Superintendent, the removal of temporary restoration.

In other than roadways, the Contractor shall place the backfill sufficiently high to compensate for expected settlement and further backfilling shall be carried out or the original backfill trimmed at the end of the defects liability period in order that the surface of the completed trench may then conform to the adjacent surface. Surplus material shall be removed and disposed of to areas arranged by the Contractor. Where dry weather conditions have persisted after the original backfilling, including during the defects liability period, the Contractor shall take all necessary steps to consolidate the trench before removing surplus materials from the site.

In locations where, in the opinion of the Superintendent, surplus material left in the vicinity of the trench would not be objectionable, the surplus material may be disposed by spreading neatly in the vicinity of the trench to the satisfaction of the Superintendent in such a way as to avoid future erosion of the backfill and adjacent ground surfaces. The Contractor shall maintain the backfill and adjacent ground until the expiry of the defects liability period.

Where, within public or private property, the reasonable convenience of persons will require such, the Contractor shall level trenches at the time of backfilling or otherwise as directed by the Superintendent. The Contractor shall make good any subsequent settlement, as required by placing additional fill.

The Contractor shall immediately restore any damaged or disturbed private property and services.

Should the Contractor elect to tunnel under paving, kerb and channel or other improved surfaces in lieu of trenching, backfilling shall be so carried out as to restore full support to those surfaces, and payment shall be made for the restoration of the surfaces as though they had been removed and replaced. The Contractor shall remain responsible for the repair of the improved surfaces, if subsequently damaged due to subsidence of the backfill, until the end of the defects liability period.

The Contractor shall provide notice to affected property owners of any pending works.

SC6.4.6.2.6 Pump stations

(1) Pumps

Pump construction materials for centrifugal end suction pumps shall comply with the following:

DESCRIPTION	MATERIAL
PUMP	
Casing and suction bend	Cast iron AS1830 Gr T200
Wear rings	Cast iron AS1830 Gr T200
Impeller	316 Stainless steel AS1449
Impeller nut	Gunmetal AS 1565-905C
Shaft	316 Stainless steel AS2837
Shaft sleeve	Phosphor bronze AS1565-9060/316
Neck bush, lantern ring	Phosphor bronze AS1565-9060
Gland	Cast Iron AS1830 Gr T200
Gland studs	316 Stainless steel AS 2837
Gland nuts	316 Stainless steel AS2837
Fixing nuts and bolts handhold	316 Stainless steel AS2837
Covers	316 Stainless steel AS1449
Fitted bolts and nuts, casing and dowels	316 Stainless steel AS2837
Forcing screws	316 Stainless steel AS2837
Water thrower and drip tray	316 Stainless steel AS1449
Pump set base plate	Cast iron AS1830 Gr T200/Fabricated steel
MOTOR	

Motor frame and end shield	Cast iron/Mild steel
Motor terminal box	Cast iron/Mild steel
Motor fan cover	Mild steel
Motor fan	Metal
HOLDING DOWN BOLTS	316 Stainless steel AS2837
MECHANICAL SEALS	
Seal faces	Tungsten carbide or equal
Springs	Nickel chrome steel
Secondary seal	Fluoro carbon or nitrile rubber

The Contractor shall provide a written warranty from the Manufacturer of the equipment. This action constitutes a hold point. The Superintendent's approval of the warranty is required prior to the release of the hold point.

The Manufacturer's warranty shall require the Manufacturer to accept liability for any defect in materials or workmanship which becomes apparent at any time within two years after the date of delivery of any piece of equipment used in Work under the Contract.

All nuts and bolts shall be manufactured in accordance with AS/NZS1111 and AS/NZS1112 150 metric series and fitted with washers beneath bolts heads and nuts. Requirements are:

(a) all bolts, nuts and washers shall be stainless steel to AS1449 and AS2837, minimum grade 316. All bolts, nuts and washers are to be of the same grade and supplied passivated;

(b) all threads are to be rolled;

(c) all bolt heads and nuts shall be hexagonal;

(d) all bolts, studs, set screws and nuts for bolting flanges and other pressure containing purposes shall conform to AS2528;

(e) all nuts and bolts subjected to vibration shall be fitted with lock washers or lock nuts;

(f) all concrete anchor bolts, nuts, locking nuts and large series washers required for the bolting down of pump set discharge bends shall be provided. These anchor bolts shall be as recommended by the equipment designer with a minimum diameter of 16mm; and

(g) concrete anchor bolts shall be chemical masonry anchor type, set to their full depth, suitable for the required duty.

Bolts on all flanges will protrude no more than 10mm past the nut when tightened.

The Contractor shall apply sufficient anti-seize/anti-galling material to the threads of all stainless steel fasteners. The material shall be Polytetrafluoroethylene (PTFE), either tape to AS 1272, dipped or sprayed, or molybdenum disulphide.

(2) Pressure gauges

The Contractor shall install one diaphragm protected, glycerine oil filled, direct mounting, bottom connection pressure gauge complying with AS1349 per centrifugal pump installation. Cases shall be fabricated from stainless steel complying with AS1449 or bronze. The protective diaphragm shall be suitable for dismantling for cleaning without affecting the accuracy of the gauge.

The gauge face shall be 100mm in diameter and calibrated in metres head of water. The gauge shall accurately indicate the pump operating head and the pump no-flow head.

Each gauge shall be supplied with the nominally sized metric equivalent of three of the following bronze fittings: gate valve, union, nipple and reducing nipple.

Gauges and fittings shall be screwed into the pipe wall of ductile iron pipes, or pipe fittings, 150mm and larger. In pipework less than 150mm, gauges and fittings shall be screwed into a tapping band. Where shown on the design drawings, the Contractor shall install a ball valve to allow removal of the gauge.

The pressure gauge range for single or parallel pumps duty shall be 0 to 1.7 times the closed valve head of the pumps.

(3) Electrical compliance

The Works shall be in accordance with the requirements specified in SC6.4.3.21.4 Electrical and mechanical except where this sub-section or the Design drawings indicate otherwise. The technical requirements detailed on the Design drawings shall take precedence over the requirements of this sub-section should clauses be in disagreement.

Except where SC6.4.3.21.4 Electrical and mechanical requires a higher standard, works shall be carried out in accordance with AS/NZS3000, the service rules of the supply authority and all relevant statutory authorities.

The Contractor shall supply the Superintendent a proof of compliance with a standard or specified test. Such proof shall comprise a test certificate from an approved independent testing authority.

The Contractor shall submit all designs and material to each Authority having jurisdiction for approval. The Contractor shall arrange for each Authority having jurisdiction to inspect the works. The Superintendent shall be advised a minimum of 7 working days in advance of the date of any inspection by an Authority. The Superintendent shall advise at the time of notification by the Contractor whether the option to attend the inspections is to be exercised.

(4) Switchgear and control gear assembly (SCA)

The Contractor shall supply and install the SCA designed and assembled by a manufacturer approved by the Superintendent.

The SCA shall be of outdoor, stationary, free standing, metal-enclosed, cubicle type series with a minimum degree of protection of IP56D as specified in AS 60529.

All equipment shall be securely mounted on suitable mounting panels and comprise individual compartments. A hot dipped galvanised steel channel base shall be provided.

Starter contactors shall have the appropriate rating for the proposed pumps to AC3.

All necessary terminals with terminal and cable numbers shall be supplied and installed in accordance with the Design drawings.

The Contractor shall liaise with the electricity supply authority to supply pad locks for the metering equipment, at the Contractor’s expense. The Superintendent shall supply pad locks for use on the SCA at no cost to the Contractor.

The electrical characteristics of the SCA shall be:

Main Circuit: 415/240 V, 50 Hz, 3-phase, 4-wire.
Motor Control Circuit: 240 V, 50 Hz.
Common Control Circuit: 240 & 24 V, A.C.
Prospective short-circuit current: 14kA for 1 second.
Peak Factor: 2.2
Power Factor Correction (Determined in consultation with Townsville Water and Waste)
Earthing (M.E.N. system)

All cables shall enter the SCA from below.

The Contractor shall supply data from the switchgear supplier confirming Type “2” co ordination between contactors, motor protection relays and corresponding circuit breakers, to the Superintendent.

Refer to standard specification TCC24 clause 18 for starter selection requirements and functional specification

for the project.

The Contractor shall carry out factory tests in the presence of the Superintendent's Representative and in accordance with the requirements stipulated in SC6.4.3.21.4 Electrical and mechanical and the results shall comprise all routine Tests specified in AS3439.

Inspections and functional tests shall be in accordance with TCC24 clause 21.

The Contractor shall ensure, after approval has been given by the Superintendent, that any relays, programmable logic controllers, and fittings likely to be adversely affected during delivery shall be adequately protected or shall be removed and packed separately in protected containers. Where equipment has been removed, cover plates shall be provided.

The Contractor shall be responsible for any damage that may occur during transit and unloading at site.

The Contractor shall ensure that spare parts, tools etc., are packed separately from the main plant and shall be marked “Spare Parts”, “Tools” etc., as applicable.

The Contractor shall supply spare parts in accordance with the schedule supplied by the Superintendent.

The Contractor shall supply and install control equipment that is compatible with the existing equipment.

(5) Electrical installation

The Contractor shall liaise with the Supply Authority for the electricity supply to the pump station site.

The Contractor shall be responsible for all facilities required by the Supply Authority for revenue metering equipment and the payment of all associated connection, inspection fees and capacity charges.

The Contractor shall supply and install all cabling including consumer mains, motor, control and instrumentation cables, conduits and electrical pits.

The Contractor shall install all wiring in HD-PVC underground conduits laid in accordance with the Supply Authority’s requirements, with a minimum 500mm below the finished ground level in non-trafficable areas and 600mm below the finished ground level in trafficable areas. The trench and backfill material shall be free of rocks and other foreign matter likely to damage the conduits.

The Contractor shall run electrical marker tape 150mm below the finished ground level directly above the conduits for the entire length of the conduits. Marker tape shall be orange in colour, 150mm wide and stamped with the words “DANGER – ELECTRIC CABLES BELOW” or similar.

The Contractor shall route all underground cabling with the approval of the Superintendent. Brass marking plates shall be positioned on a concrete surround clearly showing the direction of the incoming consumer mains. Wording and markings shall read “DANGER – ELECTRICAL CABLES BELOW”. The Superintendent’s approval of the route of all underground cabling is required prior to the release of the hold point.

The Contractor shall determine the points of attachment on site and the Contractor shall supply and install any consumer’s connection poles for the consumer mains required by the Supply Authority.

The consumer mains shall be generally run underground and commence at the point of attachment on a steel consumers pole (if applicable), installed near the property boundary and run in conduit to the switchboard.

No aerial conductors are to be installed over structures, access road or vehicle manoeuvring areas.

The minimum size of the consumers’ mains shall be sized to satisfy the following requirements:

(a) current carrying capacity to suit the maximum demand with an excess current carrying capacity of 30% minimum;

(b) be sized for a voltage drop less than 1.5% to the maximum demand as calculated;

(c) be single core PVC/PVC cables. XLPE insulated cable may also be used;

(d) comply with the requirements of the Supply Authority; and

(e) AS/NZS3000 and AS/NZS3008.

In addition to the requirements of the Supply Authority and as specified in SC6.4.3.21.4 Electrical and mechanical (Townsville Water planning and design guidelines) the main earthing conductor shall be run in conduit to the main earthing electrode. The main earthing connection shall be contained in an earthing electrode connection box similar to ALM type ERB-1 up to 50mm2 cable and a Type 4 pit for larger cable.

Earth electrode shall be bonded and suitably labelled with an engraved brass label.

Surge diverters shall be earthed in accordance with manufacturer's instructions.

The Contractor shall bond the pump station metallic pipework to the main earth.

Refer also to TCC24 clause 28.1 for installation instruction requirements.

Metering equipment and installation shall comply with the Queensland Electricity Connections and Metering Manual.

The Contractor shall gland cables entering the outdoor SCA compartment using non-ferrous metallic or plastic glands with neoprene compression seals and connect the on-flow switch and pump motor cables to the appropriate terminals. Cables shall not be jointed.

The Contractor shall seal, at the completion of commissioning tests, all conduits into the outdoor SCA with a non-setting sealing compound to prevent the ingress of vermin.

(6) Testing and commissioning of pump station

The Contractor shall test and/or inspect all materials, equipment, installation and workmanship to prove compliance with the sub-section requirements. The submission to the Superintendent of satisfactory test results constitutes a hold point. The approval of the Superintendent is required prior to the release of the hold point.

Tests and inspections shall comply with relevant Australian Standards.

Testing shall include pre-commissioning, field testing and performance testing of each part of the whole installation.

Pre-commissioning is the preparation of plant or equipment so that it is in a safe and proper condition and ready for commissioning and operation. It includes all aspects of plant operation such as safety, electrical, mechanical and instrumentation.

The Contractor shall conduct pre-commissioning in a logical sequence in accordance with the programme prepared by the Contractor and approved by the Superintendent.

The Contractor shall prepare pre-commissioning record sheets for each item of equipment to ensure results of tests are satisfactorily recorded and that all necessary checks or tests have been performed.

Specific requirements for pre-commissioning shall include, but are not limited to:

(a) initial charges of lubricant in addition to any special lubricant requirements for initial flushing or treatment of the system or for "running in";

(b) physical checks and tests such as completeness of assembly, rotational tests (including checking that the rotation of electrical motors is in the correct direction), alignment checks, balancing and vibration checks, temperature, pressure and flow measurements, clearances, belt alignment and tension, etc.,

depending on the type of equipment;

(c) electrical and instrument installation tests, including motor insulation tests and checking instruments against certified instruments and correcting as necessary;

(d) tests of the correct functioning of automatic and manual control and protection equipment, including simulating danger conditions, mal-operations or failures, to check that all instruments and controls function correctly. These tests shall also include adjusting instrument set points and alarm settings and proving correct operation of alarms; and

(e) equipment and system operating tests. The Contractor shall certify compliance of each item and submit a signed copy to the Superintendent prior to commissioning.

The Contractor shall carry out pre-commissioning tests to the satisfaction of the Superintendent and shall record the results of the tests on the appropriate Pre-commissioning Record Sheet.

Refer to TCC24 clause 28.1.11 for electrical test documentation requirements.

The Contractor shall furnish the Superintendent with one signed copy of each completed Pre-commissioning Record Sheet countersigned by the Superintendent's Representative who witnessed the test.

Commissioning is the running of the plant and equipment to ensure flow through the pumping system, carrying out any necessary testing and adjustments until it is ready and suitable for normal starting and running under service conditions.

The Contractor shall give the Superintendent 5 working days notice of the Contractor’s intention to undertake commissioning and supply to the Superintendent the copies of each of the pre-commissioning record sheets and three copies of the operational and maintenance manuals at the time that notice of commissioning is given.

The Contractor shall conduct commissioning in a logical sequence in accordance with a programme prepared by the Contractor and approved by the Superintendent.

Throughout commissioning the Contractor shall be responsible for the test programme.

The Contractor shall provide continuous supervision by personnel experienced in the operation of the equipment and shall have qualified personnel in attendance to carry out all necessary adjustments and/or remedial work during the commissioning tests.

The Contractor shall prepare schedules, test record sheets and programmes for approval by the Superintendent prior to each stage of the overall commissioning.

The Contractor shall carry out final testing and commissioning (min 1 day duration) of the electrical services in conjunction with the mechanical equipment (e.g. pump, etc.) including setting and adjustment of equipment in accordance with the requirements in SC6.4.3.21.4 Electrical and mechanical (Townsville Water planning and design guidelines).

The Contractor shall arrange for all testing, commissioning and any adjustments to be carried out by qualified personnel.

(7) Practical completion of pump station

The Contractor shall fulfil the following requirements before the Certificate of Practical Completion is issued:

(a) receipt by the Superintendent of a certificate of approval from the relevant statutory authorities;

(b) pump station is in working order as demonstrated by the testing and commissioning;

(c) approval by the Superintendent of Operating and maintenance manuals; and

(d) receipt by the Superintendent of as-built drawings of the pump station.

(8) Telemetry

The Contractor shall make provision for equipment to link the pump station to the existing telemetry network to be provided by Townsville Water and Waste at the Contractor's expense. Refer to TCC24 clause 17.1, 28.2, Appendix B2 and Appendix C.

The pump station shall operate automatically by control signals from the telemetry system. In addition, either one or any combination of pumps may operate at any one time by control signals from the telemetry system.

(9) Operation and maintenance manuals

(a) Manuals shall contain the following information:

(i) contractor's name, address and telephone number;

(ii) client's contract number, job name; and

(iii) pump station general arrangement drawing showing pumps, motors, valves, pipework, switchboard and electrical installation.

(b) Manuals for pumps shall contain the following information:

(i) manufacturer;

(ii) type and model number;

(iii) serial number;

(iv) dimensioned general arrangement drawing of pump and motor;

(v) sectional arrangement drawing with parts and list;

(vi) dimensioned sectional arrangements detailing:

(A) maximum and minimum shaft/bearing clearance (radial);

(B) maximum and minimum impeller/bowl clearance (radial);

(C) maximum and minimum impeller/bowl clearance (axial);

(D) impeller/bowl wear rings;

(E) motor/pump coupling - type, make and model number; and

(F) mechanical seals where applicable.

(c) Manual for motors shall contain the following information:

(i) manufacturer;

(ii) type and model number;

(iii) serial number;

(iv) dimensioned general arrangement drawing;

(v) sectional arrangement drawing for submersible motor power cabling where applicable;

(vi) gland sealing arrangement drawing for submersible motor power cabling where applicable;

(vii) cables where applicable; and

(viii) terminal block arrangement drawing where applicable.

(d) Manuals for electrical equipment shall comply with TCC24 clause 23 and requirements for electrical drawings are described in TCC24 clause 22.

(e) Manuals for valves shall contain a dimensioned sectional arrangement drawing with parts and material list for all valves.

(f) Manuals shall contain the following test curves:

(i) pump witnessed test curves;

(ii) motor test curves; and

(iii) motor torque/speed/efficiency characteristic curves.

(g) The operating and maintenance manual shall include:

(i) safe working procedures: for switching and isolating the supply and distribution system;

(ii) description of operation;

(iii) maintenance procedures: recommended maintenance periods and procedures;

(iv) tools: particulars of maintenance equipment and tools provided, with instructions for their use.

(v) equipment: a technical description of the equipment supplied, with diagrams and illustrations where appropriate;

(vi) dismantling: where necessary, procedures for dismantling and reassembling equipment; and

(vii) spare parts: a list of the spare parts provided.

(10) Trouble shooting instructions shall be included for pumps, motors, valves and SCA.

(11) Step by step procedures for dismantling and reassembly of pumps, motors and valves using any special tools shall be detailed together with step by step procedures for replacement of wearing parts such as bearing, seals, wear rings, etc.

SC6.4.6.2.7 Construction compliance

(1) Work-as-executed details and operation and maintenance manual

The Contractor shall submit to the Superintendent work-as-executed drawings showing the actual location and alignment of pipelines, and all pump station details together with operating and maintenance manuals.

Details shall include the size, type, levels of pipelines, valve and hydrant chamber types and cover details, easement requirements for maintenance, pump details, switchboard equipment details and station structural details.

The Contractor shall ensure that a Registered Surveyor certifies the plans showing location and alignment.

The Contractor shall provide records, for Townsville Water and Waste's Asset Register, to the Superintendent at the time of practical completion of the Contract. The records are to be in a form consistent for inputting into the Asset Register as directed by the Superintendent.

SC6.4.6.3 Sewerage system

SC6.4.6.3.1 Introduction

(1) Scope

This sub-section is for the construction of the following:

(a) gravitation sewers up to DN600 nominal size;

(b) common effluent sewers, both gravity and pressurised;

(c) vacuum sewerage systems;

(d) rising mains up to DN600 nominal size;

(e) standard appurtenances such as maintenance holes, maintenance shafts and property connection sewers; and

(f) small pump stations, usually limited to single wells with submersible pumps.

This sub-section excludes the construction activities for:

(a) treatment plants;

(b) headworks;

(c) dosing plant;

(d) larger pump stations; and

(e) works controlled by others, including overflow management.

The Contractor shall carry out the work, and supply materials meeting the requirements of the reference documents and, in particular, in accordance with the requirements of the Water Services Association of Australia publications WSA 02-2014 – *Gravity Sewerage Code of Australia*, WSA 07 – 2005 - *Sewerage Pumping Station Code of Australia*, and WSA 07-2011 *Pressure Sewerage Code of Australia*, except as otherwise specified herein. Sewerage works should be designed in accordance with SC6.4.3.21 Townsville Water planning and design guidelines in conjunction with Department of Energy and Water Supply's *Planning Guidelines for Water Supply and Sewerage.*

For the purposes of this sub-section, "access chambers" are referred to as "maintenance holes".

(2) Reference and source documents to be read and applied in conjunction with this policy is sub-section are as follows:

Documents referenced in this sub-section are listed below whilst being cited in the text in the abbreviated form or code indicated. The Contractor shall possess, or have access to, the documents required to comply with this sub-section.

References to the *Sewerage Code of Australia* are made where there are parallel sections or equivalent clauses to those in this sub-section. Where not called up as part of this sub-section, these references are identified by edition, part and section numbers and enclosed in brackets thus (WSA Edition, Part, Section).

(a) Development manual planning scheme policy sub-sections:

SC6.4.3.21 Townsville Water and Waste planning and design guidelines
SC6.4.4.8 Standard drawings
SC6.4.6.28 Minor concrete works
SC6.4.6.30 Control of traffic

Note—where any standard drawing used in conjunction with this sub-section includes technical requirements that conflict with this sub-section, the requirements of this sub-section shall take precedence.

(b) Australian Standards:

Note—references in this sub-section or on the design drawings to Australian Standards are noted by their prefix AS or

AS/NZS. Where not otherwise specified in this sub-section or the design drawings, the Contractor shall use the latest Australian Standard, including amendments and supplements, available within two weeks of close of tenders.

SC6.4.6.3.2 Materials

(1) General

The Contractor shall comply with the requirements of the manufacturer's recommendations regarding the handling, transport and storage of materials and as further specified in this sub section.

Prior to the delivery of products and materials, the contractor is expected to obtain relevant product or material certification from the manufacturer which shall be presented to the Superintendent if requested.

The Contractor shall not use damaged or defective materials, including coatings and linings, outside the manufacturer's recommended limits.

All gravity reticulation pipes shall be rubber ring (elastomeric), complying with AS 1646, jointed to the type, size and class as shown on the design drawings.

If the Contractor proposes to use alternative products and materials other than the products and materials authorised by the Townsville Water and Waste, the design drawings and this sub-section, an approval from the Townsville Water and Waste is required prior to delivery and use of alternative products or materials.

(2) Unplasticised and modified PVC (uPVC and PVC-M) pipe and fittings

Unplasticised PVC (uPVC) pipes and fittings for gravity systems shall comply with AS/NZS 1260, shall be suitable for rubber rings (elastomeric) joints and shall be of the class and size as shown on the design drawings (WSA 02- 2014, Part 2, Section 13.).

Unplasticised PVC (uPVC) pipes and fittings for rising mains and suction pipes shall comply with AS/NZS 1477 and AS/NZS 4765, shall be suitable for rubber ring (elastomeric) joints and shall be of the class and size as shown on the design drawings. Modified PVC (PVC-M) pipes and fittings shall comply with AS/NZS 4765, shall be suitable for rubber ring (elastomeric) joints and shall be of the class and size as shown on the design drawings.

PVC pipes and fittings for mains and suction pipes shall be installed in accordance with AS/NZS 2032 and AS/NZS 2566.1.

Pipes and fittings are to be handled and stored protected from sunlight. The Contractor shall provide protection for the pipes and fittings from ultra violet light and damage. The Contractor shall take account of the time for storage and type of shelter.

(3) Polyethylene (PE) pipe and fittings

Polyethylene pipe shall comply with AS/NZS 4129 and AS/NZS 4130 and shall be of the class and size shown on the design drawings and installed in accordance with AS 2033 (WSA 02-2014, Part 2,Section 13.).

Jointing shall be by butt thermal fusion or by electrofusion couplings, or with compression fittings.

The Contractor shall provide pipe of the appropriate external diameter consistent with the required internal diameter shown on the design drawings.

(4) Glass reinforced plastic (GRP) pipe and fittings

Glass filament reinforced thermosetting plastics (GRP) pipes shall comply with AS 3571 and shall be of the class and size as shown on the design drawings and installed in accordance with AS/NZS 2566.1 (WSA 02-2014, Part 2, Section 13.).

Pipes and fittings are to be handled and stored protected from sunlight. The Contractor shall provide protection for the pipes and fittings from ultra violet light and damage. The Contractor shall take account of the time for storage and type of cover.

(5) Ductile iron (DI) pipe and fittings

Ductile iron (DI) pipes and fittings shall comply with AS/NZS 2280 and shall be of the class, size and lining, as shown on the design drawings, and installed in accordance with AS/NZS 2566.1. Jointing shall be with rubber rings (elastomeric) to the class and type as shown on the design drawings and in accordance with WSA 02-2014, Part 2, Section 13.

Flanges shall be to the table shown on the design drawings. Bolts and nuts for flanged joints shall be galvanised, or stainless steel as for the pumps specified herein, unless shown otherwise on the design drawings.

All pipework shall be sleeved externally with polyethylene sleeving in accordance with the requirements of AS 3681 unless specified otherwise to be coated and lined. All fittings shall be thermal bonded polymeric coated, in accordance with AS/NZS 4158, or wrapped. The Contractor shall wrap all unprotected joints in the trench with a petrolatum tape system approved by the Superintendent.

(6) Steel pipeline

Steel pipelines and fittings shall comply with AS 1579 and AS/NZS 1594 and shall be of the class, size, lining and coating as shown on the design drawings or as specified in WSA 02- 2014, Part 2, Section 13.

The Contractor shall wrap all unprotected joints in the trench with a petrolatum tape system approved by the Superintendent.

The jointing system shall be rubber ring (elastomeric) unless shown otherwise on the design drawings.

(7) Vitrified clay

Vitrified clay (VC) pipes and fittings shall comply with AS 1741 and shall be of the class of pipe, complying with the loading requirements of AS 4060, and size as shown on the design drawings and suitable for rubber ring (elastomeric) joints (WSA 02-2002, Part 2, Section10).

(8) Precast maintenance holes (MH)

Precast maintenance hole components shall comply with AS/NZS 1477 for PVC, AS 2033 for PE, AS 3518 for ABS, AS 3571 for GRP and AS 4198 for concrete (WSA 02-2014, Part 2, Section 17.2).

If approved by the Superintendent, precast systems, complying with the drawings, may be used in lieu of cast in-situ systems (WSA 02-2014, Part 2, Section 17.2.2). Precast system components shall not be delivered to the site before satisfactory documentary evidence has been submitted to the Superintendent that quality tests have been carried out.

(9) Preformed maintenance shafts (MS) and terminal maintenance shafts (TMS) including cover

Preformed maintenance shaft and terminal maintenance shaft components shall comply with AS/NZS 1477 for PVC, AS 2033 for PE, AS 3518 for ABS, AS 3571 for GRP and AS 4198 for concrete (WSA 02-2014, Part 2, Section 17).

(10) Maintenance hole covers and frames

Cast iron maintenance hole covers and frames shall comply with AS 3996 and shall be of a type that is flush top cast cover, identifiable as SEWER, size, opening and class as shown on the design drawings. Covers and frames shall not be delivered to the site before satisfactory documentary evidence has been submitted to the Superintendent that quality tests have been carried out.

(11) Steelwork

Structural steelwork, including ladders, brackets and covers, complying with AS 1657, shall be abrasive blast cleaned to AS 1627.4, Class 2.5 and hot dip galvanised to AS/NZS 4680.

SC6.4.6.3.3 Pipeline construction

(1) General

The Contractor, employees, or subcontractors, engaged in excavations, including tunnelling, are to be accredited for the work. Proof of accreditation must be provided to the Superintendent prior to the release of the hold point (WSA 02-2014, Part 2, Section 16.).

The Contractor shall not change the pipeline alignment without the prior concurrence of Townsville Water and Waste. The Contractor shall provide full details, of any proposed changes to the pipeline alignment, to the Superintendent for submission to Townsville Water and Waste. The Superintendent shall obtain the decision of Townsville Water and Waste prior to the release of the hold point.

(2) Location

The location of the sewers, maintenance holes, rising mains and pump stations, sizes and grades of sewers and rising mains, the types of maintenance holes and maintenance hole covers and the classes of pipes shall be as shown on the design drawings. The Contractor shall commence laying of pipelines at the lower end of the line unless directed otherwise by the Superintendent. The Contractor shall lay pipelines to grades and locations shown on the design drawings unless directed otherwise by the Superintendent (WSA 02-2014, Part 2, Section 16.).

(3) Cover over pipelines

The minimum depth of cover to be provided over pipelines shall be as follows: (WSA 02-2014, Part 1, Section 5.6.3).

LOCATION	MINIMUM COVER (mm)
Private property non vehicular new developments	600
Private property non vehicular existing developments	450
Private residential property subject to vehicular loading	750
Footpaths, sealed roads (non arterial)	900
Unsealed roads	1200
Arterial roads	1200

Lesser covers may be permitted where special protection of the pipelines has been shown on the design drawings or directed by the Superintendent (WSA 02-2014, Part 1, Section 5.6.3.)

(4) Crossings

Where a pipeline crosses a main or state road, creek or involves features shown on the design drawings, under the control of any Authority, the Contractor shall carry out the work in accordance with the requirements of that Authority. The Contractor shall provide written notification to the Authority of the intention to carry out the work, and pay the appropriate fees. The Contractor shall obtain the written approval from the Authority prior to

commencement of work. Such written approval shall be supplied to the Superintendent if requested.

Where shown on the design drawings, the Contractor shall use trenchless methods for the installation of the sewer mains. The installation of the sewer main by open trenching shall not be permitted over the lengths designated for trenchless installation (WSA 02-2014, Part 2, Section 14.12).

The Contractor shall address, in its method statement for trenchless conduit installation, the following:

(a) general description of method and sequence of operation;

(b) size, depth and position of temporary pits required;

(c) use of specialist subcontractors;

(d) specialist equipment to be used; and

(e) grout type and method of injection.

The encasement pipe shall be as detailed on the design drawings. The encasement pipe shall extend 1.0 m behind the back of the kerb on either side of the carriageway.

The carrier pipe shall be positioned on support cradles and the carrier pipe shall be centrally located within the encasement pipe.

After installation and pressure testing of the carrier pipe, the Contractor shall fill the annular space between the carrier pipe and the encasement pipe with suitable grout or cementitious grout filler.

Where the carrier pipe is ductile iron cement lined (DICL), any length of pipe which is enclosed within the encasement pipe need not be wrapped in polyethylene tubing.

(5) Earthworks

The Contractor shall carry out all excavations for structures and pipelines to the lines, grades and forms shown on the design drawings, or as directed by the Superintendent, within the specified tolerances.

Prior commencement of excavation, the Contractor shall be responsible in obtaining approval from the appropriate Authorities and shall comply with all requirements of the approval including having regard for drainage, dewatering, silt control, noise abatement, proximity to existing buildings and generally for the amenity of adjacent owners.

The Contractor shall leave a clear space of 600 mm minimum between the edge of any excavation and the inner toe of stockpiles. No excavated materials shall be stockpiled against the walls of any building or fence without the written permission of the owner of such building or fence. Topsoil from excavations shall be stockpiled separately and utilised to restore the surface after backfilling.

At the completion of work each day, the Contractor shall install safety fencing to statutory requirements along the edges of open excavations to isolate them from the public. The Contractor shall provide fenced walkways and vehicular crossways across trenches to maintain access at all times from carriageway to individual properties or within individual properties and advise beforehand all affected residents. All such installations shall be of adequate size and strength and shall be illuminated to prevent accidents.

The Contractor shall locate, protect and repair, as necessary, all services affected by the Works at the Contractor’s expense. The Contractor shall give notice of any interference to the works caused by an existing service and submit a proposed work method statement.

The Contractor shall carry out erosion and sedimentation control at all construction sites in accordance with *Best Practice Erosion and Sediment Control*.

The Contractor shall take account of safety issues and possible wet weather effects to limit the extent of excavation left open.

(6) Minimum trench width for pipelines

The minimum clear width of trench (inside internal faces of timbering or sheet piling, if used) to a height of 150 mm above the top of the pipe shall be as shown in Table SC6.4.6.3.1 (SC6.4.4.8 Standard drawings SD-460).

Table SC6.4.6.3.1 Minimum trench widths

Nominal size of PIPE (DN)	Minimum clear width of trench(mm) (inside timbering or sheet piling, if any)	
	Pipe other than PVC/PE	PVC/PE Pipe
80	400	350
100	400	350
150	450	400
200	500	450
225	550	500
250	550	500
300	600	550
375	700	650
400	700	650
450	750	700
500	850	800
525	850	800
600	950	900

Where the design drawings provide for a trench to be excavated across a paved surface, the width of the trench shall be kept to a minimum. Bitumen and concrete surfaces shall be carefully cut, by sawcutting, or other means approved by the Superintendent, so as to provide a neat straight line free from broken ragged edges (WSA 02-2014, Part 2, Section14.7).

The Contractor shall widen the trench where necessary for the installation of valves and fittings and protective coating systems.

(7) Maximum trench width

For gravitation sewers or rising mains of pipe materials other than PVC or PE, no restriction shall be placed on the maximum width of trench due to the structural strength of the pipe provided the depth to invert of the pipe does not exceed the depths shown in column (ii) of Table SC6.4.6.3.2.

The Superintendent may, however, restrict the width of trench due to local conditions. The Superintendent shall not restrict the width of trench to less than as shown in column (iii) of Table SC6.4.6.3.2.

Where the depth to invert exceeds that shown in column (ii) of Table SC6.4.6.3.2 – Maximum trench widths, the maximum width of trench (outside timbering or sheet piling, if used) to a height of 150 mm above the top of the pipe shall be as shown in column (iii) of Table SC6.4.6.3.2.

Table SC6.4.6.3.2 Maximum trench widths

Nominal size of pipe (mm) (i)	Maximum depth to invert, unlimited width trench (m) (ii)	Maximum trench width, depths greater than in column (ii) (mm) (iii)
150	8.0	750
225	6.5	825
300	5.5	900
375	4.5	975
400	4.5	975
450	4.5	1050
525	4.0	1125
600	4.0	1200

For gravitation sewers or rising mains of PVC/PE pipe the maximum width of trench from the trench base to a height of 150 mm above the top of the pipe shall be the outside diameter of the pipe barrel plus 400 mm. However, in timbered or travelling box excavated trenches, the width of trench when measured to the outside of the support used may be increased to a maximum of 580 mm plus the outside diameter of the pipe barrel.

The Contractor shall supply a method statement of any special construction control, where shown on the design drawings, to the Superintendent's approval.

(8) Excavation depth

The Contractor shall excavate trenches to a minimum of 100 mm below the underside of the pipe barrel and socket or coupling except for rising mains to be laid on other than rock foundations or as otherwise shown on the design drawings (SC6.4.4.8 Standard drawings SD 461).

The excavation shall be carried out such as to ensure solid and uniform support for each pipe over the whole length of the barrel with chases provided for joints and wrapping.

(9) Support of excavation

The Contractor shall adequately support all excavations to Statutory requirements as the Works proceed. When withdrawing supports, the Contractor shall exercise every precaution against slips or falls.

The Contractor shall ensure that timber is left in place where its removal may endanger structures in the vicinity of the excavation.

(10) Pipe bedding

When excavation of the trench has been completed the Contractor shall obtain the Superintendent's approval prior to commencing pipe laying, jointing and bedding. The Superintendent's approval of the excavated trench is required prior to the release of the hold point, or where sewers are to be located in water charged ground (present or predicted to occur) will require specialist geotechnical analysis and design. The contractor shall inform the Superintendent immediately upon encountering ground water and await further direction.

Crusher screenings may only be used for pipe bedding where sand or other non- cohesive material is not readily available locally or where the Contractor can demonstrate that its use will not impede repair operations.

Pipes for gravitation sewers (excluding PVC/PE pipes), shall be bedded on sand or other non-cohesive material. Pipe bedding shall consist of a non-cohesive granular material, having a minimum thickness of 75 mm below the barrel and socket of the pipe, and its grading shall generally fall within the following limits shown in Table SC6.4.6.3.3.

Table SC6.4.6.3.3 Grading of bedding material for pipes other than PVC and PE

Sieve size aperture width (AS 1152)	Equivalent BS sieve size (BS410)	Percentage passing
22.4 mm	1 inch	100
6.7 mm	¼ inch	90 - 100
425 µm	No. 36	40 - 90
75 µm	No. 200	0 - 10

Pipes for rising mains (excluding PVC/PE pipes) may be laid directly on other than rock foundation. The Contractor shall provide non-cohesive granular bedding, having a minimum thickness of 100 mm below the barrel (SC6.4.4.8 Standard drawings SD-461) and socket of the pipe, where rock or other hard material occurs in the bottom of the trench or where specified or directed by the Superintendent. The bedding material shall be either loose clean sand and /or medium dense clean sand or as directed by the Superintendent.

For PVC/PE pipes, irrespective of foundation, the material to be used for pipe bedding (underlay a minimum of 100 mm below the underside of the pipe barrel (SC6.4.4.8 Standard drawings SD-461) and socket, side support and overlay to a depth of 150 mm above the top of the pipe) as shown in Figure 5.1 in AS 2032 shall be in sand or other non-cohesive granular material, either crushed, natural or blended, and its grading shall fall within limits shown in Table SC6.4.6.3.4 Grading of bedding material for PVC and PE Pipes, except that where the materials cannot be reasonably sourced from within the vicinity, the Contractor may use materials satisfying the classification in the second paragraph above, provided also that the material meets the requirements for passing sieve sizes 9.5 mm and 6.7 mm as shown in Table SC6.4.6.3.4.

Table SC6.4.6.3.4 Grading of bedding material for PVC and PE Pipes

Sieve size aperture width (AS1152)	Equivalent BS sieve size (BS410)	Percentage passing
9.5mm	3/8 inch	100
6.7mm	1/4 inch	90 - 100
425µm	No. 36	40 - 90
150µm	No. 100	0 - 10

The Contractor shall bed all gravitation sewers laid on grades of 15 per cent to 50 per cent on 20 MPa concrete complying with sub-section SC6.4.6.28 Minor concrete works. Such concrete bedding shall have a thickness of at least 75 mm below the underside of the barrel and socket of the pipe and shall extend to a level above the bottom of the pipe of one quarter of the external diameter of the pipe and a width across the trench not less than the minimum width shown in Table SC6.4.6.3.1 Minimum trench widths.

The Contractor shall encase all gravitation pipelines and rising mains, laid on grades steeper than 50 per cent, in concrete as detailed on the design drawings.

(11) Laying and jointing of pipes

Unless detailed otherwise in this Specification, the Contractor shall install pipes in accordance with AS 2032, AS 2033, AS/NZS 2566.1 or AS 3690 as appropriate (WSA 02-2014, Part 2, Section 16).

Before being laid, all pipes, fittings, valves, and materials to be used shall be cleaned and examined by the Contractor and, if required by the Superintendent, the Contractor shall suspend each one in a sling to enable the

The Superintendent to inspect it. If directed by the Superintendent, the Contractor shall oil valves and repack valve glands.

The Contractor shall ensure that the interior of the pipeline is clean and free from obstructions. Plugs shall be used to prevent foreign matter entering sections of pipeline which are left uncompleted overnight.

The Contractor shall take all necessary precautions to prevent flotation of pipes during laying, backfilling and initial testing. The Contractor shall remove any temporary supports prior to completion of backfilling.

Except where solvent cement joints are needed to make up or install fittings, joints in pipelines shall be flexible, rubber ring (elastomeric) joints (either roll-on rubber ring (elastomeric) or skid type) or, where shown on the design drawings, mechanical joints (either fixed flange or bolted gland type).

For pipes with roll-on rubber ring (elastomeric) joints, spigots and sockets shall be clean and dry. The Contractor, after making the joint, shall check that the rubber ring (elastomeric) has rolled in evenly, and, if not, the Contractor shall withdraw the pipe and remake the joint.

For pipes with skid type rubber ring (elastomeric) joints, only the lubricant specified in writing by the manufacturer shall be applied in making the joint. The Contractor shall make the joint such that the witness mark shall, at no point, be more than 1 mm from the end of the socket.

Pipes may be cut as needed, or directed by the Superintendent, to suit closing lengths, to remove damaged pipe or fittings or to remove sockets if necessary when jointing a socketed fitting.

For field cuts, a mechanical pipe cutter shall be used, except that PVC/PE pipes may be cut using a power saw or a fine toothed handsaw and mitre box. For field cuts of ductile iron or steel, the Contractor shall ensure that fire fighting equipment, in working order, is on the site prior to the field cuts being made. If the Contractor proposes to use a petrol-engine pipe cutter in an excavation, the Contractor shall ensure that a safe atmosphere is maintained in the excavation at all times.

The Contractor shall prepare the ends of any pipes cut in the field to the manufacturer’s written instructions, or as directed by the Superintendent.

Where pipes are cut in the field, the Contractor shall make a witness mark on the pipe at the length specified by the manufacturer from the end of the pipe. The Contractor shall not use PVC/PE pipes with scored witness marks. Where the same manufacturer does not make spigots and sockets, the Contractor shall refer to the socket manufacturer for the correct marking depth.

Where PVC pipes are to be joined to pipes of another material, the joints shall be made as follows:

(a) for jointing PVC/PE spigot to VC socket or PVC/PE socket to VC spigot, the Contractor shall use a PVC/PE adaptor shall be used. The joints in both instances shall be made using a ring conforming to AS 1646.

(b) for jointing PVC/PE to ductile iron, the Contractor shall use a rubber ring (elastomeric) joint with an adaptor coupling.

The Contractor shall conform with the relevant Statutory and work, health and safety requirements when cutting and disposing of asbestos cement pipes.
Gravitation pipelines shall be constructed to the following tolerances:

(c) the maximum horizontal deviations to either side from the design axis of a pipeline shall be 20mm for all sizes of pipes (WSA 02-2014, Part 2, Section 22.1); and

(d) the invert level shall not deviate from the design grade line by more than 10 mm (WSA 02-2014, Part 2, Section 22.2).

Flexibly jointed pipelines with gradual changes in alignment or grade shall be laid with the joint being deflected after it has been made. The Contractor shall comply with the manufacturer’s written recommendations in respect of maximum deflection for each joint provided that no joint shall be deflected to such an extent as to impair its effectiveness.

The maximum angle of deflection between adjacent pipes shall be limited to 2º or 0.035 radian in areas subject to mine subsidence or slippage.

Unless otherwise directed by the Superintendent, the Contractor shall lay pipes for rising mains on continuously rising grades from scour valve to air release valve, notwithstanding any minor irregularities in the ground surface.

Detectable identification tape to AS/NZS 2648.1 shall be laid along the line of the rising main within 150 mm of

the finished surface or as otherwise directed by the Superintendent (WSA 02-2014, Part 2, Section 16.11.2 and SC6.4.4.8 Standard drawings SD-460).

(12) Connections to maintenance holes and structures

The Contractor shall connect pipelines to maintenance holes, structures or embedded concrete by means of 600 mm long pipes such that two flexible joints are provided, the first joint being at or within 150 mm of the face of the structure. The contractor shall not core any connections into wall sections of precast or cast insitu manholes <150 mm from any joint to the closest edge of core. Where flexible joints cannot be made with cut pipes, the Contractor shall select pipes from the various lengths provided in order to make the second joint within 300 mm of the position shown on the drawings (SC6.4.4.8 Standard drawings SD-470 and SD484).

The Contractor may vary slightly the positions of maintenance holes shown on the design drawings, subject to final approval by the Superintendent immediately prior to construction, to suit changes, such as erection of structures, growth of flora and installation of services. The positioning of a maintenance hole shall be such as to comply with occupational health and safety requirements for access by maintenance staff, providing a proper working area around the top and access into the hole. Once the final position of a maintenance hole has been established, construction shall be subject to the following requirements:

(a) for deviations from the design levels of maintenance holes as shown on the design drawings or as directed by the Superintendent during construction, the following tolerances shall apply (WSA 02-2014, Part 2, Section 22):

(i) where the difference in levels between the inlet pipe and the outlet pipe in a maintenance hole is 100mm or less:

Pipe Tolerance
Inlet - nil; + 10 mm
Outlet - 10 mm; + nil; and

(ii) where the difference in levels, as above, is greater than 100 mm:

Pipe Tolerance
Inlet - 10 mm; + 10 mm
Outlet - 10 mm; + 10 mm; and

(b) allowable lateral deviations from the final design position of maintenance holes shall be +/- 300 mm.

(13) Junctions and property connection sewers

The Contractor shall provide junctions for dead ends and property connection sewers or risers to properties to serve existing and future dwellings in accordance with this sub-section and the design drawings. Such junctions shall be inserted along pipelines in locations shown on the design drawings or directed by the Superintendent, with the service connection, where not shown on the design drawings, provided at a depth no deeper than 1.5 m provided the property still has service to the sewer, as follows:

(a) for existing dwellings, at the most practical point not outside the property boundary to facilitate the connection, considering existing sewage outlets. Separate connections shall be provided for dual occupancies; and

(b) for vacant blocks, at the most practical point not outside the property boundary to facilitate the connection, considering topography and likely positioning of sewage outlets.

Where the sewer is intended to serve a large block and/or where the sewer line is located more than 75 m from the premises, the Contractor shall extend the property connection sewer onto that block such that the maximum horizontal measurement in a straight line between the sewer connection point and the premises on the block is not more than 75 m.

Concrete support shall be provided for the full trench width in accordance with SC6.4.4.8 Standard drawings SD-455 complying with sub-section SC6.4.6.28 Minor concrete works.

Except where concrete encasement is ordered by the Superintendent, the Contractor shall sand compact backfill around risers to the top of the socket or coupling on the highest branch off the riser, for the full width of trench and for a minimum distance of 500 mm upstream and downstream of the riser. Compaction density shall

be as for the requirements for the trench pipeline.

All property connection sewers and junctions shall have a minimum diameter of 150 mm and have a screwed access cap. Property connection sewers shall have a maximum length of 10 m.

(14) Marking of junctions and property connection sewers

The Contractor shall clearly mark the position of each riser, junction or end of a property connection sewer on completion of backfilling. The marking shall be made by one of the following methods but the location of the mark or peg shall be consistent with the method(s) in use by Townsville Water and Waste and to the approval of the Superintendent (WSA 02-2014, Part 2, Section 16.9).

Where the position of a riser, junction or the end of a property connection sewer is at a substantial boundary fence or structure located on the boundary, a neatly stencilled letter "J" 50 mm high shall be painted thereon. An underground identification tape, as specified hereafter, shall finish flush with the existing ground surface as close to the boundary fence or structure as possible.

Elsewhere, the Contractor shall drive into the ground, a peg, 75 mm x 50 mm x 600 mm long at that position, and left flush with the surface of the surrounding ground. The Contractor shall connect the peg to an underground identification tape as specified hereafter.

The Contractor shall tie the identification tape to the junction or end of the property connection sewer, hold the tape in a vertical position during backfilling operations and finish tape flush with finished ground level.

The identification tape shall be 75 mm wide fawn coloured polyethylene tape with the inscription "Caution - buried sewer line", printed in heavy black letters every 200 mm.

(15) Trench stops

Where a sewer or rising main is laid on bedding at a grade of 5 per cent to 14 per cent, the Contractor shall construct, as below, trench stops consisting of bags filled with clay, or sand or cement stabilised sand and sealed. Reference shall be made to SC6.4.4.8 Standard drawings SD-482 and SD-483.

(a) At the socket side of the joint nearest to the position of a stop required in accordance with the formula hereinafter, a recess 100 mm deep to suit the width of bag shall be excavated into the bottom of the trench across its full width and into both sidewalls and extend to within 300 mm below finished surface level.

(b) The bags shall be placed around and above the pipe, as in (a) above, so as to give close contact with the pipe and to fill the entire space between the excavated recess and the pipe. Bags shall not be placed onto sand bedding.
The distance between trench stops shall be determined by the following formula:

D = 100, whereby G
D = Distance between stops in m
G = Grade of pipe expressed in per centum.

(16) Concrete bulkheads

Where a gravitation sewer or rising main is installed at a grade of 15 per cent to 29 per cent, the Contractor shall construct concrete bulkheads. Where a gravitation sewer or rising main is installed at a grade 30 per cent to 50 per cent, the Contractor shall construct concrete bulkheads integral with concrete encasement. Where any sewer line is to be installed with a grade exceeding 50 per cent, the contractor must provide a site specific design to incorporate all aspects of the site conditions including soil conditions. Bulkheads shall be of 20 MPa concrete complying with sub-section SC6.4.6.28 Minor concrete works, 150 mm minimum thickness as follows: (SC6.4.4.8 Standard drawing SD-482, WSA 02-2014, Part 1, Section 9.10 and WSA 02-2014, Part 2, Section 16.6)

(a) where concrete bedding or encasement to pipe is required, the 150 mm thick bulkhead shall be cast integral with the concrete bedding or encasement across the width of trench and shall be keyed into both sidewalls a minimum of 150 mm. The bulkhead shall extend to 150 mm below finished surface level or such other level as directed by the Superintendent;

(b) where other bedding, or no bedding, is applicable, the bulkhead shall also be keyed into the bottom of the trench 150 mm for the full width of trench; and

(c) a 75 mm nominal diameter drain hole shall be provided in the concrete bulkhead immediately above the top of the encasement bedding or foundation and crushed rock or gravel shall be placed in and at the upstream end of the drain hole to act as a filter. The gravel shall be 10 to 20 mm in size within 150 mm in all directions upstream and above the invert of the drain hole beyond which another 150 mm thick surround of gravel 2 to 10 mm in size shall be placed.

The distance between concrete bulkheads shall be determined by the following formula: (WSA 02-2014, Part 1, Section 9.10.)

Concrete bulkhead

$$S = \frac{L_P}{G}$$

Concrete encasement (continuous) and concrete bulkhead S = 100/G, whereby

L_P = 80 X Pipe length, m

= 450 m max

if L_P > 100 m use intermediate trench stops at spacing < 100/G

S = Distance between bulkheads in m

G = Grade of pipe expressed in per centum

(17) Thrust and anchor blocks for rising mains

The Contractor shall construct thrust and anchor blocks where shown on the design drawings to the dimensions depicted therein or as otherwise directed by the Superintendent where it is deemed that the allowable bearing pressure of the ground and the design pressure on the pipeline are different to the actual pressures on site. The blocks shall be provided at valves, flexibly jointed bends, tees, enlargers and reducers or any other point where unbalanced forces resulting from internal pressures will occur.

The Contractor shall provide permanent thrust blocks of 20 MPa concrete, complying with sub-section SC6.4.6.28 Minor concrete works, such that the thrust blocks bear against undisturbed material normal to the direction of thrust resulting from internal pressures over the bearing area not less than that directed by the Superintendent.

The Contractor shall provide permanent anchor blocks of 20 MPa concrete, complying with sub-section SC6.4.6.28 Minor concrete works, of a volume and dimension not less than that directed by the Superintendent.

The Contractor shall provide temporary anchorages adequate to restrain the pipe when under test. The cost of providing such anchorages shall be deemed to be included in the rates tendered for laying and jointing rising mains.

The Contractor shall obtain the consent of Townsville Water and Waste for the type and use of restrained joints, as an alternative to thrust blocks, in the case of congested service corridors and urgent commissioning.

(18) Rising main fittings

The Contractor shall install rising mains, air release valves and inspection pipes where shown on the design drawings or directed by the Superintendent. All rising mains shall be topped with an appropriate identification tape.

The Contractor shall provide marking plates bearing the letters "DAV" for double air valves, "SCOUR" for scour pipes and "SRM" for sewage rising main at changes of direction and at such chainages that the location of the main is marked, at least once each 100 metres, as specified hereinafter. In urban areas, the kerb adjacent to each fitting is to be painted with 2 coats of non-slip paint coloured black.

Where, in the opinion of the Superintendent, a valve or fitting is at too great a distance from any existing wall, fence or post to which the notice plate could be conveniently fixed, the Contractor shall provide and set in the ground a post with the relevant marking plate fixed at the top of the post, facing the fitting. The distance to the fitting in metres, to an accuracy of 0.1 m, shall be permanently marked on the plate with legible numbers a

minimum 80 mm high. Wooden posts are not to be used where there is evidence, by rotting or termite activity, that the integrity of the posts will be affected.

The post shall conform to the following requirements:

(a) the post shall be of sufficient length to be set firmly in place under saturated ground conditions.

(b) when installed, the post shall project 1000 mm above the ground, provided that where tall grass or crops are likely to obscure the post, or where directed by the Superintendent, its height above the ground shall be increased to 1500 mm.

(c) the post shall be painted with 2 coats of white enamel for exterior use.

The Contractor shall encase in concrete pipes in gravity sewers or rising mains, as shown on the design drawings, with less than the specified cover above the top of the pipe barrel, or where directed by the Superintendent. Concrete shall be 20 MPa complying with sub-section SC6.4.6.28 Minor concrete works and have the following minimum dimensions (WSA 02-2014, Part 1, Section 9.7 and SC6.4.4.8 Standard drawing SD-463):

(a) for trenches in other than rock: 150 mm minimum under, on both sides and on top of the pipe barrel; and

(b) for trenches in rock: 100 mm minimum under the pipe barrel, 150 mm on top of the pipe barrel and for the full width of trench excavated.

In trenches of other than rock or fissured rock, a contraction joint consisting of a layer of bituminous felt 12 mm thick shall be formed in the concrete encasement at the face of each socket or at one face of each coupling.

Reinforcement in concrete encasement shall be as shown on the design drawings.

(19) Wrapping of pipelines

Where shown on the design drawings or directed by the Superintendent, the Contractor shall enclose a pipeline or a section thereof, in layflat polyethylene sleeving (WSA 02-2014, Part 2, Section 16.10).

The materials to be used shall be high impact resistance polyethylene sleeving of minimum thickness 0.2 mm polyethylene film, approved by the Superintendent, and 50 mm wide plastic adhesive tape.

The width of the sleeving when flat shall be in accordance with the pipe manufacturer's written recommendations for the size and type of the pipeline which is to be encased. Precautions shall be taken so that exposure to direct sunlight does not exceed 48 hours.

Where necessary to distinguish pipes within close proximity, pipelines shall be identified by colour sleeving or an appropriate identification tape.

Application of the polyethylene sleeving and plastic adhesive tape shall be in accordance with the pipe manufacturer's written instructions or as directed by the Superintendent. The Contractor shall take due care not to damage the sleeving during its application or during the backfilling of the trench. Each pipe shall be encased in a length of sleeving overlapped for a minimum of 250 mm at each field joint, and the ends of each length of sleeving shall be held in position with at least three circumferential turns of adhesive tape. As the polyethylene sleeve material covering the pipe will be loose, excess material shall be neatly drawn up around the pipe barrel, folded into an overlap on top of the pipe and held in place by means of strips of plastic tape at approximately 1 metre intervals. Bends, tapers and similar fittings shall be covered by polyethylene sleeving as specified for the pipes. The Contractor shall hand wrap valves, hydrants and irregular shaped fittings and joints using flat polyethylene sheets secured with plastic adhesive tape, or other suitable material, to provide an adequate seal. The flat polyethylene sheets may be obtained by splitting suitable lengths of sleeving.

The Contractor shall rectify any damage done to the polyethylene tubing before, during or after backfilling of the trench. The Contractor shall present the wrapped pipeline for inspection by the superintendent prior to commencing backfilling operations.

(20) Corrosion protection of steel bolts and nuts

The Contractor shall wrap all galvanised steel bolts and nuts, used for installation below ground, of flanges, bolted gland joints, mechanical joints, tapping bands using a tape, approved by the Superintendent consisting

of synthetic fibre open weave cloth impregnated with saturated hydrocarbons applied in accordance with the manufacturer's recommendations. Bolts and nuts shall be dry, clean and free from rust immediately before wrapping.

(21) Cast-in-situ maintenance holes

For all maintenance holes concrete work, the Contractor shall comply with sub-section SC6.4.6.28 Minor concrete works in relation to the supply and placement of concrete and steel reinforcement, formwork, tolerances, construction joints, curing and protection except as specified below (WSA 02-2014, Part 2, Section 17.2.3 and SC6.4.4.8 Standard drawings SD-470 and SD-476).

Cement used in all concrete shall be Type SR to AS 3972. The Contractor may use fly ash additive to a maximum 20 per cent. Cement used shall be no older than 3 months since manufacture.

The minimum cement content shall be 360 kg/m³ of concrete and the water/cement ratio of the mix shall not be greater than 0.50 by mass.

(22) Covers and frames

Covers and frames shall not be warped or twisted. Surfaces shall be finished such that there are no abrupt irregularities and gradual irregularities shall not exceed 3 mm. Unformed surfaces shall be finished to produce a surface that is dense, uniform and free from blemishes. Exposed edges shall have a minimum 4 mm radius.

Tolerances for the dimensions on the COVER shall be – 3 mm + NIL.

Tolerances for the dimensions on the FRAME shall be -3 mm +3mm.

Maintenance hole covers shall be seated on a layer of bitumen impregnated fibre board, having a cross-section of 25 x 25 mm. Alternatively another seating material of a cross-section and composition approved by the Superintendent may be used.

Maintenance hole covers shall be finished flush with the surface in roadways, footpaths and paved surfaces of any type. Elsewhere, covers shall be finished 25 mm above the surface of the ground where not shown otherwise on the design drawings, or such other level as directed by the Superintendent, in a manner designed to avoid as far as possible, the entry of surface water.

In locations where shown on the design drawings or directed by the Superintendent, the Contractor shall install a cast iron cover and frame. Where it is evident, or otherwise shown on the design drawings, the Contractor shall install bolt down frames and covers in areas subjected to 1 in 100 year flooding. Cast iron covers and frames shall be manufactured in accordance with AS 3996, and shall be installed and filled with concrete, as necessary, in accordance with the manufacturer's written requirements.

(23) Preformed maintenance hole and maintenance shaft systems

The Contractor shall supply components that make a watertight system and have a satisfactory surface finish.

Generally, preformed maintenance holes shall be made up in accordance with the design drawings, with components consisting of a base section, shaft sections, converter, cover and frame. Make-up Rings (1 only) of 100-150 mm may be used between converter section and cover to make up height differentials. The wall thickness of any reinforced component below the frame shall not be less than 84 mm.

Preformed maintenance shafts shall be made with section lengths that once constructed comprise the least amount of joints as required to satisfy height parameters and unit joint/wall penetration coring clearances.

The installation of all preformed components shall be in accordance with the manufacturers' recommended procedures and requirements.

Backfill for all preformed maintenance holes and maintenance shafts shall be placed and compacted evenly around the maintenance hole to the required finished surface level according to location requirements. If

necessary, the Contractor shall import and compact non-cohesive granular material.

(24) Bedding and backfill compaction requirements

After laying and jointing of a pipeline has been completed the Contractor shall present the laid and jointed pipes for inspection by the Superintendent prior to commencement of trench backfilling (WSA 02-2014, Part 2, Section 19). Backfill shall not be placed until the Superintendent has given approval.

Material for the bedding, side support and overlay of the pipe shall be as for pipe bedding specified in SC6.4.6.3.3(10) Pipe bedding. The material shall be compacted in layers of not more than 150 mm to a Density Index of 70 for the material used when determined in accordance with AS 1289.5.6.1.

The Contractor shall backfill the remainder of the excavation and compact the backfill in layers of not more than 150 mm thick as follows:

(a) Where the trench is within a roadway, proposed roadway, the remainder of the trench shall be:

(i) backfilled with a non-cohesive granular material, with a grading falling generally within the limits shown in Table SC6.4.6.3.3, and compacted to Density Index of 70 when determined in accordance with AS 1289.5.6.1:

(A) below 0.3 m of the subgrade road surface; and

(B) in the road reserve, up to top of overlay zone;

(ii) backfilled with selected material, and compacted to 100 per cent of the standard maximum dry density of the material when determined in accordance with AS 1289.5.4.1, to top of subgrade level of the road surface, but excluding the pavement layers;

(iii) backfilled with selected material, and compacted to 95 per cent of the standard maximum dry density of the material when determined in accordance with AS 1289.5.4.1, to finish surface level of the areas of trench outside of roadways; and

(iv) backfilled with road base and sub-base material as per existing or proposed pavement layers and compacted to 100 per cent of the standard maximum dry density of the material when determined in accordance with AS 1289.5.4.1.

(b) Elsewhere, unless stated otherwise, the remainder of the trench shall be backfilled with ordinary excavated backfill material. Where suitable material is not available, granular material may be used for the full depth of backfilling. The material shall be compacted to a density Index of 70 when determined in accordance with AS 1289.5.6.1 for cohesionless materials or 98 per cent of the standard maximum dry density of the material when determined in accordance with AS 1289.5.4.1 for cohesive materials.

The Contractor shall carry out backfilling and compaction without damaging the pipe or its external coating or wrapping or producing any movement of the pipe.

The Contractor is to submit to the Superintendent for approval any proposal for construction of embankments in conformance with the drawings, including the method of placement and compaction and any limitations to the placement/ compaction over the top of any pipeline.

Where a roadway is to be sited over existing infrastructure, excavation of trench material down to overlay zone and subsequent backfilling with appropriate select material to the underside of sub-base to the compaction requirements stated above must be undertaken by the contractor.

The Contractor may compact backfill by trench flooding only where:

- the ground and backfill material is cohesionless sand;
- water for flooding has been sourced at the site;
- the process will not create mud which would be moved off site by vehicles or construction plant; and
- additives are not used.

The contractor shall carry out compaction tests to the full depth of zone being tested and present NATA certified test results to the Superintendent.

SC6.4.6.3.4 Pipeline testing and restoration

(1) General

The Contractor shall subject all sewers and maintenance holes to an initial test as soon as practicable after construction and backfilling is completed (WSA 02-2014, Part 2, Section 21).
All lines shall be clear and free from soil, slurry, liquids and other foreign substances at the time of initial and acceptance testing.

Where a vacuum system has been specified, the Contractor shall test the system in accordance with the testing schedule as shown on the design drawings.

(2) Initial test of gravitation sewers

The Contractor shall make the initial testing of gravitation sewers with compressed air. Before the initial test is performed, all pipe laying on the section shall be completed, and backfill shall be compacted to at least the level of the top of overlay section of trench filling. The Superintendent shall advise at the time of notification by the Contractor whether the option to inspect the initial testing is required.

The initial test shall not be carried out before risers and/or property connection sewers are constructed.

Where the Superintendent approves the construction of pipelines in other than full lengths between maintenance holes, each length of pipeline shall be tested before backfilling together with the downstream portion of the maintenance hole length under construction.

The Contractor shall rectify any fault detected and obtain a satisfactory test before the remainder of backfill is placed.

(3) Initial test of maintenance holes

The Contractor shall test each maintenance hole for leakage, as soon as practicable after the maintenance hole is constructed and the maintenance hole cover surround fitted.

Maintenance holes may be tested in conjunction with both upstream and downstream sections of mains using the low pressure vacuum method for the initial testing only in accordance with WSA 02-2014, Part 2, Section 21.4.2.2. It is advised that a pressure relief valve be installed inline with a maximum setting release of 50 kPa.

Alternatively, the Contractor may request to test manholes initially using hydrostatic means. The test shall be made by plugging all pipe openings in the walls and by filling the maintenance hole with water to the lowest point on the top of the maintenance hole cover surround. The plugs shall be positioned in the pipes as near as practicable to the internal face of the maintenance hole. The Contractor shall provide details of the alternative method proposed, for approval by the Superintendent, prior to its use.

(4) Ovality test and CCTV inspection

The Contractor shall carry out deflection (ovality) testing in conformance with WSA 02-2014 Part 2, Section 21.6.2 upon completion of placement and compaction of trench and embankment fill. Submit proposal for deflection testing to the Superintendent for acceptance. Carry out a CCTV inspection of the sewer system and maintenance structures to WSA 05 Attachment E and WSA 02-2014 Part 2, Section 21.7 and SC6.4.2.2.6 Conduit assessment.

The Contractor shall undertake ovality testing as follows:

(a) all sewers to DN 300 shall be tested to determine any excessive ovality using either a proving tool approved by the council or by CCTV light ring and approved measurement software. Ovality testing shall be undertaken after all earthworks on the subdivision are complete and no sooner than 14 days after backfill of trenches has been completed. Sewer pipes having excessive ovality shall be replaced and the line retested (WSA 02-2014, Part 2, Section 21.6.2 & WSA 05-2013);

(b) the proving tool shall be rigid and non-adjustable having an effective length of not less than its nominal diameter. The minimum diameter at any point along the length shall be as specified in WSA 02-2014, Appendix K;

(c) the proving tool shall be fabricated from steel and have pulling rings at each end. The prover shall be marked to indicate the nominal pipe size and the prover outside diameter;

(d) Maximum Allowable Deflection = 3% of Mean Outside Diameter; and

(e) the testing shall require a “prover” to be pulled through each section of the pipeline by hand winching to demonstrate that the maximum allowable deflection is not exceeded.

(5) Acceptance test of gravitation sewers and maintenance holes

Acceptance testing shall be carried out before the issue of the Certificate of Practical Completion. Sewers or maintenance holes failing any test, shall be repaired and the test repeated. The process of testing, repair of defects and retesting shall continue until a satisfactory test is obtained. (WSA 02-2014, Part 2, Section 21.) The Contractor shall make the acceptance test on all components in the section of the sewer in the same manner and to the same methods as the initial test. The Contractor shall submit to the Superintendent satisfactory test results from the acceptance testing.

The Superintendent may permit hydrostatic testing as an alternative to air testing for acceptance of gravitation pipelines and maintenance holes after approval from council.

Where the project contains a combination of precast and cast insitu maintenance holes, then each group must be regarded as a separate population and testing frequencies shall be in accordance with WSA 02-2014, Part 2, Table 21.5.

The Superintendent may reject any pipeline or maintenance hole in which there is visible or detectable leakage.

(6) Testing with compressed air

The Contractor shall supply and keep all necessary equipment in a condition acceptable to the Superintendent.

All test gauges must have a current calibration certificate and have a range that is suitable to be able to read decimal increments. The minimum diameter of readable face shall be 100 mm.

Sewer lines may be tested by either vacuum (negative pressure) or by positive pressure. The use of inline manhole through connectors can be utilised for ease of testing multiple lines. Manholes and sewer lines shall be tested separately.

Compressed air shall be supplied by a compressor of the rotary vane type capable of supplying at least 1 m^3/minute at 35 kPa. The air shall be fed through a pressure-reducing valve capable of reducing pressure from that supplied to 28 kPa ± 4 kPa. The air shall then pass through an airtight line fitted with a pressure gauge reading from 0 to 50 kPa, a pressure relief valve that shall be set to blow off at 28 kPa ± 4 kPa and a gate valve to the pipeline to be tested.

The method of setting up and carrying out the test shall be as specified in WSA 02-2014, Part 2, Section 21.4.2.

(7) Allowable pressure drop times

The time taken for the pressure to drop from 25 kPa to 18 kPa shall be greater than that specified in WSA 02-2014, Part 2, Table 21.3.

Pressure drop times which are less than these may indicate leakage or excessive air permeability through unsaturated pipe walls with some materials. Vitrified clay pipes, in particular, suffer from excessive air permeability under dry summer conditions. When this occurs, pipes shall be thoroughly saturated with water before testing or a hydrostatic test applied.

In any case, where the allowable pressure drop time cannot be attained and there are no visible leaks, the Contractor shall apply a hydrostatic test.

(8) Hydrostatic testing

The Contractor shall not carry out hydrostatic testing unless prior approved by the superintendent.

The pipeline under test, and the pipe or hose with container, shall be filled with water until the free surface is level with the top of the container, when that container is suspended in accordance with the requirements set out below.

The test container shall be suspended at a level such that the test head applied to the pipeline is as follows:

(a) for initial test:

(i) when no property connection sewers or risers are constructed – a minimum head of 2 metres above the pipe invert at the upstream end of the line under test; or

(ii) where property connection sewers and/or risers are constructed – a minimum head of 2 metres above the highest invert in the line under test, including its risers and property connection sewers;

(b) for acceptance test, a minimum head of 2 metres above the highest invert in the line under test, including its risers and property connection sewers, or above the free standing level of ground-water in the vicinity whichever is the higher; and

(c) such other lesser head as the Superintendent, at the Superintendent's discretion, may direct.

The Contractor shall determine, at the Contractor's expense, the free standing level of groundwater, by a method acceptable to the Superintendent.

After allowing an interval for absorption, to be determined by the Superintendent, any fall of the free water surface shall be made good by adding extra water to the container. The Contractor shall measure the fall in water level during ten minutes thereafter.

The pipeline will be regarded as satisfactory if there are no visible leaks, and if the fall in water level is not more than 25 mm for each standard test length of the pipeline under test including property connection sewers and/or risers.

A standard test length in metres is defined as 1370 m divided by the effective diameter of the pipeline in millimetres. Where the pipeline under test is all of the same size, the effective diameter shall be the nominal size of that pipeline. Where the pipeline under test has property connection sewers and/or risers of smaller nominal size than the main sewer line, then the effective diameter shall be calculated as the product of the length and the nominal size of the larger pipe added to the product of the length and the nominal size of the smaller pipe; this sum shall be divided by the total length of pipeline under test; the result shall be the effective diameter.

(9) Visual inspection and measurement of infiltration

Whenever, in the case of acceptance testing, the pipeline is subjected to a significant head of groundwater (i.e. 1500 mm or more above the soffit of the sewer main provided that groundwater is at least 150 mm above any property connection sewer included in the test), the tests previously prescribed may be dispensed with in favour of visual inspection and measurement of infiltration upon request to the Superintendent.

In such circumstances, the Contractor shall propose full details of the method by which the infiltration is to be measured (WSA 02-2014 Part 2, Section 21.5).

If the Superintendent, at the Superintendent's discretion, approves of an inspection and infiltration test being performed for the purposes of acceptance, the Superintendent shall determine the duration over which infiltration is to be measured. The rate of infiltration shall not exceed that determined by the following formula:

Rate of Infiltration

$$Q.I. = 0.65 (L^1d^1h^1 + L^2d^2h^2 + \ldots\ldots\ldots L^nd^nh^n) + H^a$$

Where:

Q.I. = rate of infiltration in litres/hour

L = length of pipe in metres

d = nominal size of pipe in metres

h = average head of groundwater over the invert level of the pipe in the section under test

H^a = head of groundwater above the invert level of the outlet pipe of the maintenance hole when the

maintenance hole is included in the infiltration test.

The Contractor shall determine the head of groundwater, by a method approved by the Superintendent.

(10) Testing of rising mains

The Contractor shall pressure test rising mains to detect leakage and defects in the pipeline including joints, thrust and anchor blocks. Acceptance testing shall be carried out before the issue of the Certificate of Practical Completion. Rising mains failing any test, shall be repaired and the test repeated. The process of testing, repair of defects and retesting shall continue until a satisfactory test is obtained (WSA 07-2007, Part 3, Section 21). The Contractor shall submit to the Superintendent satisfactory test results from the acceptance testing.

Pipelines shall be tested in sections approved by the Superintendent as soon as practicable after each section has been laid, jointed and backfilled, provided that:

(a) if so specified or if the Contractor so desires, some or all of the pipe joints shall be left uncovered until the whole of the section has been successfully pressure tested to the satisfaction of the Superintendent; and

(b) the pressure testing shall not be commenced earlier than 7 days after the last concrete thrust or anchor block in the section has been cast.

For the purpose of this clause, a section shall be defined as a length of pipeline which can be effectively isolated for testing, e.g. by means of main stop valves. A maximum length of 1000 m can be tested in one continuous section unless otherwise approved by the superintendent.

Pressure testing shall not be carried out during wet weather unless otherwise approved by the Superintendent.

During pressure testing, all field joints which have not been backfilled shall be clean, dry and accessible.

During the pressure testing of a pipeline, each stop valve shall sustain at least once, the full test pressure on one side of the valve in closed position with no pressure on the other side for at least 15 minutes.

Before testing a pipeline section, the Contractor shall clean it to the satisfaction of the Superintendent and fill it slowly with water, taking care that all air is expelled. Purging of air from rising mains shall be promoted by opening air valves. In order to achieve conditions as stable as possible for testing by allowing for absorption, movement of the pipeline and escape of entrapped air, the section shall be kept full of water for a period of not less than 24 hours prior to the commencement of the pressure testing.

The hydrostatic test pressure which shall be applied to each section of the pipeline shall be equivalent to 1.25 times the maximum operating pressure of the pipeline but do not exceed 1.25 times the maximum operating pressure rating of the lowest rated pipe/fitting. The test procedure shall be in accordance with WSA 07-2007, Part 3, Section 21.4.

The Contractor shall maintain the specified test pressure for as long as required by the Superintendent, while the Contractor examines the whole section. In any case, the specified test pressure shall be maintained for not less than 4 hours. For the purpose of determining the actual leakage losses, the Contractor shall carefully measure and record the quantity of water added in order to maintain the pressure during the period of testing.

The pressure testing (pipes other than PE) of a section shall be considered to be satisfactory if:

- there is no failure of any thrust block, anchor block, pipe, fitting, valve, joint or any other pipeline component;
- there is no visible leakage; and
- the measured leakage rate does not exceed the permissible leakage rate as determined by the following formula:

  $Q_1 = (0.14 \times D \times L \times H)$

  where:

  Q_1 = permissible leakage rate (litres per hour)

  D = nominal internal diameter of pipe (m)

L = length of section tested (km)
H = average test head (m)

Any failure, defect, visible leakage and/or excessive leakage rate, which is detected during the pressure testing of the pipeline or during the defects liability period shall be rectified by the Contractor at the Contractor's expense. Where a thrust block or an anchor block fails, and such thrust block or anchor block has been constructed in accordance with the design drawings, and the failure is not, in the opinion of the Superintendent, the fault of the Contractor, the thrust or anchor block shall be strengthened or reconstructed as directed by the Superintendent. The cost of strengthening or reconstruction of such thrust or anchor block and the cost of retesting shall be paid as a Variation to the Contract, at such rates as are determined in accordance with the provisions of the General Conditions of the Contract.

For PE rising mains, testing shall be in accordance with WSA 07-2007, Part 3, Section 21.5.

Alternatively, the rising main may be tested by the use of compressed air. In this case, the Contractor shall provide details of the alternative method proposed, for approval by the Superintendent, prior to its use.

(11) Connection to existing sewers

The Contractor must request approval (request for private works quotation) for connection to existing sewers from Townsville Water and Waste. Works shall be either performed by the Sewer Agency or delegated to the contractor at the discretion of the Sewer Agency. Approval must only be requested upon satisfactory completion of all backfilling and testing. All necessary works required in completing connections to "live" maintenance holes (that is, accesses to sewer system that is currently in service), including all works undertaken by the Sewer Agency at "live" maintenance holes in delivering the works shall be the responsibility of the Contractor (WSA 02-2014, Part 2, Section 23).

(12) Restoration of surfaces

The Contractor shall clean pavements, lawns and other improved areas and leave them in the same order as they were at the commencement of the Works. The Contractor shall restore any fencing removed during construction and shall restore lawns with turf cut and set aside from the original surface and with imported turf from a source approved by the Superintendent. (WSA 02-2014, Part 2, Section 24.) The restoration works shall be done progressively and as soon as possible after the section of works is completed.

The Contractor shall maintain all restored surfaces in the condition to which they are restored until the expiry of the defects liability period applicable to those surfaces, notwithstanding that any deterioration of the restored surfaces, and the need for their maintenance may or may not be due to defects which become apparent or arise from events which occur during the defects liability period. The Contractor shall maintain pavements with crushed igneous rock, gravel or other suitable material allowing for consolidation and shall then restore them to a condition equivalent to that of the original pavement.

Immediately the backfilling of a trench excavated through a pavement has been completed, the Contractor shall temporarily restore the pavement. Where the trench crosses bitumen or concrete pavement, the surface is to be protected from deterioration. A pre-mixed asphaltic material may be used for such temporary restoration. The Contractor shall maintain the temporary restoration until final restoration is carried out. Final restoration of the pavement shall be carried out in accordance with SC6.4.4.8 Standard drawings SD-055 to restore the pavement and its sub-base to no less than the original condition. Final restoration may include, if required by the Superintendent, the removal of temporary restoration.

In other than roadways, the Contractor shall place the backfill sufficiently high to compensate for expected settlement and further backfilling shall be carried out or the original backfill trimmed at the end of the defects liability period in order that the surface of the completed trench may then conform with the adjacent surface. Surplus material shall be removed and disposed of to areas arranged by the Contractor. Where dry weather conditions have persisted after the original backfilling, including during the defects liability period, the Contractor shall take all necessary steps to consolidate the trench before removing surplus materials from the site.

In locations where, in the opinion of the Superintendent, surplus material left in the vicinity of the trench would

not be objectionable, the surplus material may be disposed by spreading neatly in the vicinity of the trench to the satisfaction of the Superintendent in such a way as to avoid future erosion of the backfill and adjacent ground surfaces. The Contractor shall maintain the backfill and adjacent ground until the expiry of the defects liability period.

Where, within public or private property, the reasonable convenience of persons will require such, the Superintendent may order the Contractor to level trenches at the time of backfilling. The Contractor shall make good any subsequent settlement, as required by placing additional fill.

The Contractor shall immediately restore any damaged or disturbed private property and services.

Should the Contractor elect to tunnel under paving, kerb and channel or other improved surfaces in lieu of trenching, backfilling shall be so carried out as to restore full support to those surfaces, and payment shall be made for the restoration of the surfaces as though they had been removed and replaced. The Contractor shall remain responsible for the repair of the improved surfaces, if subsequently damaged due to subsidence of the backfill, until the end of the defects liability period.

The Contractor shall provide notice to affected property owners of any pending works.

SC6.4.6.3.5 Pump stations

(1) General

Provide only products and materials authorised by Townsville Water and Waste, the drawings and this specification. The Contractor shall submit for approval any alternative or not authorised products and materials.

The Contractor must conform to manufacturer's recommendations for handling, transport and storage of materials and in a manner to prevent damage or deterioration or excessive distortion. Inspect all products and materials at the time of delivery and reject products and materials not in conformance with this specification and the manufacturers' recommendations. Maintain protective crating or packaging until immediately before use.

Damaged or defective materials are not to be installed or used, including coatings and linings, outside the manufacturer's recommended limits.

(2) Pumps

Pump construction materials for centrifugal end suction pumps shall comply with the following:

DESCRIPTION	MATERIAL
PUMP	Cast iron AS 1830 Gr T200
Casing and suction bend	Cast iron AS 1830 Gr T200
Wear rings	316 Stainless steel/AS 1449
Impeller	Gunmetal AS 1565-905C
Impeller nut	316 Stainless steel/AS 2837
Shaft sleeve	Phosphor bronze AS 1565-9060/316
Neck bush, lantern ring	Phosphor bronze AS 1565-9060
Gland studs	Cast Iron AS1830 Gr T200
Gland nuts	316 Stainless steel/AS 2837
Fixing nuts and bolts handhole	316 Stainless steel/AS 2837
Covers fitted bolts and nuts, casing and dowels	316 Stainless steel/AS 2837
Forcing screws	316 Stainless steel/AS 1449
Water thrower and drip tray	316 Stainless steel/AS 2837
Pump set base plate	316 Stainless steel/AS 2837
	316 Stainless steel/AS 1449
	Cast iron AS 1830 Gr T2000/Fabricated steel
MOTOR	Cast iron/Mild steel
Motor frame and end shield	Cast iron/Mild steel
Motor terminal box	Mild steel
Motor fan cover	Metal
Motor fan	
HOLDING DOWN BOLTS	316 Stainless steel/AS 2837
MECHANICAL SEALS	Tungsten carbide or equal
Seal faces	Nickel chrome steel
Springs	Fluoro carbon or nitrile rubber
Secondary seal	

The Contractor shall provide a written warranty from the manufacturer of the equipment. This action constitutes a hold point. The Superintendent's approval of the warranty is required prior to the release of the hold point.

The manufacturer's warranty shall require the manufacturer to accept liability for any defect in materials or workmanship which becomes apparent at any time within 2 years after the date of delivery of any piece of equipment used in work under the contract.

All nuts and bolts shall be manufactured in accordance with AS/NZS 1111 and AS/NZS 1112, 150 metric series and fitted with washers beneath bolts heads and nuts. Requirements are:

(a) all bolts, nuts and washers shall be stainless steel to AS 1449 and AS 2837, minimum grade 316. All bolts, nuts and washers are to be of the same grade and supplied passivated;

(b) all threads are to be rolled;

(c) all bolt heads and nuts shall be hexagonal;

(d) all bolts, studs, set screws and nuts for bolting flanges and other pressure containing purposes shall conform to AS 2528;

(e) all nuts and bolts subjected to vibration shall be fitted with lock washers or lock nuts;

(f) all concrete anchor bolts, nuts, locking nuts and large series washers required for the bolting down of pump set discharge bends shall be provided. These anchor bolts shall be as recommended by the equipment designer with a minimum diameter of 16 mm; and

(g) concrete anchor bolts shall be chemical masonry anchor type, set to their full depth, suitable for the required duty.

Bolts on all flanges will protrude no more than 10 mm past the nut when tightened.

The Contractor shall apply sufficient anti-seize/anti-galling material to the threads of all stainless steel fasteners. The material shall be Polytetrafluroethylene (PTFE), either tape to AS 1272, dipped or sprayed, or molybdenum disulphide.

(3) Preformed pump stations and package pump stations

Preformed components or systems, complying with the design drawings, if any, otherwise complying with AS 3518, AS 3571 or AS 4198 may be used in lieu of in-situ construction provided:

(a) preformed concrete wall units are to be manufactured to AS 4058 except as modified as for the requirements for precast maintenance hole units;

(b) joints shall be internal flush; and

(c) the Contractor shall supply components that make a watertight system and have a satisfactory surface finish.

Package pump stations may be supplied and installed provided:

(a) The proposed packaged system has been appraised and recommended by WSAA;

(b) all components comply with the requirements of this sub-section; and

(c) the units are at least equivalent to the requirements of this sub-section and the design drawings.

(4) Electrical compliance

The Works shall be in accordance with the requirements contained in clause SC6.4.3.21.4 Electrical and mechanical except where this sub-section or the design drawings indicate otherwise. The technical requirements detailed on the design drawings shall take precedence over the requirements of this sub-section should clauses be in disagreement.

Except where clause SC6.4.3.21.4 Electrical and mechanical requires a higher standard, works shall be carried out in accordance with AS 3000, the Service Rules of the Supply Authority and all relevant statutory authorities.

The Contractor shall supply proof of compliance with a standard or specified test. Such proof shall comprise a test certificate from an approved independent testing authority.

The Contractor shall submit all designs and material, to each Authority having jurisdiction for approval. The Contractor shall arrange for each Authority having jurisdiction to inspect the Works. The Superintendent shall be advised a minimum of 7 working days in advance of the date of any inspection by an Authority. The Superintendent shall advise at the time of notification by the Contractor whether the option to attend the inspections is to be exercised.

(5) Switchgear and control gear assembly (SCA), controls

The Contractor shall supply and install the SCA designed and assembled by a manufacturer approved by the Superintendent.

The SCA shall be of outdoor, stationary, free standing, metal-enclosed, cubicle type series with a minimum degree of protection of IP56D as specified in AS 60529.

All equipment shall be securely mounted on suitable mounting panels and comprise individual compartments. A hot dipped galvanised steel channel base shall be provided.

The Contractor shall provide an effective barrier to prevent gases from the wet well entering the SCA.

Starter contactors shall have appropriate ratings for the proposed pumps to AC3.

All necessary terminals with terminal and cable numbers shall be supplied and installed in accordance with the design drawings.

The Contractor shall liaise with the electricity supply authority to supply padlocks for the metering equipment, at the Contractor's expense. The Superintendent shall supply padlocks for use on the SCA at no cost to the Contractor.

The electrical characteristics of the SCA shall be:

Main Circuit: 415/240 V, 50 Hz, 3-phase, 4-wire.
Motor Control Circuit: 240 V, 50 Hz.
Common Control Circuit: 240 & 24 V, A.C.
Prospective short-circuit current:
14kA for 1 second. Peak Factor: 2.2
Power Factor Correction (determined in consultation with the Superintendent)
Earthing (M.E.N. system)
Characteristics

All cables shall enter the SCA from below:

The Contractor shall supply data from the switchgear supplier confirming Type “2” co-ordination between contactors, motor protection relays and corresponding circuit breakers, to the Superintendent.

Refer to Standard Specification TCC24 clause 18 for starter selection requirements and functional specification for the project.

The Contractor shall carry out of factory tests in the presence of the Superintendent's Representative and in accordance with clause SC6.4.3.21.4 Electrical and mechanical and the results shall comprise all routine Tests specified in AS 3439. The Superintendent shall be given 7 days notice of the proposed date of such tests.

Inspections and functional tests shall be in accordance with TCC24 clause 21.

The Contractor shall pack the equipment for transport after satisfactory final factory inspection and tests, and after approval has been given by the Superintendent. The Contractor shall ensure that any relays, programmable logic controllers, and fittings likely to be adversely affected during delivery shall be adequately protected or shall be removed and packed separately in protected containers. Where equipment has been removed, cover plates shall be provided.

The Contractor shall be responsible for any damage that may occur during transit and unloading at site.

The Contractor shall ensure that spare parts, tools etc., are packed separately from the main plant and shall be marked “Spare Parts”, “Tools” etc., as applicable.

The Contractor shall supply spare parts in accordance with the schedule supplied by the Superintendent.

Automatic control of the pump station pumping equipment shall be by way of hydrostatic level sensor providing single pump duty operation unless shown otherwise on the drawings. The level sensor will be compatible with those in use in the system. A float switch shall be used to provide a HIGH HIGH(overflow) level alarm. Refer to TCC24 clauses18.2, 18.2, 19.1 and 19.2.

The following wet well levels shall be used in the automatic control of the pump operation system:

(a) STOP level;

(b) Duty Start level;

(c) Standby Start level; and

(d) High level.

Pump operation requirements are described in TCC24 clause 18.

The Contractor shall supply and install control equipment that is compatible with the existing equipment.

(6) Electrical installation

The Contractor shall liaise with the Supply Authority for the electricity supply to the pump station site.

The Contractor shall be responsible for all facilities required by the Supply Authority for revenue metering equipment and the payment of all associated connection, inspection fees and capacity charges.

The Contractor shall supply and install all cabling including consumer mains, motor, control and instrumentation cables, conduits and electrical pits.

The Contractor shall install all wiring in HD-PVC underground conduits laid in accordance with the Supply Authority's requirements, with a minimum 500 mm below the finished ground level in non-trafficable areas and 600 mm below the finished ground level in trafficable areas. The trench and backfill material shall be free of rocks and other foreign matter likely to damage the conduits.

The Contractor shall run electrical marker tape 150 mm below the finished ground level directly above the conduits for the entire length of the conduits. Marker tape shall be orange in colour, 150 mm wide and stamped with the words "DANGER – ELECTRIC CABLES BELOW" or similar.

The Contractor shall route all underground cabling with the approval of the Superintendent. Brass marking plates shall be positioned on a concrete surround clearly showing the direction of the incoming consumer mains. Wording and markings shall read "DANGER – ELECTRICAL CABLES BELOW". The Superintendent's approval of the route of all underground cabling is required prior to the release of the hold point.

The Contractor shall determine the points of attachment on site and the Contractor shall supply and install any consumer's connection poles for the consumer mains required by the Supply Authority.

The consumer mains shall be generally run underground and commence at the point of attachment on a steel consumers pole (if applicable), installed near the property boundary and run in conduit to the switchboard.

No aerial conductors are to be installed over structures, access road or vehicle manoeuvring areas.

The minimum size of the consumers mains shall be sized to satisfy the following:

(a) current carrying capacity to suit the maximum demand with an excess current carrying capacity of 30 per cent minimum;

(b) be sized for a voltage drop less than 1.5 per cent to the maximum demand as calculated;

(c) be single core PVC/PVC cables. XLPE insulated cable may also be used;

(d) comply with the requirements of the Supply Authority; and

(e) AS 3000 and AS 3008.

In addition to the requirements of the Supply Authority and clause SC6.4.3.21.4 Electrical and mechanical, the Contractor shall run the main earthing conductor in conduit to the main earthing electrode. The main earthing connection shall be contained in an earthing electrode connection box similar to ALM type ERB-1 up to 50 mm2 cable and a Type 4 pit for larger cable.

Earth electrode shall be bonded and suitably labelled with an engraved brass label.

Surge diverters shall be earthed in accordance with manufacturer's instructions.

The Contractor shall bond the pump station metallic pipework to the main earth.

Refer also to TCC24 clause 28.1 for installation instruction requirements.

Metering equipment and installation shall comply with the *Queensland Electricity Connections and Metering Manual.*

The Contractor shall gland cables entering the outdoor SCA compartment using non-ferrous metallic or plastic glands with neoprene compression seals and connect the on-flow switch and pump motor cables to the appropriate terminals. Cables shall not be jointed.

The Contractor shall seal, at the completion of commissioning tests, all conduits into the outdoor SCA with a non-setting sealing compound to prevent the ingress of vermin.

(7) Pressure gauges

The Contractor shall install one diaphragm protected, glycerine oil filled, direct mounting, bottom connection pressure gauge complying with AS 1349 per centrifugal pump installation. Cases shall be fabricated from stainless steel complying with AS 1449 or bronze. The protective diaphragm shall be suitable for dismantling for cleaning without affecting the accuracy of the gauge.

The gauge face shall be 100 mm in diameter and calibrated in metres head of water. The gauge shall accurately indicate the pump operating head and the pump no-flow head.

Each gauge shall be supplied with the nominally sized metric equivalent of three of the following bronze fittings: gate valve, union, nipple and reducing nipple.

Gauges and fittings shall be screwed into the pipe wall of ductile iron pipes, or pipe fittings, 150 mm and larger. In pipework less than 150 mm, gauges and fittings shall be screwed into a tapping band. On rising mains, where shown on the design drawings, the Contractor shall install a ball valve to allow removal of the gauge.

The pressure gauge range for single or parallel pumps duty shall be 0 to 1.7 times the closed valve head of the pumps.

(8) Valves

The Contractor shall ensure that the valves supplied are compatible with the pipework such that proper sealing is provided between the pipe flanges and the valve. The concrete lining in pipework shall not be chipped away or reduced to provide clearance from the working parts of valves.

The Contractor shall ensure that valves are installed so as to facilitate maintenance. The Contractor shall take into account the manufacturer’s recommendations, the requirements shown on the design drawings, the type of connection, and lubrication of connecting bolts.

Flanges shall comply with AS 2129 to the class shown on the design drawings.

Unless shown otherwise on the design drawings, all valves shall be anti-clockwise closing.

The Contractor shall size “Tee” Key valve operators and hand wheels to operate the valves under all operating conditions throughout their full range with no greater than 180 Newtons applied to the ends of the key bar or the rim of the wheel.

Hand wheels shall display an embossed or engraved arrow, together with “open” and/or “close” corresponding to the valve operation.

One “Tee” key operator per pump station, of suitable length for operating the respective valve from the surface level, shall be provided for each size of valve installed in each pump station.

Non-return valves shall be of the swing check type to AS 3578 of cast iron or steel body, cover and disc with bronze body and disc seat rings. The leaf shall swing clear and provide an unobstructed waterway.

The body cover shall be located and sized to allow the valve flap to be removed and the seat to be inspected without removing the valve.

Each non-return valve shall have an extended spindle, minimum grade 316 stainless steel, fitted with an adjustable counterweight.

The knife gate valve shall be constructed in accordance with the following:

(a) the design shall include an enclosed bonnet;

(b) the spindle shall be of the non-rising type;

(c) valves shall be anti-clockwise closing;

(d) the gland around the spindle shall be adjustable or formed by a double O-ring;

(e) flange jointing shall be rubber O-rings; and

(f) seating shall be achieved by flexible seats which shall be designed in a manner that will allow easy replacement. The material of the seat is to be nominated.

All assembly bolts and nuts shall be fitted with fibre or nylon isolating washers to prevent bimetallic corrosion where required.

Each valve spindle shall be fitted with a cast steel or forged steel spindle guard secured to the valve spindle with a gun metal set screw or a handwheel secured to the spindle with gun metal set screw and washer.

Valves shall be drilled and threaded, where required, in accordance with AS 2129.

(9) Testing and commissioning of pump station

The Contractor shall test and/or inspect all materials, equipment, installation and workmanship to prove compliance with the sub-section requirements. The submission to the Superintendent of satisfactory test results constitutes a hold point. The approval of the Superintendent is required prior to the release of the hold point.

Tests and inspections shall comply with relevant Australian Standards.

Testing shall include pre-commissioning, field testing and performance testing of each part of the whole installation.

Pre-commissioning is the preparation of plant or equipment so that it is in a safe and proper condition and ready for commissioning and operation. It includes all aspects of plant operation such as safety, electrical, mechanical and instrumentation.

The Contractor shall conduct pre-commissioning in a logical sequence in accordance with the programme prepared by the Contractor and approved by the Superintendent.

The Contractor shall prepare pre-commissioning record sheets for each item of equipment to ensure results of tests are satisfactorily recorded and that all necessary checks or tests have been performed.

Specific requirements for pre-commissioning shall include, but are not limited to:

(a) initial charges of lubricant in addition to any special lubricant requirements for initial flushing or treatment of the system or for “running in”;

(b) physical checks and tests such as completeness of assembly, rotational tests (including checking that the rotation of electrical motors is in the correct direction), alignment checks, balancing and vibration checks, temperature, pressure and flow measurements, clearances, belt alignment and tension, etc., depending on the type of equipment;

(c) electrical and instrument installation tests, including motor insulation tests and checking instruments against certified instruments and correcting as necessary;

(d) tests of the correct functioning of automatic and manual control and protection equipment, including simulating danger conditions, mal-operations or failures, to check that all instruments and controls function correctly. These tests shall also include adjusting instrument set points and alarm settings and proving correct operation of alarms; and

(e) equipment and system operating tests. The Contractor shall certify compliance of each item and submit a signed copy to the Superintendent prior to commissioning.

The Contractor shall carry out pre-commissioning tests to the satisfaction of the Superintendent and shall record the results of the tests on the appropriate Pre-commissioning Record Sheet.

Refer to TCC24 clause 28.1.11 for electrical test documentation requirements.

The Contractor shall furnish the Superintendent with one signed copy of each completed Pre-commissioning Record Sheet countersigned by the Superintendent's Representative who witnessed the test.

Commissioning is the running of the plant and equipment to ensure flow through the pumping system, carrying out any necessary testing and adjustments until it is ready and suitable for normal starting and running under service conditions.

The Contractor shall give the Superintendent 5 working days notice of the Contractor’s intention to undertake commissioning and supply to the Superintendent the copies of each of the pre-commissioning record sheets and three copies of the operational and maintenance manuals at the time that notice of commissioning is given.

The Contractor shall conduct commissioning in a logical sequence in accordance with a programme prepared by the Contractor and approved by the Superintendent.

Throughout commissioning the Contractor shall be responsible for the test programme.

The Contractor shall provide continuous supervision by personnel experienced in the operation of the equipment and shall have qualified personnel in attendance to carry out all necessary adjustments and/or remedial work during the commissioning tests.

The Contractor shall prepare, schedules, test record sheets and programmes for approval by the Superintendent prior to each stage of the overall commissioning.

The Contractor shall carry out final testing and commissioning (min 1 day duration) of the electrical services in conjunction with the mechanical equipment (e.g. pump, etc) including setting and adjustment of equipment in accordance with SC6.4.3.21 Townsville water and planning design guidelines.

The Contractor shall arrange for all testing, commissioning and any adjustments.

(10) Practical completion of pump station

The Contractor shall fulfill the following requirements before the Certificate of Practical Completion can be issued which constitutes a hold point:

(a) receipt by the Superintendent of a certificate of approval from the relevant statutory authorities;

(b) pump station is in working order as demonstrated by the testing and commissioning;

(c) approval by the Superintendent of operating and maintenance manuals; and

(d) receipt by the Superintendent of as-built drawings of the pump station.

(11) Telemetry

The Contractor shall make provision for equipment to link the pump station to the existing telemetry network to be provided by Townsville Water and Waste at the Contractor's expense. Refer to TCC24 clause 17.1, 28.2, Appendix B2 and Appendix C.

The pump station shall be capable of being operated automatically by control signals from the existing or proposed telemetry system. In addition, either one or any combination of pumps may operate at any one time by control signals from the telemetry system.

(12) Operation and maintenance manuals

(a) Manuals shall contain the following information:

(i) contractor’s name, address and telephone number;

(ii) client’s contract number, job name; and

(iii) pump station general arrangement drawing showing pumps, motors, valves, pipework, switchboard and electrical installation.

(b) Manuals for pumps shall contain the following information:

(i) manufacturer;

(ii) type and model number;

(iii) serial number;

(iv) dimensioned general arrangement drawing of pump and motor;

(v) sectional arrangement drawing with parts and list; and

(vi) dimensioned sectional arrangements detailing:

(A) maximum and minimum shaft/bearing clearance (radial);

(B) maximum and minimum impeller/bowl clearance (radial);

(C) maximum and minimum impeller/bowl clearance (axial);

(D) impeller/bowl wear rings;

(E) motor/pump coupling – type, make and model number; and

(F) mechanical seals where applicable.

(c) Manual for motors shall contain the following information:

(i) manufacturer;

(ii) type and model number;

(iii) serial number;

(iv) dimensioned general arrangement drawing;

(v) sectional arrangement drawing for submersible motor power cabling where applicable;

(vi) gland sealing arrangement drawing for submersible motor power cabling where applicable;

(vii) cables where applicable; and

(viii) terminal block arrangement drawing where applicable.

(d) Manuals for electrical equipment shall comply with TCC24 clause 23 and requirements for electrical drawings are described in TCC24 clause 22.

(e) Manuals for valves shall contain a dimensioned sectional arrangement drawing with parts and material list for all valves.

(f) Manuals shall contain the following test curves:

(i) pump witnessed test curves;

(ii) motor test curves; and

(iii) motor torque/speed/efficiency characteristic curves.

(g) The operating and maintenance manual shall include:

(i) safe working procedures - for switching and isolating the supply and distribution system;

(ii) comprehensive description of operation, including flow charts detailing each operational activity (e.g. manual pump operation, routine test procedures);

(iii) maintenance procedures - recommended maintenance periods and procedures;

(iv) tools - particulars of maintenance equipment and tools provided, with instructions for their use;

(v) equipment - a technical description of the equipment supplied, with diagrams and illustrations where appropriate;

(vi) dismantling - where necessary, procedures for dismantling and reassembling equipment; and

(vii) spare parts - a list of the spare parts provided.

Trouble shooting instructions shall be included for pumps, motors, valves and SCA.

Step by step procedures for dismantling and reassembly of pumps, motors and valves using any special tools shall be detailed together with step by step procedures for replacement of wearing parts such as bearing, seals, wear rings, etc.

SC6.4.6.3.6 Construction compliance

(1) As-constructed details and operation and maintenance manuals

The Contractor shall submit as-constructed drawings showing the actual location and alignment of pipelines, maintenance holes and junctions, all pump station details together with operating and maintenance manuals in accordance with SC6.4.7. Refer to SC6.4.3.21.3(5)(n) for the pump station documentation requirements.

Details shall include the size, type, levels, grade of pipelines, maintenance hole, and maintenance shaft location, types and cover details, easement requirements for maintenance, pump details, switchboard equipment details and station structural details. The Contractor shall record on as-constructed drawings the area of side fill which should not be disturbed in future without special precautionary measures where side fill construction is part of the structural integrity of a constructed pipeline of a diameter more than 225 mm.

The Contractor shall ensure that a registered surveyor certifies the plans showing location and alignment.

The Contractor shall provide records, for Townsville Water and Waste's Asset Register, to the Superintendent at the time of practical completion of the Contract. The records are to be in a form consistent for inputting into the Asset Register as directed by the Superintendent.

(2) Video records

Unless advised otherwise by the Superintendent, the Contractor shall provide a video recording of the internal condition of all mains. The video recording shall be undertaken at the time of practical completion of the Contract.

SC6.4.6.4 Stormwater drainage

SC6.4.6.4.1 Introduction

(1) Introduction

Drainage works shall form a complete system carrying water through and away from the Works.
This is the general sub-section common and applicable to all types of drainage lines, open drains, kerb and channel, and drainage structures and shall be read in conjunction with drainage specifications:

(a) SC6.4.6.6 Pipe drainage;

(b) SC6.4.6.7 Precast box culverts;

(c) SC6.4.6.5 Drainage structures; and

(d) SC6.4.6.9 Open drains.

(2) General scope

The work to be executed under this sub-section consists of:

(a) preparation for stormwater drainage construction;

(b) temporary drainage during construction;

(c) siting of pipes, pipe arches and box culverts;

(d) all activities and quality requirements associated with excavation and backfilling; and

(e) all concrete work associated with stormwater drainage.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(3) Extent of work

Details of the work are shown on the drawings. The extent of works under this specification is summarised as follows:

(a) pipe culvert stormwater drainage;

(b) precast box culvert stormwater drainage;

(c) drainage pits, headwalls, wingwalls and aprons;

(d) kerb and channel;

(e) open concrete dish drains;

(f) scour protection of open drains at outlets to drainage structures; and

(g) demolition and removal of existing redundant pipe culverts, headwalls and pits.

(4) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.10 Earthworks (construction)
SC6.4.6.28 Minor concrete works

(b) Australian Standards:
AS 1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS 1289.5.7.1 - *Compaction control test Hilf density ratio and Hilf moisture variation (rapid method)*
AS 1597 - *Precast reinforced concrete box culverts*
AS/NZS2566.2 - *Buried flexible pipelines installation*
AS/NZS3725 - *Design for installation of buried concrete pipes*

(c) other:
International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

SC6.4.6.4.2 Construction

(1) Temporary drainage during construction

(a) For each part of the drainage system, complete the erosion and sedimentation control measures before commencing the drainage works (except those parts of the drainage system forming part of the control measures). Measures for erosion and sedimentation control must be provided in accordance with the requirements of the accepted project erosion and sediment control plan and/or *Best Practice Erosion and Sediment Control* and make adequate provision for runoff flows at drainage works under construction or at surrounding areas/structure.

(b) The Contractor shall make adequate provision for runoff flows at drainage works under construction to avoid damage or nuisance due to scour, sedimentation, soil erosion, flooding, diversion of flow, damming, undermining, seepage, slumping or other adverse effects to the Works or surrounding areas and structures as a result of the Contractor's activities.

(c) The Contractor shall not implement any proposals to dam up or divert existing watercourses (either temporarily or permanently) without the prior approval of council by way of approved drawings or written instruction.

(d) The Contractor's material and equipment shall be located clear of all watercourses.

(2) Siting of culverts

(a) Before commencing construction of any culvert, the Contractor shall set out on site the culvert inlet and outlet positions to the location and levels shown on the drawings, and shall present this set-out for inspection by the Superintendent.

(b) The Superintendent may amend the inlet or outlet locations or designed levels or the culvert length to suit actual site conditions. Any such amendments must ensure no negative impacts on neighbouring land parcels and existing properties. Prior approval must be sought from council.

(c) Should the Contractor propose changes to the culvert location, length, designed levels, culvert strength, conditions of installation or cover to suit the construction procedures, the Contractor shall present the proposed culvert set-out in addition to the designed set-out for consideration by the Superintendent and council. No changes shall be made unless prior written approval from council is obtained.

(3) Excavation

(a) Before undertaking stormwater drainage excavation, topsoil shall be removed in accordance with SC6.4.6.10 Earthworks (construction).

(b) In undertaking trench excavation, the Contractor shall provide any shoring, sheet piling or other stabilisation of the sides necessary to comply with statutory requirements.

(c) Where public utilities exist in the vicinity of stormwater drainage works the Contractor shall obtain the approval of the relevant authority/corporation to the method of excavation before commencing excavation.

(d) Excavation by blasting, if permitted by council, shall be carried out to ensure that the peak particle velocity measured on the ground adjacent to any previously installed culvert or drainage structure does not exceed 25mm per second. The Contractor shall comply with other requirements concerning blasting operations in SC6.4.6.10 Earthworks (construction).

(e) Trench or foundation excavation for stormwater drainage works shall be undertaken to the planned level for the bottom of the specified bedding or foundation level. All loose material shall be removed by the Contractor.

(f) Any material at the bottom of the trench or at foundation level which the Superintendent deems to be unsuitable and inadequate to support the proposed drainage structure shall be removed and disposed in accordance with SC6.4.6.10 Earthworks (construction) by the Contractor and replaced with backfill material in accordance with the requirements of this sub-section and the sub-sections for particular culvert types. The bottom of the excavated trench or foundation, after any unsuitable material has been removed and replaced, shall be parallel with the specified level and slope of the culvert.

(g) The excavated material shall be used in the construction of embankments backfilling or spoiled in accordance with SC6.4.6.10 Earthworks (construction).

(4) Backfilling

Backfilling shall be carried out in accordance with the requirements of the relevant culverts or drainage structures sub-sections and to the compaction requirements specified in SC6.4.6.4.2(5) Compaction.

In situ concrete structures are not to be backfilled in accordance with Clause 6.4.6.5.2 8(a) unless otherwise directed by the Superintendent.

The shape of the culvert must be checked by the Contractor during backfilling to ensure that on completion of backfilling, the vertical and horizontal centreline dimensions of the pipe or structure do not vary from the manufacturer's specified dimensions by more than ± 2% for pipes and pipe arches.

(5) Compaction

Foundations, bedding (other than for pipe drainage) and backfilling shall be compacted to the following requirements when tested in accordance with AS 1289.5.4.1 or AS 1289.5.7.1 for standard compactive effort.

Refer to Table SC6.4.6.4.3 for details of compaction and moisture tolerances.

Compaction requirements adjacent to pipe drainage for concrete, steel or UPVC pipes are set out in sub-section SC6.4.6.6 Pipe drainage.

(6) Concrete work

For all concrete work, the Contractor shall comply with sub-section SC6.4.6.28 Minor concrete works in relation to the supply and placement of normal class concrete and steel reinforcement, formwork, tolerances, construction joints, curing and protection.

(7) Sprayed concrete

If sprayed concrete has been specified, shown on the drawings or directed by the Superintendent, it shall comply with requirements in sub-section SC6.4.6.28 Minor concrete works.

(8) Construction traffic

If proposing to move heavy construction plant or vehicles over pipe or box culverts structures, provide verification and certification of protective measures to the Superintendent for confirmation and approval of protection measure proposed.

SC6.4.6.4.3 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.4.3 below:

Table SC6.4.6.4.3 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Excavation by Blasting**		
	(a) peak particle velocity	≤25mm/sec	SC6.4.6.4.2(3)
2.	**Relative Compaction (Standard)**		
	(a) Foundations or trench base to a depth of 150mm below foundation levels.	95%	SC6.4.6.4.2(5)
	(b) Material replacing unsuitable material.		
	(c) Bedding material.		
	(d) Selected backfill and ordinary backfill material: • other than sub-grade (sand 70% Density Index) • other than sub-grade (other than sand) • at sub-grade level to 300mm below • in a pavement zone		
	(e) Backfill material within the selected material zone.		
3.	**Backfill**		
	(a) Layers	≤ 150mm	SC6.4.6.4.2(5)
	(b) Moisture Content	>60%, <95%	SC6.4.6.4.2(5)

SC6.4.6.5 Drainage structures

SC6.4.6.5.1 Introduction

(1) Scope

(a) This policy sub-section provides standards, advice and guidelines for the construction of drainage structures and shall be read in conjunction with the sub-section SC6.4.6.4 Stormwater drainage, and other drainage specifications as applicable:

(i) SC6.4.6.6 Pipe drainage;

(ii) SC6.4.6.7 Precast box culverts; and

(iii) SC6.4.6.9 Open drains.

(b) This sub-section details the construction of headwalls, wingwalls, pits, gully pits, inspection pits, junction boxes/pits, drop structures, inlet and outlet structures, energy dissipators, batter drains and other supplementary structures.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editors note - A reference to drawings is a reference to construction drawings.

(2) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.10 - Earthworks (construction)
SC6.4.6.4 - Stormwater drainage
SC6.4.6.6 - Pipe drainage
SC6.4.6.7 - Precast box culverts
SC6.4.6.9 - Open drains
SC6.4.6.28 - Minor concrete works

(b) Australian Standards
AS 3996 - *Access covers and grates*

SC6.4.6.5.2 Construction

(1) General

(a) Drainage structures shall be constructed in concrete and in accordance with sub-section SC6.4.6.28 Minor concrete works.

(b) All structures shall be constructed as soon as practicable and shall be completed not later than 28 days after the construction of the associated culverts, unless otherwise approved by the Superintendent.

(2) Alignment

(a) Unless otherwise shown on the drawings, headwalls and pits shall be constructed parallel to the road centreline and wingwalls at 120º to the headwall or as shown on the drawings.

(b) Where the culvert is laid skew to the road, the wingwalls and headwalls shall be splayed so that the front edge of the wing bisects the angle between the centreline of the culvert and the headwall.

(c) Energy dissipaters shall be constructed in accordance with the drawings and with centreline on the axis of the culvert.

(3) Headwalls and wingwalls

(a) The wingwalls shall be constructed to retain the batters effectively. Where the dimensioned drawings do

not satisfy this requirement the Superintendent shall be notified before the headwalls and wingwalls are constructed. The Superintendent shall direct the Contractor as to the action to be taken. Where rock is encountered at the bottom of excavations for wingwalls and headwalls, and after approval is given by the Superintendent, the depth of cut-off walls in uniform rock over the full width of the foundations may be reduced to less than that shown in the drawings, but must be not less than 150 mm into sound rock.

(4) Pits

(a) All new pits, including access covers, gully grates and frames complying with AS 3996, shall be constructed to the details shown on the drawings. Modification of existing pits is only to be carried out if shown on the drawings.

(b) Where the full depth of the excavation is in sound rock, and the Superintendent approves, part of the concrete lining of gully pits and sumps may be omitted, provided that a neatly formed pit of the required dimensions is constructed. In all such cases the wall of the pit adjacent to and parallel to the road shall be constructed of concrete

(c) Inlet and outlet pipes shall be integrally cast into the pit at the time of pouring the concrete for the pit walls.

(d) Step irons are not required.

(e) A subsoil drain where required shall be installed into the pit or headwall in accordance with the general requirements in sub-section SC6.4.6.6 Pipe drainage.

(5) Precast units

(a) Where precast units including kerb inlet lintels, are provided in the design they shall be handled and installed in accordance with the manufacturer's instructions.

(b) If the Contractor proposes to use precast units, detailed drawings and complete details of installation procedures shall be submitted for the approval of the Superintendent.

(c) The Superintendent is required to adopt pre-cast units which are in accordance with council’s standard drawings and specifications unless otherwise agreed by council.

(6) Jointing

Where drainage structures abut concrete paving, kerb and channel or other concrete structures, a 10 mm wide joint shall be provided between the structure and paving, or kerb and channel or other concrete structures. The joint shall consist of preformed jointing material of bituminous fibreboard.

(7) Mass concrete bedding

(a) Mass concrete bedding for reinforced concrete bases shall not be placed on earth or rock foundations until the foundations have been inspected and approved by the Superintendent. Following such approval, the surface of the foundation shall be dampened and a layer of concrete not less than 50 mm thick, shall be placed over the excavated surface and shall be finished to a smooth even surface.

(b) Unreinforced concrete bases may be cast on earth or rock foundations without the mass concrete bedding.

(8) Backfill

(a) Backfilling shall not commence until the compressive strength of concrete has reached at least 15MPa unless otherwise approved by the Superintendent.

(b) Selected backfill shall be placed against the full height of the vertical faces of structures for a horizontal distance equal to one-third the height of the structure.

(c) Selected backfill shall consist of a granular material in accordance with the requirements in sub-section SC6.4.6.6 Pipe drainage.

(d) Special care shall be exercised to prevent wedge action against vertical surfaces during the backfilling. Where the sides of the excavation are steeper than 4 horizontally to 1 vertically they shall be cut in the form of successive horizontal terraces at least 600 mm in width, as the backfill is placed.

(e) Backfill on both sides of the structure shall be carried up to level alternately in layers so as to avoid wedge action or excessive horizontal forces. Backfilling and compaction shall commence at the wall. Compaction shall be in accordance with sub-sections C6.4.6.4 Stormwater drainage and SC6.4.6.6 Pipe drainage.

(9) Tolerances

(a) On the completed works shall be as detailed in subsection SC6.4.6.28 Minor concrete works.

SC6.4.6.5.3 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.5.1 below.

Table SC6.4.6.5.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Cut-off Walls**		
	Depth into sound rock	>150mm	SC6.4.6.5.2(3)
2.	**Mass Concrete Bedding**	>50mm	SC6.4.6.5.2(7)

SC6.4.6.6 Pipe drainage

SC6.4.6.6.1 Introduction

(1) Scope

(a) This sub-section covers the supply and installation of pipe culverts and pipe arches for stormwater drainage.

(b) This sub-section should be read and applied in conjunction with sub-section SC6.4.6.4 Stormwater drainage.

(c) The work to be executed under this sub-section consists of supply of pipes and pipe arches, bedding, installation and backfilling.

(d) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.10 Earthworks (construction)
SC6.4.6.4 Stormwater drainage
SC6.4.6.5 Drainage structures
SC6.4.6.21 Subsurface drainage
SC6.4.6.28 Minor concrete works

(b) Australian Standards:
AS 1141.11 - *Particle size distribution –sieving method.*
AS 5101.4 - *Unconfined compressive strength of compacted materials.*
AS/NZS 1254 – *PVC-U pipes and fittings for stormwater or surface water applications.*
AS 1289.3.3.1 - *Calculation of the plasticity index of a soil.*
AS 1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS 1289.4.3.1 - *Determination of the pH value of a soil - Electrometric method.*
AS 1289.4.4.1 - *Determination of the electrical resistivity of a soil – Method for sands and granular materials.*
AS 1289.5.6.1 - *Compaction control test - Density index method for a cohesionless material.*
AS 1397 – *Continuous hot-dip metallic coated steel sheet and strip – coatings of zinc and zinc alloyed with aluminium and magnesium.*
AS 1646 - *Elastomeric seals for waterworks purposes.*
AS 1762 - *Helical lock-seam corrugated steel pipes - Design and installation.*

MRTS 26 - Manufacture of fibre reinforced concrete drainage pipes

(d) Other:
AASHTO Standard, *M190 - Bituminous coated corrugated metal culvert pipe and pipe arches.*
ASTM F2562/F2562M-08 - *Specification for steel reinforced thermoplastic ribbed pipe and fittings for non-pressurised drainage and sewerage*
Safety in Design CWPHESS

SC6.4.6.6.2 Common requirements

(1) General

(a) Pipes and/or pipe arches shall not be placed in position until the Contractor has produced documentary evidence to the Superintendent, that the manufacture of the products to be used in the works has complied with the Manufacturer's Quality Plan in accordance with ISO 9001.

(b) Documentation shall comprise a conformance certificate to AS 4058 or AS 4139 as appropriate for each batch of pipes or pipe arches to be included in the works, including manufacturer's installation recommendations. The above documentations certificates are to be supplied at least 24 hours in advance of dispatch to site.

Note—Table 3.6 of AS 4058 shall be replaced by Table 7A of *MRTS 25 - Manufacture of Precast Concrete Pipes* in determining the acceptability of pipe wall and joint surface defects.

(c) Each unit shall be marked at time of manufacture with:

(i) class and size;

(ii) manufacturer's name; and

(iii) date of casting.

(d) Where a Contractor wishes to use drainage pipe other than the pipes described in SC6.4.6.6.3(1) to (5) inclusive, the Contractor shall submit, for agreement by the Superintendent, full details in accordance with AS/NZS 2566.1 of the characteristics of the pipe materials and embedment and design loads, together with certification from the manufacturer of its suitability and quality for use in each particular application. Certification of the suitability of any pipe will address the bedding requirements, deflection, strength, buckling and any other considerations appropriate to the particular application. Upon agreement, the Superintendent must submit an application for a variation to the development consent for approval by council.

(e) The Contractor shall take all necessary steps to drain the excavation to allow the foundation, the bedding and any backfilling to be compacted to the specified relative compaction.

(f) Culverts shall be installed within 10mm of the grade line and within 50mm of the horizontal alignment specified on the drawings. The Contractor shall relay any culvert which is not within these tolerances. Where longitudinal gradients are less than 0.5 per cent, culverts shall be installed within +/- 6mm of the grade line.

(g) Where shown on the drawings at the discharge end of culverts terminating at pits and headwalls a 3m length of 100mm diameter subsurface drain shall be laid in the trench 100mm above the invert level of the culvert and discharging through the wall of the pit or headwall at 100mm above the invert level of the culvert or headwall. The subsurface drainage pipe shall be sealed at the upstream end and shall be enclosed in a seamless tubular filter fabric in accordance with SC6.4.6.21 Subsurface drainage.

(h) Excavation and backfilling for pipe drainage shall be undertaken in a safe manner and in accordance with all statutory requirements. The Contractor must present to the Superintendent the installed pipe drainage upon completion of backfill to the top side of the side zone for inspection prior completion of backfill.

(i) Where the Contractor proposes to travel construction plant in excess of 5 tonnes gross mass over pipe drainage structures, the Contractor shall design and provide adequate protective measures for the crossings and shall submit the proposals to the Superintendent for prior approval.

(j) Upon completion of installation of pipe drainage, the Contractor shall submit relevant test results to demonstrate compliance to the requirements indicated on clauses.

SC6.4.6.6.3 Precast reinforced concrete

(1) Pipes

(a) Precast reinforced concrete pipes shall comply with AS 4058 and shall be of the class and size as shown on the drawings.

Note—Table 3.6 of AS 4058 shall be replaced by Table 7A of *MRTS25 - Manufacture of Precast Concrete Pipes* in determining the acceptability of pipe wall and joint surface defects.

(b) Fibre reinforced concrete drainage pipes shall comply with AS 4139 and shall be of the class and size as shown on the drawings.

(c) Unless specified otherwise, joints shall be flush type with external elastomeric bands complying with AS 1646 and as recommended by the manufacturer.

(d) Where precast pipes are to be installed into a marine or saline environment, the contractor is to ensure and provide documentation that the supplied pipes are “fit for purpose” and are suitable for the intended site application.

(2) Excavation

(a) Unless otherwise indicated on the drawings, or approved by the Superintendent, the formation shall be completed to subgrade level and the pipes then installed in the normal trench condition.

(b) For normal trench conditions, the pipe shall be laid in an excavated trench with bedding as specified in SC6.4.6.6.2(3). The trench shall be excavated to a width as specified in Figure SC6.4.6.6.1.

(c) Care is necessary to avoid laying pipe drainage in trenches excavated to excessive width. Pipes laid in wide trench conditions will be deemed to be in embankment conditions (positive projection). Wide trench conditions apply when, for a single pipe, the width of trench, $W \geq D + 0.6$ metre where D is the pipe diameter. For multi-cell pipes wide trench conditions apply when the width of trench, $W \geq \sum D + \sum S + 0.6$ metre where S is the square spacing between the pipelines. This definition of wide trench conditions as equivalent to embankment conditions relates to the size and geometry of the excavation utilised at construction. Pipes shown on the drawings to require trench conditions shall not be placed under embankment conditions without a design check for compliance of the pipe strength and trench support requirements in accordance with AS 3725.

(3) Bedding

(a) Bedding shall be in accordance with this sub-section, AS 3725 and AS 3725 Supplement 1 for the pipe support types as shown on the drawings. Where the pipe support type is not shown on the drawings, the support type shall be HS3 within road reserves (HS3 is recommended for high embankment fill) and H2 elsewhere.

(b) Figure SC6.4.6.6.1 below and Table 5 – Bedding factors for Working Dead Loads (U, H and HS Supports) in AS/NZS 3725 indicate the dimensions of bedding and backfilling for pipes laid in trench conditions and embankment conditions for all AS 3725 pipe support types.

		Pipe Support Type						
		U	H1	H2	H3	HS1	HS2	HS3
Dimension (minimum)	x	75 on rock Nil on soil	100 for D ≤ 1500 150 for D > 1500		0.25 D but >100	100 for D ≤ 1500 150 for D > 1500		
	y	—	0.1D	0.3D	0.3D	0.1D	0.3D	0.3D
	z	—	—	—	—	≥ 0.7D		

D = External diameter of pipe

Figure SC6.4.6.6.1 Pipe installation conditions

(c) Bedding material for the bed and haunch zones shall consist of a granular material having a grading, determined by AS 1141.11, complying with Table SC6.4.6.6.1 Bedding Material Grading Limits, and a Plasticity Index, determined by AS 1289.3.3.1 of less than 6. Select fill material in the side zones, for pipe support type HS, shall also comply with Table SC6.4.6.6.1.

Table SC6.4.6.6.1 Bedding material grading limits

Sieve size mm	Weight passing %	
	Bed and Haunch Zones	Side Zones/Overlay Zones
75.0	-	100
19.0	100	-
9.5	-	50 - 100
2.36	50 -100	30 - 100
0.60	20 - 90	15 - 50
0.30	10 - 60	-
0.15	0 - 25	-
0.075	0 - 10	0 - 25

(d) The Contractor shall advise the Superintendent of the source of bedding material.

(e) All material shall be compacted in layers not exceeding 150mm compacted thickness except where explicitly approved by the Superintendent, for the first placed layer above the pipe crown in the overlay zone, in order to protect the pipe from construction damage. Each layer shall be compacted to the relative compaction specified before the next layer is commenced. Cohesionless materials can be

compacted in one operation by saturation and vibration to achieve the minimum Density Index (DI) specified.

(f) At the time of compaction, the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content which, unless otherwise approved by the Superintendent, is neither less than 60 per cent nor more than 95 per cent of the apparent optimum moisture content, as determined by AS 1289.5.4.1 (standard compaction).

(g) Compaction of select fill material in the bed and haunch zones shall be to the appropriate pipe support requirements shown in Table 5 – Bedding factors for Working Dead Loads (U, H and HS Supports) in AS/NZS 3725, when tested in accordance with AS 1289.5.6.1. H3 Pipe Support includes concrete bedding. Concrete shall be grade N20 to AS 3600. Pipe shall be suitably reinforced in accordance with AS 3725 as standard elliptically reinforced pipe may not be adequate for H3 Pipe Support. Unless specifically selected pipes are nominated for use with H3 bedding, a design check shall be required to confirm the suitability of the proposed pipes.

(h) The top 0.1Dmm of the bedding and haunch material directly under the pipe shall be placed and shaped accurately to house the pipe after compaction is achieved in the bedding and haunch zone external to the area of direct pipe support.

(i) Where the impermeability of the natural ground and the slope of the drainage line is such that erosion of bedding material is considered by the Superintendent to be a likely problem, the Superintendent may specify cementitious stabilisation of the bedding material used in the bedding and haunch zones.

(4) Installation

(a) General

Pipes shall be laid with the socket (female) end placed upstream. Pipes which have marks indicating the crown or invert of the pipes shall be laid strictly in accordance with the markings. Unless specified, no individual length of pipe shall be shorter than 1.2m.

The contractor is to ensure that all trenching is to conform to the requirements of Workplace Health and Safety (WHS) Act and regulations and Excavation Work Code of Practice 2013.

Pipes can be stiffened temporarily by the use of timber structs, erected before filling is placed. Struts shall be of hardwood measuring at least 100mm by 100mm or 125mm diameter. One strut shall be placed in a vertical position at each pipe joint, thence at a spacing not greater than 1,200mm. Struts shall bear against a sill laid along the invert of the pipe and a cap bearing against the crown of the pipe. Both the sill and the cap shall be continuous throughout the length of the pipe. Struts shall be made to bear tightly against the pipe by the use of wedges between the top of the struts and the cap. Struts, sills and caps shall be removed on completion of the embankment, unless removal is ordered earlier.

Lifting holes in all pipes shall be sealed with plastic preformed plugs approved by the Superintendent, or a 3:1 sand:cement mortar, before the commencement of backfilling.
Bulkheads shall be constructed in accordance with SC6.4.6.5 Drainage structures on all lines where the pipe gradient exceeds 5 per cent.

The Contractor shall present the laid and jointed pipes for inspection by the Superintendent prior to commencement of trench backfilling.

(b) Joints in reinforced concrete pipes

(i) Rubber Ringed Joints

Before making the joint, the spigot and socket and the rubber ring shall be clean and dry.

The rubber ring shall be stretched on to the spigot end of the pipe, square with the axis and as near as possible to the end, care being taken that it is not twisted. The spigot end of the pipe shall then be pushed up to contact the socket of the pipe with which it is to join, and be concentric with it. The spigot end shall then be entered into the socket of the already laid pipe and forced home by means of a bar, lever and chain, or other method approved by the Superintendent.

The joint shall be tested to ensure that the rubber ring has rolled evenly into place.
Where wedge shaped “skid” rubber rings are prescribed the Manufacturer’s instructions, which include the use of lubricants, shall be followed.

(ii) Flush or butt jointsThe ends of the pipes shall be butted together so as to be as tight and as even as possible.

The joints shall be sealed externally with proprietary E.B bands, supplied and installed in accordance with the manufacturer's recommendations, care being taken that the bands are not twisted.

(c) Joints in fibre-reinforced cement pipes

(i) New Pipes
Joints shall be of a flexible type. Rubber rings shall be used to seal joints in both rebated and spigot and socket jointed pipes in the manner specified in SC6.4.6.6.3(4) Installation.
Alternatively, a jointing compound comprising plasticised butyl rubber and inert fillers may be used to seal such pipes in accordance with the manufacturer's instructions.

(ii) Direct Side Connections to Other Pipes
Direct side connections to other pipes shall be as detailed on the drawings.

(5) Backfill

(a) Select fill material to the side zones shall be compacted to the requirements shown in Table 5 – Bedding factors for Working Dead Loads (U, H and HS Supports) of AS/NZS 3725 when tested in accordance with AS 1289.5.4.1 for standard compactive effort.

(b) Ordinary fill to the side zones and overlay zones, for all pipe support types, except type HS shall consist of Selected Backfill as defined in SC6.4.6.10 Earthworks (construction) or alternatively cohesionless material in accordance with Table 6.4.6.6.1 Bedding material grading limits. It shall be placed around the pipe to the dimensions shown in Figure SC6.4.6.6.1 Pipe installation conditions.

(c) All material shall be compacted in layers not exceeding 150mm compacted thickness. Each layer shall be compacted to the relative compaction specified before the next layer is commenced, or compacted in one operation by saturation and vibration to achieve a minimum Density Index as specified in Table 5 – Bedding factors for Working Dead Loads (U, H and HS Supports) of AS/NZS 3725.

(d) At the time of compaction, the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content which, unless otherwise approved by the Superintendent, is neither less than 60 per cent nor more than 95 per cent of the apparent optimum moisture content, as determined by AS 1289.5.4.1 (standard compaction).

(e) The remainder of the trench to the underside of the subgrade, or selected material zone as specified in SC6.4.6.10 Earthworks (construction), shall be backfilled with material satisfying the requirements for embankment material as defined in SC6.4.6.10 Earthworks (construction). Where excavation is approved through the selected material zone, the section of trench within the select material zone shall be backfilled with selected material as defined in SC6.4.6.10 Earthworks (construction).

(f) When compacted adjacent to culverts or drainage structures, the Contractor shall adopt compaction methods which will not cause damage or misalignment to any culvert or drainage structure. Any damage caused shall be rectified by the Contractor. Backfilling and compaction shall commence at the pipe or wall so as to confine remaining uncompacted material at commencement.

SC6.4.6.6.4 Steel pipes and pipe arches

(1) Nestable steel pipe and drainage units

(a) Nestable steel pipes and drainage units shall be supplied in accordance with AS 2041 and shall be of the class and size as shown on the drawings.

(b) The galvanised steel sheets used in manufacture shall comply with AS 1397 for steel base grade G250

and a minimum coating Class of Z600.

(c) Where specified, the pipes and drainage units shall be given a protective coating over the steel, after assembly of a coal tar epoxy paint or equivalent as approved by the Superintendent, to a thickness of 400 microns.

(d) Field cut ends shall be carefully wire brushed to remove any scale followed immediately by two coats of zinc-rich organic primer complying with AS/NZS 3750.9 or two coats of inorganic zinc silicate paint complying with AS/NZS 3750.15.

(2) Helical lock-seam corrugated steel pipe

(a) Helical lock-seam corrugated steel pipe shall be supplied in accordance with AS 1761 and AS 1762 and shall be of the class and size as shown on the drawings.

(b) The galvanised steel sheet used in manufacture shall comply with AS 1397 for steel based grade G250 and a minimum coating Class of Z600.

(c) Unless otherwise approved by the Superintendent, no part of the pipe shall incorporate steel strips which have been joined by welding. Field cut ends shall be carefully wire brushed to remove any scale followed immediately by two coats of organic zinc-rich primer complying with AS/NZS 3750.9 or two coats of inorganic zinc silicate paint complying with AS/NZS 3750.15. Pipes and coupling bands shall be given a protective hot-dip coating of bitumen on both sides to AASHTO standard M190 or equivalent as part of the process of manufacturing.

(3) Bolted steel pipes, pipe arches and special shapes

(a) Bolted steel pipes, pipe arches and special shapes shall be supplied in accordance with AS 2041 and shall be of the class and size as shown on the drawings. The corrugated pipe or plate shall be hot-dip galvanised on both sides after fabrication in accordance with the requirements for coating thickness and mass for articles in AS/NZS 4680.

(b) Also, after assembly, all bolted steel pipes, pipe arches and special shapes shall be given a protective coating on the outside of the steel plate, of a coal tar epoxy paint complying with AS 3887 or equivalent paint approved by the Superintendent. Invert plates shall be coated on the outside before they are placed on the pipe bed. The plate surface shall be cleaned and degreased with a cleaning solution recommended by the protective coating manufacturer. The protective coating shall be applied to give a uniform minimum dry thickness of 400 microns. Any coating damaged shall be recoated by first cleaning any grease, mud or other foreign matter from the affected area. The area shall then be recoated so that the minimum dry thickness of the coating is 400 microns.

(4) Materials and surface treatment of steel pipes and pipe arches

All steel pipes and pipe arches will require an Engineer's certification that the pipe materials and surface treatments are adequate to provide for installation and in-service loading, as well as corrosion protection for a satisfactory design life of 100 years, unless indicated otherwise on the drawings. Such certification shall address the chemistry of the soil, groundwater, stream and backfill material as specified SC6.4.6.6.4(5).

(5) Materials against steel structures

(a) The severity of corrosive attack on steel structures will depend on the pH value and electrical resistivity of the soil surrounding the structure and the pH value of the water in the stream.

(b) Besides meeting the normal requirements of the bedding, selected backfill materials and the materials used for embankment construction above the steel structures and within a horizontal distance from the structure equal to the height of the filling over the structure, the pH and resistivity limits as shown in Figure SC6.4.6.6.2 will determine the level of corrosion protection required.

(c) Notwithstanding the height of fill, embankment material within 6m of the structure shall conform to these requirements.

(d) The pH and electrical resistivity of the material shall be determined in accordance with AS 1289.4.3.1 and AS 1289.4.4.1.

(e) The Contractor shall nominate the sources of the various materials and submit documentary evidence

from a NATA registered laboratory that the representative samples conform to the requirements of this clause and the protective treatment provided. The samples shall be pre-treated if necessary so as to represent the condition and grading when compacted and in service.

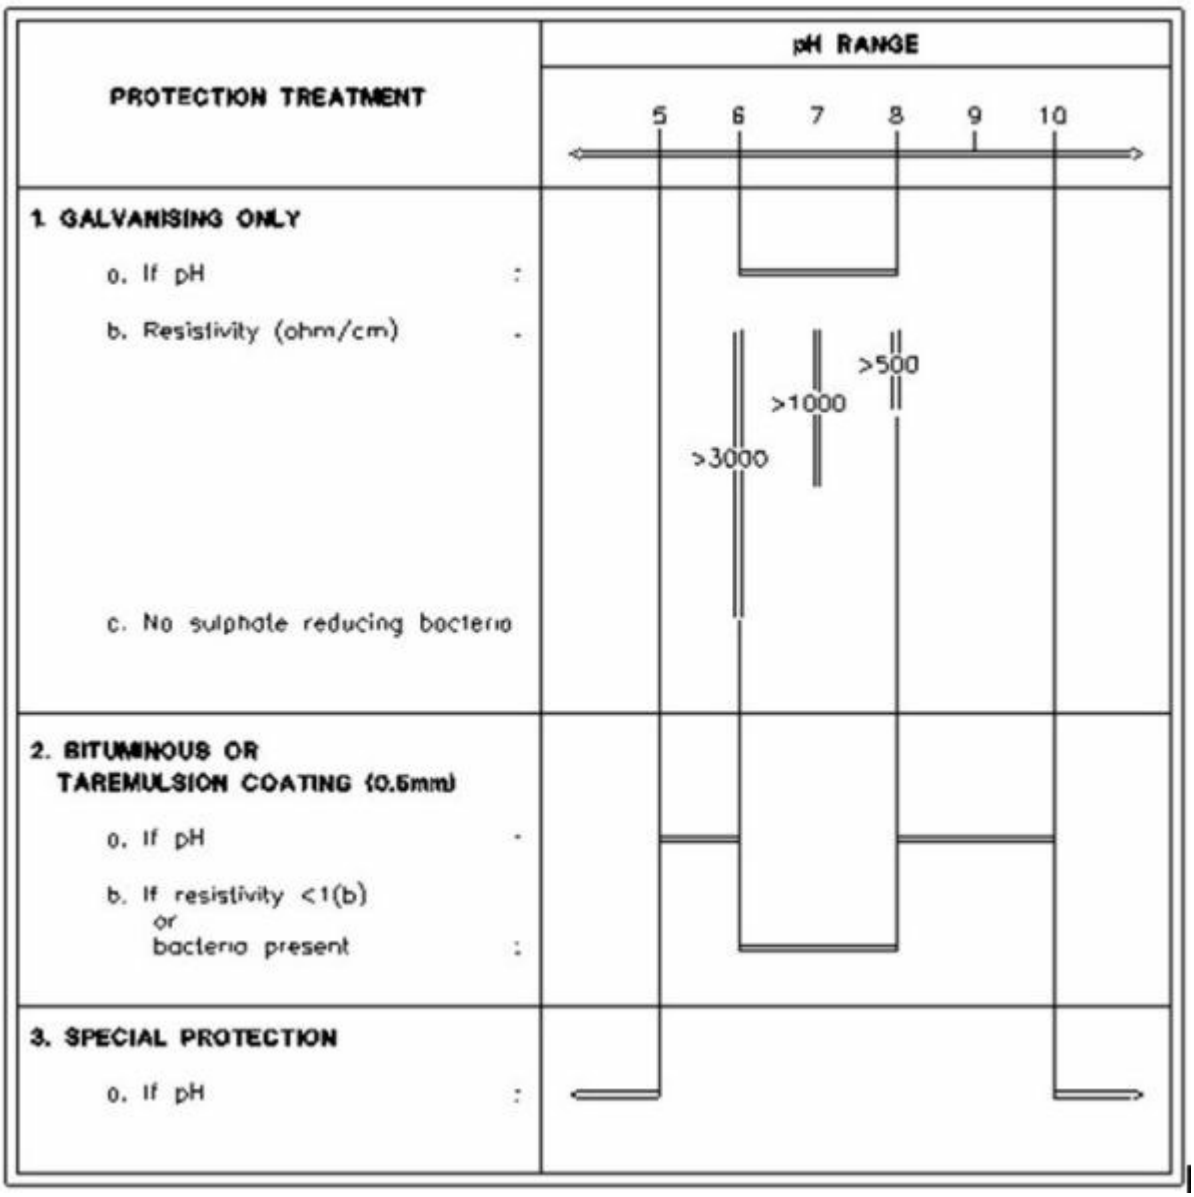

Figure SC6.4.6.6.2 Corrosion protection requirements for steel structures

(6) Excavation and foundation preparation

(a) Unless otherwise indicated on the drawings or approved by the Superintendent, the formation shall be completed to subgrade level and the pipes then installed in the normal trench condition.

(b) The trench shall be excavated to a level 75mm below the design invert and for a minimum width of 600mm on each side of the structure.

(c) Where unsuitable material, as determined by the Superintendent, is encountered at the foundation level, it shall be removed to a depth approved by the Superintendent. The additional excavation shall be backfilled with material complying with, selected material as per SC6.4.6.10 Earthworks (construction).

(d) Where rock is encountered at the foundation level, the foundation shall be excavated for an additional depth of 250mm, or 0.25 times the structure width, whichever is the lesser and for a width equal to the width of the structure. The additional excavation shall be backfilled with material complying with, and compacted to, the requirements for HS3 pipe support as specified in SC6.4.6.6.3 3(b).

(7) Bedding

Bedding shall meet the requirements of SC6.4.6.6.3(3)(f). The thickness of uncompacted bedding material

between the foundation and the outer surface of corrugation shall not be less than 75mm. The uniform blanket of loose material which provides the minimum 75mm thick bedding, shall be placed on the shaped, compacted selected material foundation to allow the corrugations of the structure invert to bed in and become filled with the material.

(8) Installation

(a) General
The assembly of all corrugated steel pipes and pipe arches as well as helical lock-seam corrugated steel pipes shall be carried out in accordance with the manufacturer's recommendations. These recommendations shall be submitted to the Superintendent before assembly or laying of the culverts is commenced.

If deemed necessary after consultation with the manufacturer, temporary bracing of corrugated steel pipes or pipe arches shall be carried out in accordance with the manufacturer's recommendations.

(b) Joints
Corrugated steel pipes or pipe arches shall be joined in accordance with the manufacturer's recommendations and AS 2041.

Where helical-lock seam corrugated steel pipes are to be joined, both ends of the join shall be rerolled with four annular corrugations of pitch 68mm. Coupling of the re-rolled ends shall be made in accordance with AS 1761 by using semi-corrugated bands. Rubber ring joint seals shall be used in conjunction with the coupling bands except where specifically indicated otherwise in the drawings.

All joints or lap joints in pipes or pipe arches (excluding rubber ring joint coupling bands) shall be covered with strips of non-woven geotextile material, of minimum 250mm width and of minimum mass 270 grams per square metre in accordance with the requirements for geotextile in SC6.4.6.20 Subsoil, foundation and pavement drains, to prevent loss of sand backfill or bedding into the pipe.

(9) Backfill

(a) Compaction of the material in the side support and overlay zones shall comply with the requirements of clause SC6.4.6.6.3(5) except that the required relative compaction in the side support and overlay zones shall be 95 per cent (AS 1289.5.4.1 standard compaction). Backfill shall be placed around the steel pipe or structure, to a minimum dimension equal to the pipe width, on both sides.

(b) All material shall be compacted in layers not exceeding 150mm compacted thickness. Each layer shall be compacted to the relative compaction specified before the next layer is commenced.

(c) At the time of compaction, the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content which, unless otherwise approved by the Superintendent, is neither less than 60 per cent nor more than 95 per cent of the apparent optimum moisture content, as determined by AS 1289.5.4.1 (standard compaction).

(d) The remainder of the trench to the underside of the subgrade, or selected material zone as specified in SC6.4.6.10 Earthworks (construction), shall be backfilled with material satisfying the requirements for embankment material as defined in SC6.4.6.10 Earthworks (construction). Where excavation is approved through the selected material zone, the section of trench within the select material zone shall be backfilled with selected material as defined in SC6.4.6.10 Earthworks (construction).

(e) The Contractor shall check the shape of the culvert during backfilling to ensure that on completion of backfilling, the vertical and horizontal centreline dimensions of the pipe or structure shall not vary from the manufacturer's specified dimensions by more than plus or minus 2 per cent for pipes and pipe arches.

(10) Invert protection of corrugated steel pipes and pipe arches

(a) Where shown on the drawings, the invert of corrugated steel pipes and pipe arches shall be protected using sprayed concrete.

(b) The sprayed concrete shall be placed to a thickness of not less than 100mm over the crest of the

corrugations and to a width such that the bottom third of the pipe circumference is covered symmetrically about the invert of the pipe.

(c) All foreign material shall be removed from the surface to be protected. Where corrosion has occurred all loose scale shall be removed.

(d) The production, application and curing of sprayed concrete shall be in accordance with sub-section SC6.4.6.28 Minor concrete works.

(e) The sprayed concrete shall be reinforced with a fabric of hard drawn steel wire 4mm diameter with 200mm square mesh. The fabric shall be securely supported at a central location within the sprayed concrete by non-metallic supports.

(f) Laps in fabric shall be 300mm and a cover of 50mm of sprayed concrete shall be provided to the fabric at all edges.

(g) Immediately after placement of the sprayed concrete, all free water shall be removed and the surface coated with cement slurry.

(h) No water shall be allowed to flow over the surface of the sprayed concrete for twenty-four hours after the placement of sprayed concrete.

SC6.4.6.6.5 UPVC pipes

(1) Materials

(a) Unplasticised PVC (UPVC or similar material) Pipes and Fittings shall be manufactured in accordance with AS/NZS 1254 and shall be of the type and size as shown on the drawings. Where pipes with extreme external diameter are equal to or greater than 450mm (375mm nominal internal diameter) are proposed, a separate approval from the Superintendent and council is required.

(b) Embedment material in the bedding, side support and overlay zones shall be in accordance with bed and haunch zone material in SC6.4.6.6.3(3).

(c) Trench backfill material shall satisfy the requirements for embankment material as defined in SC6.4.6.10 Earthworks (construction).

(2) Excavation and bedding

(a) Unless otherwise indicated on the drawings or approved by the Superintendent, the formation shall be completed to subgrade level and the pipes then installed in the normal trench condition.

(b) Figure SC6.4.6.6.3 and Table SC6.4.6.6.2 indicate the dimensions of bedding and backfilling for pipes laid in trench conditions and embankment conditions, unless otherwise indicated on the drawings.

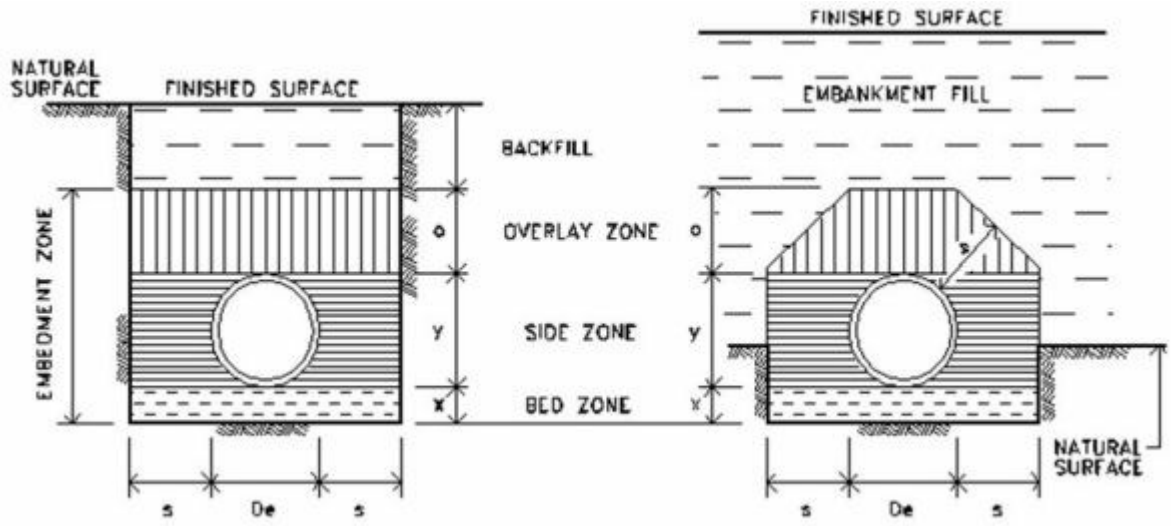

Figure SC6.4.6.6.3 Pipe installation conditions

Table SC6.4.6.6.2 Trench and embedment dimensions

Extreme External	Minimum Dimensions (mm)			
Dia (De)mm	x	s	o	y
[3]75≤150	75	100	100	Pipe dia.
>150≤300	100	150	150	Pipe dia.
>300≤450	100	200	150	Pipe dia.

Note—Where multiple pipes are laid side by side, the minimum distance between the pipes shall be dimension "s" for the larger of adjacent pipes.

(c) Bedding zone material shall be placed and compacted in accordance with the requirements in Table 5.5 of AS/NZS 2566.2.

(3) Installation

(a) Embedment of the UPVC pipe shall be in accordance with the requirements of AS/NZS 2566.2 and to the dimensions shown in Figure SC6.4.6.3.

(b) Pipe laying shall be in accordance with Part 7 of AS 2032 and solvent-cement pipe jointing shall be in accordance with Part 3 of AS 2032. Jointing may be performed with the pipes either in the trench or at ground level. All pipes, or jointed pipelines, shall be lowered into the trench without being dropped. Pipelines shall be placed so that joints are not strained.

(4) Backfill

(a) Compaction of the material in the side support and overlay zones shall comply with the requirements of SC6.4.6.6.3(5) for HS3 support type.

(b) All material shall be compacted in layers not exceeding 150mm compacted thickness. Each layer shall be compacted to the relative compaction specified before the next layer is commenced, or compacted in one operation by saturation and vibration to achieve a minimum Density Index as specified in Table 5.5 of AS/NZS 2566.2 – Buried Flexible Pipelines – Installation.

(c) At the time of compaction, the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content, which, unless otherwise approved by the Superintendent, is neither less than 60 per cent nor more than 95 per cent of the apparent optimum moisture content, as determined by AS 1289.5.4.1 (standard compaction).

(d) The remainder of the trench to the underside of the subgrade, or selected material zone as specified in SC6.4.6.10 Earthworks (construction), shall be backfilled with material satisfying the requirements for embankment material as defined in SC6.4.6.10 Earthworks (construction). Where excavation is approved through the selected material zone, the section of trench within the select material zone shall be backfilled with selected material as defined in SC6.4.6.10 Earthworks (construction).

SC6.4.6.6.6 Limits and tolerances

The limits and tolerances for materials and product performance related to the various clauses in this sub-section are summarised in Table SC6.4.6.6.3 Summary of Limits and Tolerances below:

Table SC6.4.6.6.3 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
	Culvert Position	± 10mm	SC6.4.6.6.2(1)
	(a) Grade Line	± 6mm	
	(b) Grade line <0.5%		
	(c) Horizontal Alignment	± 50mm	SC6.4.6.6.2(1)

SC6.4.6.7 Precast box culverts

SC6.4.6.7.1 Introduction

(1) Scope

(a) This sub-section covers the installation of precast concrete box culverts and should be read in conjunction with sub-section SC6.4.6.4 Stormwater drainage.

(b) The work to be executed under this Specification consists of:

(i) preparation of foundations;

(ii) provision of bedding;

(iii) construction of base slabs;

(iv) installation of precast culvert units;

(v) headwalls and wingwalls;

(vi) backfilling against structures;

(vii) provision and removal of coffer dams; and

(viii) excavation of inlet and outlet channels.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

(2) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.10 Earthworks (construction)
SC6.4.6.4 Stormwater drainage
SC6.4.6.9 Open drains
SC6.4.6.12 Flexible pavements
SC6.4.6.28 Minor concrete works

(b) Australian Standards:
AS1597.1 - *Precast reinforced concrete box culverts - Small culverts*
AS1597.2 - *Precast reinforced concrete box culverts - Large culverts*
AS/NZS ISO 9001:2008 - *Quality management systems - Requirements.*

(c) Other:
Austroads, *Guide to Geotextiles*
Department of Transport and Main Roads
MRTS05 - *Unbound Pavements*
MRTS24 - *Manufacture of precast concrete culverts*

SC6.4.6.7.2 Materials

(1) Culvert units, link and base slabs

(a) The supply and testing of precast reinforced concrete box culvert units, link and base slabs shall be in accordance with AS1597 with the following alterations or additional requirements:

(i) proof load testing must be arranged by the Contractor in batches as specified in either AS1597.1 or AS 1597.2 as appropriate;

(ii) proprietary lifting anchors must be provided in the culvert units, link and base slabs;

(iii) delivery and unloading is the Contractor's responsibility; and

(iv) the supplier must implement and maintain a Quality System in accordance with ISO 9001 to ensure materials, manufacture and proof load testing conform to the appropriate Standards.

(b) A conformance certificate, to AS1597 must be submitted to the Superintendent at least 3 working days prior to dispatch.

(c) Each unit must be marked at time of manufacture with:

(i) type and size;

(ii) casting date;

(iii) manufacturer's name; and

(iv) inspection pass and date.

(2) Handling, delivery and storage

(a) Ensure adequate equipment and load shifting machineries are available for safe handling and unloading.

(b) Upon delivery of precast units, ensure that the following criteria have been achieved:

(i) 70% of the minimum concrete strength;

(ii) small culvert units: Cured to AS 1597.1 clause 2.6.3; and

(iii) large culvert units: Cured to AS 1597.2 clause 2.7.

(c) Prior inspection of the stored precast box culvert units is to be undertaken for dimensional accuracy and defects following delivery. Results of the inspections must show that the units conform to the following:

(i) small culvert unit: To AS 1597.1; and

(ii) large culvert unit: To AS 1597.2.

(3) Concrete

The concrete and reinforcement for cast-in-situ base slabs shall comply with sub-section SC6.4.6.28 Minor concrete works.

(4) Selected backfill

The quality of selected backfill shall comply with the requirements in AS 1597.2, or alternatively comply with the requirements of side/overlay zone materials in Table SC6.4.6.6.1 *Bedding material grading limit* of sub-section SC6.4.6.6 Pipe drainage.

(5) Ordinary backfill

Ordinary backfill is material obtained from culvert excavations, cuttings and/or borrow areas which are in accordance with the requirements for the upper 0.3 m of embankment construction as detailed in SC6.4.6.10 Earthworks (construction).

SC6.4.6.7.3 Construction

(1) Coffer dams

(a) At some sites it may be expedient for the Contractor to construct a coffer dam. The construction of coffer dams shall be the responsibility of the Contractor.

(b) Coffer dams shall be sufficiently watertight to prevent damage of the concrete by percolation or seepage through the sides, and shall be taken sufficiently below the level of the foundations to prevent loosening of the foundation materials by water rising through the bottom of the excavation. Coffer dams shall be adequately braced and shall be so constructed that removal will not weaken or damage the structure.

(c) A coffer dam may be constructed to the actual size of the reinforced concrete invert slab and used as side forms for the concrete. The details of the coffer dam and formwork, and the clearances proposed shall be subject to the approval of the Superintendent, but the Contractor shall be responsible for the successful construction of the work.

(d) Coffer dams which have tilted or have moved laterally during sinking, shall be righted or enlarged to provide the clearances specified. This work will be at the Contractor's expense.

(e) No timber or bracing shall be left in the concrete or in the backfill of the finished structure. Coffer dams, including temporary piles, shall be removed at least to the level of the invert after completion of the

structure. Upon completion of works, remove coffer dams, including temporary piles, at least to the level of the culvert invert after completion of the structure. Ensure that no material associated with the coffer dam or dewatering can enter the culvert.

(2) Excavation

Excavation shall be carried out in accordance with the provisions in sub-section SC6.4.6.4 Stormwater drainage.

(3) Foundations

(a) Rock foundations shall be neatly excavated to the underside of the mass concrete or selected fill bedding shown on the drawings. All minor fissures shall be thoroughly cleaned out and refilled with concrete, mortar or grout. All loose material shall be removed.

(b) Where rock is encountered over part of the foundation only, or lies within 300mm below the underside of the mass concrete or selected fill, all material shall be removed to a depth of 300mm below the mass concrete or selected fill for the full width of the foundation over the length where the rock is encountered. This additional excavation shall be backfilled with ordinary backfill material.

(c) Over-excavation or uneven surfaces shall be corrected with mass concrete so as to provide a uniform surface at least 50mm above the highest points of rock.

(d) Earth foundations shall be finished to line and level to the underside of bedding shown on the drawings. Care shall be taken to avoid disturbing material below this level.

(e) All soft, yielding or unsuitable material shall be removed and replaced with ordinary backfill material as directed by the Superintendent and backfilled in accordance with sub-section SC6.4.6.4 Stormwater drainage.

(4) Bedding

(a) Cast-in-situ base slabs

No bedding material shall be placed until the foundations have been inspected and approved by the Superintendent.

Bedding shall be either mass concrete or lightly bound paving material which complies with the requirements of at least a Type 3, Subtype 3.3 material as defined in the Specification MRTS05 (04/11), whichever is shown on the drawings.

Mass concrete bedding blinding layer shall be 20 mpa compressive strength and shall not be less than 50mm thick over any point in the foundation. It shall be laid to the line and level of the underside of the base slab to a tolerance of ±10mm in level and ±50mm in line. The bedding shall be finished to a smooth surface. Where longitudinal gradients are less than 0.5 per cent, concrete blinding layers shall be installed with +/- 6mm of the grade line.

(b) Precast base slabs

Precast base slabs, U-shaped culvert units and one piece culvert units shall be supported on a bed zone of selected backfill of minimum compacted depth 150mm in accordance with AS 1597.2.

If suitable compaction of the trench subgrade cannot be achieved, it will be the responsibility of the developer to recommend an alternate solution to council to achieve the desired bearing capacity for the structure prior to construction.

(5) Cast-in-situ base slabs

(a) Cast-in-situ base slabs shall be constructed to the dimensions shown on the drawings and in accordance with the requirements of sub-section SC6.4.6.28 Minor concrete works. The invert levels shall be within -10mm to +10mm of the design level, grade 5mm in 2.5m (1 in 500) and plan position ±50mm. Where longitudinal gradients are less than 0.5 per cent cast insitu base slabs shall be installed within +/- 6mm of the grade line.

(b) Recesses or nib walls to accommodate the walls of the precast crown units shall be formed in the base

slab to the dimensions shown on the drawings.

(6) Installation of precast units

(a) Precast units shall not be installed until the base slab has attained a minimum compressive strength of 20 MPa.

(b) Precast crown units shall be placed on a bed of mortar either on the slab or in the recesses in the base slab. Any gaps between the side walls and the sides of the recesses shall be packed with cement mortar. Lifting holes and butt joints between units shall be packed or sealed with cement mortar or grout or flexible joint filler.

(c) Before placement of top slabs on U-shaped units or link slabs on adjacent crown units, the bearing areas of the supports shall be thoroughly cleaned and covered with a bed of mortar of minimum thickness 5mm after placement of precast unit.

(d) Lifting anchor recesses shall be filled to the surface with cement mortar.

(e) In the case of multi-cell culverts, a nominal 50mm gap shall be provided between adjacent cells. This gap shall be filled with cement mortar or grout.

(f) All mortar joints shall be protected from the sun and cured in an approved manner for not less than 48 hours.

(g) All external surfaces of vertical joints between precast crown units, shall be covered full length, and minimum 100mm width, with strips of denso tape or similar as an alternative to joint filling.

(7) Backfill

(a) All bracing and formwork shall be removed prior to backfilling. Prior to backfill placing, present to the Superintendent for inspection all seals, joints and levels.

(b) Selected backfill shall be placed in the side zones of the box culverts and wingwalls, and to a depth of 300mm in the overlay zone of the culverts, in layers with a maximum compacted thickness of 150mm in accordance with the backfilling and compaction requirements of AS 1597.2. Alternatively cohesionless materials can be compacted in one operation by saturation and vibration to achieve a minimum Density Index of 70. The remainder of the excavation shall be backfilled with ordinary embankment fill in accordance with SC6.4.6.10 Earthworks (construction).

(c) Backfill shall be placed against wingwalls, headwalls and retaining walls in accordance with SC6.4.6.28 Minor concrete works.

(d) Backfill layers shall be placed simultaneously on both sides of the culvert with a maximum 600mm level difference to avoid differential loading. Backfilling and compaction shall commence at the wall and proceed away from it.

(e) Where the slopes bounding the excavation are steeper than 4:1, they shall be cut in the form of successive horizontal terraces of at least 1m width before the backfill is placed.

(8) Excavation of inlet and outlet channels

(a) Excavation of inlet and outlet channels shall be carried out as shown on the drawings and shall extend to join the existing stream bed in a regular manner as detailed SC6.4.6.9 Open drains.

(9) Construction loading on culverts

(a) Construction vehicles and plant shall not pass over the culvert until 28 days after the casting of the base slab or until the cylinder compressive strength of the base slab concrete has reached 32 MPa.

(b) Construction vehicle loads on culverts for various design fill heights shall be in accordance with AS 1597.2.

SC6.4.6.7.4 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.7.1 Summary of Limits and Tolerances below:

Table SC6.4.6.7.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Spec Clauses
1.	**Mass Concrete Correction**		
	a) Over highest points of rock	50mm	SC6.4.6.7.3(3)
2.	**Mass Concrete Bedding**		
	a) Level	± 10mm	SC6.4.6.7.3(4)
	b) Level where grade line <0.5%	+/- 6mm	
	c) Line	± 50mm	SC6.4.6.7.3(4)
3.	**Culvert Location**		
	a) Invert Level	±10mm	SC6.4.6.7.3(5)(a)
	b) Invert where grade line is <0.5%	+/- 6mm	
	c) Grade	5mm in 2.5m (1 in 500)	SC6.4.6.7.3(5)(a)
	d) Plan Position	±50mm	SC6.4.6.7.3(5)(a)

SC6.4.6.8 Drainage mats

SC6.4.6.8.1 Introduction

(1) Scope

(a) The purpose of this policy sub-section is to provide standards advice and guidelines for the use and installation of drainage mats.

(b) Drainage mats shall be constructed where and as shown on the drawings or as directed by the Superintendent.

(c) This sub-section should be read in conjunction with SC6.4.6.21 Subsurface drainage.

(d) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in the SC6.4.5 Supervision and construction guidelines

(2) Terminology

Type A drainage mats	are intended to ensure continuity of a sheet flow of water under fills, to collect surface seepage from a wet seepage area or for protection of vegetation or habitat downstream of the road reserve where a fill would otherwise cut the flow of water.
Type B drainage mats	are constructed to intercept water which would otherwise enter pavements by capillary action or by other means on fills and to intercept and control seepage water and springs in the floors of cuttings.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section one as follows:

SC6.4.6.21 Subsurface drainage
SC6.4.6.20 Subsoil, foundation and pavement drains

(b) Australian Standards:

AS 1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio.*

(4) Order of construction

(a) Type A drainage mats shall be constructed after the site has been cleared and grubbed and before commencement of embankment construction.

(b) Type B drainage mats shall be constructed after completion of the subgrade construction and before construction of the pavement.

SC6.4.6.8.2 Construction

(1) Type A mats

(a) Type A drainage mats shall be constructed under embankments as and where shown on the drawings or as directed by the Superintendent.

(b) After the embankment foundation has been trimmed and any necessary trench drains installed, a geotextile complying with the requirement of SC6.4.6.21 Subsurface drainage, shall be laid on the embankment foundation. The area of geotextile laid shall be sufficient to cover the area of the Type A drainage mat and an additional amount for enclosing the sides of the drainage mat after the filter material has been placed. Laps of minimum width of 500 mm shall be provided at each join in the geotextile.

(c) Type C filter material or Type D filter material, as shown on the drawings or as determined by the Superintendent, shall be placed on the geotextile and compacted to the satisfaction of the Superintendent. The minimum thickness of the compacted filter material shall be 300 mm plus an allowance for the expected consolidation of the embankment foundation under the embankment load or 500 mm if the amount of the expected total consolidation of the embankment foundation is not known.

The filter material shall be placed in two or more layers so that no layer, when compacted, has a thickness greater than 250 mm.

(d) After completion of placement and compaction of the filter material, geotextile shall be placed on top of and around the sides of the filter material so that the filter material is completely enclosed by geotextile. The geotextile shall be secured in such a manner as to prevent movement of the geotextile by wind or by construction plant placing subsequent layers of filter material or earth filling over the drainage mat.

(e) An additional layer of geotextile shall be placed on the drainage mat under the base of any rock facing which may be placed as part of the embankment construction. The additional layer of geotextile shall extend beyond the outside and inside faces of the bottom layer of rock.

(f) Care shall be taken not to damage the geotextile during the construction of the drainage mat or during placement of subsequent layers of filter material, earth filling or rock facing. Any geotextile so damaged shall be repaired or replaced by the Contractor to the satisfaction of the Superintendent. The cost of repairing or replacing such damaged geotextile shall be borne by the Contractor.

(g) Type A drainage mats shall extend 2 m beyond the toes of embankments and such extensions shall be covered by a 300 mm thick layer of Type C filter material or Type D filter material, as determined by the Superintendent. This protective layer shall be placed immediately after completion of construction of each drainage mat.

(h) Outlets from Type A drainage mats may be surface outlets at the toes of embankments or piped outlets connected to other drainage systems. Where piped outlets are constructed they shall conform to the requirements of SC6.4.6.21 Subsurface drainage.

(2) Type B mats

(a) Type B drainage mats shall be constructed in cuttings as and where shown on the drawings or as directed by the Superintendent. Type B drainage mats shall be constructed for the full width of cuttings and for the pavement width in other locations.

(b) After the subgrade material has been compacted and trimmed, a geotextile complying with the requirements of SC6.4.6.21 Subsurface drainage, shall be laid on the subgrade. Laps of minimum width of 500 mm shall be provided at each join in the geotextile.

(c) Slotted thick walled unplasticised PVC pressure pipe complying with AS 1477, shall be laid on the geotextile at a distance of 200 mm from and parallel to the longitudinal edges of the drainage blanket as shown in the drawings. Details of slot sizes and spacings are shown in SC6.4.6.20 Subsoil, foundation and pavement drains.

(d) Type A filter material shall be placed on the geotextile and compacted to achieve a relative compaction, determined by AS 1289.5.4.1, of at least 100 per cent (standard compaction). Alternatively, the Superintendent may approve the use of a coarser filter material having a maximum particle size of 75 mm and a maximum D90/D10 ratio of three.

(e) The thickness of the compacted filter material shall be as shown on the drawings or as directed by the Superintendent. If the required thickness of compacted filter material is greater than 250 mm, the filter material shall be placed in two or more layers so that no layer, when compacted, has a thickness greater than 250 mm.

(f) After completion of placement and compaction of the filter material, geotextile shall be placed on top of and around the sides of the filter material so that the filter material is completely enclosed by geotextile. The geotextile shall be secured in such a manner as to prevent movement of the geotextile by wind or by construction plant placing pavement layers over the drainage mat.

(g) Outlets from Type B drainage mats shall conform to the requirements of SC6.4.6.21 Subsurface drainage.

Table SC6.4.6.8.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Filter Material**		
	(a) Layer thickness	250 mm max	SC6.4.6.8.2(1) SC6.4.6.8.2(2)
	(b) Compaction (Relative) Type A filter material	100% Standard	SC6.4.6.8.2(2)
2.	**Type B Mats**		
	(a) Design level at top of mat	+0, -40 mm	SC6.4.6.8.2(2)

SC6.4.6.9 Open drains

SC6.4.6.9.1 Introduction

(1) Scope

(a) This policy sub-section provides standards, advice and guidelines for the construction, lining and protection of all types of open drains including the construction of rock filled wire mattresses and gabions associated with stormwater drainage infrastructure.

(b) This sub-section should be read in conjunction with SC6.4.6.4 Stormwater drainage, and other drainage sub-sections as applicable:

(i) SC6.4.6.6 Pipe drainage;

(ii) SC6.4.6.5 - Drainage structures; and

(iii) SC6.4.6.7 Precast box culverts.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

Editors note - A reference to drawings is a reference to construction drawings.

(2) Terminology

Open drains	are all drains other than pipe and box culverts and include catch drains, contour drains, diversion drains, table drains, batter drains, swales, channels, gutters and kerb and channel.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:

SC6.4.6.4 Stormwater drainage
SC6.4.6.6 Pipe drainage
SC6.4.6.5 Drainage structures
SC6.4.6.21 Subsurface drainage
SC6.4.6.28 Minor concrete works
SC6.4.6.7 Precast box culverts
SC6.4.6.26 Landscaping

(b) Australian Standards:

AS 1141.22 - *Wet/dry strength variation*
AS 1289.5.4.1 - *Compaction control test – Dry density ratio, moisture variation and moisture ratio*
AS 1289.5.7.1 - *Compaction control test Hilf density ratio and Hilf moisture variation (rapid method)*
AS 2758.4 - *Aggregate for gabion baskets and wire mattresses*
AS 2876 - *Concrete kerbs and channels (gutters) – Manually or machine placed*
AS/NZS 4534 - *Zinc and zinc/aluminium-alloy coatings on steel wire.*
AS/NZS 4680 - *Hot-dip galvanized (zinc) coatings on fabricated ferrous articles*

(c) Other:

Austroads, *Guide to Pavement Technology, Part 4B – Asphalt (AGPT04B)*
Austroads, *Guide to Pavement Technology, Part 4G – Geotextiles and Geogrids (AGPT04G)*
ASTM International, ASTM A975 - *Standard specification for double-twisted hexagonal mesh gabions and revet mattresses (metallic coated steel wire or metallic coated steel wire with PVC coating)*
International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

SC6.4.6.9.2 Unlined open drains general

Open drains shall be designed and constructed in accordance with the relevant clauses in Chapter 9 of QUDM 2013. Locate and construct open drains to avoid recharging groundwater, a shallow water table and salinity degradation of

adjacent land.

Any unsuitable material must not be used for the bed and banks of the drain and must be removed from the site. Where a tree is marked for preservation, any drain must be diverted around it with sufficient clearance to avoid damage to the tree's root system.

Where open drains pass through private property, drainage easements of sufficient width to contain the flow and vehicular access for maintenance must be provided and registered as an encumberance on the title of the land through which the drain passes.

Prior to works commencing, temporary drainage measures must be implemented in accordance with the requirements of Best Practice Erosion and Sediment Control.

(1) Types

Catch drains shall be provided above the top and at the toe of embankments as part of the construction of the adjacent roadway. The edges of catch drains shall be positioned not less than 2 m from the tops of cuttings or the toes of embankments nor more than is necessary to maintain the fall of the drains unless otherwise approved.

Minor diversion and contour drains shall be constructed where shown on the construction drawings. Minor diversion drains shall have the same capacity as the nearest pipe culvert on the line of the drain unless otherwise approved by the Superintendent.

Table drains, swales and depressed medians shall be constructed to the line and level shown or calculated from the drawings. Their construction is deemed to be part of the earthworks.

(2) Inlet, outlet and diversion drains shall extend to join the existing stream bed and be of sufficient size to accommodate the design flows from the upstream catchment. The drain shall be excavated to the full width of the structure and care must be taken to ensure the stream bed can accommodate the additional flow with only minimal disturbance.

(3) Construction material excavated from drains shall be placed on the lower sides of the drains and formed as banks with slopes graded in accordance with QUDM Third edition 2013 – Provisional. This material shall be compacted in accordance with AS 1289.5.4.1 and shall be not less than 95 per cent for standard compactive effort.

The Contractor shall ensure that none of the activities associated with the work disturbs any watercourse outside the site. Any excavation below the level of the natural channel shall be backfilled with suitable material compacted to a density equal to and compatible with that existing naturally.

Any excess material shall be legally and responsibly disposed of by the Contractor.
Unlined drains and areas adjacent to open drains shall be treated and revegetated immediately after the drains are complete, in accordance with SC6.4.6.26 Landscaping.

SC6.4.6.9.3 Lined open drains general

(1) The Contractor must only use proprietary products which are suited to the terrain and have been approved for use by council. This would include the use of

(a) organic fibre and vegetation mats installed in accordance with the manufacturer's instructions;

(b) rock filled wire mattresses; or

(c) concrete where there is insufficient width to accommodate the required water way area, or the flow velocity in the drain will exceed the non-scouring velocities or where the trail is likely to be used as a bikeway of footpath during dry periods. Lining shall conform to the profile of the drain and shall be provided as soon as possible after forming the drain.

Before placing any lining material, the foundation material shall be shaped and compacted to not be less than 95 per cent for standard compactive effort as determined by AS 1289.5.7.1 or AS 1289.5.4.1

This section does not include kerb and channel.

(2) Concrete lining

Concrete lining for open drains shall be cast-in-situ or sprayed concrete supplied and placed to a minimum thickness of 100 mm measured at right angles to the surface of the lining in accordance with sub-section SC6.4.6.28 Minor concrete works.

Polyfibres must not be used in marine environments, or where there is risk of fibres escaping into the environment, without approved controls to capture loose polyfibre strands.

Weepholes shall be provided in the concrete at intervals of 2 m spacing with non-horizontal elements or as determined by the Superintendent.

Contraction joints in concrete lining, consisting of narrow transverse and vertical grooves, 5-10 mm in width, 20 mm deep, shall be formed neatly in the surface of the freshly placed concrete at intervals of 3 m unless otherwise specified by the Superintendent.

Expansion joints shall be placed at intervals not more than 15 m with a minimum width of 15 mm and shall consist of preformed jointing material of bituminous fibreboard or alternate approved material and shall be of sufficient depth to fill the joint.

(3) Stone pitching

Stone pitching shall consist of sound durable rock not less than 100 mm thick, properly bedded on approved loam or sand and mortared to present a uniform surface. The exposed surface of each stone or block shall be generally flat and not less than 0.05 square metres in area. Spaces between adjacent stones or blocks shall not exceed 20 mm in width.

(4) Batter drains

Batter drains shall be constructed using either half round steel pipes or precast nestable concrete units as shown and detailed on the drawings.

The units shall be installed in carefully excavated and template controlled trench to produce an even rim line of +0 mm to –50 mm from the batter line at the underside of topsoil.

Any over excavation and undulations in the batter line shall be backfilled and both sides of the drain compacted over the full length to form a firm shoulder against the rim of the batter drain.

When topsoil is placed it shall be tapered over a width of 1 m to zero thickness at the rim of the drain. Both sides of the drain shall then be turfed for minimum width of 1 m and pinned down as provided in SC6.4.6.26 Landscaping.

(5) Proprietary products

Unless shown on the drawings, proprietary products may only be used with the approval of the Superintendent. Where specified, they must be used strictly in accordance with the manufacturer’s instructions.

SC6.4.6.9.4 Rock filled wire mattresses and gabions general

(1) Prior to installation of rock filled wire mattress or gabion excavate so the mattresses finish flush and level with the surrounding ground. Rock-filled wire mattresses and gabions shall be placed at the locations shown on the drawings. Installation shall be in accordance with the manufacturer's instructions. A geotextile, as shown on the drawings, shall be placed between the wire cage and the material being protected.

Foundations of floors of gabions should ideally be within cut material, however if in fill areas or embankments then material must be compacted in layers not greater than 150 mm thick, to a relative compaction of 95 per cent when tested in accordance with AS 1289.5.4.1, for standard compactive effort.

(2) Materials

For wire mattresses and gabions, the galvanising requirements for wire of circular cross section cited in this Clause as "heavily galvanised", shall comply with the coating mass requirements for round wire, Class W10, in AS/NZS 4534. The contractor must submit for approval the type of mattress/gabion proposed along with confirmation of compliance to ASTM A975 and a schedule of installation locations.

(a) Gabions

The gabions shall be of the sizes shown on the drawings and fabricated of woven heavily galvanised wire mesh and PVC coated where specified on the drawings. Each gabion shall be divided by diaphragms into cells whose length shall not be greater than the width of the gabions plus 100 mm. Gabions shall have a nominal mesh size of 80 mm x 100 mm and body wire shall be a minimum diameter of 2.7 mm heavily galvanised with an additional thickness of 0.4 mm PVC coating where specified on the drawings. The minimum core diameters of heavily galvanised selvedge wire and lacing wire shall be 3.4 mm and 2.2 mm respectively.

(b) Wire mattresses

Unless specified otherwise, the wire mattresses shall be supplied in units having dimensions of 6 m x 2 m x 230 mm, and shall be cut to suit areas as shown on the drawings. The mattresses shall be divided by diaphragms into cells of length not exceeding 600 mm. Unless otherwise specified, they shall be fabricated of woven heavily galvanised wire and PVC coated where specified on the drawings.

Mattresses shall have a mesh size of 60 mm x 80 mm and body wire shall be a minimum diameter of 2.0 mm heavily galvanised with an additional minimum thickness of 0.4 mm PVC coating where specified on the drawings. The minimum core diameters of heavily galvanised selvedge wire and lacing wire shall be 2.7 mm and 2.2 mm respectively.

(c) Geotextile

A chemically and biologically stable geotextile with a minimum strength rating (G) of 1350 and minimum mass of 180 grams per square metre, in accordance with Guide to Pavement Technology Part 4G Geotextiles, shall be used.

Samples, manufacturer's specification and instructions on installation shall be submitted to the Superintendent seven days before the intended use of geotextile.

(d) Rock Fill Material

The rock fill shall consist of clean hard rock complying with the requirements of AS 2758.4.
Rock fill for gabions shall have particle sizes between 100 mm and 250 mm. Rock fill material should be placed by hand and only when approved by the superintendent shall they be placed using a suitable mechanical device to ensure fill is tightly packed with a minimum of voids. Fill material shall be levelled off 25 mm to 50 mm above the top of the mesh to allow for settlement.
When the mattress is on a slope, rock fill material shall be placed into the units starting from the low end. Units shall be filled slightly overfull by 25 mm to 50 mm to allow for settlement and to provide an even tight and smooth surface of the required contour.

(3) Assembly and erection

Before laying out the gabions or wire mattresses, geotextile shall be placed on the founding material and against any surface that will be in contact with either drainage course or earth backfill.

Adjust the position of the diaphragms so that the sides hinge up on the thicker wire woven in the mesh. Lace the gabion boxes along all diaphragm points and edges at to all adjacent boxes. Internal bracing wires 4 per metres at 330 mm centres to prevent distortion. Face bracing wires 4 per metres of face.

Ensure star pickets are either driven or cut off level with the top of the mattress.

After tying diaphragms and adjacent units of mattresses/gabions on all three adjacent corners(rear, floor and front face), leave top edge untied to allow for securing along with the lid section. The end corners of wire mattress/gabion tied sections shall be firmly tied after galvanised star pickets are driven and stretched in place a minimum of 900 mm into the surrounding ground in the final location at one end.

Carefully secure the opposite end of the gabions without damaging or distorting the dimensions of the units to a

suitable mechanical device and apply a stretching force to the assembled mattress/gabion section to be filled. Whilst under tension, secure each corner of each unit using galvanised star pickets driven into foundation ensuring each unit is stretched tight in all directions.

(4) Filling

Fill whilst the gabion boxes are under tension. Place the rocks at the front face and other exposed faces by hand to produce a neat face free of excessive bulges, depressions and voids.

Redistribute the filling materials by hand to ensure that all diaphragm compartments are fully filled to produce a neat and level top surface. Overfill by 25 to 50 mm to allow for subsequent settlement.

Mechanical filling equipment may be used with caution ensuring to protect any PVC or galvanized coatings from abrasion. Release the tension on the mattress/gabion boxes only when fully laced so as to prevent any slackening.

The upstream edge of wire mattresses shall be folded down into a trench of minimum depth 300 mm and filled with rock fill. This edge shall be tied to star pickets.

Final lacing should be undertaken as soon as practicable after filling particularly if there is a storm or flood expected. Stretch lids tightly over the filling and lace down securely. The works should be inspected upon completion of lacing.

SC6.4.6.9.5 Summary of limits and tolerance

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.9.1 below.

Table SC6.4.6.9.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Open Drains - General**	Grade - QUDM 2013 Table 9.5.2	SC6.4.6.9.2(3)
	(a) Grading		
	(b) Depth	Based on hydraulic capacity of the channel	SC6.4.6.9.2
	(c) Freeboard	QUDM 2013 table 9.3.1 & Fig 9.8	SC6.4.6.9.2
	(d) Channel Side Slopes	QUDM 2013 Section 9.5.3	SC6.4.6.9.2(3)
	(e) Compaction	>95% (standard compaction)	SC6.4.6.9.2(3)
2.	**Open Drains - Lining**	>95% (standard compaction)	SC6.4.6.9.3(1)
	(a) Compaction of Foundation		
3.	**Stone Pitching**	>100mm thickness	SC6.4.6.9.3(3)
	(a) Rock Dimensions		
	(b) Exposed Surface Area	>0.05 sq m	SC6.4.6.9.3(3)

	(b) Trench Depth for upstream edge	Depth >300mm	SC6.4.6.9.4(3)

SC6.4.6.10 Earthworks (construction)

SC6.4.6.10.1 Introduction

(1) Scope

(a) This sub-section provides standards, advice and guidelines for earthworks and associated construction, including:

(i) removal of topsoil;

(ii) all activities and quality requirements associated with site regrading, the excavation of cuttings, the haulage of material and the construction of embankments to the extent defined in the drawings and sub-section;

(iii) removal and replacement of any unsuitable material;

(iv) any spoil or borrow activities associated with earthworks; and

(v) any additional processing of selected material for the selected material zone.

(b) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section one as follows:

SC6.4.6.30 Control of traffic
SC6.4.6.11 Clearing and grubbing
SC6.4.6.4 Stormwater drainage

(b) Australian Standards:

AS1141.11 - *Soil classification test – Determination of the particle size distribution of a soil – Standard method of analysis by sieving*
AS1289.3.3.1 - *Calculation of the plasticity index of a soil.*
AS1289.5.1.1 - *Determination of the dry density/moisture content relation of a soil using standard compactive effort.*
AS1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio.*
AS1289.5.7.1 - *Compaction Control Test Hilf density ratio and Hilf moisture variation (Rapid Method).*
AS1289.6.1.1 - *Determination of the California Bearing Ratio of a soil - Standard laboratory method for a remoulded specimen.*
AS1289.7.1.1 - *Soil reactivity tests – Determination of the shrinkage index of a soil*
AS2187.0 - *Explosives - Storage, transport and use - Terminology*
AS2187.1 - *Explosives - Storage, transport and use - Storage*
AS2187.1 - *Explosives - Storage, transport and use - Use of explosives*

(c) QLD Government Legislation:

Environmental Protection Act 1994
Environmental Protection (Noise) Policy 2008
Explosives Act 1999
Explosives Regulation 2003
Sustainable Planning Act 2009
Work Health and Safety Act 2011

(d) Other:

International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

Workplace Relations Ministers' council, *Australian Code for the Transport of Explosives by Road and Rail*
MRTS55 Use of Explosives in Roadworks

(3) Natural surface and earthworks materials

(a) Natural surfaces

The Contractor must verify the accuracy of the model by field surveys. If the Contractor considers any areas of the model not to be representative of the approved plans, the Contractor shall give not less than seven days' notice, prior to commencement of Works to the Superintendent to allow checking. If the subsequent check survey reveals the ground model to be incorrect, any plans that are affected are to be resubmitted for approval.

(b) Earthworks materials

The Contractor shall be responsible for any assumptions made by the contractor in relation to the nature and types of the materials encountered in excavations and the bulking and compaction characteristics of materials incorporated in embankments.

The estimated quantity for general earthworks at any cutting includes all types of materials which may be encountered in the cutting.
Where material from excavations is acceptable for use in embankments, but the Contractor elects to:

(i) spoil it; or

(ii) use it for the Contractor's own purposes; or

(iii) use it as a source of pavement materials; or

(iv) construct embankments with dimensions in excess of those specified.

and a deficiency of material for embankment construction is thereby created, the Contractor shall make good that deficiency from sources of material meeting the quality requirements specified in clause SC6.4.6.10.6(2). The cost of making good such deficiency of material shall be borne by the Contractor.

(4) Protection of earthworks

The Contractor's responsibility for care of the Works shall include the protection of earthworks.
The Contractor shall install effective erosion and sedimentation control measures in accordance with accepted *Best Practice Erosion and Sediment Control* procedures, prior to commencing the earthworks, and shall maintain these control measures for the duration of the contract.

Details of the proposed sediment and erosion control measures and procedures are to be documented by a suitably qualified person in accordance with council's soil and sediment erosion control standards. The proposed measures and procedures are to be approved by council prior to implementation on site.

Adequate drainage of all working areas shall be maintained throughout the period of construction to ensure run-off of water without ponding, except where ponding forms part of a planned erosion and sedimentation control system.

When rain is likely or when work is not proposed to continue in a working area on the following day, precautions shall be taken to minimise ingress of any excess water into earthworks material. Ripped material remaining in cuttings and material placed on embankments shall be sealed off by adequate compaction to provide a smooth tight surface.

Should insitu or stockpiled material become wet as a result of the Contractor not providing adequate protection of earthworks, the Contractor shall be responsible for replacing and/or drying out the material and for any consequent delays to the operations.

(5) Setting out of earthworks

Before earthworks operations commence and after survey controls are in place, batter profiles shall be established by the Contractor and the necessary pegs driven at 25m intervals, at each cross section shown on the drawings or at each change in batter slope, whichever is the lesser. The chainage/station, offset from-control line and slope distance to finished surface level, shall be clearly marked on each peg.

The batter profiles shall be repositioned by the Contractor at each change in the slope of the batter and at

intervals of not more than 5m of vertical height.

All pegs and batter profiles shall be maintained in their correct positions. Additional pegs and profiles may be required to suit the Contractor. These shall not be painted with the same colours used for the specified setting out pegs and stakes.

The position and extent of all transitions from cuttings to embankments and foundations for shallow embankments shall be marked with clearly labelled stakes in accordance with Clauses SC6.4.6.10.3(5) and SC6.4.6.10.6(3).

(6) Stockpile sites

The Contractor shall obtain the written consent of the Superintendent to the use of any stockpile site which is not shown on the drawings. Proposals in this regard shall be submitted at least three working days before stockpiling is due to commence and shall specify the maximum dimensions of the proposed stockpile.

Any clearing and grubbing required for these sites shall be carried out in accordance with SC6.4.6.11 Clearing and grubbing. Temporary erosion and sedimentation control measures shall be taken in accordance with *Best Practice Erosion and Sediment Control.*

Restoration of stockpile sites following completion of the work shall be carried out in accordance with IECA *Best Practice Erosion and Sediment Control.*

SC6.4.6.10.2 Removal of topsoil

(1) Scope

Topsoil is surface soil which is reasonably free from subsoil, refuse, clay lumps and stones.

Removal of topsoil from any section of the Works shall only commence after erosion and sedimentation controls have been implemented and when clearing, grubbing and disposal of materials have been completed on that section of the works in accordance with relevant parts of *Best Practice Erosion and Sediment Control* and SC6.4.6.11 Clearing and grubbing.

Topsoil throughout the length of the Work shall be removed and stockpiled separately clear of the Work with care taken to avoid contamination by other materials. The work shall include the following:

(a) Cuttings

Removal of the topsoil to a depth quoted in SC6.4.6.10 Attachment A Earthworks supplementary information, or as directed by the Superintendent.

(b) Embankments

Removal of topsoil over the base of embankments up to the depth below the natural surface quoted in SC6.4.6.10 Attachment A Earthworks supplementary information, or as directed by the Superintendent. For those embankments or sections of embankment where the height of embankment from natural surface to underside of pavement is less than two metres, topsoil which is deeper than the depth quoted in SC6.4.6.10 Attachment A Earthworks supplementary information shall be removed to its full depth as directed by the Superintendent.

(c) Other locations

Removal of topsoil as directed by the Superintendent.

(2) Topsoil stockpiles

The maximum height of stockpiles shall not exceed 2.5m and the maximum batter slope shall not exceed 2h:1v.

Topsoil stockpiles shall not contain any timber or other rubbish and shall be trimmed to a regular shape.

Keep topsoil and underburden stockpiles separate.

Stabilise stockpiles and batters that will remain bare for more than 28 days by covering with mulch or anchored

fabrics or seeding with sterile grass.

Establish sediment controls around unstabilised stockpiles and batters. Locate stockpiles away from drainage lines, at least 10m away from natural waterways and where they will be least susceptible to wind erosion.

To minimise erosion, stockpile batters shall be track rolled or stabilised by other means acceptable to the Superintendent.

Where seeding of stockpiles to encourage vegetation cover is specified, such work shall be carried out in accordance with SC6.4.6.26 Landscaping.

SC6.4.6.10.3 Cuttings

(1) Scope

Construction of cuttings shall include all operations associated with the excavation of material within the limits of the batters including benching, treatment of cutting floors and transition from cut to fill.

(2) Excavation

Materials encountered in cuttings shall be loosened and broken down as required so that they are acceptable for incorporation in the Works. In this regard, the Contractor's attention is drawn to clauses SC6.4.6.10.5 Unsuitable material, SC6.4.6.10.6(1) Scope and SC6.4.6.10.6(2) Embankment material.

Cuttings shall have batter slopes as shown on the drawings or as redetermined by the Superintendent on the basis of site inspection and investigation during the excavation.

The tops of all cuttings shall be neatly “rounded”.

In all cuttings, undulations in the general plane of the batter shall not be permitted except that batters may require progressive flattening at the ends of cuttings due to the presence of less stable material.

Cut faces shall be cleaned of loose or unstable material progressively as the excavation proceeds.

Where, after the removal of topsoil as specified in clause SC6.4.6.10.2(1) Scope, material of variable quality or moisture content is encountered, the Contractor shall adjust his excavation methods to ensure blending of the materials, to obtain material meeting the requirements of clause SC6.4.6.10.6(2) Embankment material.

(3) Batter tolerances

If the Contractor excavates the batter beyond the batter slope line and the tolerance applicable thereto, the Superintendent may authorise a minor change in the general slope of the batter to suit the convenience of

the Contractor, but such a change shall not be regarded as a redetermination of the batter slope under clause SC6.4.6.10.3(2) Excavation. Alternatively the Contractor shall submit details of the material and/or methods proposed to restore the specified slope and stability of the batter for the Superintendent's approval.

For batters steeper than 1:1, if any section of the batter up to a height of 3m above the table drain level has been over excavated beyond the tolerance limit specified, the Superintendent may direct that the batter be restored to the average batter slope using randomly mortared stone. The stone shall be similar to the sound rock in the cutting and the mortar shall be coloured to match the colour of the rock.

The tolerances for the excavation of batters, measured at right angles to the design grade line, are given in Table SC6.4.6.10.1 Excavation tolerances for batters.

Table SC6.4.6.10.1 Excavation tolerances for batters

Location	Tolerance (mm)	
	Slope 1:1 or flatter	Steeper than 1:1
Toe of batter and level of table drain	+ 0 - 150	+ 0 - 200
2m above table drain and higher	+ 300 - 300	+ 300 - 600
Between level of table drain and 2m above table drain	pro rata basis	pro rata basis

Note—tolerances are measured normal to the batter surface with (+) measured towards the roadway.

(4) Benching in cuttings

Cut batters shall be benched as shown on the drawings to provide drainage and erosion control. Notwithstanding the tolerances permitted under clause SC6.4.6.10.3(3) Batter tolerances, bench widths shall not be less than those shown on the drawings.

Benches shall be maintained and cleaned of loose stones and boulders regularly throughout the Contract period. The cost of such maintenance and cleaning of benches shall be borne by the Contractor.

(5) Subgrade of cuttings

The subgrade of cuttings shall be excavated, parallel to the designed grade line, to a designed subgrade level. The subgrade must then be trimmed to a level of not more than +0mm, -50mm from the designed subgrade level. Prior to ripping or removal of the cut material, the Contractor shall determine the CBR of the material in at the subgrade level in accordance with AS1289.6.1.1, Plasticity Index AS1289.3.3.1 and Shrink-Swell Index AS1289.7.1.1. Sufficient tests shall be taken to represent all the various materials which may exist within the subgrade.

Adequate sampling and testing shall be undertaken to satisfy all necessary requirements to verify the intended pavement design. Where the Superintendent considers that any underlying material is unsuitable for pavement support, the Superintendent may direct that it be removed in accordance with clause SC6.4.6.10.5 Unsuitable material.

The Contractor shall rip or loosen all material in the subgrade to a minimum depth of 200mm below the designed subgrade level for the width of the selected material zone (or subbase layer, where no selected material zone), including areas of rock. The maximum dimension of any particles in the ripped or loosened zone shall not exceed 150mm.

After recompaction, the subgrade within cuttings shall be re-trimmed parallel with the finished wearing surface so that their levels do not vary more than +0mm, -50mm from the designed subgrade level. It shall be recompacted in accordance with Clause SC6.4.6.10.7(1).

Horizontal tolerance – the width of the cutting at subgrade level for support of the pavement shall not be less than that specified.

Prior to placing any subsequent layers over the completed subgrade level, the Contractor shall present the completed surface to the Superintendent for inspection. The Contractor shall verify as part of the quality system that the completed surface has achieved full conformance with all respects to relevant specifications.

In placing subsequent layers, the Contractor shall use equipment and techniques to avoid surface heaving or other damage to the subgrade surface.

(6) Transition from cut to fill

After the removal of topsoil and before the excavation of any cutting commences the contractor shall survey and mark the position of the intersection line between cutting and embankment occurring at the underside of

the selected material zone or pavement subbase.

The contractor is to ensure that the transition from cut to fill is undertaken in accordance with best practice geotechnical procedures and guidelines.

SC6.4.6.10.4 Blasting general

(1) When explosives are permitted to be used by council, the contractor shall obtain all necessary licences from the appropriate authorities, and shall comply with all government and council regulations relating to transport, storage, handling and the use of explosives and also to the rules set out in AS2187.1 and AS2187.2. The transport of explosives shall be in accordance with the *Australian Code for the Transport of Explosives by Rail and Road. The requirements of the Explosives Act 1999* and *Explosives Regulation 2003* and Local laws, if applicable, shall be complied with.

The contractor shall be liable for any accident, damage or injury to any person, property or thing, resulting from the use of explosives.

Before the start of blasting operations, the contractor, in the presence of the superintendent, shall conduct a dilapidation survey to determine and record the existing condition of all structures likely to be affected by any blast.

The survey shall include all structures including public utilities within 500m of any blast but shall be extended where the maximum instantaneous charge proposed is likely to produce peak particle velocities greater than allowable at structures more remote from a blast site. A written report of the survey, supported by photographs where necessary, together with a list of any existing defects in the structures, shall be submitted to the owner of each structure, to the superintendent and council before blasting commences.

The contractor shall advise the superintendent of the proposed maximum instantaneous charge and the contractor's validation of the adequacy of the proposed structural survey at least three working days before the survey is due to commence. The superintendent may direct amendments to the scope of the survey as a result of blast monitoring during the work. All costs associated with the surveys and reports shall be borne by the contractor.

Before each blasting operation, the contractor shall submit to the Superintendent written details of the proposed blasting procedure including the quantity and type of explosive to be detonated, the blasting pattern to be used and measures proposed to limit noise and to ensure that vibration from blasting does not adversely affect nearby structures.

Ground vibration caused by blasting shall not exceed the values of peak particle velocity listed in Table SC6.4.6.10.2 Limiting peak particle velocity.

Table SC6.4.6.10.2 Limiting peak particle velocity

Point of Potential Damage (within 1 km of blasting site)	**Peak Particle Velocity**
Completed and cured bridge structures or sub‐structures (e.g. completed abutment).	25mm/sec
Bridgeworks and structural retaining walls under construction.	20mm/sec
Residential premises, schools, hospitals and other buildings.	5mm/sec (with 10% not to exceed 10 mm/sec)
Buildings or monuments of historical significance.	2mm/sec

The contractor shall advise all residents within a radius of 1km, by letter drop before blasting operations

commence, of the likely times, frequency and duration of blasting and precautions being taken to ensure that damage to property will not result.

Unless otherwise approved, blasting operations shall be confined to the periods Mondays to Fridays (excluding public holidays), 9am to 3pm.

When blasting operations are being carried out, precautions shall be taken relating to the safety of persons and animals and the road shall be closed to traffic and the appropriate signs erected in accordance with the sub-section SC6.4.6.30 Control of traffic. A standard warning procedure such as that given in the AS2187.2 shall be established and observed at all times.

(2) Presplitting

Where presplitting is carried out the spacing of presplit drill holes shall not exceed 750mm centre to centre.

(3) Blasting records

The Contractor shall maintain accurate records of each blast showing the details listed below:

(a) date and time of blast;

(b) location, number and diameter of holes loaded;

(c) depth of each hole loaded;

(d) inclination of holes;

(e) maximum and minimum burden;

(f) types of explosives used;

(g) charge distribution in each hole;

(h) maximum instantaneous charge;

(i) delay periods and sequence;

(j) total amount of charges in the blast; and

(k) length and type of stemming in each hole.

The records shall be prepared as holes are loaded and signed by the Powder man. A copy shall be provided to the Superintendent on the day of the blast.

(4) Control of air blast over-pressure

This clause shall apply only where a noise sensitive location exists within 1km of the blasting site.

The Contractor's attention is drawn to the recommendations given in the *Environmental Protection (Noise) Policy 2008* or as amended - for the reduction of air blast over-pressure.

The noise emanating from blasting operations shall not exceed an over-pressure level of 115dB (linear peak) at any noise sensitive location (such as residential premises, schools or hospitals). Up to 10 per cent of the total number of blasts may exceed this value provided a level of 120dB is not exceeded at any time.

The Contractor shall arrange for the monitoring of air blast over-pressure to ensure compliance with the specified limits. All monitoring shall be carried out by personnel possessing current NATA registration for such monitoring. All test results shall be reported on NATA endorsed test certificates which shall include a clear statement as to compliance or non-compliance with the requirements of this sub-section. In general, a monitoring location will be near the perimeter of the noise sensitive location at the point closest to the maximum charge. The Contractor shall submit a copy of the monitoring record to the Superintendent.

In the event that the measured air blast over-pressure exceeds the specified limits, the Contractor shall suspend further blasting work and shall submit to the Superintendent proposals detailing any additional steps and precautions the Contractor shall take to ensure that for any future blast, the limiting over-pressure shall not be exceeded. The Contractor shall not resume any blasting until such proposals have been submitted.

(5) Control of ground vibration

The Contractor shall arrange for the monitoring of ground vibrations to ensure compliance with the peak particle velocity limits shown in Table SC6.4.6.10.2 Limiting peak particle velocity. All monitoring shall be carried out by personnel possessing current NATA registration for such monitoring. All test results shall be reported on NATA endorsed test certificates which shall include a clear statement as to compliance or non-compliance with the requirements of this part of the sub-section. In general a monitoring location shall be near the perimeter of the structure or building at the point closest to the maximum charge. The Contractor shall submit a copy of the monitoring record to the Superintendent.

To minimise the risk of peak particle velocity limits being exceeded, the Contractor shall develop a blasting site relationship between peak particle velocity, distance and blasting charge.

For the first blast, monitors shall be set up at not less than five points at varying distances away from the blasting site. The Maximum Instantaneous Charge for the first blast shall not exceed that calculated from the following formula:

$$MIC = 0.5\left[\frac{D}{\left[\frac{PPV}{1140}\right]^{-0.625}}\right]^2$$

where MIC = Maximum Instantaneous Charge in kilograms
D = Distance in metres from charge to the point of potential damage
PPV = limiting peak particle velocity from Table SC6.4.6.10.2.

A log-log (base 10) graph of measured peak particle velocity (vertical axis) versus Scaled Distance (horizontal axis) shall be plotted, where

$$\text{Scaled Distance} = \frac{D}{\sqrt{MIC}}$$

The mean regression line shall be obtained by the least squares method.

For subsequent blasts, the MIC and other aspects of blast design may be adjusted provided that further ground vibration monitoring is undertaken and the mean regression line redetermined to demonstrate that peak particle velocity limits are not exceeded. The Contractor shall make the regression line plots available to the Superintendent, if so requested.

SC6.4.6.10.5 Unsuitable material

Unsuitable material is that occurring below the designed floor level of cuttings and below the nominated depth for stripping topsoil beneath embankments, which the Superintendent deems to be unsuitable for embankment or pavement support in its present position. Unsuitable material also includes material in cuttings which the Superintendent deems to be unsuitable for embankment construction.

Such material shall be excavated to the extent directed by the Superintendent. Material removed as unsuitable, as directed by the Superintendent, shall be incorporated in embankments in accordance with SC6.4.6.10.6(2) Embankment material or spoiled in accordance with clause SC6.4.6.10.6(13) Spoil.

After removal of the unsuitable material, the floor of the excavation shall be re-presented to the Superintendent for inspection, prior to backfilling with replacement material, to determine whether a sufficient depth of unsuitable material has been removed. Prior to placing replacement material the excavated surface shall be compacted in accordance with SC6.4.6.10.8(1) Compaction and moisture requirements.

The unsuitable material which has been removed shall be replaced with material from cuttings, or with material borrowed in accordance with clause SC6.4.6.10.6(14) Borrow, of the quality specified in clause SC6.4.6.10.6(2).

Embankment materials. Replacement material is deemed to form part of embankment construction. It shall be placed in accordance with clause SC6.4.6.10.6(5) Placing Fill for embankment construction and compacted in accordance with clause SC6.4.6.10.8(1) Construction management.

Reworking or replacing any material which the Superintendent deems to have become unsuitable because of inappropriate construction activities shall be borne by the Contractor.

Excavate and dispose of all contaminated material in an environmentally responsible manner including the following:

(1) assay material uncovered on-site prior to disposal. If the wastes include putrescibles wastes, then also analyse leachate and landfill gases;

(2) excavate material in a manner which avoids off-site environmental problems;

(3) seal remaining contaminated material or wastes, where only part of the tip has been excavated, to ensure than there is no off-site effect now or in the future;

(4) transport odorous wastes in covered vehicles; and

(5) dispose of contaminated material in a landfill licensed to take the type of contaminated material or wastes uncovered.

SC6.4.6.10.6 Embankment construction

(1) Scope

Embankment construction includes all operations associated with the preparation of the foundation areas on which fill material is to be placed, the placing and compacting of approved material within areas from which unsuitable material has been removed in accordance with clause SC6.4.6.10.5 Unsuitable material, the placing and compacting of fill material and of materials of specified quality in nominated zones throughout the Works and all other activities required to produce embankments as specified to the alignment, grading and dimensions shown on the drawings. It also includes any pre-treatment such as breaking down or blending material or drying out material containing excess moisture.

(2) Embankment material

Material for embankment construction shall be obtained from the cuttings within the Works in accordance with clause SC6.4.6.10.3(2) Excavation supplemented by borrow in accordance with clause SC6.4.6.10.6(14) Borrow and from other sources as approved by the Superintendent if necessary. The material shall be free of tree stumps and roots, clay, topsoil, steel, organic material and other contaminants and shall be capable of being compacted in accordance with clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The work shall be programmed so that material of the quality specified in clause SC6.4.6.10.6(5) Placing fill for embankment construction and SC6.4.6.10.6(9) Selected material zone for the upper zones of the formation is available when required.

(3) Foundations for embankments

(a) Following removal of topsoil in accordance with clause SC6.4.6.10.2 Removal of top soil, the embankment foundation area shall be made available for inspection by the Superintendent.
Where the Superintendent considers that any underlying material is unsuitable, the Superintendent may direct that it be removed and replaced in accordance with clause SC6.4.6.10.5 Unsuitable material.

(b) Foundations for Shallow Embankments
Shallow embankments are those embankments of a depth less than 1.0m from the top of pavement to natural surface. After removal of topsoil the Contractor shall survey and work out the extent of the area of shallow embankments.

Material in the foundations for shallow embankments which does not meet the requirements specified in SC6.4.6.10 Attachment A Earthworks – supplementary information, shall be deemed unsuitable in

accordance with clause SC6.4.6.10.5 Unsuitable material and shall be replaced by material of the specified quality.

Foundations for shallow embankments shall be prepared for embankment construction after removing topsoil and unsuitable material, by loosening the material exposed to a depth of 200mm, adjusting the moisture content of the loosened material and compacting as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements. The Contractor shall use equipment and techniques to minimise surface heaving or other foundation damage.

(c) Other embankments

For all other embankments the foundation shall be prepared by grading and levelling the general area, adjusting the moisture content where necessary and compacting the top 200mm as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The bridging layer shall consist of free-draining granular material with or without geofabric interlayer as specified on the drawings. The granular material shall be end-dumped and spread in a single layer and in sufficient depth to allow the passage of earthmoving equipment with minimal surface heaving. The compaction requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements shall not apply to the bridging layer.

A bridging layer may also be employed, subject to the approval of the Superintendent, where ground water or seepage is encountered in the foundation area or where the Contractor demonstrates that it is impracticable to achieve the degree of compaction specified for the foundation in clause SC6.4.6.10.8(1) Compaction and moisture requirements. A bridging layer shall not be acceptable if its proximity to the pavement is likely to affect the pavement design. As an alternative to a bridging layer, approval of a working platform created by the chemical stabilisation of in situ material to conform with sub-section SC6.4.6.19 Stabilisation may be required.

(4) Hillside embankments

Where embankments are to be constructed on or against any natural slopes or the batters of existing embankments, the existing slope or batter, if it is steeper than 4 horizontal to 1 vertical in any direction, shall be cut in the form of horizontal terraces over the whole area to be covered by new filling. The existing slope or batter shall be stepped in successive terraces, each at least 1m in width, the terraces to be cut progressively as the embankment is placed. Wherever possible terraces shall coincide with natural discontinuities. Subsoil drainage may be required in some instances. Material thus excavated shall be compacted as part of the new embankment material.

(5) Placing fill for embankment construction

The methods of excavation, transport, depositing and spreading of the fill material shall be selected so as to ensure that the placed material is uniformly mixed.
The embankment shall be constructed so as to derive its stability from the adequate compaction of the fine material embedding the large rock pieces rather than mechanical interlock of the rock pieces. The fine material shall be compacted to meet the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements.

Fill material for embankment construction shall be placed in layers parallel to the grade line and compacted in accordance with clause SC6.4.6.10.8(1) Compaction and moisture requirements. The layers shall be of uniform compacted thickness not exceeding 200mm, except that where more than 25% by volume of the filling consists of rock with any dimension larger than 150mm, the Superintendent may approve an increase in the compacted layer thickness to 300mm, provided that the relative compaction specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements is attained.

The maximum dimension, measured in any direction, of rock pieces in the fill material for embankment construction shall not exceed two-thirds of the approved compacted layer thickness. Any larger rock pieces shall be reduced in size for incorporation in the embankment layers.

Rock material shall be broken down and evenly distributed through the fill material, and sufficient fine material

must be placed around the larger material as it is deposited to fill the voids and produce a dense, compact embankment. Where the Superintendent considers insufficient fine material is present to fill the voids, additional fine material shall be obtained from other places in the work or by a change in the method of winning fill material.
Stony patches with insufficient fine material to fill the voids shall be reworked with additional fine material being blended in to achieve a dense, compact layer.

In placing embankment layers, the Contractor shall use equipment and techniques to avoid surface heaving or other damage to the foundations and underlying embankment layers.
After compaction, embankment material in the zone(s) below the selected material zone (or subbase layer, where no selected material zone) shall have a CBR value not less than that quoted in and for the depth(s) specified in SC6.4.6.10 Attachment A Earthworks Supplementary Information.

For the purpose of this clause, the CBR value of the material shall be determined by Test Method AS1289.6.1.1.

The Contractor shall be responsible for determining suitable sources of material and for any processing to satisfy these quality requirements.

(6) Embankment batters

The batter slopes shown on the drawings represent the estimated requirements for the expected types of materials, and may be subject to redetermination by the Superintendent according to the Superintendent's assessment of the materials encountered.

When completed, the slope of embankment batter shall conform to those shown on the drawings and conform to the following tolerances:

(a) for a vertical distance to 1m below the shoulder, no point on the completed batter to vary from the specified slope line by more than 150mm when measured at right angles to the slope line;

(b) at distances greater than 1m vertically below the shoulder, no point on the completed batter to vary from the specified slope line by more than 300mm when measured at right angles to the slope; and

(c) in no case is the edge of the formation at the underside of the pavement to be nearer to the roadway than shown on the drawings and the batter slope at no point be steeper than the specified slope.

However, in no case shall the edge of the formation at the underside of the pavement be nearer to the roadway than shown on the drawings.
Undulations in the general plane of the batter shall not be permitted.

(7) Rock facing of embankments

Where shown on the drawings, embankment batters (including embankments at bridge abutments) shall be provided with a facing of clean, hard, durable rock.

The rock facing shall be built up in layers ahead of each layer of filling. Rock may be placed by hand or plant but shall be placed in such a manner that its least dimension is vertical and that mechanical interlock between the larger stones occurs. Any rock deposited in the rock facing which has an excess of fine material surrounding it shall be removed together with the excess fine material and replaced.

The Contractor shall adjust its working methods and programme the work so as to obtain hard and durable rock of the specified dimensions as it is required. The space between larger batter rocks shall be filled with progressively smaller rocks to form a 'graded filter' which prevents the leaching out of fines from the fill material but which does not overfill the voids between larger rocks, or cause the larger rocks to lose contact with one another. Fine material shall not cover the outside of the rocks on the face of the batter.

The Contractor shall exercise extreme caution whilst placing the rock facing. Where embankment material is placed above other roads in use the outer rock layer shall be placed in such a manner as to prevent spillage down the batter.

The Contractor shall ensure that, under no circumstances, could any rock be dislodged and roll onto any adjacent roadway or track in use.

(8) Trimming tops of embankments

The tops of embankments shall be trimmed parallel to the designed grade line at levels equal to the finished surface level less the thicknesses of pavement courses and the selected material zone.

The tops of embankments at these levels shall be compacted to meet the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements and trimmed so that they do not vary by more than ±50mm from the calculated level. The width of the embankment at subgrade level shall not be less than that specified.

Prior to placing any subsequent pavement layers over the completed top of embankment filling, the contractor shall present the completed surface to the superintendent for inspection. The contractor shall verify as part of the quality system that the completed surface has achieved full conformance with all respects of the relevant specifications.

(9) Selected material zone

A selected material zone must be provided in accordance with the following quality requirements:

(a) it shall be free from stone larger than 75mm maximum dimension and have no less than 50% passing the 19mm AS sieve;

(b) a CBR value not less than the specified in SC6.4.6.10 Attachment A Earthworks Supplementary Information for the fraction passing AS 19mm sieve; and

(c) Plasticity Index of 15 maximum.

If chemical stabilisation is specified these requirements must apply to the selected material immediately prior to incorporating the stabilising agent.

The Contractor shall use working methods to yield material for the selected material zone by breaking down oversize rock or by other means, including processing through a crusher, to ensure that the resulting material conforms to the requirements of this clause.

The Contractor shall ensure that any material encountered of the quality specified for the selected material zone shall be either placed directly in the selected material zone or stockpiled at locations approved by the Superintendent for future use by the Contractor in the selected material zone until at least sufficient material is reserved to complete the selected material zone over the whole work. Should the Contractor fail to conserve material of the specified quality, the Superintendent may direct that material of equivalent quality be provided.

The selected material zone shall be placed and compacted in layers with the compacted thickness of each layer not exceeding 150mm. The selected material shall be homogeneous and free from patches containing segregated stone or excess fines. There shall be no areas containing material which does not comply with the specified requirements of this clause and compaction shall be as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The top of the selected material zone shall be compacted and trimmed parallel with the designed grade line at a level equal to the finished surface level minus the thickness of pavement layers adopted. The tolerances for the trimmed levels are given in SC6.4.6.10 Attachment A Earthworks – Supplementary Information.

Prior to placing any subsequent pavement layers over the completed select material zone surface, the Contractor shall present the completed surface to the Superintendent for inspection. The Contractor shall verify as part of the quality system that the completed surface has achieved full conformance with all respects of relevant Specification.

(10) Fill adjacent to structures

For the purpose of this clause, structures shall include bridges, precast and cast-in-situ box culverts and

retaining walls. Fill adjacent to other culverts and drainage structures to be provided in accordance with SC6.4.6.4 Stormwater Drainage, SC6.4.6.6 Pipe Drainage, SC6.4.6.7 Precast Box Culverts and SC6.4.6.5 Drainage Structures.

No filling shall be placed against structures, retaining walls, headwalls or wingwalls within 21 days after placing of the concrete, unless the walls are effectively supported by struts to the satisfaction of the Superintendent, or when the contractor can demonstrate that 85% of the design strength of the concrete has been achieved. This includes concrete in bridge decks and fill placement that impacts the position, stability and serviceability of bridge deck member bearings.

(11) Treatment at weepholes

Drainage adjacent to weepholes shall be provided by either a layer of broken stone or river gravel consisting of clean, hard, durable particles graded from 50 mm to 10 mm such that:

(a) the maximum particle dimension shall not exceed 50mm; and

(b) no more than 5% by mass shall pass the 9.5mm A.S. sieve.

The broken stone or river gravel shall be continuous in the line of the weepholes, extend at least 300mm horizontally into the fill and extend from 200mm below to at least 450mm vertically above the level of the weepholes, where practicable.

Alternatively the Contractor may provide a synthetic membrane (geotextile) of equivalent drainage characteristics. It shall be stored and installed in accordance with Manufacturer's instructions. The use of a synthetic membrane (geotextile) shall be subject to the Superintendent's approval.

(12) Selected backfill

(a) Selected backfill shall be placed adjacent to structures in accordance with Table SC6.4.6.10.3 Selected backfill, width and height. The selected backfill shall consist of a granular material having a maximum dimension not exceeding 50mm and a Plasticity Index, determined by AS1289.3.3.1, neither less than 2 nor more than 12.

Table SC6.4.6.10.3 Select backfill, width and height

Structure Type	Selected Backfill	
	Width	Height
Bridge abutments	2m	H
Cast-in-situ Box Culverts and Precast Culverts	H/3	H + 300mm
Corrugated Steel Pipes and Arches	0.5m	H + 500mm
Retaining Walls	H/3	H

(Where H = height of structure)

The selected backfill shall be placed in layers, with a maximum compacted thickness of 150mm. Layers shall be placed simultaneously on both sides of box culverts to avoid differential loading. Compaction shall start at the wall and proceed away from it, and shall meet the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements.

The existing embankment slope behind the structure shall be cut in the form of successive horizontal terraces, each terrace being at least 1m in width, and the selected backfill shall be placed in accordance with clause SC6.4.6.10.6(5) Placing fill for embankment construction.

Where a bridge deck is being concreted adjacent to an abutment, no filling shall be placed against the abutment within 21 days after placing concrete in the bridge deck, unless approved by the Superintendent.

In the case of spill-through abutments, rocks shall not be dumped against the columns or retaining walls but shall be built up evenly by individual placement around or against such structures.

In the case of framed structures, embankments at both ends of the structure shall be brought up simultaneously, the difference between the levels of the embankments at the respective abutments, shall not exceed 500mm.

(13) Spoil

Spoil is surplus material from excavations which is not required to complete the Works as specified or other material from excavations whose quality the Superintendent deems to be unacceptable for incorporation in the Works.

Where there is surplus material the Superintendent may direct that flatter batter slopes be provided on embankments which have not been commenced, and/or direct that the excess material be used in the uniform widening of embankments, the surface of which shall be shaped so as to provide a tidy appearance and effective drainage. The surplus material shall be spread and compacted as specified in clauses SC6.4.6.10.6(5) Placing fill for embankment construction and SC6.4.6.10.8(1) Compaction and moisture requirements for material in embankments.

Alternatively, spoil shall be disposed of in the manner and at locations approved by the Superintendent within the specified working area for the Works or be removed and disposed of off site by the Contractor. Surplus material so deposited shall be compacted as specified in clause SC6.4.6.10.8(1) Compaction and moisture requirements for material in embankments or to such lesser extent as may be approved by the Superintendent.

(14) Borrow

Borrow will only be authorised by the Superintendent if, in constructing cuttings and embankments to the batter slopes specified or directed by the Superintendent or in providing materials of the quality specified, and not by reason of excess widening of embankments or wastage by the Contractor of material of the quality specified in clauses SC6.4.6.10.6(2) Embankment material, SC6.4.6.10.6(7) Rock facing of embankments, SC6.4.6.10.6(8) Trimming tops of embankments or SC6.4.6.10.6(10) Fill adjacent to structures, there is an overall deficiency in either the quantity or the quality of material required to complete the Works.

Where borrow material is required to complete the Works as specified, the location of borrow sites shall be as approved by the Superintendent, and the quality of material shall be acceptable to the Superintendent in accordance with clauses SC6.4.6.10.6(2) Embankment material, SC6.4.6.10.6(7) Rock Facing of Embankments or SC6.4.6.10.6(10) Fill Adjacent to Structures as appropriate. The edges of borrow sites must be no closer than 3m from any fence line, or edge of excavation or embankment. Adequate clearance shall be provided for the construction of catch drains. Borrow sites shall have drainage outlets acceptable to the Superintendent, cut batter slopes not steeper than 4h to 1v, and shall be left by the Contractor in a tidy and safe condition (i.e. stabilising disturbed areas).

For borrow within the defined working area for the Works as specified, site preparation shall be in accordance with SC6.4.6.11 Clearing and grubbing and clause SC6.4.6.10.2 Removal of top soil. Restoration of borrow sites shall be carried out by Contractor in accordance with Best Practice Erosion and Sediment Control.

If borrow material is obtained by uniformly widening a cutting, the requirements of Clauses SC6.4.6.10.3(2) Excavation, SC6.4.6.10.3(3) Batter tolerances and SC6.4.6.10.3(5) Treatment of floors of cuttings as to the redetermination of batter slopes, the trimming of batters and the compaction of floors of cuttings respectively shall apply to the borrow area.

The Contractor shall be responsible for obtaining any permits required for entry on land and for the payment of any royalty for such borrow material. The Contractor shall also comply with any requirements of the *Planning Act 2016* – as amended, Townsville City Plan, Local laws and land owners, as appropriate.

SC6.4.6.10.7 Acid sulfate soils

(1) Objective

To minimise disturbance to areas of potential acid sulphate soils (PASS) and/or actual acid sulphate soils (ASS). If disturbance of PASS/ASS cannot be avoided, appropriate treatment is required to minimise the

potential for environmental harm.

PASS and ASS are soils that have the potential to generate acid through oxidation of iron sulphides when exposed to air. ASS and PASS are generally found in coastal areas, and generally in soils at an elevation of 5m AHD or lower.

(2) References

Dept of Environment and Resource Management, *Nov 2002*
Queensland Acid Sulfate Soil Technical Manual Soil Management Guidelines
State Planning Policy
EF006: Daily Dredging Checklist Form
CE020: Regulated Waste Transport Procedure
QAF004 Incident, Hazard, Improvement reporting form

(3) Safety requirements

Works shall comply with provisions of the Work Health and Safety Act 2011 and subsequent regulations. Personnel are responsible for their own Personal Protective Equipment (PPE) and the safety of the surrounding workplace during works.

Care is to be taken when using hydrogen peroxide, including gloves and eye protection.

(4) Environmental Requirements

Compliance with Environmental Protection Act 1994 and subordinate legislation.
Compliance with *Queensland Acid Sulfate Soil Technical Manual Soil Management Guidelines*
Compliance with the State Planning Policy.
Compliance with all other environmental legislation.
Compliance with TCC Environmental Policy.

(5) Equipment and materials

Testing should be undertaken by a suitably qualified laboratory.

(6) Method

(a) Identifying ASS/PASS on site

The following points can assist in determining if soil has a likelihood of containing ASS/PASS. Affirmative answers to the following questions may indicate the presence of ASS/PASS. Field observations and tests should be complemented by laboratory testing.

(i) Is the site elevation 5m AHD or less?

(ii) Are mangroves, she-oaks or melalueca species (i.e. paper barks) present on site?

(iii) Is there other vegetation that is stunted or dying?

(iv) Does the soil have a dark grey to grey appearance?

(v) Is there a rotten egg smell (hydrogen sulphide) to disturbed soil?

(vi) Is there a mottled-yellow mineral present in the soil (Jarosite)?

(vii) Is there water bodies nearby that have a very clear blue-ish appearance, or does it appear to be reddish (rust) in colour?

(viii) Is the pH of the excavated sediment, or water, below 4?

(b) Managing and treating ASS and PASS

(i) Determine if works can be undertaken without disturbing ASS/PASS material.

(ii) If ASS/PASS is to be disturbed as a result of project activities then undertake testing to determine the severity of the potential acidification and extent of ASS/PASS material.

(iii) ASS/PASS material excavated on site must either be treated on site or transported to a treatment location. A treatment pad should be set up as per the *Queensland Acid Sulfate Soil Technical*

Manual, Soil Management Guidelines.

(iv) ASS material should be transported as regulated waste as it has the potential to be generating acid while exposed to the atmosphere.

(v) All treatment of PASS/ASS must be undertaken in compliance with the *Queensland Acid Sulfate Soil Technical Manual, Soil Management Guidelines.*

(vi) ASS/PASS treatment must be undertaken as per the laboratory recommendations.

(c) Corrective/Emergency Actions

If PASS and/or ASS are identified through site inspection and confirmed through lab testing, follow procedure outline in (6) above.

If corrective actions are identified, an Incident, Hazard, Improvement Report is to be completed and subsequent review of this procedure undertaken in accordance with these guidelines.

(d) Waste Control

Treat PASS and ASS in accordance with guidelines (State Policy)

Ensure wastes generated as a result of field testing or work activities are disposed of correctly.

(e) Responsibilities

(i) Site foreperson/works controller is responsible for:

(A) monitoring and testing soils; and

(B) Minimising disturbance to PASS/ASS.

(ii) The Environmental Engineer is responsible for ensuring any environmental non-compliances are reported.

(iii) The Executive Manager Engineering Services is responsible for:

(A) notifying relevant personnel of changes to this procedure; and

(B) delivering training to personnel (if required).

(f) Monitoring and reporting

The foreperson will monitor and test soils prior to commencement of works and record results of field tests on daily dredging checklist.

SC6.4.6.10.8 Compaction and quality control

(1) Compaction and moisture requirements

In areas listed below, all layers shall be uniformly compacted to not less than the relative compaction specified before the next layer is commenced. Each layer of material shall be trimmed prior to and during compaction to avoid bridging over low areas. A smooth surface shall be presented at the top of each layer.

(a) The following areas shall be compacted to provide a relative compaction, determined by AS1289.5.1.1 using AS1289.5.4.1 or AS1289.5.7.1 for standard compactive effort, of not less than 95%.

(i) each layer of material replacing unsuitable material as detailed in clause SC6.4.6.10.5 Unsuitable material

(ii) each layer of material placed in embankments, up to 300mm from the top of the sub-grade;

(iii) fill placed adjacent to structures up to 300mm from the top of sub-grade;

(iv) material in unsealed verges and within medians up to the level at which topsoil is placed;

(v) spoil (excluding unsuitable material); and

(vi) all other areas except those where a higher relative compaction is specified.

Unsuitable material shall be stockpiled as directed by the Superintendent and compacted by track rolling.

(b) The following areas shall be compacted to provide a relative compaction of not less than 97% as determined by AS1289.5.1.1 using AS1289.5.4.1 or AS1289.5.7.1 for standard compactive effort:

(i) foundations for shallow embankments;

(ii) foundations other than shallow embankments;

(iii) the whole area on the floors of cuttings;

(iv) each layer of the embankment or cutting within 300mm from the top of sub-grade;

(v) each layer of the selected material zone as specified in clause SC6.4.6.10.6(9) Selected material zone;

(vi) any areas of material of specified quality which may be shown on the drawings or specified elsewhere behind kerbs and/or gutters or adjacent to rigid pavements; and

(vii) the fill material placed adjacent to structures as specified in clauses SC6.4.6.10.6(10) Fill adjacent to structures and SC6.4.6.10.6(12) Selected backfill in each layer within 300mm from the top of the sub-grade.

Where the vertical alignment design is such that a substantial portion of the road is required to be built at or close to the natural surface, cut the prepared subgrade to a depth below natural surface of less than 0.5m. Approval is required when shallow cutting conditions occur, the specified transition from cut to fill may be modified such that the depth of terrace excavation at the transition from cut to fill is reduced from 900mm to 250mm.

Treat the floor of shallow cutting as specified in clause SC6.4.6.10.3(5) Treatment of floors of cuttings and clause SC6.4.6.10.3(6) Trasition from cut to fill and compact to provide a relative compaction of not less than 100% for a depth of 200mm determined by AS1289.5.4.1, for standard compactive effort.

At the time of compaction the moisture content of the material shall be adjusted so as to permit the specified compaction to be attained at a moisture content which, unless otherwise approved by the Superintendent, is within the range set out in SC6.4.6.10 Attachment A Earthworks Supplementary Information of the optimum moisture content as determined by AS1289.5.1.1 or AS1289.5.7.1. Material which becomes wetted up after placement shall not be compacted until it has dried out so that the moisture content is within this range. The drying process may be assisted by aeration, or where approved by the Superintendent, by the use of hydrated or quick lime. Alternatively the Contractor may transport the wet material to a stockpile site for drying out and later use as fill material. If there is insufficient moisture in the material for it to be compacted as specified, water shall be added. The added water shall be applied uniformly and thoroughly mixed with the material until a homogeneous mixture is obtained.

Compaction shall be undertaken to obtain the specified relative compaction for the full depth of each layer in embankments and for the full width of the formation over the entire length of the work. Compaction shall be completed promptly to minimise the possibility of rain damage.

Any material placed by the Contractor that has attained the specified relative compaction but subsequently becomes wetted up so that the moisture content is greater than the apparent optimum, determined by AS1289.5.4.1, shall be dried out and uniformly recompacted to the required relative compaction in accordance with this clause before the next layer of material is placed. Alternatively, the Contractor may remove the layer of wetted material to a stockpile site for drying and later re-use.

(2) Test locations

The specified compaction and moisture tests shall be taken at the random test locations established in each lot in accordance with the specified minimum testing frequency. Prior to testing the Contractor shall work the lot to ensure uniform moisture content and compaction of all material within the lot.

The test(s) then taken shall be considered to represent the total volume of material placed within the lot.

Where the Superintendent considers that the material which is present has not achieved uniformity required by this clause or clause SC6.4.6.10.6(5) Placing fill for embankment construction, the Superintendent may take or

direct further testing. The Superintendent shall nominate the area represented by the additional testing.

If such testing confirms that material not conforming to the Specification, the Contractor shall carry out remedial work as necessary to achieve conformance to the requirements of clause SC6.4.6.10.8(1) Compaction and moisture requirements.

(3) Deflection monitoring

Following completion of the formation to the underside of the selected material zone in accordance with clause SC6.4.6.10.6(3) Foundations for embankments and SC6.4.6.10.6(5) Placing fill for embankment construction, completion of the selected material zone in accordance with clause SC6.4.6.10.6(9) Selected material zone and SC6.4.6.10.3(5) Treatment of floors of cutting, the Contractor shall make the work available in lots, for the Superintendent or council to carry out deflection monitoring.

A lot for deflection testing shall consist of a continuous length of formation, in compliance with council requirements, and a single carriageway width which is generally homogeneous with respect to material and appearance. The contractor shall identify the boundaries of each lot with stakes clearly labelled to the satisfaction of the Superintendent.

Prior to the release of the lot, a proof roll is to be performed with a single drive axle truck with an axle load of 8.2 t covering all lanes of carriage way including parking bays having no evident movement.

(4) Widening of formation

Road shoulders and formation shall be widened to accommodate footpaths, guard fence, streetlight plinths, emergency telephone bays and vehicle standing areas as shown on the drawings.

(5) Subgrade testing and treatment

Refer to SC6.4.4.2.4

SC6.4.6.10.9 Summary of limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.10.4 Summary of limits and tolerances below.

Table SC6.4.6.10.9 Summary of limits and tolerances

Item	Activity	Limits/Tolerances
1.	**Batter Slopes**	± 300mm
	a) Excavation	
	b) Embankment	± 300mm
2.	**Subgrade**	Parallel to designed grade line. Tolerance is to be within +0mm - 50mm of the levels specified.
	Vertical Tolerance	
	Horizontal Tolerance	The width of the cutting at subgrade level for support of the pavement shall not be less than that specified on the drawings or documentation.
3.	**Tops of Embankments**	Parallel to the designed grade line. Tolerance is to be within, ±50mm from the levels specified
	Vertical Tolerance	
	Horizontal Tolerance	The width of an embankment at subgrade shall not be less than that specified on the drawings or documentation.
4.	**Selected Material**	SC6.4.6.10 Attachment A: Earthworks – Supplementary Information

Note—tolerances are measured at right angles to design surfaces.

SC6.4.6.10.10 Attachment A: Earthworks - supplementary information

Clause	Description	Value
SC6.4.6.10.2(1)	The depth below natural surface up to which the removal and measurement of top soil shall apply: (a) Cutting area; and (b) Embankment area	75mm
SC6.4.6.10.3(5)	Minimum CBR value in cutting floors used for design of pavement	3%
SC6.4.6.10.6(3)	Requirements of material in foundations for shallow embankment Moisture Content - within the range of 60% to 90% of optimum	
SC6.4.6.10.6(5)	Upper Zones of Formation and SC6.4.6.10.6 (9) Select Material Zone Material within each zone shall have a CBR value of not less than the following, under the nominated test conditions:	

Location	Minimum CBR Value	Depth	Nominated Soaking Period (Days)
a. Select Material Zone	10	200	4
b. Material below Selected Material Zone to 1.5 metre from top of pavement	3	N/A	4

SC6.4.6.10.6(9) Construction tolerances for selected material zones is to be ±50mm of the designed grade and crossfall profile

SC6.4.6.10.8(1) Moisture content of material placed in embankments:

(a) Material in upper zones of formation - within the range of 60% to 90% of optimum

(b) All other embankment material - within the range of 60% to 90% of optimum

SC6.4.6.11 Clearing and grubbing

SC6.4.6.11.1 Introduction

(1) Scope

This sub-section provides standards, advice and guidelines for the clearing of all vegetation, both living and dead, all minor man-made structures (such as fences and livestock yards), all rubbish and other materials, including the chipping of the crowns of trees and the branches of shrubs, and the grubbing of trees stumps from the area. The work also includes the disposal, in accordance with clause SC6.4.6.11.3(2) Chipping of cleared vegetation and SC6.4.6.11.3(3) Disposal of materials, of all materials that have been cleared and grubbed.

(2) General requirements

Site works shall take all measures to prevent damage to existing underground and overhead utility services.

Before commencing earthworks, locate and mark existing underground services in the areas to be affected by the works including clearing, excavating and trenching.

All existing utilities, natural landscape features, including natural rock outcrops, natural vegetation, trees to be preserved, soil and watercourses are to remain undisturbed.

Explosives shall not be permitted to be used in clearing, grubbing or other demolition activities.

Editor's note—DIAL 1100 BEFORE YOU DIG is a free service, from anywhere in Australia, through which underground pipes and cables are located (possible within two working days). For more information go to the Dial 1100 Before you Dig website.

SC6.4.6.11.2 Clearing

(1) Clearing operations

The area within the limits of clearing shall be cleared of all vegetation, both living and dead, all minor man-made structures (such as fences and livestock yards), all rubbish and other materials which, are unsuitable for use in the works with the exception of certain trees marked for preservation. The contractor shall plan clearing operations such that wherever possible, clearing is carried out progressively and only the minimum area of land is left disturbed at any time.

The contractor shall give the superintendent written notice of seven days of the intention to clear any area of the work. The superintendent shall mark or indicate to the contractor the trees that shall be preserved. The contractor shall arrange for an inspection by an authorised council officer and shall obtain council's approval to proceed with clearing and grubbing. The contractor must conform to the requirements of SC6.4.5.2(18) when protecting identified trees and bushland within or adjacent to the construction site.

The erection of structures, excavation and filling, changes to soil profiles, stockpiling of spoil, storage of other materials and driving or parking of any vehicle or machinery within 4m of the trunks of trees to be retained shall not be permitted unless they form part of the works as approved by the council.

The Contractor shall plan all operations to ensure that there is no damage to any trees outside the limits of clearing specified or directed by the Superintendent. No growing trees shall be destroyed or damaged by the Contractor other than those specified and those indicated by the Superintendent.

Any tree remaining within the road reserve but outside the limits of clearing which is, in the opinion of the Superintendent, unsound and likely to fall upon the roadway shall be cleared and disposed of in accordance with clause SC6.4.6.11.3(2) Chipping of cleared vegetation, subject to prior approval of council.

If directed by the Superintendent, any branch, which overhangs the road formation, shall be cut back to within 0.5 m of the tree trunk and disposed of in accordance with clause SC6.4.6.11.3(2) Chipping of cleared vegetation.

(2) Fallen timber and tree damage

Every precaution shall be taken to prevent timber from falling onto private property. The Contractor shall dispose of any timber that has fallen onto private property or produce written consent from the property owner to its remaining there.

The cost of disposal of such fallen timber shall be borne by the Contractor. Prior to entering the private property, the Contractor shall obtain consent from the Superintendent and the property owner. Damage of any kind, including damage to trees, fencing, occurring during clearing operations shall be made good by the Contractor. The cost of making good such damage shall be borne by the Contractor. Any damage to trees or vegetation which in councils opinion, will require its removal, is to be in rectified in accordance with SC6.4.5.2.1(19)(d).

SC6.4.6.11.3 Grubbing

(1) Grubbing

All trees and stumps, on or within the limits of clearing, unable to be felled and removed by the clearing methods used by the Contractor shall be removed by grubbing.

Grubbing operations shall be carried out to a depth of 0.5m below the natural surface or 1.5m below the finished surface level, whichever is the lower.

Holes remaining after trees and stumps have been grubbed shall be backfilled promptly with sound material to prevent the infiltration and ponding of water. The backfilling material shall be compacted to at least the relative density of the material existing in the adjacent ground.

(2) Chipping of cleared vegetation

The Contractor shall produce a wood-chip mulch derived from crowns of trees and branches of shrubs cleared under this sub-section. The wood-chip mulch produced shall be stockpiled for subsequent use or for use at other locations as appropriate.

The wood-chip mulch shall be produced from branches having a maximum diameter of 100mm and the chipped material produced shall not have two orthogonal dimensions exceeding 75mm and 50mm.

(3) Disposal of surplus materials

Unless otherwise specified elsewhere, all surplus materials cleared and grubbed in accordance with this sub-section shall either be removed from the site or used for landscaping within the site in accordance with the approved plans and any conditions set by council.

Unless otherwise approved by council in writing, disposal of timber and other combustible materials by burning shall not be permitted.

SC6.4.6.12 Flexible pavements

SC6.4.6.12.1 Introduction

(1) Scope

This policy sub-section provides standards, advice and guidelines for the supply, spreading, compaction and trimming of base and subbase courses of flexible pavements.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

Editor's note—A reference to drawings is a reference to construction drawings.

(2) Pavement structures

Flexible pavement material types and layer thicknesses must be as per design requirements.

(3) Activity plan

Prior to commencement of work, the Contractor must provide the Superintendent a Pavement construction plan and detail the following activities:

(a) allocation of plant and personnel for the contract period;

(b) work programming to meet the constraints of all inspection points; and

(c) prepare and submit a Pavement construction plan for the flexible base and subbase construction consistent with the drawings and subject to direction by the Superintendent. Include the following:

(i) a time based program;

(ii) a drawn sectional plan showing lots and sequence;

(iii) site availability, assumptions on weather, plant and materials;

(iv) a list of activities requiring approvals or notification of local authorities, statutory bodies, and local residents; and

(v) off-site storage of plant, personnel and maintenance facilities.

(4) Inspection, sampling and testing

Inspection, sampling and testing of the pavement must be undertaken by the Contractor in accordance with the requirements of this sub-section before, during and after the construction of the pavement. Testing must be carried out by a NATA registered laboratory with appropriate accreditation and suitably qualified personnel.

The Contractor must provide the Superintendent with written notice when testing is being carried out and copies of all test reports for approval to proceed.

Field density tests must be carried out in accordance with AS 1289.5.3.1, or, with the Superintendent's concurrence, with a Nuclear Density Meter in accordance with Clause SC6.4.6.12.6(3).

(5) Terminology

Base material	materials designated as Base are of a suitable quality that form the uppermost structural element of a pavement and on which the surfacing may be placed.
Bound material	bound material incorporates binder/s to produce structural stiffness (UCS > 1.5MPa at 28 days in accordance with TMR Test Method Q115).

Flexible pavement	a flexible pavement consists of a base and a subbase constructed of unbound granular materials or modified material, obtaining its load spreading properties from intergranular pressure, mechanical interlock and cohesion between the particles of the pavement material.
Modified material	modified material incorporates small amounts of stabilising binder to improve the properties of the material without significantly affecting structural stiffness. A modified material must have sufficient stabilising binder to achieve a UCS range of 0.8MPa - 1.5MPa at 28 days in accordance with TMR Test Method Q115.
Subbase material	materials designated as Subbase are laid on the subgrade (or selected material), below the base, either for the purpose of making up additional pavement thickness, to prevent intrusion of the subgrade into the base, or to provide a working platform.
Unbound material	unbound materials are granular materials with no significant capacity to resist tensile stresses.

(6) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.16 - Sprayed bitumen surfacing
SC6.4.6.19 - Stabilisation
SC6.4.4.2 - Pavement design

(b) Queensland Department of Transport and Main Roads specifications:
MRTS05 - Unbound Pavement

(c) Queensland Department of Transport and Main Roads Test Methods:
Q142A - Dry Density - Moisture Relationship (Standard Compaction).
Q115 - Unconfined Compressive Strength of Compacted Materials.
Q701 - Benkelman Beam Deflections.

(d) Australian Standards:

AS 1141.14 *- Particle shape, by proportional calliper*
AS 1141.22 *- Wet/dry strength variation*
AS 1289.3.1.1 *- Determination of the liquid limit of a soil - Four point Casagrande method*
AS 1289.3.3.1 *- Calculation of the plasticity index of a soil*
AS 1289.3.6.1 *- Determination of the particle size distribution of a soil - Standard method of analysis by sieving*
AS 1289.3.6.3 *- Determination of the particle size distribution of a soil - Standard method of fine analysis using a hydrometer*
AS 1289.5.1.1 *- Determination of the dry density/moisture content relation of a soil using standard compactive effort*
AS 1289.5.3.1 *- Determination of the field density of a soil - Sand replacement method using a sand-cone pouring apparatus*
AS 1289.5.4.1 *- Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS 1289.5.8.1 *- Determination of field density and field moisture content of a soil using a nuclear surface moisture - density gauge - Direct transmission mode*
AS 1289.6.1.1 *- Determination of the California bearing ratio of a soil - Standard laboratory method for a remoulded specimen*
AS 5101.4 *- Methods for preparation and testing of stabilized materials. Method 4: Unconfined compressive strength of compacted materials*

SC6.4.6.12.2 Materials

(1) General

The Contractor must submit details of all constituents of the proposed base and subbase materials, including sources of supply and the proposed type and proportion of any binder including targeted 28 days unconfined compressive strength (UCS). These details must be submitted to the Superintendent, supported with test results from a nominated NATA registered laboratory confirming that the constituents comply with the requirements of this sub-section.

If the proposed base or subbase is a bound material, the Contractor must submit a completed SC6.4.6.19 Attachment A Stabilisation mix design contained in the sub-section SC6.4.6.19 Stabilisation.

No material may be delivered until the Superintendent has approved the source of supply.

If, after the Contractor's proposals have been approved, the Contractor wishes to make changes in any of the material constituents the Contractor must inform the Superintendent in writing of the proposed changes. No delivery of material produced under the altered proposal must take place without the approval of the Superintendent.

At least 2 weeks before placement of the material on site, the Contractor must submit a Certificate from a laboratory with appropriate NATA registration demonstrating and stating that the unbound material or the mix and its constituents comply with the requirements of this sub section.

Ongoing testing of materials during delivery and construction must be undertaken on samples taken from the site.

(2) Unbound base and subbase

Base materials must comply with the requirements of type 2.1 materials as per clause 7.2 of MRTS05, grading B or C.

Sub-base materials must comply with the requirements of type 2.3 materials as per clause 7.2 of MRTS05, grading B or C.

Lower sub-base must comply with the requirements of type 2.4 materials as per clause 7.2 of MRTS05, grading B or C.

Unbound materials, including blends of two or more different materials, must consist of granular material which does not develop significant structural stiffness when compacted. Material produced by blending must be uniform in grading and physical characteristics.

(a) **Surface Evenness**

Townsville City Council reserves the rights to carry out the necessary test procedure and supply results to the Contractor.

(b) **Layer Thickness**

Unbound pavement material must be laid at a minimum thickness of 125mm and a maximum thickness of 250mm.

(c) **Longitudinal Joins**

Longitudinal joins for paving runs for the top layer of the base courses must be aligned to coincide with the position of the traffic lane markings, except where approved otherwise in writing by the Superintendent.

(d) **Segregation**

Segregation is the uneven distribution of particle sizes. The construction process must minimise segregation. There must be no visible signs of segregation on each lot. Samples must be taken from each lot to check that segregation of the material in the lot has not occurred. Additional samples must be taken from any areas which show visible signs of segregation. Each sample must be tested in accordance with Test Method Q103A.

(3) Lime modified base and subbase materials

Modification of unbound base and subbase materials to meet the requirements of clause SC6.4.6.12.2(2) Unbound base and subbase by the addition of hydrated lime or quicklime is subject to approval by the Superintendent and to the additional requirements of this clause. After modification, the material must meet the requirements of clause SC6.4.6.12.2(2) Unbound base and subbase.

Modification of materials must be by means of blending either hydrated lime through a stationary mixing plant or by hydrated lime or quicklime utilising in-situ operations.

Material requirements of hydrated lime and quicklime must be in accordance with sub-section SC6.4.6.19 Stabilisation.

The method of incorporating lime through the stationary mixing plant must ensure that the lime is mixed uniformly through the material.

In-situ operations must be in accordance with sub-section SC6.4.6.19 Stabilisation.

The proportion of lime must be not less than 1.5% nor more than 4% by mass. The material prior to lime treatment must contain no added pozzolanic material.

The lime treated material must yield an unconfined compressive strength not exceeding 1MPa, when tested in accordance with Test Method Q115 where sampling is undertaken within 24 hours of adding the lime and testing is after 28 days curing.

(a) **Curing Final Layer**

Moist curing process has the potential to "wash" the cementitious paste from the upper surface, which leaves an unbound, non-cohesive, soft pavement matrix with high embedment potential for the subsequent sealing aggregate. Therefore, wherever possible the completed pavement should not be moist cured within 48 hours of placing. Moist curing must be carried out using equipment fitted with spray jets that deliver water to the pavement as a fine mist. The use of conventional spray bars or high pressure water nozzles with large aperture sprays holes will not be permitted. Conventional bituminous surface curing may be used within 48 hours.

(4) Bound base and subbase materials (Including Modified Material)

Bound material for a UCS>1.5MPa (28 days) to be used as subbase generally or base layer may be supplied as a pugmill quarry product with stabilising agent and laid using a paving machine or grader laid. Alternatively it may be produced by the in-situ stabilisation of natural or blended gravel where stabilisation is undertaken by mobile plant at the site.

Prior to stabilisation, the layer to be stabilised must meet the appropriate requirements for subbase material.

Material requirements for the stabilising agent must be in accordance with sub-section SC6.4.6.19 Stabilisation.

The stabilisation process must meet the requirements of sub-section SC6.4.6.19 Stabilisation.

The unconfined compressive strength (UCS) of the material after 28 days curing as determined by Test Method Q115 must be not less than 2.5MPa for stabilised pavements and not less than 0.8MPa for modified pavements. Sampling and test specimen compaction of the material must be undertaken within one hour of the incorporation of the stabilising agent.

The maximum period (working time) between mixing cement with the gravel material and the completion of compaction must be 3 hours. Council reserves the rights to reject the work if working time is not achieved and the material must be removed from site.

(a) **Surface Evenness**

Townsville City Council reserves the rights to carry out the necessary test procedure and supply results to the contractor.

(b) **Layer Thickness**
Bound pavement material (including Modified Material) must be laid at a minimum thickness of 150mm and a maximum thickness of 250mm. If bound layers are placed with a paving machine, Council may approve thinner layers.

(c) **Longitudinal Joins**
Longitudinal joins for paving runs for the top layer of the base courses must be aligned to coincide with the position with the traffic lane markings, except where approved otherwise in writing by the Superintendent.

(d) **Segregation**
Segregation is the uneven distribution of particle sizes. The construction process must minimise segregation. There must be no visible signs of segregation of the material in the lot has not occurred. Additional samples must be taken from any areas which show visible signs of segregation. Given the presence of cement additive in the material, the relevant test for segregation must be as specified in AS 1289.3.6.1.

(e) **Curing Final Layer**
Moist curing process has the potential to “wash” the cementitious paste from the upper surface, which leaves an unbound, non-cohesive soft pavement matrix with high embedment potential for the subsequent sealing aggregate. Therefore, the completed pavement must not be moist cured within 48 hours of placing. After 48 hours, moist curing must be carried out using equipment fitted with spray jets that deliver water to the pavement as a fine mist. The use of conventional spray bars or high pressure water nozzles with large aperture sprays holes will not be permitted. Conventional bituminous surface curing may be used within 48 hours.

SC6.4.6.12.3 Delivery, stockpiling and processing of pavement material

(1) Delivery to site
Materials must be supplied sufficiently damp to avoid segregation and loss of fines during transit.

(2) Stockpiling of unbound materials
Stockpile sites must be located as shown on the drawings or as approved by the Superintendent.

Stockpile sites, which must be cleared of all vegetation and extraneous matter, must be shaped to form a crown so as to be free draining and compacted over the whole area to provide a relative compaction, determined by AS1289.5.4.1 for standard compactive effort, of not less than 95%.

Stockpiles and stockpile sites must be maintained so as to prevent the stockpiled materials from becoming intermixed or contaminated with foreign material.

The total height of any stockpile must not exceed 3m.

Stockpiles must be of uniform shape with side slopes neither steeper than 1.5h to 1v nor flatter than 3h to 1v.

The worked face of any stockpile must be the full face of the stockpile. The stockpiled material must be maintained at a moisture content sufficiently damp to avoid loss of fines.

At the completion of the works, stockpile sites must be cleared of all surplus material and left in a clean and tidy condition.

(3) Delivery of modified or bound materials
Modified or bound materials must be delivered in vehicles fitted with covers of canvas or other suitable material to prevent loss of moisture during transport.

The time between mixing and conveyance by delivery trucks to the site, must be such as to allow incorporation into the works including trimming and compaction within the nominated field working period.

Each truck load of bound material must be identified by delivery dockets, indicating the time and date of mixing and registration or fleet number of the delivery truck, and such dockets must be made available to the Superintendent at the point of delivery.

Bound materials must comply with the requirements of sub-section SC6.4.6.19 Stabilisation.

SC6.4.6.12.4 Spreading pavement materials

The contractor must present the underlying layer to the Superintendent prior to placement of subsequent layers and must ensure that moisture content of the underlying layer does not exceed 90% of the laboratory optimum moisture content as determined by AS1289.5.1.1. If the underlying layer has become rutted or mixed with foreign matter, it must be corrected to comply with this Sub-section before spreading of the next layer of pavement.

Where the underlying layer was constructed by the Contractor, or where the Contractor's activities caused the underlying layer constructed by others to become non-complying with this sub-section, correcting the underlying layer to comply is the responsibility of the Contractor.

Each layer of material must be deposited and spread in a concurrent operation and, after compaction, the finished surface levels on the base and subbase courses must be within the permitted tolerances stated in Clause SC6.4.6.12.6(6)(c) Levels and surface trim without subsequent addition of material. The thickness of each compacted layer must be neither less than 125mm nor more than 250mm for all pavement layer types, unless otherwise approved by the Superintendent.

At all work boundaries in bound materials the Contractor must provide vertical faces to provide for transverse and longitudinal joints.

When spread for compaction processes the moisture content of the unbound and bound base materials must be in the range of 60-90% and subbase materials must be in the range of 75-100% of laboratory optimum moisture content in accordance with AS1289.5.1.1.

Bound materials with UCS > 1.5MPa (28 days) must not be spread with a self-propelled paver when the ambient air temperature in shade is either below 5°C or above 35°C. Where the materials are to be spread outside the required ambient air temperature range, the Contractor must submit a work proposal to the Superintendent for approval.

SC6.4.6.12.5 Compaction

(1) General requirements

Each layer of the base and subbase courses must be uniformly compacted over its entire area and depth to satisfy the requirements of relative compaction set out in clauses SC6.4.6.12.6(3) Relative compaction and SC6.4.6.12.6(4) Compaction requirements and acceptance.

On sections of pavement with one way crossfall, compaction must begin at the low side of the pavement and progress to the high side. On crowned sections, compaction must begin at the sides of the pavement and progress towards the crown. Each pass of the rollers must be parallel with the centreline of the roadway and uniformly overlap each preceding pass. The outer metre of both sides of the pavement must receive at least two more passes by the compaction plant than the remainder of the pavement.

At locations where it would be impracticable to use self propelled compaction plant, the pavement material must be compacted by alternative hand operated plant approved by the Superintendent.

Watering and compaction plant must not be allowed to stand on the pavement being compacted.
If any unstable areas develop during rolling, the unstable material must be rejected. The rejected material must be removed for the full depth of the layer, disposed of and replaced with fresh material in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses. This operation will be at cost to the Contractor.

The placement of subsequent layers must not be allowed until the requisite testing has been completed and the test results for each layer have been accepted by the Superintendent and correct curing times for bound

layers has been attained.

Any unbound material in a layer that has attained the specified relative compaction but subsequently becomes wetted up must be dried out and, if necessary, uniformly recompacted and trimmed to meet the specified density requirements and level tolerances.

(2) Curing of bound materials
The curing of the surface layer of a lot must commence after compaction is completed and must be in accordance with the SC6.4.6.19 Attachment A Stabilisation mix design.

The stabilised work must be protected against rapid drying out by keeping it continuously wet or damp during the period prior to the provision of a subsequent layer or the application of a prime or primer-seal. Also refers to the requirements of SC6.4.12.2 (5) (e) Curing of final layer.

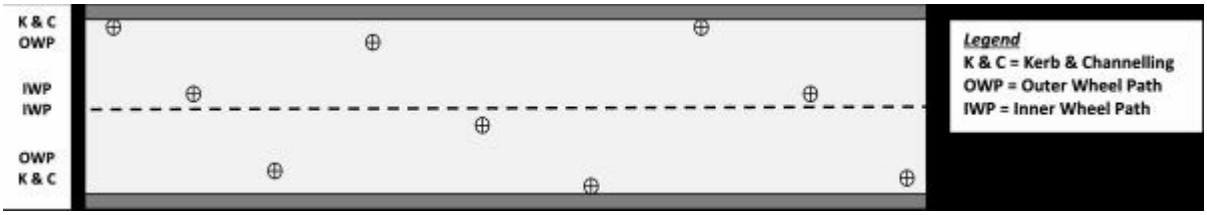
SC6.4.6.12.6 Acceptance of compaction

(1) Lots for acceptance
Acceptance of work, as far as compaction is concerned, must be based on density testing of the work in lots. A lot must be nominated by the Contractor, but must conform to the following:

(a) cover only a single layer of work which has been constructed under uniform conditions in a continuous operation and not crossing any transverse construction joints; and

(b) for unbound materials, it may equal a day's output using the same material.

(2) Compaction assessment
The Superintendent must assess compaction for each lot based on arranged test locations for in-situ dry density testing in line with the following diagram. The intention is that one in every three density tests must be positioned against the inner line of the kerb and channel on either side. This arrangement must be repeated or truncated as appropriate depending on the number of tests required per lot.



Similar arrangement must be adopted for roads with no kerb and channel or edge constraint, with the test locations at the edge shifted to the OWP position. A random arrangement for test locations at intersection is acceptable, provided that one in every three density test is positioned along the inner kerb and channel / edge line.

The Contractor must arrange for testing to assess compaction on the basis of a pro rata testing frequency of 10 tests per 5,000sqm with a minimum of three tests per lot.

The elastic rebound deflection must be taken as the maximum deflection in accordance with Test Method Q701 utilising the Benkelman Beam or equivalent. The average maximum deflection for any lot must not exceed 1mm, and the co-efficient of variation (CV) in recorded deflections must not exceed 30%.

Measurements must be taken at the rate of 4 per 1,000sqm, with a minimum of ten measurements per lot.

Proof rolling must be undertaken with the use of a single drive axle truck with a rear single axle/dual wheels load of 8.2t or tandem rear axle/dual wheels carrying a load of 13.8t. Proof rolling cover all lanes of the carriage way including parking bays and must show no evident movement.

(3) Relative compaction
The relative compaction of pavement material at each location tested for in-situ dry density must be calculated

in accordance with AS 1289.5.4.1 as follows:

Relative Compaction (per cent) = $\frac{\text{In-situ dry density}}{\text{Comparative dry density}} \times 100$

Note—the comparative dry density must be the maximum dry density determined in the laboratory.

The council Superintendent may approve some or all of the in-situ dry density testing to be carried out with a single probe Nuclear Density Meter in the direct transmission mode in accordance with AS 1289.5.8.1. Council reserves the right to request additional testing at the discretion of the Inspector.

Each day that material is produced for placement in a layer or layers, a sample of the material must be taken by the Contractor for maximum dry density testing to represent that day's production.

For unbound layers, the sample must be tested in accordance with AS 1289.5.1.1 to determine the maximum dry density (standard compactive effort) for the material.

For bound layers the sample must be tested within two hours after the addition of stabilising agent to the mix in accordance with Test Method Q142A to determine the maximum dry density (standard compactive effort) for the material. This test method must also be used to determine the standard optimum moisture content.

The maximum dry density so determined must be used as the comparative dry density in relative compaction calculations for all like material from that lot or day's production placed in a single layer of work whichever is the lesser.

(4) Compaction requirements and acceptance

All compaction test results must exceed the minimum requirements in accordance with:

(a)	Unbound pavement	MRTS05
(b)	Insitu stabilised subgrade using lime	MRTS07A
(c)	Insitu stabilised pavement using cement	MRTS07B
(d)	Insitu stablised pavement using foam bitumen	MRTS07C
(e)	Plant mixed stabilised pavement	MRTS08

(5) Reworking of rejected unbound layers

Lots or areas of pavement that have been rejected in regard to compaction must be reworked before resubmission for compaction assessment.

Material that has become degraded, segregated or otherwise reduced in quality by reworking must be rejected. The rejected material must be removed, disposed of and replaced with fresh material complying with this Sub-section in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses. When a lot or area of pavement is resubmitted for compaction assessment, testing must be carried out in accordance with clauses SC6.4.6.12.6(2) Compaction assessment and SC6.4.6.12.6(3) Relative compaction.

All corrective work must be carried out by the Contractor before the resubmission of a lot for compaction assessment, including rewatering, rerolling, removal and replacement of material as well as reworking. All costs associated with corrective work carried out before the resubmission of a lot for compaction assessment, including rewatering, rerolling, removal and replacement of material as well as reworking must be borne by the Contractor. Reworking of rejected modified or stabilised material is not accepted.

(6) Tolerances

(a) General

The tolerances stated are the acceptable limits of departure from the dimensions shown on the drawings, which may occur during construction.

Areas for assessment of conformity with tolerance requirements must be divided into lots and presented to the Superintendent together with survey reports covering line and level.

(b) Width

At any cross section without kerb and /or guttering channel or a dish drain, and for pavement layers extending under the kerb and channel or dish drain/or guttering , the horizontal dimension measured from the design centre line to the edge of the constructed pavement surface must be neither less than 50mm less than the dimension nor more than 300mm greater than the dimension shown on the drawings.
The average width of the layer determined from measurements at three sites selected at random by the Superintendent over any 200m road length, or part thereof, must be not less than the specified width.

(c) Levels and surface trim

The levels of the finished surface of the top of the unbound subbase course must not vary from the design levels by more than ±15mm.

Level tolerances at the top of the unbound base course must not exceed those stated above for subbase. In addition, where kerb and channel exists or is being constructed, the level of the top of the base course adjacent to the kerb and channel must not vary by more than ±5mm from the lip level of the gutter minus the design thickness of the wearing surface.

The design level of the top of the subbase course must be determined from the design level of the finished road surface less the thickness of the base course and the wearing course, including an allowance for any flush seal layer in the pavement design.

The pavement surface after trimming and immediately prior to sealing must be of a quality such that the deviation under a 3m straight edge placed in any direction does not exceed 12mm. Measurements for conformance must be taken in accordance with the maximum lot size and minimum test frequencies in SC6.4.5 Construction management.

(7) Action on rejection

(a) Unbound materials

A lot that has not complied with the requirements for width or level tolerance as set out in clauses SC6.4.6.12.6(6)(b) Width and SC6.4.6.12.6(6)(c) Levels and surface trim respectively must be rejected except as otherwise provided in this clause. Rejected lots must be removed, disposed of and replaced with fresh material in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses.

Notwithstanding the above, where the rejected lot can be corrected by further trimming, the Superintendent may allow the surface to be corrected without complete removal and replacement with fresh material. Such trimming must be undertaken in a manner that produces a uniform, hard surface and must be achieved by cutting only without filling. After any such cutting, the level tolerances in clause SC6.4.6.12.6(6)(c) Levels and surface trim must apply.

The required surface correction or replacement work ordered in accordance with this clause including removal of material, disposal and supply and transport of replacement material, must be borne by the Contractor.

(b) Bound materials

An area of bound material that has not complied with the requirements for width or level tolerance as set out in clauses SC6.4.6.12.6(6)(b) Width and SC6.4.6.12.6(6) Levels and surface trim respectively must be rejected except as otherwise provided for in this clause. Rejected areas must be removed, disposed of and replaced with fresh material in accordance with clause SC6.4.6.12.6(8) Removal and replacement of rejected courses.

The removal and disposal of rejected material and its replacement with fresh material must be borne by the Contractor.

Notwithstanding the above, the Superintendent may allow the Contractor to rectify the area in the following cases:

(i) Where the cause for rejection is under clause SC6.4.6.12.6(6)(c) Levels and surface trim, the course is a subbase course and rejection is due to departures from design level being too far below the design level, the Contractor may increase the thickness of the base course to make up such deficiency in thickness.

(ii) Where the cause for rejection is under clause SC6.4.6.12.6(6)(c) Levels and surface trim, the course is a subbase course and rejection is due to departures from design level being too far above the design level, the Contractor may propose a regrading of the design level of the base course, to allow for its design thickness to be laid, up to a maximum of 20mm above the original design level. Approval by the Superintendent must be subject to the following requirements:

(A) the rate of change of grade from the original finished design surface level must be less than 3mm per metre;

(B) the regrading must not interfere with the proper design functioning of the drainage system;

(C) the regrading must not interfere with levels at the property boundary, or increase or decrease footpath or footpath crossover levels or grades beyond council's allowable design limits; and

(D) the regrading must not interfere with clearances.

(iii) Where the cause for rejection is under clause SC6.4.6.12.6(6)(c) Levels and surface trim, the course is a base course and rejection is due to departures from design level being too far above the design level, the Contractor may propose a regrading of the design level of the base course. Approval by the Superintendent is subject to the requirements of this clause in (ii) above.

(8) Removal and replacement of rejected courses
Sections of work that have been rejected by the superintendent are to be removed from the work site and replaced with fresh material.

Any rejected pavement sections are to be removed and replaced over the full length of the rejected lot for a minimum length of 20m of the pavement layer. Any damage to underlying or abutting layers or structures must be made good by the Contractor using methods approved by the Superintendent.

The Superintendent may approve removal for less than the full width as constructed if the cause of the rejection of the work can be isolated transversely to the Superintendent's satisfaction. In this case, the new longitudinal cold joint must be formed and located along the centreline of the road pavement.
After removal of rejected base or subbase course material, the section must be presented for inspection by the Superintendent before replacement work is commenced.

Materials used as replacement materials, and the subsequent spreading, compaction, trimming, curing and testing of the replacement materials, must comply with the requirements of this sub-section.

The removal, replacement and correction of base and subbase courses required under this clause must be the responsibility of the Contractor in respect of delays caused by such removals, replacements and corrections must be borne by the Contractor.

All costs associated with the corrective work must be borne by the Contractor.

(9) Maintenance before completion of wearing surface
Following the Superintendent's acceptance of any section of the work, the Contractor must maintain the prepared surface of the base in the condition specified for acceptance until the wearing surface is completed. The preparation work must be carried out in a manner which will promote the adhesion of the bituminous material to the surface of the pavement. Preparation work must include:

(a) Removal of all foreign and loose material from the surface; and

(b) Light watering on dry and dusty surface

Ball Penetration testing on inner and outer wheelpaths must be carried out on all pavements before application of bituminous material. Where a ball penetration result exceeds 4.0mm the surface must not be sprayed until Council is advised and approval to proceed granted.

The base course of sections of the accepted work must be covered with a primerseal over the full width of pavement in accordance with sub-section SC6.4.6.16 Sprayed bitumen surfacing within 7 days of the date of the acceptance of such sections, unless otherwise approved by the Superintendent.

Should the pavement condition deteriorate before the application of the primerseal and consent to proceed with the bitumen surfacing work is withdrawn by the Superintendent, the Contractor must re-prepare the pavement and re-present the pavement for inspection by the Superintendent.

The maintenance and re preparing areas of the deteriorated pavement is the responsibility of the Contractor.

The Contractor must maintain adequate drainage of the pavement, and remove any ponded water within 12 hours of its creation if free drainage cannot be achieved, prior to the completion of the wearing course.

SC6.4.6.12.7 Opening pavement to traffic

General requirements

For unbound pavement layers, construction plant and vehicles not involved in the current construction or testing of the work must not be permitted to use the pavement until the primerseal has been applied, unless otherwise approved.

For bound pavement layers, construction plant and vehicles not involved in the current construction or testing of the work should not use the pavement until the primerseal has been applied and seven days have elapsed since placement of the base. In any case only vehicles registered for legal road usage and loaded within legal limits will be allowed to use the pavement.

SC6.4.6.12.8 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.12.1 below.

Table SC6.4.6.12.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Stockpile Sites**	(i) Relative Compaction >97% (ii) Stockpile height <3m (iii) Stockpile batter <1.5:1 and >3:1	SC6.4.6.12.3(2) SC6.4.6.12.3(2)
2.	**Spreading Pavement Materials**		
	(i) Compacted Layer Thickness	≥150mm (modified material) ≥125mm (unmodified material) ≤250mm (all material)	SC6.4.6.12.4
3.	**Compaction Acceptance**		
	Minimum value of all calculated relative compaction results	All compaction test results must exceed the minimum referenced requirements	SC6.4.6.12.6(4)
4.	**Width of Pavement**	-50mm to +300mm of dimensions on drawings	SC6.4.6.12.6(6)(b)
	(i) Design centre-line to edge of constructed pavement		
	(ii) Average Width	The average width determined from 3 random sites over any 200m road length, or part thereof, must be not less than the specified width.	SC6.4.6.12.6(6)(b)
5.	**Surface Level**		
	(i) Subbase levels	<± 15mm from design level	SC6.4.6.12.6(6)(c)
	(ii) Base levels	<± 15mm from design level	SC6.4.6.12.6(6)(c)

(iii) Base levels adjacent to kerb and channel	<±5mm from the lip levels of adjacent gutter minus design thickness of wearing surface.	SC6.4.6.12.6(6)(c)
(iv) Shape	Deviation from a 3m long straightedge on base surface immediately prior to sealing must be less than 12mm	SC6.4.6.12.6(6)(c)
(v) Ball Penetration	>4.0mm	SC6.4.6.12.6(9)

SC6.4.6.13 Asphaltic concrete

SC6.4.6.13.1 Introduction

(1) Scope

(a) This policy sub-section provides standards, advice and guidelines for the production and placing of asphalt including the supply of materials, sampling, testing and any other operations necessary to provide asphalt. The extent of the policy sub-section includes:

(i) manufacture/supply of the production mix;

(ii) provision of a testing laboratory;

(iii) preparation of the surface on which asphalt is to be placed;

(iv) transport of asphalt;

(v) laying and compaction of asphalt; and

(vi) sampling and testing.

(b) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note—A reference to drawings is a reference to construction drawings.

(2) Plant

The Contractor must provide all the plant, equipment and labour necessary for carrying out the work in accordance with this sub-section.

All plant and equipment used on the work must be in accordance with the submitted quality documentation and kept in good operating condition. The Contractor must not use in the work any plant or equipment demonstrated to be faulty in operation so as to effect the product quality or unsafe in operation as assessed by the Superintendent.

All plant must be registered and insured as appropriate to its use on a public road and must comply with statutory environmental regulations.

(3) Protection of services and road fixtures

The Contractor must take all necessary precautions to prevent asphalt or other material used on the work from entering or adhering to gratings, hydrants or valve boxes, access chamber covers, bridge or culvert decks and other road fixtures. Immediately after the asphalt has been spread the Contractor must clean off or remove any such material as directed by the Superintendent and leave the services and road fixtures in a condition satisfactory to the Superintendent.

(4) Control of traffic

The Contractor must provide for traffic control in accordance with the requirements of sub-section SC6.4.6.30 Control of traffic while undertaking the work.

The Contractor must take all necessary steps to avoid or minimise delays and inconvenience to road users during the course of the work but without compromise to the safety of the road users or employees.

(5) Work records

Particulars of the work performed must be recorded by the Contractor on the Asphalt Work Record at SC6.4.6.13 Attachment A Asphalt Work Record or as per the Contractor's own procedures where equivalent. The Contractor must complete the Asphalt Work Record, which must be countersigned by the Superintendent each day as a true record of the work performed.

Delivery dockets stating the mass of each truck load of asphalt must be attached to the Asphalt Work Record.

(6) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections:

SC6.4.6.30 - Control of traffic

(b) Australian Standards:

AS 1141.11	*- Particle size distribution by dry sieving*
AS 1141.14	*- Particle shape, by proportional calliper*
AS 1141.17	*- Voids in dry compacted filler*
AS 1141.18	*- Crushed particles in coarse aggregate derived from gravel*
AS 1141.22	*- Wet/dry strength variation*
AS 1141.42	*- Pendulum friction test (PAFV)*
AS 1160	*- Bitumen emulsions for the construction and maintenance of pavements*
AS 2008	*- Residual bitumen for pavements*

AGPT04B-2007 *Guide to Pavement Technology Part 4B - Asphalt*

SC6.4.6.13.2 Materials

Materials and mix ingredients must be in accordance with MRTS30. Binder must be in accordance with MRTS17 and polymer modified binder in accordance with MRTS18.

SC6.4.6.13.3 Asphalt mix design

(1) Approved mix

The supply only of an approved mix in accordance with MRTS 30.

The Contractor may not make any changes to the approved mix, or constituent materials without the prior written approval of the Superintendent.

Notwithstanding any approval given by the Superintendent to a proposed asphalt mix, the Contractor is responsible for producing asphalt which satisfies all requirements of this policy sub-section.

Asphalt produced in the plant and delivered to the site must be known as the "production mix".

(2) Production

(a) Asphalt production must comply with the requirements of MRTS30.
The Superintendent, upon provision of notice to the asphalt supplier or the supplier's representative, must have access to the mixing plant for purposes of inspection to verify production procedures and the supplier's compliance with the Contractor's Quality Management Manual and Project Quality Plan. The Superintendent must have the right to declare any non-conformance and be entitled to request correction

of either the Contractor's Quality Management Manual or the Project Quality Plan or both.

(b) Storage of asphalt
Asphalt may be stored in an insulated storage bin prior to delivery. Asphalt which has been stored for more than twenty four hours or is below the minimum temperature specified must not be used. Binder manufacturer's instructions must be followed when polymer modified asphalt is stored.

(c) Contractor's laboratory
The Contractor must maintain and operate an appropriately registered NATA testing laboratory at or near the mixing plant to control the quality of the asphalt produced.

The Contractor will make the laboratory available for inspection by the Superintendent at any time during the course of the works.

All documented test results must be submitted to the Superintendent for inspection and approval in a format and to a timetable suitable to the Superintendent.

The Contractor is responsible for taking samples and must supply all facilities, equipment and labour for that purpose. The samples must be taken by the Contractor.

(d) Frequency of sampling
For the purpose of testing production mix the Contractor must sample production lots at the minimum frequencies set in MRTS30. This testing frequency requirement must apply to each asphalt mix type. The test results must be related to production intervals with samples representing the full lot of production of the relevant mix for the production interval.

Test results from this production control sampling are acceptable as representative of deliveries made under this contract subject to the traceability of production from specific production intervals to the location at the paving site.

Such traceability shall include registration of lot number and time of production on the delivery docket system. The size of any production lot shall be limited to production from a 12 hour "shift".

Sampling shall be performed in accordance with Test Method Q301. Samples shall be identified so as to allow traceability of the mix to the paving site. Each sample or sample portion as appropriate sampled as a referee sample shall be stored in an airtight container labelled so as to be traceable to the job and paving site location.

Testing required shall be arranged by the Contractor at an appropriately registered NATA laboratory. Test reports will be made available to the Superintendent as soon as they are available and always within 7 days of delivery of material.

Dense graded asphalt that does not include modified bitumen may include a proportion of RAP up to but not exceeding 20% by mass. The resultant asphalt shall meet all requirements for the Nominated Mix.

The RAP to be utilised shall be nominated by source and/or stockpile. Testing of the Nominated Mix shall include RAP sampled from the stockpile and of similar physical properties as that to be utilised for the contract. Any change in RAP supply shall be brought to the attention of the Superintendent prior to proposed usage in asphalt under this contract.

(3) Delivery
The bodies of haulage trucks shall be kept clean and coated with a thin film of an approved release agent to prevent asphalt sticking to the body of the truck. Any surplus release agent shall be removed before loading.

During transport asphalt shall be covered with a canvas or other suitable cover which is held down securely.

When transported to site until delivery to the hopper, the mix must be covered with a heavy duty canvas or similar waterproof cover which shall overlap the sides of the truck body by at least 250mm and shall be tied down securely. The bodies of all trucks shall be suitably insulated.

Delivery of the asphalt shall be at a uniform rate within the capacity of the spreading and compacting equipment.

The mass of all truck loads of asphalt shall be measured on a registered weighbridge.

(4) Placing

Placing of asphalt shall not be permitted when the surface of the road is wet or while rain appears imminent, or when cold winds chill the asphalt to such an extent that, in the opinion of the Superintendent, spreading and compaction will be adversely affected. The Superintendent may order work to cease temporarily on account of adverse weather, unsatisfactory pavement surface condition, or other circumstance which the Superintendent feels may adversely affect the subsequent operations.

(5) Preparation of pavement

The existing surface shall be dry, clean and free from any loose stones, dirt and foreign matter. The surface shall be swept beyond the edge of the proposed asphalt layer by at least 300mm. Any foreign matter adhering to the pavement and not swept off shall be removed by other means. Any areas significantly affected by oil contamination shall be cleaned to the satisfaction of the Superintendent.

Surface preparation shall be in accordance with AS 2734. Thermoplastic linemarking or other linemarking, where indicated necessary by the Superintendent will be removed prior to paving. Raised pavement markers shall be removed prior to paving.

The Contractor, when paving over existing road pavement, shall be responsible for the recording of lane marking positions including the extent of barrier line. After paving the Contractor will mark up the pavement to re-establish such positions using conventions agreed with the Superintendent and to a standard adequate to allow accurate re-establishment of line marking.

The Contractor shall repair any damage to the existing pavement surface caused by the Contractor's activities. Affected areas designated by the Superintendent shall be removed and reinstated to the Superintendent’s satisfaction.

A corrector course shall be used to correct irregularities in an existing surface and/or modify the shape of an existing surface. Any surface depressions greater than 25mm in depth and any uneven surface shall be brought to the general level of the surrounding pavement/deck surface. Where a corrector course is used to modify the shape of an existing surface, the course shall be laid to the reduced levels and/or shape specified in the documents.

The Contractor shall mark out, in the presence of the Superintendent, the areas where corrector course is to be applied and shall not lay corrector course prior to receiving acceptance of the proposed areas from the Superintendent.
The asphalt in these patches shall be compacted to comply with the general level of the existing surface to the Superintendent’s satisfaction.
Back filling and stress absorbing fabric strips is to be carried out in accordance MRTS30 where indicated on the drawings or directed by the superintendent.
Preparation of the prepared surface is to be to the satisfaction of the Superintendent. Subsequent inspection and Superintendent’s approval of surface condition shall be required prior to the release of the hold point.

(6) Tack coat

Only on multiple courses shall tack coat be used between each course unless directed otherwise by the Superintendent. The whole of the area to be sheeted with asphalt shall be tack coated with a light and even coat of bitumen emulsion. Bitumen emulsion shall comply with the requirements of MRTS21.

The bitumen emulsion shall be applied at a rate of between 0.1 litres per square metre and 0.2 litres per square metre of undiluted bitumen unless otherwise specified.

The bitumen emulsion shall be applied by a mechanical sprayer with spray bar. Where the areas to be sprayed are small, irregular or inaccessible to mechanical sprayers, such areas shall be tack coated by hand spraying or brushing.

The bitumen emulsion may be warmed or diluted with water to facilitate spraying. Adequate time shall be allowed for the emulsion to break before asphalt is laid. Over application of tack coat, due to surface depressions, shall be removed or dispersed by brushing.

All contact surfaces of kerbs and other structures and all cold joints shall be coated with a thin uniform application of tack coat.

Care shall be taken to ensure that bitumen emulsion is not sprayed on, or allowed to coat, any services or exposed fixtures including concrete kerbs, guardfence or bridge handrails. Appurtenances susceptible to overspray shall be protected with suitable paper.

When trucks or other vehicles are likely to move from tack coated areas onto adjacent finished surfaces, the Superintendent may require that the finished surfaces be suitably protected from carryover of bituminous material.

In locations of heavy pedestrian traffic, such as shopping areas, the Contractor shall take appropriate precautions in accordance with sub-section SC6.4.6.30 Control of traffic to keep pedestrians off tack coated areas.

(7) Laying

(a) Paver
The paver(s) shall be expected to have a minimum spreading capacity of 50t of asphalt per hour and be capable of spreading a width of at least 3.7m to the requirements of this sub-section. It shall be expected to have automatic screed control operated from joint matching shoe, fixed line, travelling straight edge or levelling beam. The Contractor shall provide the Superintendent with notice of proposed pavers without these capabilities and obtain Superintendent's agreement to their use.

(b) Laying operations
The work shall be so arranged as to keep the number of joints, both longitudinal and transverse to a minimum.

The paver shall operate at a uniform speed and the delivery of asphalt shall match the output of the paver such that continuous laying of asphalt is achieved.

When laying asphalt in echelon the distance between pavers shall be such that the temperature of the asphalt at the edge of the asphalt laid by the advance paver is not less than 80 °C by the time the following paver matches the longitudinal joint.

In the event of faulty operation of the paver causing irregularities in the spread asphalt, work shall cease until the fault is rectified.

Unless otherwise approved by the Superintendent, asphalt shall not be spread by hand behind the paver. Workers shall not stand or walk on the hot surface until compaction has been completed except where necessary for correction of the surface.

The Superintendent may approve spreading asphalt by hand for minor correction of the existing surface and in areas inaccessible to mechanical pavers.

Asphalt shall not be placed when the surface of the pavement is wet or while rain appears imminent.

AS 2734 shall constitute a valid reference of good practice for asphalt laying practice.

(c) Laying temperature

Weather restrictions and minimum asphalt temperatures at the time of discharge into the paver shall be in accordance with MRTS30. Measurement may be made by calibrated infra-red thermometers when accepted by both Contractor and Superintendent.

The Superintendent may reject that part of any truck load which contains lumps of cooled asphalt which are liable to affect the quality of the finished surface.

The laying temperature shall be measured in the paver hopper. A suitable stem type thermometer readable and accurate to within plus or minus 2 °C with a range from at least 0 °C to 200 °C shall be used. The stem shall be inserted into the asphalt to a depth of approximately 200mm at a location at least 300mm from the side of the paver. The average of two readings shall be adopted as the temperature of the mix. Measurements of asphalt and road surface temperatures and wind velocity to comply with this Clause shall be recorded on the Asphalt Work Record Sheet.

(d) Level control

The minimum controls for level set out below shall be used. Additional controls may be necessary to obtain the required finished pavement properties.

Corrective courses shall be automatically controlled by programmed computer control of the paver, joint matching shoe or stringline sensor. Where the correction is only minor, the Superintendent may allow the use of levelling beams at least 10m long.

Intermediate courses shall be automatically controlled by programmed computer control of the paver or a joint matching shoe.

The wearing course shall be controlled by levelling beams at least 10m long and, as required by the Superintendent or a joint matching shoe. When identified in the Project Quality Plan and/or approved in writing by the Superintendent, small areas (as defined) may be paved as wearing course without the use of levelling beam to achieve target levels.

(e) Layer thickness

The compacted thickness of each course shall be as shown on the drawings. A course may comprise one or more layers. The nominal compacted layer thickness shall be in accordance MRTS30.

(8) Joints

(a) General

The location of longitudinal and transverse joints shall be as approved by the Superintendent and at the spacing nominated in the drawings. All joints shall be compacted and finished with a smooth, planar surface coinciding with, and being of similar appearance to the remainder of the layer.

(b) Longitudinal joints

An automatically controlled joint matching device shall be used to control the levels of adjacent runs. Care shall be taken to provide positive bond between adjoining runs. Longitudinal joints shall be:

(i) continuous and parallel;

(ii) coincident within 150mm of line of change in crossfall;

(iii) offset by at least 150mm from joints in underlying layers;

(iv) located away from traffic wheel paths; and

(v) located beneath proposed traffic linemarkings in the case of a wearing course.

Work shall be arranged to avoid longitudinal joint faces being left exposed overnight.

When pavers are laying asphalt in echelon, the hot joint so produced shall be constructed by leaving an uncompacted strip approximately 150mm wide along the edge of the first run, and after the adjoining run has been spread, both sides of the joint shall be rolled simultaneously.

A joint shall be considered “cold” when the temperature of the asphalt has dropped below 60ºC for dense graded mix. Cold joints will require tack coating.

(c) Transverse joints

When the end of the asphalt layer has cooled due to disruption of the work, or when resuming work on the next day, a transverse joint shall be formed.

Transverse joints shall be at right angles to the direction of laying. They shall be staggered by at least 1m between successive layers and between adjacent runs.

Runs shall end either against a timber bulkhead to ensure a straight vertical, well compacted edge or by feathering out and compacting. In the latter case, before continuing the run the feathered material shall be cut back to a line where the full layer thickness exists. The surface shape of the end of the run shall be checked by a straight edge to locate the line of cut. The end of the previous run shall be lightly tack coated before the laying of the next run proceeds.

When the asphalt layer is required to join and match the level of an existing pavement surface, bridge deck or other fixture, sufficient of the existing material shall be cut out to achieve the minimum layer thicknesses requirements.

SC6.4.6.13.4 Compaction

(1) Plant and equipment

The proposed compaction fleet and rolling pattern shall be adequate to achieve the specified compaction and finish.

The minimum number of rollers used for compaction of asphalt laid at various rates should be as shown in Table SC6.4.6.13.1 Minimum roller combinations for compaction.

For compaction of confined areas or patching works a small vibrating roller, or hand operated vibrating compactor acceptable to the Superintendent shall be used.

Table SC6.4.6.13.1 Minimum roller combinations for compaction

ASPHALT OUTPUT	ALTERNATIVE ROLLER COMBINATION		
	Dense Graded Asphalt		
Tonnes per hour per paver	Static Steel	Steel Vibrating	Pneumatic Tyred
Up to 45	1	-	1
	-	1	1
45 to 85	1	-	2
	-	1	1
85 to 120	1	-	3
	2	-	2
	-	2	1
Above 120	As for 85 to 120 plus additional rollers as determined by Compaction Trials		

Note— 1. At the discretion of the Superintendent, the minimum number of rollers may be decreased for layer thicknesses in excess of 60mm.

2. Additional pneumatic tyred rollers to those specified may be required for backrolling asphalt.

(2) Dense graded asphalt

(a) Initial rolling

Initial rolling shall be carried out using steel rollers. Vibratory steel rollers may be used, but they shall be operated in the static mode for the first pass. On deep lift asphalt, pneumatic tyred rollers may be used.

Initial rolling shall commence as soon as possible after laying has commenced. Rollers shall be operated as close as possible to the paver.

The transverse and longitudinal joints and edges shall be compacted first.

The minimum asphalt temperature at the commencement of rolling shall be as detailed in MRTS30.

(b) Secondary rolling
Secondary rolling shall immediately follow initial rolling. In secondary rolling, static steel rollers or pneumatic tyred rollers shall be used. The tyre pressures of pneumatic tyred rollers should equal or exceed 550 kilopascals.

Rolling shall commence at the longitudinal joint side of the run.

Secondary rolling shall be completed before the mix temperature falls below 80 °C.

(c) Final rolling
Final rolling shall be carried out by a pneumatic tyred roller to eliminate all roller marks and to produce a uniform finish. If secondary rolling has been carried out with a pneumatic tyred roller, a steel roller may be used for final rolling instead of the pneumatic tyred roller specified.

Final rolling shall be completed before the asphalt temperature falls below 60 °C.

(3) Acceptance criteria for compaction
The acceptance for compaction shall be on a lot by lot basis where each day's work in one layer is generally one lot. Any defective areas which show cracking, bony material or exhibiting excessive binder shall be excluded from the lot and shall be rectified by the Contractor before being tested.

When directed by the Superintendent the Contractor shall arrange for the determination of the relative compaction of the lot by either of the following methods:

The acceptance for compaction on a lot shall be on the basis of characteristic value of relative compaction in accordance with MRTS30.

(4) Finished pavement properties
Each course of asphalt shall be finished parallel to the finished surface of the wearing course.

(5) Thickness
The thickness of asphalt shall be specified and/or measured in one of the following ways:

(a) No finished surface levels specified
When asphalt is placed over an existing pavement in one or more courses and no corrective course is applied, the calculated average compacted thickness of each course shall be in accordance with the course thickness specified in the Drawings and tolerances indicated in MRTS30.

(b) Finished surface levels specified
When asphalt is placed to specified levels, vertical tolerances and thicknesses shall be in accordance with MRTS30.

(6) Shape
The surface shall not deviate from the bottom of a 3m long straightedge laid in any direction by more than 5mm.

(7) Removal and replacement of rejected material
The sections of work that have been rejected under the preceding clauses of this sub-section or as otherwise determined by the Superintendent shall be removed within 15 days from the work and replaced with fresh asphalt mix material corresponding in grade and quality to that material specified in the Approved Mix unless otherwise approved by the Superintendent.

If removal of the single nonconforming pavement strata is impossible, the affected area as determined by the Superintendent shall be removed to subbase or subgrade depth as appropriate to provide a smooth level

surface on which to found the reinstated base and/or subbase course.

The perimeter of the nonconforming area shall be prepared in accordance with the practice pertaining to longitudinal and transverse cold joints (AS 2734).

In rejected sections the material is to be removed over the full length of the affected area except that a minimum length of 5m and a minimum width equal to the paver width shall be removed.

The Superintendent shall have the right to alter the constitution, quality, grading, or other parameters of the "reinstatement pavement" if it is felt that reconstruction of the affected area with the Approved Mix would produce nonconforming pavement as a result of non-continuous pavement structure.

After removal of the rejected base or subbase course the area shall be made available to the Superintendent for inspection and approval to proceed with the works. Superintendent inspection and approval is required prior to release of hold point.

All materials used in the reinstatement of the nonconforming area shall comply with the requirements of this sub-section unless otherwise directed by the Superintendent.

SC6.4.6.13.5 Limits and tolerances

The limits and tolerances applicable to the various clauses of this sub-section are summarised in Table SC6.4.6.13.2 below:

Table SC6.4.6.13.2 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	Materials and mix ingredients and manufacture	AC Asphalt - MRTS 30 and current TMR supplementary specifications. Bitumen - MRTS 17 Polymer modified binder - MRTS 18	SC6.4.6.13.2
2.	**Preparation of Pavement** (a) Cleaning of Surface	>300mm beyond the edge of proposed layer	SC6.4.6.13.3(1)
3.	**Tack Coat** (a) Bitumen Emulsion	Application Rate > 0.10 and < 0.20 litres per square metre	SC6.4.6.13.3(1)
4.	**Laying** (a) Paver Capacity	>50 tonnes asphalt per hour	
	(b) Spread Width	>3.7m	
	(c) Laying in Echelon	Distance between pavers is such that temperature of asphalt at edge (or laid by leading paver) is >80˚C when following paver matches the longitudinal joint.	
	(d) Laying Temperature		
	(i) Dense Grade AC	As per MRTS30	
	(e) Level Control	>10m length	SC6.4.6.13.3(7)(d)
	(i) Levelling Beam for Corrective Course		
	ii) Levelling Beam for Wearing Course	>10m length	SC6.4.6.13.3(7)(d)
	(f) Course and Layer Thickness	Nominal size mix and compacted layer thickness as per MRTS30.	
5.	**Longitudinal Jointing** (a) Change in Crossfall	Within 150mm of line of change.	
	(b) Where Underlying Layers	Offset at least 150mm from joints in underlying layers.	
6.	**Transverse Jointing** (a) Where Underlying Layers	Stagger to be >1m between successive layers and adjacent runs.	

Item	Activity	Limits/Tolerances	Clause
7.	**Compaction**	Initial Rolling:	SC6.4.6.13.3(2)(c)
	(a) Dense Graded Asphalt	To be commenced before asphalt temperature falls below 115ºC for layer ≤40mm. Refer to MRTS30	
		Secondary Rolling:	SC6.4.6.13.3(2)(d)
		Tyre pressures on pneumatic rollers to be≥550kPa.	
		Rolling to be completed before the asphalt temperature falls below 80ºC.	
		Final Rolling:	SC6.4.6.13.3(2)(d)
		Rolling to be completed before asphalt temperature falls below 60ºC.	
	(b) Acceptance Criteria for Compaction	On bases of characteristic value of relative compaction as per MRTS30 AC7 90% AC10 90% AC14 91% (92% > 50mm) AC20 93%	SC6.4.6.13.3(4)
8.	**Finished Pavement**	Max. compacted thickness tolerance as for	
	(a) Thickness	Table 12.3.3.2 of MRTS30 AC7 ± 5mm AC10 ± 5mm AC14 ± 7mm Where finished surface levels are specified, thickness and level shall comply with requirements of MRTS30. Reduced level primary tolerance ± 10mm.	
	(b) Shape	Shall not deviate from bottom of 3m straight edge by more than 5mm	SC6.4.6.3(6)

SC6.4.6.13 Asphalt Work Record

SC6.4.6.14 Mass concrete sub-base

SC6.4.6.14.1 Introduction

(1) Scope

This policy sub-section provides standards advice and guidelines for the construction, by mechanical or hand placement of mass concrete sub-base including trial sections and sub-grade beams.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note—A reference to drawings is a reference to construction drawings.

(2) Thickness and levels of subbase

The sub-base thickness and levels shall be as per design requirement.

(3) Provision for base slab anchors

During construction of the sub-base, in advance of concrete base construction the Contractor shall make provision to permit construction of base slab anchors at the locations and to the dimensions shown on the design. Excavation of material, trimming of trenches, compacting of the bottom of the trench, disposal of surplus material and construction of the concrete anchors shall be carried out in accordance with sub-sectionSC6.4.6.15 Plain and reinforced concrete base as part of the concrete base construction.

(4) Reference and source documents

Documents referenced in this Sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:

SC6.4.6.15 - Plain and reinforced concrete base

SC6.4.6.28 - Minor concrete works.

(b) Australian Standards:

AS1012.1 - *Sampling of fresh concrete*

AS1012.3.1 - *Determination of properties related to the consistence of concrete - Slump test*

AS1012.4.2 - *Determination of air content of freshly mixed concrete - Measuring reduction in air pressure in chamber above concrete*

AS1012.8 - *Method of making and curing concrete – Compression and indirect tensile test specimens*

AS1012.8 - *Method of making and curing concrete – Flexure test specimens*

AS1012.9 - *Determination of the compressive strength of concrete specimens*

AS1012.13 - *Determination of the drying shrinkage of concrete for samples prepared in the field or in the laboratory*

AS1012.14 - *Securing and testing cores from hardened concrete for compressive strength*

AS1141.11.1 - *Particle size distribution – Sieving method*

AS1141.14 - *Particle shape, by proportional calliper*

AS1141.22 - *Wet/dry strength variation*

AS1160 - *Bitumen emulsions for the construction and maintenance of pavements*

AS1379 - *Specification and manufacture of concrete*

AS1478.1 - *Chemical admixtures for concrete, mortar and grout – Part 1: Admixtures for concrete*

AS2758.1 - *Concrete aggregates*

AS3582.1 - *Supplementary cementitious materials for use with portland and blended cement - Flyash*

AS3799 - *Liquid membrane-forming curing compounds for concrete*

AS3972 - *General purpose and blended cements*

(c) Other:

Austroads, *Guide to Pavement Technology Part 4G: Geotextiles and Geogrids*

SC6.4.6.14.2 Materials for concrete

(1) Cement

Cement shall be Type GP Portland cement or Type GB blended cement complying with AS3972. Cement shall be from a source approved under the Queensland Government's State Purchasing Policy.

When submitting details of the nominated mix in accordance with clause SC6.4.6.14.4(1) General the Contractor shall nominate the brand and source of the cement. On approval of a nominated mix by the Superintendent, the contractor shall use only the nominated cement in the work.

Documentary evidence of the quality and source of the cement shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

If the Contractor proposes to use cement which has been stored for a period in excess of three months from the time of manufacture, the Superintendent may require a retest to ensure the cement complies with AS3972, before the cement is used in the work.

Cement shall be transported in watertight containers and shall be protected from moisture until used. Caked or lumpy cement shall not be used.

(2) Flyash

Flyash shall be from a source approved under the Queensland Government's State Purchasing Policy. The use and the quality of flyash shall comply with AS3582.1.

When submitting details of the nominated mix in accordance with clause SC6.4.6.14.4(1) General, the Contractor shall nominate the powerhouse source of the flyash. On approval of a nominated mix by the Superintendent, the Contractor shall use only flyash from the nominated powerhouse.

Documentary evidence of the quality and source of the flyash shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

(3) Water

Water used in the production of concrete shall be potable, free from materials harmful to concrete or reinforcement, and be neither salty nor brackish.

(4) Admixtures

Chemical admixtures and their uses shall comply with AS1478.1. Admixtures shall not contain calcium chloride, calcium formate, or triethanolamine or any other accelerator. Admixtures or combinations of admixtures other than specified below shall not be used. An air entraining agent may be included in the mix. If an air entrainer is used, the air content of the fresh concrete shall comply with Clause SC6.4.6.14.3(5) Air content.

Fresh concrete with an air content not complying with Clause SC6.4.6.14.3(5) Air content shall be rejected.

During the warm season (October to March inclusive), a lignin or lignin based ("ligpol") set retarding admixture approved by the Superintendent, shall be used to control slump within the limits stated in Clause SC6.4.6.14.3(4) Consistency. The dosage shall be varied to account for air temperature and haul time in accordance with the manufacturer's recommendations. A copy of the NATA endorsed Certificate of Compliance with AS1478.1 shall be submitted to the Superintendent, together with the proposed `dosage chart' in accordance with SC6.4.6.14.4(1) General.

If the Contractor proposes to vary the admixture between the warm and cool seasons such variation shall constitute a proposed change to an approved mix for the purposes of Clause SC6.4.6.14.4(2) Variations to approved mixes.

When submitting details of the nominated mix in accordance with Clause SC6.4.6.14.4(1) General, the Contractor shall nominate the proprietary source, type and name of each admixture to be used. Documentary evidence of the quality shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

(5) Aggregates

(a) General

(i) When submitting details of the nominated mix in accordance with clause SC6.4.6.14.4(1) General, the Contractor shall nominate the sources of aggregate to be used and shall submit details of the geological type of each aggregate.

(ii) Aggregates shall all pass the 37.5mm AS sieve and shall comply with AS2758.1 in respect of bulk density, water absorption (maximum 5%), material finer than 75 micrometres, impurities and reactive materials. The proportion of misshapen particles (2:1 ratio) determined by AS1141.14 shall not exceed 35%.

(iii) When submitting details of the nominated mix, the Contractor shall submit to the Superintendent a NATA Certified Laboratory Test Report on the quality and grading of the aggregate proposed to be used. The grading shall be known as the "Proposed Grading".

(iv) If the Contractor proposes to blend two or more aggregates to provide the Proposed Grading the Test Reports for each constituent material shall be submitted separately and the Superintendent advised of the proportions in which the various sizes and constituents are to be combined. The aggregate from each source and the combined aggregate shall comply with the requirements of this clause.

(v) All aggregate used in the production of concrete shall be clean, hard, durable rock fragments free from the inclusion of mineral salts, oils, organic matter or other materials deleterious to the performance of concrete.

(b) Grading

(i) The grading of the combined aggregate used in the work, determined by AS1141.11, shall not deviate from that of the proposed grading by more than the amounts shown in Table SC6.4.6.14.1 Aggregate grading deviation limits.

Table SC6.4.6.14.1 Aggregate grading deviation limits

Australian Standard Sieve	Maximum Deviation Per Cent Passing by Mass of Total Sample
37.5mm	-5
19.0mm	+ or -10
4.75mm	+ or -10
1.18mm	+ or -5
600mm	+ or -5
150mm	+ or -2

(c) Durability

Any fraction of any constituent and any fraction of combined aggregate shall conform to the following requirements:

(i) Wet Strength AS1141.22 Shall not be less than 50kN; and

(ii) 10 per cent Fines Wet/Dry Variation AS1141.22 Shall not exceed 35%.

(d) Storage

(i) Storage and handling facilities shall be such as to prevent the aggregates becoming intermixed or mixed with foreign materials, and to prevent segregation occurring.

(ii) The area surrounding the storage facilities and mixing plant shall be so constructed that delivery vehicles, loaders and trucks shall not be capable of introducing foreign matter to the aggregates at any time. If foreign matter is introduced or the area reaches a condition where, in the opinion of the

Superintendent, foreign matter may be introduced to the aggregates, production of concrete and delivery of materials shall cease until the condition is corrected to the satisfaction of the Superintendent.

SC6.4.6.14.3 Quality requirements of concrete

(1) Cement and flyash content
When a cement and flyash blend is nominated the minimum acceptable range is 40 – 75% by mass of the total cementitious material (cement and fly ash) in accordance with AS3582.1.

(2) Compressive strength
The compressive strength of concrete shall be determined in accordance with AS1012.9. The minimum compressive strength at 7 days shall be 4MPa and at 28 days shall not be less than 5MPa for flyash blended cement. The maximum compressive strength at 28 days shall be less than 15MPa, with the exception that where the nominated mix demonstrates a 28 day shrinkage less than 400 microstrains, then the concrete achieving a strength less than 20MPa shall be accepted.

(3) Shrinkage
The drying shrinkage of the nominated mix, determined by AS1012.13 shall not exceed 450 microstrain after 21 days air drying. The drying shrinkage at the nominated slump plus 10mm shall be taken as the average of the reading or readings within 5% of the median of the three readings obtained in accordance with AS1012.13.

(4) Consistency
The Contractor's nominated slump, determined in accordance with AS1012.3.1, shall be neither less than 25mm nor more than 40mm for mechanically placed concrete and shall be neither less than 50mm nor more than 65mm for hand placed concrete. The compactibility index range shall be between 60 and 80 in accordance with AS1012.3.4.

(5) Air content
If an air entraining agent is used, the air content of the fresh concrete, determined in accordance with AS1012.4.2, shall be neither less than 3% nor more than 7% when discharged from the transport vehicle ready for placement.

SC6.4.6.14.4 Design and control of concrete mixes

(1) General
The Contractor shall submit, for approval by the Superintendent, details of the concrete mix or mixes and the materials, including source, to be used for each of mechanically placed and hand placed subbase, including nominated slump and moisture condition of the aggregates (oven dry, saturated surface dry, or other specified moisture content) on which the mix is based. Each such mix shall be known as a “nominated mix”.

The Contractor shall provide a Certificate from a laboratory with appropriate NATA registration stating that each nominated mix and its constituents meet the requirements of this Specification. All relevant test results shall accompany the Certificate. All phases of any particular test must be performed at one laboratory. The certificate shall confirm that the required testing has been carried out in the twelve month period before the date of submission to the Superintendent.

In the tests supporting the above certification, the compressive strength gain curve shall be submitted showing the compressive strengths at ages 3, 7, 10 and 28 days determined in accordance with AS1012.9. Each of the results shall be based on three specimens of concrete produced from a batch of the nominated mix. The compressive strength shall be the average of individual results within 1MPa of the median.

These details shall be submitted at least 21 days before using the nominated mix in the work.

(2) Variations to approved mixes
The Contractor shall not make any changes to the approved mix, its method of production or source of supply

of constituents without the prior written approval of the Superintendent.

Where changes to an approved mix are proposed, the Contractor shall provide details of the nominated mix and materials, in accordance with clause SC6.4.6.14.4(1) General. If the variations to the quantities, qualities or sources of the constituents in the approved mix are less than 10kg for Portland cement, 20kg for other cementitious material and 5% by mass for each other constituent, except admixtures, per yielded cubic metre of concrete, the superintendent may approve the changes without new trials being carried out.

Notwithstanding these tolerances, the minimum cement content shall be 90kg per yielded cubic metre of concrete, the minimum flyash content shall be 100kg per yielded cubic metre of concrete.

SC6.4.6.14.5 Conformance for concrete strength and thickness

(1) Concrete cylinders

(a) Test specimens

Test specimens for determining the compressive strength of concrete shall be standard cylinders complying with AS1012.8.1. The Contractor shall supply a sufficient number of moulds to meet the requirements for the frequency of testing specified in this clause and shall also arrange for a laboratory with appropriate NATA registration to conduct the sampling of fresh concrete and the making, curing, delivery and testing of specimens. Copies of test results shall be forwarded to the Superintendent.

Samples of concrete for testing shall be taken in accordance with AS1012.1. The selection of the batches to be sampled shall be taken randomly. The specimens shall be moulded from each sample so that they are as identical as practicable.

The method of making and curing specimens shall be in accordance with AS1012.8.1 with compaction by internal vibration.

The Contractor shall mark the specimens for identification purposes.

Specimens shall be inspected, capped and crushed in accordance with AS1012.8.1 and AS1012.9.

(b) Frequency of moulding of test specimens

Test specimens shall be moulded as follows:

(i) For the determination of the compressive strength at twenty eight days:

- For each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens

(ii) For the determination of the compressive strength at seven days:

- For each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens

(iii) For the determination of compressive strength for any early testing as deemed necessary by the Contractor:

- For each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens

A lot is defined as a continuous pour of up to 50 cubic metres of concrete placed in the subbase.

(2) Compressive strength of concrete

(a) General

The compressive strength of the concrete represented by a pair of specimens moulded from one sample shall be the average compressive strength of the two specimens.
At the time of approving the mix design, the Superintendent shall nominate whether 7 day or 28 day compressive strength or both shall be the acceptance criteria for strength.

(b) Adjustment of test compressive strength for age of specimen

Should any specimen be tested more than 28 days after moulding the equivalent 28 day compressive strength shall be the test compressive strength divided by the factor applying to the age of the specimen at the time of the test shown in Table SC6.4.6.14.2 - Concrete age conversion factors.

For intermediate ages the factor shall be determined on a pro rata basis.

Table SC6.4.6.14.2 Concrete age conversion factors

Age of Specimen at time of test (days)	Factor
28	1.00
35	1.02
42	1.04
49	1.06
56	1.08
70	1.10
84	1.12
112	1.14
140	1.16
168	1.18
196	1.20
224	1.22
308	1.24
365 or greater	1.25

(c) Conformance for compressive strength
If the compressive strength of test cylinders for any lot is less than the criteria specified in Clause SC6.4.6.14.3(2) Compressive strength, the lot represented by the test cylinders shall be removed and replaced.

In case of non-conformance the Contractor may request permission of the Superintendent to core the in situ subbase for testing of the actual compressive strength to represent the particular lot. The locations for testing shall be nominated by the Superintendent. Such locations may be determined by the use of a nuclear density meter, or any alternative method. Testing shall be carried out at the request of the Contractor. Subbase concrete failing to reach the required in situ compressive strength shall not be retested for at least 72 hours after the determination of the value of the in situ compressive strength.

(3) Specimens cut from the work

(a) Specimens cut from the work shall be tested in a NATA registered laboratory nominated by the Contractor. Specimens shall be in the form of cylindrical cores of hardened concrete.

Cores shall be secured, accepted, cured, capped and tested in accordance with AS1012.14 with the following amendments:

(i) The requirement that the concrete shall be at least 28 days old before the core is removed shall not apply. However, concrete must have hardened enough to permit removal without disturbing the bond between the mortar and the coarse aggregate.

(ii) The preferred dimension for cores shall be 100mm diameter but in no case shall the diameter be less than 75mm or two and one half times the nominal size of the coarse aggregate, whichever is the greater.

(iii) When inspected in the uncapped state, cores shall be rejected if any diameter departs by more than 5mm from the mean diameter.

(iv) Cores shall be rejected where the length of the core when ready for capping is less than the diameter. The test strength determined shall be adjusted for form by a factor in accordance with Table SC6.4.6.14.3 Core strength factor.

(v) Wet Conditioning only shall be used.

Table SC6.4.6.14.3 Core strength factor

Length/Diameter Ratio	Correction Factor
2.00	1.00
1.75	0.98
1.50	0.96
1.25	0.93
1.00	0.89

Note—for intermediate form ratios, the factor shall be determined by interpolation.

Core cutting shall be carried out by the Contractor in the presence of and at the locations nominated by the Superintendent. The frequency of coring shall be such that a core is taken to represent each lot or the area of subbase placed between any two consecutive construction joints whichever is the lesser. The lot represented by each core shall be nominated by the Contractor at the time of sampling and duly recorded prior to testing.

Cores shall be despatched to arrive at the testing laboratory within 24 hours of the core being cut from the subbase. Wet curing shall commence within 24 hours of the receipt of the cores.

The cutting and transporting the cores to the testing laboratory and restoring all holes in the subbase shall be the responsibility of the Contractor. The method of restoration shall be approved by the Superintendent.

(4) Acceptance of cored concrete for compressive strength
Concrete shall achieve an in situ compressive strength of 5MPa within 28 days of placement.
If the specimen cut from the subbase reaches 4MPa for in situ compressive strength, base paving may proceed.

(5) Conformance for thickness

(a) General
No thickness measurements will be carried out if the surface of the subbase is within the level tolerances as specified in Clause SC6.4.6.14.7(5)(b) Surface tolerances.
If scabbling is required to achieve the level tolerance limits, the Superintendent may order thickness checks to be carried out. Where the survey ground model of the subgrade is available, subbase thickness shall be calculated from levels taken on a 5m grid on the plan area. Alternatively, the Superintendent may authorise coring and measurement at the edges of the layer. Thickness measurements shall be rounded off to the nearest 5mm.

(b) Thickness below specification
After making due allowance for the tolerances, subbase which is more than 20mm below the theoretical thickness shall be rejected and removed from the site. The removal and disposal from the site shall be the responsibility of the Contractor.

Subbase which is 20mm or less below the theoretical thickness may be accepted by the Superintendent providing that it represents isolated sections within a lot and such sections comprise less than 10 per cent of the area of the lot.

SC6.4.6.14.6 Productions, transport and consistency of concrete

(1) Production and transport of concrete
At least 3 weeks before commencing work under this sub-section, the Contractor shall submit, for the information of the Superintendent, details of the proposed methods of handling, storing and batching materials for concrete, details of proposed mixers and methods of agitation, mixing and transport.

(2) Handling, storage and batching materials
The methods of handling, storing and batching materials for concrete shall be in accordance with AS1379, with

the following additional requirements:

(a) certificates of calibration issued by a recognised authority shall be made available for inspection by the Superintendent, as evidence of the accuracy of the scales;

(b) cementatious material shall be weighed in an individual hopper, with the cement weighed first;

(c) the moisture content of the aggregates shall be determined at least daily immediately prior to batching. Corresponding corrections shall be made to the quantities of aggregates and water; and

(d) where a continuous type mixer is employed, the components shall be measured by a method of continuous weighing approved by the Superintendent, except for liquids which may be measured by volume or flow rate meter.

(3) Mixers and agitation equipment

Details of proposed mixers and agitation methods shall be in accordance with the plant and equipment sections of AS1379, with the following additional requirement that in Appendix A of AS1379 the maximum permissible difference in slump shall be 10mm.

(4) Mixing and transport

Mixing and transport methods shall be in accordance with the production and delivery sections of AS1379, with the following additional requirements:

(a) The mixer shall be charged in accordance with the manufacturer's instructions.

(b) For the purpose of conducting mixer uniformity tests in accordance with Appendix A of AS1379 on a split drum mixer producing centrally mixed concrete, the whole of the batch shall be discharged into the tray of a moving vehicle. The concrete shall then be sampled from the tray of the vehicle at points approximately 15% and 85% along the length of the tray.

(c) For truck mixed concrete, addition of water in accordance with the batch production section of AS1379 shall be permitted only within ten minutes of completion of batching and within 200m of the batching facilities. The delivery docket must clearly indicate the amount of water added, but in no circumstance shall the water:cement ratio be exceeded. Mixing of the concrete shall be completed at that location.

(d) After addition of the cement to the aggregate, concrete shall be incorporated into the work within:

(i) one and a half hours, where transported by truck mixer or agitator; and

(ii) one hour, where transported by non agitating trucks.

Means of verification, satisfactory to the Superintendent, of the times of addition of cement to the aggregate shall be provided.

The times within which the concrete shall be incorporated into the work may be reduced if the Superintendent considers the prevailing weather, mix type, or materials being used warrant such a change.

(e) The size of the batch in an agitator vehicle shall not exceed the manufacturer's rated capacity nor shall it exceed 80% of the gross volume of the drum of the mixer.

(5) Maximum mixing time

Where by reason of delay, it is necessary to hold a batch in the mixer, mixing may be continued for a maximum of 10 minutes except for split drum mixers where the maximum shall be 5 minutes.

For longer periods, the batch may be held in the mixer and turned over at regular intervals, subject to the time limits specified for incorporation of the concrete into the work not being exceeded.

(6) Consistency

The consistency of the concrete shall be such as to allow the production of a dense, non segregated mass with bleeding limited so as to prevent bleed water flowing over the slab edge under the conditions of placement. If bleed water does so flow, the Contractor shall cease paving until the consistency of the mix is adjusted to prevent flow or the mix is redesigned and approved by the Superintendent. The edge produced shall maintain its

shape and shall not sag or tear.

The Contractor shall provide all equipment, materials and labour for consistency testing and shall carry out tests in the presence of the Superintendent.

The consistency of the concrete shall be checked by use of a slump cone in accordance with AS1012.3.1. The test shall be made on concrete samples obtained in accordance with AS1012.1. The compactibility index range shall be between 60 and 80 in accordance with AS1012.3.4. Check tests shall be done on each truckload of concrete or as directed by the Superintendent.

SC6.4.6.14.7 Placing and finishing concrete subbase

(1) General

At least four weeks before commencing work under this Specification, the Contractor shall submit as part of the Quality Plan, for the information of the Superintendent, full details of the equipment and methods proposed for placing and finishing the concrete subbase together with a paving plan showing proposed paving widths, sequence and estimated daily outputs.

The Contractor shall give the Superintendent 7 days written notice of the intention to commence construction of the subbase on any section of work (including the placement of the trial subbase in accordance with Clause SC6.4.6.14.11.

The surface on which concrete subbase is to be placed shall be clean and free of loose or foreign matter and in damp condition.

Submit the work-as-executed survey of the subgrade to the full extent of the works to the Superintendent for confirmation, and highlight any locations where the actual level is higher than the design levels. If the underlying layer is required to be spray sealed, take levels on the top of the seal and after removal of foreign or loose material such as aggregate. Report levels to the nearest millimetre and survey on 5.0m grid on a plan area. In the case of non conforming levels, locally redesign the pavement levels as directed by the Superintendent.

Concrete shall not be placed either during rain or when the air temperature in the shade is below 5°C or above 38°C.

The temperature of the concrete placed in the work shall be neither less than 10°C nor more than 32°C.

(2) Rate of evaporation

When the value of Rate of Evaporation, determined from the graph in Figure SC6.4.6.14.1 Rate of evaporation, exceeds 0.5kg per square metre per hour the Contractor shall take precautionary measures, satisfactory to the Superintendent, for the prevention of excessive moisture loss. If, in the opinion of the Superintendent, such precautionary measures prove to be unsatisfactory, the Contractor shall cease work while the evaporation rate is in excess of 0.50kg per square metre per hour.

Should the Contractor elect to use an evaporation retarder to prevent excessive moisture loss, application shall be by fine spray after all finishing operations, except minor manual bull floating, are complete.

The Contractor shall be responsible for measuring and recording concrete temperature and wind velocity at the point of concrete placement, and for continuously measuring and recording air temperature and relative humidity daily, at the site throughout the course of the work. The Contractor shall provide and maintain all equipment and shall provide suitable personnel necessary for all such measuring and recording.

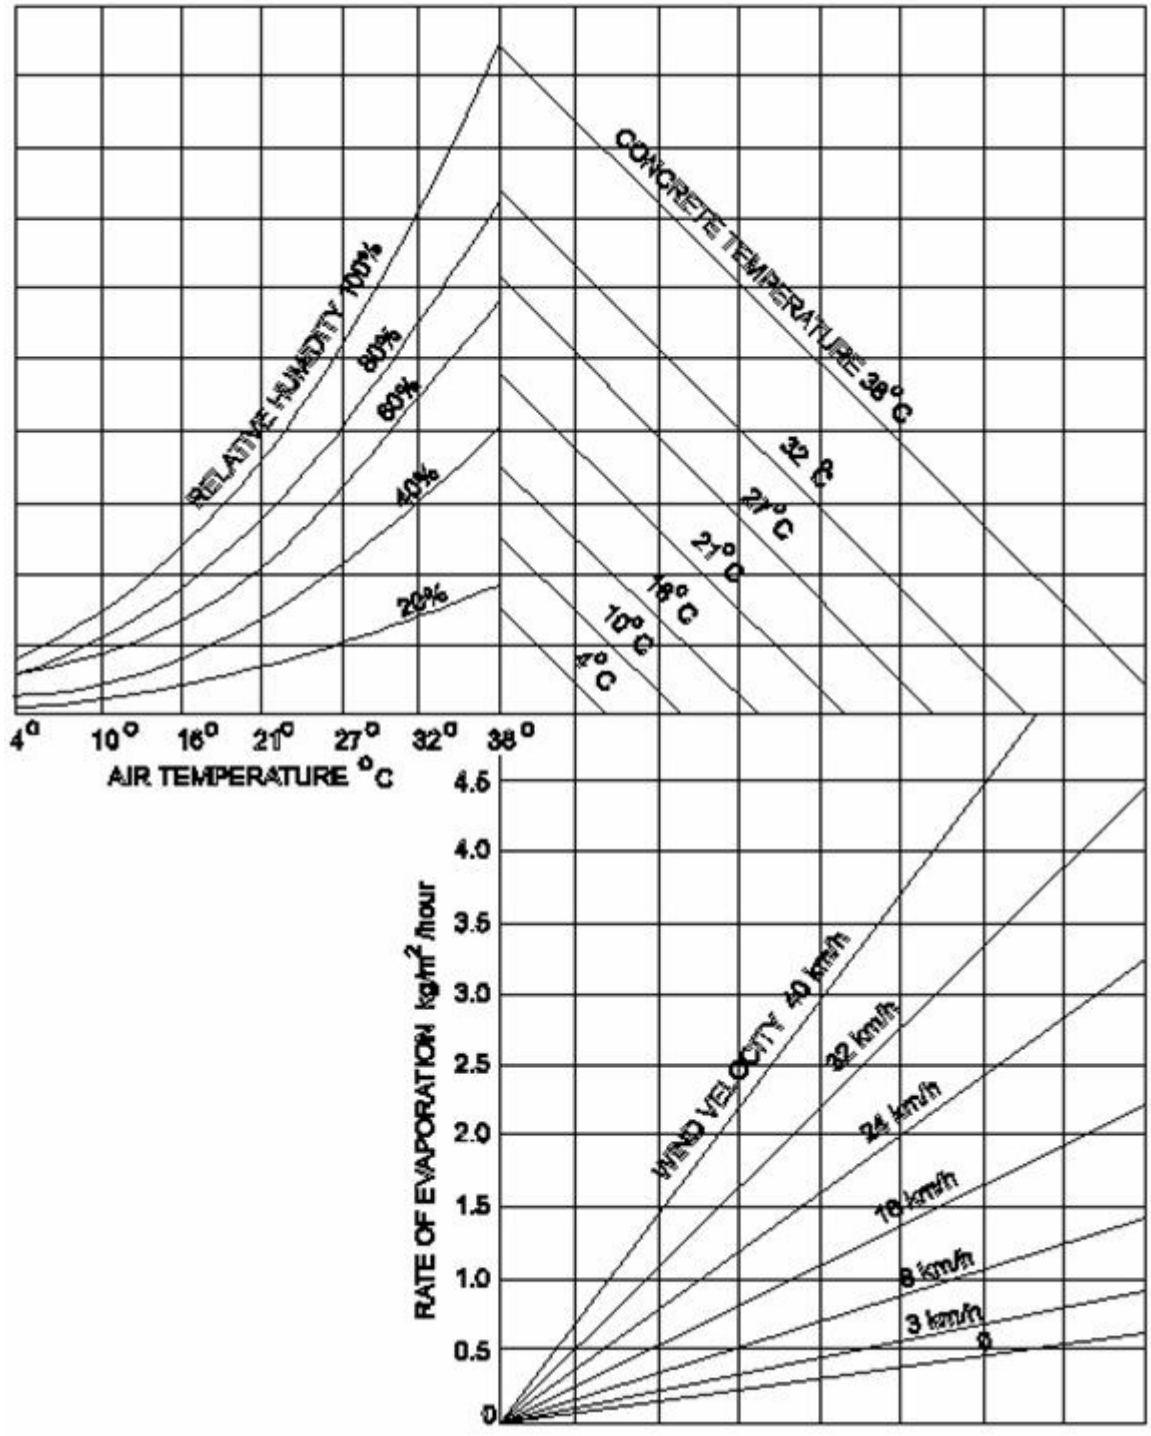

Figure SC6.4.6.14.1 Rate of evaporation

Note—the graph shows the effects of air temperature, humidity, concrete temperature and wind velocity together on the rate of evaporation of water from freshly placed and unprotected concrete.

Example:

- with air temperature at 27ºC
- with relative humidity at 40%
- with concrete temperature at 27ºC
- with a wind velocity of 26 km/h

the rate of evaporation would be 1.6 kg/m/hour.

To determine the evaporation rate from the graph, enter the graph at the air temperature (in this case 27ºC), and move vertically to intersect the curve for relative humidity encountered - here 40%. From this point move horizontally to the respective line for concrete temperature - here 27ºC. Move vertically down to the respective wind velocity curve - in this case interpolating for 26 km per hour - and then horizontally to the left to intersect the scale for the rate of evaporation.

(3) Mechanical paving

The mechanical paver shall be a self propelled machine with a gross operating mass of not less than 4 tonnes per lineal metre of paved width. It shall be capable of paving at a speed of one metre per minute or less as required to enable the continuous operation of the paver and obtain the required degree of compaction. It shall include the following features:

(a) an automatic control system with a sensing device to control line and level to the specified tolerances;

(b) means of spreading the mix uniformly and regulating the flow of mix to the vibrators without segregation of the components;

(c) internal vibrators capable of compacting the full depth of the concrete;

(d) adjustable extrusion screed and/or conforming plate to form the slab profile and produce the required finish on all surfaces; and

(e) capability of paving in the slab widths or combination of slab widths and slab depths shown on the drawings.

The mechanical paver shall spread, compact, screed and finish the freshly placed concrete in such a manner that a minimum of finishing by hand will be required. A dense and homogeneous concrete with a surface exhibiting low permeability shall be provided.

Surface texture shall be steel screed or float finish except that a hessian dragged finish shall be provided where the subbase is to be overlain by asphaltic concrete.

The supporting surface for the tracks of the paver, curing machine and any other equipment in the paving and curing train shall be in a smooth and firm condition.

Once spreading commences, the concrete paving operation shall be continuous. The mechanical paver shall be operated so that its forward progress shall not be stopped due to lack of concrete. If disruptions occur for any reason, the Superintendent may direct that a construction joint be formed before the recommencement of paving operations.

(4) Hand placing

Forms shall be so designed and constructed that they can be removed without damaging the concrete and shall be true to line and grade and braced in a substantial and unyielding manner. Forms shall be mortar tight and debonded to ensure non adhesion of concrete to the forms.

Concrete shall be delivered in agitator trucks and shall be deposited uniformly in the forms without segregation. The concrete shall be compacted by poker vibrators and by at least two passes of a hand guided vibratory screed traversing the full width of the slab on each pass. Any buildup of concrete between the forms and vibratory screed shall be prevented.

If disruptions occur for any reason, the Superintendent may direct that a construction joint be formed before the recommencement of paving operations.

A dense and homogeneous concrete with a surface exhibiting low permeability shall be provided.

Surface texture shall be steel screed or float finish except that a hessian dragged finish shall be provided where the subbase is to be overlain by asphaltic concrete.

(5) Alignment and surface tolerances

(a) Horizontal alignment tolerance

The outer edges of the subbase shall be square to the subgrade and shall be constructed 50mm wider than the plan position of the base formation with a tolerance of 25mm.

Where an edge of a slab is to form a longitudinal construction joint line, the allowable horizontal alignment tolerances shall comply with clause SC6.4.6.14.8(2) Longitudinal construction joints.

(b) Surface tolerances

The level at any point on the top of the subbase shall not vary by more than 0mm above or 20mm below

that shown on the drawings or as directed by the Superintendent. Where the concrete is found to be above the level tolerance, it shall be removed. Where the concrete is found to be below level tolerance, it shall be made up with base concrete.

The top surface of the subbase shall also not deviate from a 3m straightedge, laid in any direction, by more than 5mm.

(6) Curing

The subbase shall be cured by the use of one of the following:

(a) chlorinated rubber curing compound complying with AS3799 Class C Type 1D or resin-based curing compound complying with AS3799 Class B, Type 1D or Type 2, if an asphalt base is used; or

(b) white pigmented wax emulsion curing compound complying with AS3799 Class A Type 2, if a concrete base is used; or

(c) bitumen emulsion Grade CRS/170 complying with AS1160 for either asphalt or concrete base.

The Contractor shall submit, for the information of the Superintendent, a current Certificate of Compliance for the curing compound from an Australian Laboratory, approved by the Superintendent, showing an Efficiency Index of not less than 90% when tested in accordance with Appendix B of AS3799.

The curing compound shall be applied using a fine spray immediately following texturing at the rate stated on the Certificate of Compliance or at a minimum of 0.2 litres per square metre, whichever rate is the greater. Bitumen emulsion shall be applied at a minimum rate of 0.35 litres of residual bitumen per square metre. When applied with a hand lance the rates should be increased by 25%.

The average application rate shall be checked by the Contractor and certified to the Superintendent by calculating the amount of curing compound applied to a measured area representative of a lot and nominated by the Superintendent.

The curing membrane shall be maintained intact for seven days after placing the concrete. Any damage to the curing membrane shall be made good by handspraying of the affected areas.

Equipment and materials for curing operations shall be kept on site at all times during concrete pours.

(7) Protection of work

The Contractor shall ensure that the temperature of the concrete does not fall below 5ºC during the first twenty four hours after placing. The Contractor shall provide, for the information of the Superintendent, details of procedures and equipment proposed to be used for the protection of sections recently placed in the event of low air temperatures. If the Contractor fails to maintain the temperature of the concrete at or above 5ºC and if, in the opinion of the Superintendent, the concrete exhibits any deficiencies, due to failure to comply with this Specification, the concrete shall be rejected.

The Contractor shall protect the work from rain damage and shall provide, for the information of the Superintendent, detailed proposals for procedures and equipment to be used for such protection.

Neither traffic nor construction equipment, other than that associated with testing, shall be allowed on the subbase until the strength of the subbase has reached at least 4.0MPa. Thereafter, only construction equipment necessary for the following operations shall be permitted to traffic the subbase:

(a) bond-breaker and spall treatment;

(b) concrete or asphalt paving; and

(c) Notwithstanding the above, any damage caused to the subbase by the Contractor's operations shall be rectified to the Superintendent's satisfaction.

SC6.4.6.14.8 Joints

(1) Transverse construction joints

Transverse construction joints shall:

(a) be provided only at discontinuities in the placement of concrete determined by the Contractor's paving operations;

(b) be constructed normal to the edge line and to the dimensions shown on the drawings;

(c) not deviate from a 3m straightedge placed along the joint by more than 10mm; and

(d) cut back the edge of the previously placed concrete by sawing the concrete, to at least 1/3 the slab depth to expose an even, clean, sound, vertical surface, without disturbing the concrete that is to remain in place.

(2) Longitudinal construction joints
Longitudinal construction joints shall:

(a) be formed no closer than 300mm of the base longitudinal joints as shown in the drawings, unless directed otherwise by the Superintendent;

(b) not deviate from the plan or nominated position at any point by more than 20mm;

(c) not deviate from a 3m straightedge placed along the joint by more than 10mm, having made due allowances for any planned curvature; and

(d) be smooth across the joint.

SC6.4.6.14.9 Bond breaker and spall treatment

(1) General
Subbase to be covered by concrete base shall be provided with a wax emulsion bond breaker. The wax emulsion shall comply with AS3799 Class A Type 2.

Where the base consists of asphaltic concrete, no bond breaker shall be used. In this case bond is essential and wax emulsion curing compounds shall not be permitted.

Subbase with spalled areas shall be treated, where directed by the Superintendent, prior to application of the bond breaker or asphaltic concrete.

(2) Preparation of subbase
Immediately prior to any spalled area treatment and the application of bond breaker, the subbase surface shall be cleaned to the satisfaction of the Superintendent of all loose, foreign and deleterious material.

(3) Treatment of spalling
Where directed by the Superintendent, spalled areas shall be treated before the application of the bitumen bond breaker or asphaltic concrete by infilling with 6:1 sand/cement mortar to provide a surface flush with the surrounding concrete. The area shall be wetted and sprinkled with neat cement before screeding the mortar into the patches.

A spalled area, if directed to be treated, shall have such treatment completed no earlier than five working days before the application of the bond breaker. Treated spalled areas damaged by the Contractor or others shall be made good by the Contractor.

(4) Application of bond breaker
The wax emulsion used as bond breaker should be the same as used for curing compound. This second application shall be applied at a minimum rate of 0.2 litres per square metre and not earlier than 72 hours before the placement of the base concrete.

The method of application shall conform to the requirements of Clause SC6.4.6.14.10(6) Curing.

(5) Treatment of unplanned cracks
The Superintendent shall direct treatment of unplanned cracks whose width exceeds 0.3mm. This may take the form of applying an approved 300mm minimum width geotextile backed polymer modified bitumen strip

(reference Guide to Pavement Technology Part 4G: Geotextiles and Geogrids) over the crack prior to placement of the first asphalt base layer or concrete base, or an extra application of wax emulsion for a width of 300mm along the crack when a concrete base is required.

The Contractor shall install the Stress Alleviating Membrane strip in accordance with the manufacturer's instructions.

SC6.4.6.14.10 Subgrade beams

(1) General
Subgrade beams shall be provided below the subbase at expansion joints and isolation joints in the concrete base as shown in the drawings or as directed by the Superintendent. They shall extend the full length of joints unless otherwise indicated on the drawings.

(2) Excavation
Excavation for subgrade beams shall be to the dimensions shown on the drawings. All loose material shall be removed and the vertical faces trimmed to neat lines. The bottom of the trench shall be recompacted, where required, to the degree of consolidation of the adjacent undisturbed material. Excavated material shall be legally disposed of by the Contractor.

(3) Concrete
Concrete in subgrade beams shall comply with the requirements of sub-section SC6.4.6.28 Minor concrete works. The minimum compressive strength at 28 days shall be 32MPa.

(4) Steel reinforcement
Steel reinforcement shall be of the type and size shown on the drawings and shall be supplied and installed in accordance with sub-section SC6.4.6.15 Plain and reinforced concrete base.

(5) Construction and protection
Subgrade beams shall be constructed before construction of the subbase. The top surface of the subgrade beam shall be level with the top of the subgrade. Any loose subgrade material shall be recompacted to the correct level. If the contractor elects to remove any loose material, the voids shall be filled with mortar or concrete and screeded to provide a surface flush with the top of the subgrade beam and the surrounding subgrade.

A steel float shall be used to produce a smooth surface finish, free of any texture.

The subgrade beams shall be protected from damage by plant, motor vehicles and the paving operation. Any damage shall be made good by the Contractor.

(6) Curing
The top surface of the subgrade beam shall be cured in accordance with clause SC6.4.6.14.7 Curing before placing the subbase.

(7) Bond breaker
The top surface of the subgrade beam shall be treated with a bond breaker which shall consist of a further application of curing compound neither less than twenty four hours nor more than seventy two hours before placing of subbase concrete.

SC6.4.6.14.11 Trial concrete subbase

Before the commencement of paving, the Contractor shall construct a trial section of concrete subbase on the carriageway to demonstrate to the Superintendent the Contractor's capability of constructing subbase in accordance with the sub-section. This section shall be constructed so that it may be incorporated in the finished work.

The trial subbase shall be constructed using the same materials, concrete mix, equipment and methods the Contractor intends to use for the remaining subbase work. The Contractor shall demonstrate the methods proposed to be used for texturing, the application of curing compound and the construction of joints.

The trial shall also be used to demonstrate that the Contractor's allowances for concrete strength, compaction and slab thickness are adequate to achieve the minimum requirements specified.

A trial length of between 100m and 200m or lesser length in compliance with council requirements for mechanical paving equipment or between 20m and 50m for hand placement is required. The trial length shall be the maximum width proposed to be laid, and shall be constructed in one continuous operation.

Unless advised by the Superintendent of any deficiencies in the trial concrete subbase, due to failure to comply with this sub-section, the Contractor may proceed with placing concrete subbase from a time five working days after the completion of the trial concrete subbase or such earlier time as the Superintendent may allow. In the event of deficiencies in the trial concrete subbase, the Superintendent may order the Contractor to construct a further length of trial concrete subbase which shall be treated as the first. If, after three trials, the subbase still is deficient in some way, the Superintendent may require the Contractor to justify to the satisfaction of the Superintendent why the work should be allowed to continue using that method and/or equipment and/or materials and/or personnel.

The Superintendent shall have the right to call for a new trial section at any stage of work under the contract when changes by the Contractor in the equipment, materials, mix, plant or rate of paving are deemed by the Superintendent to warrant such procedure or when concrete as placed does not comply with this sub-section.

SC6.4.6.14.12 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.14.4 below:

Item	Activity	Limits/Tolerances	Clause
1.	**Materials for Concrete**		
	a. Misshapen Particles	2 : 1 ratio < 35%	SC6.4.6.14.3(5)(a)
	b. Aggregates Grading	Deviation from submitted sample not greater than Table C247.1	SC6.4.6.14.2(5)(b)
	c. Durability	Wet Strength > 50kN 10% Fines < 35%	SC6.4.6.14.2(5)(c)
2.	**Concrete**	Drying Shrinkage <450 microstrain	SC6.4.6.14.3(3)
	a. Shrinkage		
	b. Consistency	Mechanically placed: >25mm<40mm Hand Placed: >50mm <65mm	SC6.4.6.14.3(4)
	c. Air Content	≥3, ≤7%	SC6.4.6.14.3(5)
	d. Thickness	Concrete shall be removed if thickness >20mm below specified thickness.	SC6.4.6.14.5(5)
	e. Mixing and Transport	After addition of cement to the aggregate, concrete shall be incorporated into the work within: (i) One and a half hours where transported by truck mixer or agitator. (ii) One hour where transported by non agitating trucks.	SC6.4.6.14.6(4)

Item	Activity	Limits/Tolerances	Clause
	f. Placing	Concrete shall not be placed when the air temperature in the shade is less than 5ºC or >38ºC. Temperature of concrete shall be >10ºC but <32ºC.	SC6.4.6.14.7(1)
		Concrete shall not be placed when the Rate of Evaporation exceeds 0.5kg per square metre per hour.	SC6.4.6.14.7(2)
3.	**Alignment and Surface Tolerances** a. Horizontal Alignment	Outer edges not to deviate from plan position by more than ±25mm.	SC6.4.6.14.7(5)
	b. Surface	Level on top surface to be no more than +0mm or -20mm to that shown on the drawings.	SC6.4.6.14.7(5)
		The top surface shall not deviate from a 3m straightedge laid in any direction by more than 5mm.	SC6.4.6.14.7(5)
4.	**Joints** a. Transverse Construction	Shall not deviate from a 3m straight-edge placed along the joint by more than 10mm.	SC6.4.6.14.8(1)
	b. Longitudinal Joint	(i) Shall not deviate from the plan or nominated position at any point by more than 20mm. (ii) Shall not deviate from a 3m straightedge placed along the joint by more than 10mm after allowing for any curvature.	SC6.4.6.14.8(2)
5.	**Bond Breaker** a. Wax Emulsion	Minimum 0.2 litres per square metre, not earlier than 72 hours before placement of base.	SC6.4.6.14.9(4)

SC6.4.6.15 Plain and reinforced concrete base

SC6.4.6.15.1 Introduction

(1) Scope

(a) This policy sub-section provides standards, advice and guidelines for the construction, by mechanical or hand placement of plain or reinforced concrete, including trial sections, slab anchors and terminal slabs.

(b) The work also includes the construction of reinforced concrete approach slabs for bridge abutments and traffic signal approach slabs.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Thickness and levels of slab

The base thickness and levels shall be detailed on design and construction drawings.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.9 - Open drains - kerb and channel
SC6.4.6.20 - Subsoil, foundation and pavement drains
SC6.4.6.14 - Mass concrete sub-base

(b) Australian Standards:
AS 1012.1 - *Sampling of fresh concrete*
AS 1012.3.1 - *Determination of properties related to the consistence of concrete - Slump test*
AS 1012.4.2 - *Determination of air content of freshly mixed concrete - Measuring reduction in air pressure in chamber above concrete*
AS 1012.8 – *Method of making and curing concrete*
AS 1012.9 - *Determination of the compressive strength of concrete specimens*
AS 1012.12.2 - *Determination of mass per unit volume of hardened concrete - Water displacement method*
AS 1012.13 - *Determination of the drying shrinkage of concrete for samples prepared in the field or in the laboratory*
AS 1012.14 – *Method for securing and testing cores from hardened concrete for compressive strength*
AS 1141.11.1 - *Particle size distribution – Sieving method*
AS 1141.14 - *Particle shape, by proportional calliper*
AS 1141.18 - *Crushed particles in coarse aggregate derived from gravel*
AS 1141.22 - *Wet/dry strength variation*
AS 1141.24 – *Aggregate soundness – Evaluation by exposure to sodium sulphate solution*
AS 1160 - *Bituminous emulsions for the construction and maintenance of pavements*
AS 1379 - *Specification and supply of concrete*
AS 1478.1 - *Chemical admixtures for concrete, mortar and grout – Part 1: Admixtures for concrete*
AS/NZS 1554.3 - *Welding of reinforcing steel*
AS 2758.1 - *Concrete aggregates*
AS 3582.1 - *Supplementary cementitious materials for use with Portland and blended cenemt – Fly ash*
AS 3799 - *Liquid membrane-forming curing compounds for concrete*
AS 3972 – *General purpose and blended cements*
AS/NZS 4671 - Steel reinforcing materials.

(c) Queensland Department of Transport and Main Roads technical standard:
MRTS40 - *Concrete Base in Pavements: Jointed unreinforced, Jointed Reinforced, Continuously Reinforced and Steel Fibre Reinforced Pavements (10/10).*

(d) Queensland Department of Transport and Main Roads Materials Testing Manual:

Q461 - *Durability of Sealant*
Q462 - *Resistance of Vulcanised Rubber to the Absorption of Oil*
Q463A - *High Temperature Recovery of Preformed Polychloroprene Elastomeric Joint Seals*
Q463B - *Low Temperature Recovery of Preformed Polychloroprene Elastomeric Joint Seals*

(e) ASTM Standards:
D792 – *Standard test methods for density and specific gravity (relative density) of plastics by displacement*
C793 – *Standard test method for effects of laboratory accelerated weathering on elastomeric joint sealants*
C794 – *Standard test method for adhesion-in-peel of elastomeric joint sealants*
D2240 – *Standard test method for rubber property - durometer hardness*
D2628 – *Standard specification for preformed polychloroprene elastomeric joint seals for concrete pavements*
D2835 – *Standard specification for lubricant for installation of preformed compression seals in concrete pavements.*

(f) US Military Specification:
MIL-S-8802 - *Sealing compound, temperature resistant, integral fuel tanks and fuel cell cavities, high adhesion*

SC6.4.6.15.2 Design and control of concrete mixes

(1) General - design and control of concrete mixes

(a) Details of the concrete mix (or mixes) and the materials, including source, to be used for each of any mechanically placed and/or hand placed base, including nominated slump and moisture condition of the aggregates (oven dry, saturated surface dry, or other specified moisture content) on which the mix is based. Each such mix shall be known as a “nominated mix”.

(b) Also, a certificate from a laboratory with appropriate NATA registration stating that each nominated mix and its constituents meet the requirements of this specification. All relevant test results shall accompany the certificate. All phases of any particular test must be performed at one laboratory. The certificate shall confirm that the required testing has been carried out in the twelve month period before the date of submission to the superintendent.

(c) In the tests supporting the above certification, the compressive strength gain curve shall be submitted showing the compressive strengths at ages 3, 7, 10 and 28 days determined in accordance with AS 1012.9. Each of the results shall be based on three specimens of concrete produced from a batch of the nominated mix. The compressive strength shall be the average of individual results within 2.0 MPa of the median. The compressive strength for 28 days shall not be less than 36.0 MPa.

(d) These details shall be submitted at least 21 days before using the nominated mix in the work.

(2) Variations to approved mixes

(a) The contractor shall not make any changes to the approved mix, its method of production or source of supply of constituents without the prior written approval of the superintendent.

(b) Where changes to an approved mix are proposed, the contractor shall provide details of the nominated mix and materials, in accordance with clause SC6.4.6.15.2(1) General – design and control of concrete mixes. If the variations to the quantities, qualities or sources of the constituents in the approved mix are less than 10 kg for portland cement and flyash and 5 per cent by mass for each other constituent, except admixtures, per yielded cubic metre of concrete, the superintendent may approve the changes without new trials being carried out.

(c) Notwithstanding these tolerances the minimum portland cement content shall be 270 kilograms per yielded cubic metre of concrete and the maximum flyash content shall be 50 kilograms per yielded cubic metre of concrete.

SC6.4.6.15.3 Materials for concrete

(1) Cement

(a) Cement shall be Type GP Portland cement complying with AS 3972 and shall be from a source approved under the Queensland Government’s State Purchasing Policy.

(b) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1) General – design and control of concrete mixes the Contractor shall nominate the brand and source of the cement. On approval of a nominated mix by the superintendent, the contractor shall use only the nominated cement in the work.

(c) Documentary evidence of the quality and source of the cement shall be furnished by the contractor to the superintendent upon request at any stage of the work.

(d) If the contractor proposes to use cement which has been stored for a period in excess of three months from the time of manufacture, a re-test shall be required to ensure the cement still complies with AS 3972, before the cement is used in the work.

(e) Cement shall be transported in watertight containers and shall be protected from moisture until used. Caked or lumpy cement shall not be used.

(2) Flyash

(a) Flyash shall be from a source approved under the Queensland Government's State Purchasing Policy. The use and quality of flyash shall comply with AS 3582.1.

(b) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1), the Contractor shall nominate the powerhouse source of the flyash. The Contractor shall use only flyash from the nominated powerhouse.

(c) Documentary evidence of the quality and source of the flyash shall be furnished by the Contractor to the Superintendent.

(3) Water

Water used in the production of concrete shall be potable, free from materials that may be deterimental to the production of concrete or reinforcement, and be neither salty nor brackish.

(4) Admixtures

(a) Chemical admixtures and their use shall comply with AS 1478.1. Admixtures shall not contain calcium chloride, calcium formate, or triethanolamine or any other accelerator. Admixtures or combinations of admixtures other than specified below, shall not be used. An air entraining agent shall be included in the mix and the air content of the concrete shall comply with clause SC6.4.6.15.4(5) Air content. Fresh concrete with an air content not complying with clause SC6.4.6.15.4(5) will be rejected.

(b) The dosage of admixtures shall be varied to account for air temperature and haulage times in accordance with the manufacturer's recommendations. A copy of the NATA endorsed Certificate of Compliance with AS 1478.1 shall be submitted to the Superintendent, together with the proposed 'dosage chart' in accordance with clause SC6.4.6.15.2(1).

(c) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1), the contractor shall nominate the proprietary source, type and name for each admixture to be used. Documentary evidence of the quality shall be furnished by the Contractor to the Superintendent upon request at any stage of the work.

(5) Aggregates

(a) General

(i) At least 40 per cent by mass of the total aggregates in the concrete mix shall be quartz sand. Quartz sand is aggregate having a nominal size of less than 5 mm and shall contain at least 70 per cent quartz, by mass. Where present, chert fragments will be regarded as "quartz" for the purpose of this specification, but the ratio of chert to quartz shall not exceed unity.

(ii) When submitting details of the nominated mix in accordance with clause SC6.4.6.15.2(1), the contractor shall nominate the sources of aggregate to be used in the concrete and shall submit details of the geological type of each aggregate.

(b) Fine aggregate

(i) Fine aggregate shall consist of clean, hard, tough, durable, uncoated grains uniform in quality.

Fine aggregate shall comply with AS 2758.1 in respect of bulk density, water absorption (maximum 5 per cent), with material finer than 2 micrometres and impurities and reactive materials. The sodium sulphate soundness, determined by AS 1141.24, shall not exceed the limits in Table SC6.4.6.15.1 Sodium sulphate soundness limits

Table SC6.4.6.15.1 Sodium sulphate soundness limits

Australian Standard Sieve	Per Cent Loss by Mass
4.75mm to 2.36mm	4
2.36mm to 1.18mm	6
1.18mm to 600µm	8
600µm to 300µm	12

(ii) In the case of a blend of two or more fine aggregates, the above limits shall apply to each constituent material.

(iii) The grading of the fine aggregate, determined by AS 1141.11, shall be within the limits given in Table SC6.4.6.15.2 Fine aggregate grading.

(iv) When submitting details of the nominated mix the contractor shall submit to the superintendent a NATA certified laboratory test report on the quality and grading of the fine aggregate proposed to be used. The grading shall be known as the "proposed fine aggregate grading".

(v) If the contractor proposes to blend two or more fine aggregates to provide the proposed grading then test reports for each constituent material shall be submitted separately and the superintendent advised of the proportions in which the various sizes and constituents are to be combined. The fine aggregate from each source and the combined aggregate shall comply with the requirements of this clause.

(vi) The grading of the fine aggregate used in the work shall not deviate from that of the proposed grading by more than the amounts in Table SC6.4.6.15.2 Fine aggregate grading.

(vii) Notwithstanding these tolerances, the fine aggregate used in the work shall comply with the limits shown in Table SC6.4.6.15.2 Fine aggregate grading.

Table SC6.4.6.15.2 Fine aggregate grading

Australian Standard Sieve	Proportion Passing (% of Mass of Sample)	Deviation from Proposed Grading (% of Mass of Sample)
9.50mm	100	± 3
4.75mm	90 - 100	± 10
2.36mm	65 - 95	± 10
1.18mm	40 - 80	± 10
600µm	24 - 52	± 5
300µm	8 - 25	± 2
150µm	1 - 8	
75µm	0 - 3	

(c) Coarse aggregate

(i) Coarse aggregate shall consist of clean, crushed, hard durable rock, metallurgical furnace slag or gravel. Coarse aggregate shall comply with AS 2758.1 in respect of particle density, bulk density, water absorption (maximum 2.5 per cent), material finer than 75 micrometres, weak particles, light particles, impurities and reactive materials, iron unsoundness and falling or dusting unsoundness. In all other respects, the coarse aggregate shall comply with this sub-section. If required, coarse aggregate shall be washed to satisfy these requirements.

(ii) The grading of the coarse aggregate, determined by AS 1141.11, shall be within the limits given in Table SC6.4.6.15.3 Coarse aggregate grading.

(iii) When submitting details of the nominated mix the Contractor shall submit to the Superintendent a NATA Certified Laboratory Test Report on the quality and grading of the coarse aggregate proposed to be used. The grading shall be known as the "proposed coarse aggregate grading".

(iv) If the contractor proposes to blend two or more coarse aggregates to provide the proposed grading

then test reports for each constituent material shall be submitted separately and the superintendent advised of the proportions in which the various sizes and constituents are to be combined. The coarse aggregate from each source and the combined aggregate shall comply with the requirements of this clause.

(v) The grading of the coarse aggregate used in the work shall not deviate from that of the proposed grading by more than the amounts in Table SC6.4.6.15.3 Coarse aggregate grading.

Table SC6.4.6.15.3 Coarse aggregate grading

Australian Standard Sieve	Proportion Passing (% of Mass of Sample)	Deviation from Proposed Grading (% of Mass of Sample)
26.50 mm	100	± 2
19.00 mm	95 - 100	± 5
13.20 mm	(accepted design mix)	± 5
9.50 mm	25 - 55	± 3
4.75 mm	0 - 10	
2.36 mm	0 - 2	

(vi) Notwithstanding these tolerances, the coarse aggregate used in the work shall comply with the limits shown in Table SC6.4.6.15.3.

(vii) The coarse aggregate shall also conform to the following requirements:

(A) Wet Strength - AS 1141.22.
Shall not be less than 80 kN for any fraction and/or constituent;

(B) 10 per cent Fines Wet/Dry Variation - AS 1141.22.
Shall not exceed 35 per cent for any fraction and/or constituent;

(C) Soundness - AS 1141.24
The loss in mass when tested with sodium sulphate shall not exceed 9 per cent for any constituent;

(D) Particle Shape - AS 1141.14
The proportion of misshapen particles (2:1 ratio) shall not exceed 35 per cent;

(E) Fractured Faces - AS 1141.18.
At least 80 per cent by mass of the particles shall have two or more fractured faces; and

(F) Material finer than 75 micrometres – AS 1141.12
Shall not exceed 1 per cent for any fraction and/or constituent.

(d) Storage

(i) Storage and handling facilities shall be such as to prevent the aggregates becoming intermixed or mixed with foreign materials, and to prevent segregation occurring.

(ii) The area surrounding the storage facilities and mixing plant shall be so constructed that delivery vehicles, loaders and trucks shall not be capable of introducing foreign matter to the aggregates at any time. If foreign matter is introduced or the area reaches a condition where, in the opinion of the superintendent, foreign matter may be introduced to the aggregates, production of concrete and delivery of materials shall cease until the condition is corrected to the satisfaction of the superintendent.

SC6.4.6.15.4 Quality requirements of concrete

(1) Cement and flyash content
The minimum Portland cement content shall be 270 kilograms per yielded cubic metre of concrete. The maximum flyash content shall be 50 kilograms per yielded cubic metre of concrete.

(2) Compressive strength
The compressive strength of concrete shall be determined in accordance with AS 1012.9. The minimum compressive strength at 28 days shall be 36 MPa.

(3) Shrinkage

The drying shrinkage of the nominated mix, determined by AS 1012.13, shall not exceed 450 microstrain after 21 days air drying. The drying shrinkage at the nominated slump plus 10 mm shall be taken as the average of the reading or readings within 5 per cent of the median of the three readings obtained in accordance with AS 1012.13.

(4) Consistency

The Contractor's nominated slump, determined in accordance with AS 1012.3.1, shall be neither less than 30 mm nor more than 40 mm for mechanically placed concrete and shall be neither less than 55 mm nor more than 65 mm for hand placed concrete.

(5) Air content

The air content of the concrete, determined in accordance with AS 1012.4.2, shall be neither less than 4 per cent nor more than 7 per cent, when discharged from the transport vehicle ready for placement.

(6) Relative compaction

The minimum relative compaction, determined in accordance with AS 1012.12.2, shall be 98 per cent.

SC6.4.6.15.5 Steel reinforcement

(1) Material

(a) The type and size of bars shall be as shown on the drawings.

(b) Steel reinforcement shall be free from loose or thick rust, grease, tar, paint, oil, mud, millscale, mortar or any other coating, but is not to be brought to a smooth polished condition.

(c) The Contractor shall supply evidence satisfactory to the superintendent that steel reinforcement complies with AS 4671 *Steel reinforcing materials*. Test certificates shall show the results of mechanical tests and chemical analysis of the reinforcing steel to be used.

(d) Where the material cannot be identified with a test certificate, samples shall be taken and testing arranged by the contractor. The samples shall be selected randomly and consist of three specimens each at least 1.2 m in length.

(e) Plastic bar chairs or plastic tipped wire chairs shall be capable of withstanding a load of 200 kg mass on the chair for 1 hour at 23 ± 5ºC without malfunction. The Contractor shall demonstrate that the proposed chairs conform with these requirements.

(2) Bending

Reinforcement shall be formed to the dimensions and shapes shown on the drawings. Reinforcement shall not be bent or straightened in a manner that will damage the material. Bars with kinks or bends not shown on the drawings shall not be used. Heating of reinforcement for the purposes of bending will only be permitted if uniform heat is applied. Temperature shall not exceed 450 ºC and the heating shall extend beyond the portion to be bent. Heated bars shall not be cooled by quenching.

(3) Splicing

(a) All reinforcement shall be furnished in the lengths indicated on the drawings. splicing of bars shall only be permitted with the approval of the superintendent and as shown on the drawings. The information shown on the drawings is to detail the location and method of splicing.

(b) The length of lapped splices not shown on the drawings shall be as follows for unhooked bars:

Plain bars, Grade 250	40 bar diameters;
Deformed bars, Grade 400	35 bar diameters; and
Hard-drawn wire	50 bar diameters.

(c) Splices in reinforcing fabric shall be measured as the overlap between the outermost wire in each sheet of fabric transverse to the direction of splice. This overlap shall not be less than the pitch of the transverse wires plus 25 mm.

(d) In welded splices, bars shall only be welded by an approved electrical method. Grade 400 deformed bars

shall not be welded.

(e) Welding shall comply with AS 1554.3. The welded splice shall meet requirements of tensile and bend tests specified for the parent metal.

(4) Storage

Reinforcement, unless promptly incorporated into the concrete, shall be stored under a waterproof cover and supported clear of the ground, and shall be protected from damage and from deterioration due to exposure.

(5) Placing

(a) Reinforcing bars and wire reinforcing fabric shall be accurately placed to the dimensions and details shown on the drawings. They shall be securely held by blocking from the forms, by supporting on concrete or plastic chairs or metal hangers, as approved by the superintendent, and by wiring together where required using annealed iron wire not less than 1.25 mm diameter. These supports shall be in a regular grid not exceeding 1 m and steel shall not be supported on metal supports which extend to any surface of the concrete, on wooden supports, nor on pieces of aggregate.

(b) Tack welding instead of wire ties may be used on reinforcing steel. Cold worked reinforcing bars shall not be tack welded. Tack welding must conform to AS 1554.3.

(c) The minimum cover of any bar to the nearest concrete surface shall be 50 mm unless otherwise shown on the drawings.

(d) Tie bars shall be placed in the pavement such that after placement they remain in their specified location. Tie bars shall not be placed through the finished upper surface of the pavement. Tie bars shall be placed either ahead of paving or by a bar vibrator into the edge of the joint or by an automatic tie bar inserter on the mechanical paver. Irrespective of the method of placement, tie bars extending from any side face of base concrete or gutter shall be anchored in a manner which will develop 85 per cent of the yield strength of the bar in tension.

(e) Placing and fastening of all reinforcement in the work shall be approved by the superintendent before concrete is placed and adequate time shall be allowed for inspections and any corrective work which the superintendent may require. Notice for the superintendent's inspection shall not be less than four working hours before the intended time of commencement of concrete pour or such time as determined by the superintendent. Council is to be advised no later than (48) hours before hand.

(f) Dowelled joints shall be provided as directed by the superintendent, parallel to the pavement surface and normal to the line of the joint, or as shown on the drawings. The dowels are to be installed ahead of paving by an approved dowel support assembly. One end of the dowel is to be sleeved which is to be placed on the same side of the joint for a distance of (L/2 + 25 mm) to make sure free movement of the concrete base slab (including temperature variations). The contractor is to check each dowels before placement and make sure the dowels are straight and free of irregularities including burrs and protrusions.

SC6.4.6.15.6 Production, transport and consistency of concrete

(1) Production and handling of concrete

(a) At least 4 weeks before commencing work, the Contractor shall submit, for the information of the superintendent, details of the proposed methods of handling, storing and batching materials for concrete, details of proposed mixers and methods of agitation, mixing and transport.

(b) The methods of handling, storing and batching materials for concrete shall be in accordance with AS 1379, with the following additional requirements:

(i) certificates of calibration issued by a recognised authority shall be made available for inspection by the superintendent, as evidence of the accuracy of the scales;

(ii) cementitious material shall be weighed in an individual hopper, with the Portland cement weighed first; and

(iii) the moisture content of the aggregates shall be determined at least daily immediately prior to batching. Corresponding corrections shall be made to the quantities of aggregates and water.

(c) Details of the proposed mixers and agitation methods shall be in accordance with the plant and

equipment sections of AS 1379, with the additional requirement that in Appendix A of AS 1379 the maximum permissible difference in slump shall be 10 mm.

(2) Mixing and transport

Mixing and transport methods shall be in accordance with the production and delivery sections of AS 1379, with the following additional requirements:

(a) the mixer shall be charged in accordance with the manufacturer's instructions;

(b) for the purpose of conducting mixer uniformity tests in accordance with Appendix A of AS 1379 on a split drum mixer producing centrally mixed concrete, the whole of the batch shall be discharged into the tray of a moving vehicle. The concrete shall then be sampled from the tray of the vehicle at points approximately 15 per cent and 85 per cent along the length of the tray;

(c) for truck mixed concrete, addition of water in accordance with the batch production section of AS 1379 shall be permitted only within ten minutes of completion of batching and within 200 m of the batching facilities. The delivery docket must clearly indicate the amount of water added, but in no circumstance shall the water:cement ratio be exceeded. Mixing of the concrete shall be completed at that location;

(d) admixtures shall be separately pre-diluted with mixing water and shall be incorporated by a method which ensures that no adverse interaction occurs;

(e) After addition of the cement to the aggregate, concrete shall be incorporated into the work within:

(i) one and a half hours, where transported by truck mixer or agitator; and

(ii) one hour, where transported by non-agitating trucks.

(f) the size of the batch in an agitator vehicle shall not exceed the manufacturer's rated capacity for the vehicle nor shall it exceed 80 per cent of the gross volume of the drum of the mixer; and

(g) concrete delivery dockets must be provided for each batch of mix. The docket must record the following delivery information:

(i) supplier name and location;

(ii) volume of material supplied;

(iii) product constituents; and

(iv) dispatch time and date.

(3) Mixing time

(a) Minimum mixing time will be as determined for the approved mix and verified when trial concrete base is constructed.

(b) Where by reason of delay, it is necessary to hold a batch in the mixer, mixing may be continued for a maximum of ten minutes except for split drum mixers where the maximum time shall be five minutes.

(c) For longer periods, the batch may be held in the mixer and turned over at regular intervals, subject to the time limits specified for incorporation of the concrete into the work not being exceeded.

(4) Consistency

(a) At all times between mixing and discharge, the slump of the concrete is to be within 10 mm for mechanically placed concrete and is to be within 15 mm for hand placed concrete.

(b) The consistency of the concrete shall be checked by use of a slump cone in accordance with AS 1012.3.1. The test shall be made on concrete samples obtained in accordance with AS 1012.1.

(c) The consistency of the concrete shall be checked within 30 minutes of adding cement to the aggregate. If the actual haul time exceeds 45 minutes, the consistency shall also be checked immediately prior to discharge. Concrete which is non-conforming in relation to consistency shall not be incorporated into the work. Check tests shall be done on each truck load of concrete.

SC6.4.6.15.7 Placing and finishing concrete base

(1) General

(a) At least 4 weeks before commencing work, the Contractor shall submit as part of the quality plan, to the superintendent, full details of the equipment and methods proposed for placing and finishing the concrete base together with a paving plan showing proposed paving widths, sequence, proposed jointing locations and estimated daily outputs.

(b) The Contractor shall give the superintendent seven days written notice of the intention to commence construction of the base on any section of work (including the placement of the trial concrete base in accordance with clause SC6.4.6.15.7(11) Trial concrete base. Submit work-as-executed survey details of the sub-base to the full extent of the works to the superintendent for confirmation of the constructed based. The survey should detail the locations where the constructed level is higher than the design levels. If the underlying layer is required to be spray sealed, the surveyor is to take levels on the top of the seal and after removal of foreign or loose material such as aggregate. The survey is to report as constructed levels to the nearest millimetre and survey on 5.0 m grid on a plan area that has been certified by a licensed surveyor. In the case of non-conforming locations and levels, the contractor is to locally reconstruct the pavement levels as directed by the superintendent and to the satisfaction of council.

(c) The sub-base surface shall be clean and free of loose or foreign or vegetative matter and is to be prepared in accordance with sub-section SC6.4.6.14 Mass concrete sub-base.

(d) Concrete shall not be placed either during rain or when the air temperature in the shade is below 5 ºC or above 38 ºC.

(e) The temperature of the concrete at the point of discharge from the transport vehicle shall be neither less than 10 ºC nor more than 32 ºC.

(f) Where required, slab anchors shall be constructed prior to construction of the base.

(2) Rate of evaporation

(a) When the value of rate of evaporation, determined from the graph in Figure SC6.4.6.15.1 Rate of evaporation, exceeds 0.50 kilograms per square metre per hour the contractor shall take precautionary measures to the superintendent's satisfaction, for the prevention of excessive moisture loss. If, in the opinion of the superintendent, such precautionary measures prove to be unsatisfactory, the contractor shall cease work while the evaporation rate is in excess of 0.50 kilograms per square metre per hour.

(b) Should the contractor elect to use an evaporation retarder to prevent excessive moisture loss, application shall be by fine spray after all finishing operations, except for minor manual bull floating.

(c) The contractor shall be responsible for measuring and recording concrete temperature and wind velocity at the point of concrete placement and for continuously measuring and recording air temperature and relative humidity at the site throughout the course of the work. The contractor shall provide and maintain all equipment and shall provide suitable personnel necessary for all such measuring and recording to accurately take place.

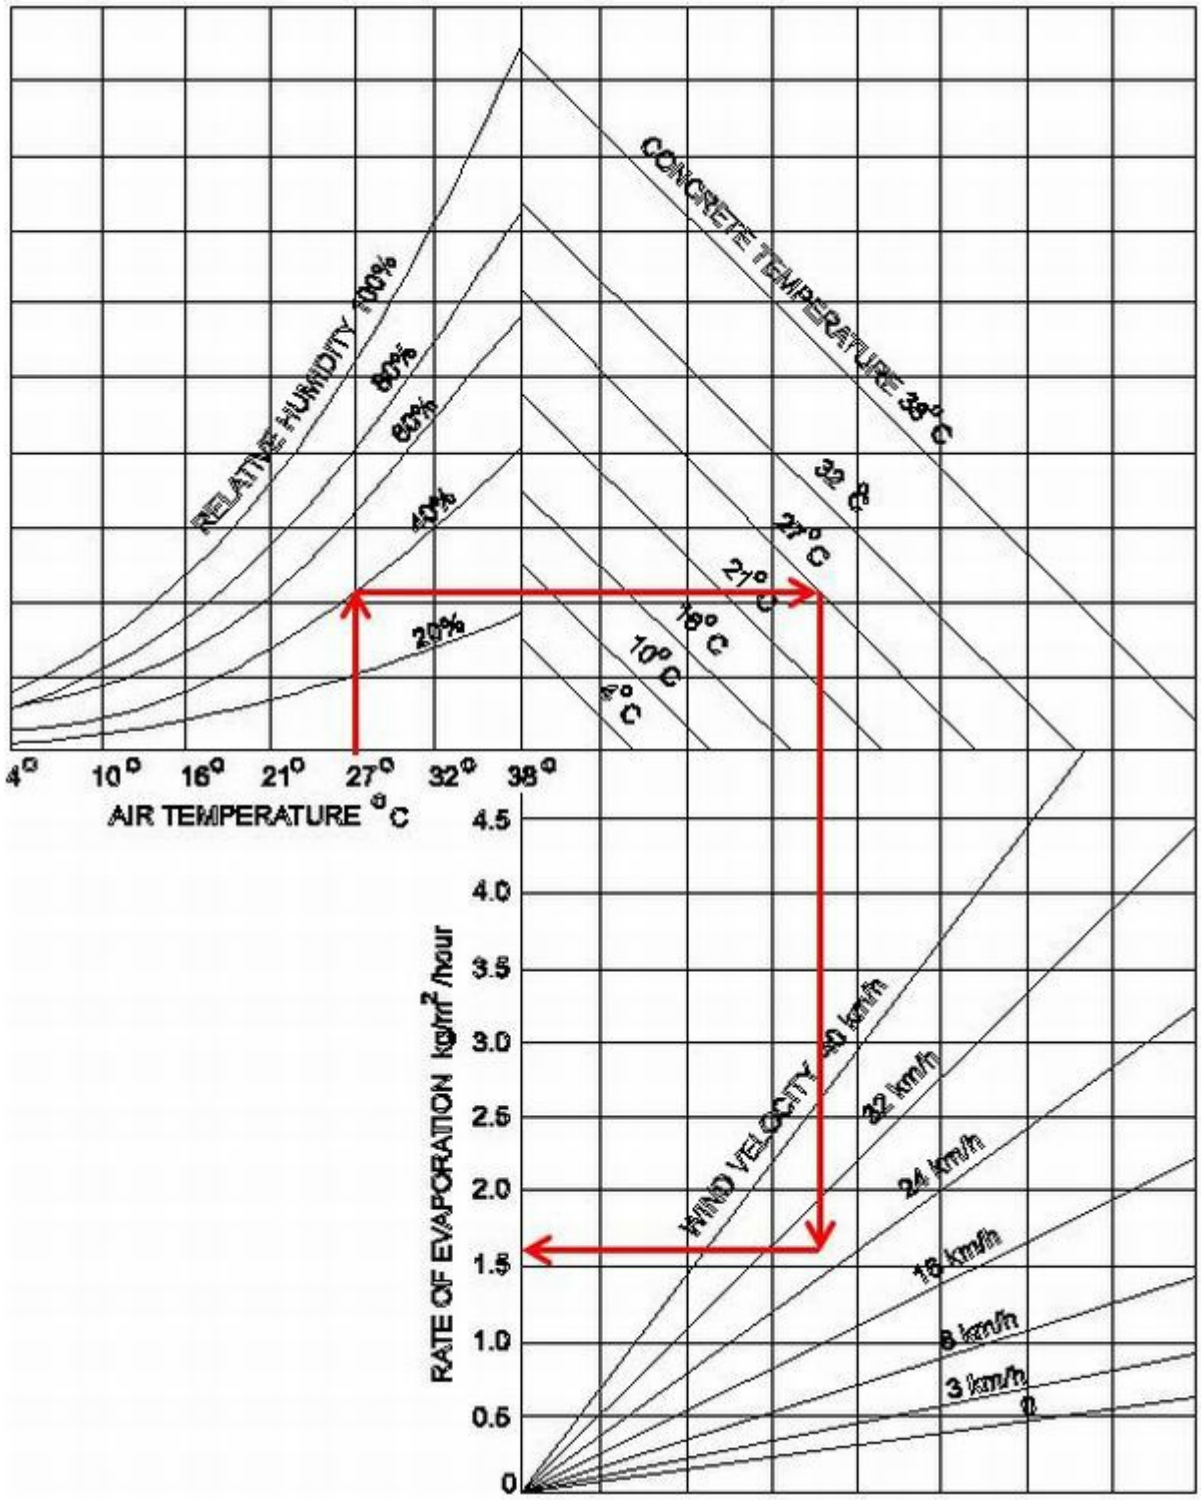

Figure SC6.4.6.15.1 Rate of evaporation

Note—the graph shows the effects of air temperature, humidity, concrete temperature and wind velocity together with the rate of evaporation of water from freshly placed and unprotected concrete.

Example:

- with air temperature at 27ºC
- with relative humidity at 40%
- with concrete temperature at 27ºC
- with a wind velocity of 26 km/h

the rate of evaporation would be 1.6 kg/m/hour.

To determine the evaporation rate from the graph, enter the graph at the air temperature (in this case 27ºC), and move vertically to intersect the curve for relative humidity encountered - here 40%. From this point move horizontally to the respective line for concrete temperature - here 27ºC. Move vertically down to the respective wind velocity curve - in this case interpolating for 26 km per hour - and then horizontally to the left to intersect the scale for the rate of evaporation.

(3) Mechanical paving

(a) The mechanical paver shall be a self-propelled machine with a gross operating mass of not less than 4 tonnes per lineal metre of paved width. It shall be capable of paving at a speed of one metre per minute or less as required to enable the continuous operation of the paver and obtain the required degree of compaction. It shall include the following features:

(i) an automatic control system with a sensing device to identify the control line and level – within the specified tolerances;

(ii) can spread the concrete mix uniformly and can regulate the flow of mix to the vibrators without segregation of the components;

(iii) has internal vibrators capable of compacting the full depth of the concrete;

(iv) has adjustable extrusion screeing and/or conforming plate to form the slab profile and produce the required finish on all surfaces; and

(v) has the capability of paving in the slab widths or combination of slab widths and slab depths shown on the drawings.

(b) The mechanical paver shall spread, compact, screed and finish the freshly placed concrete in such a manner that any finishing by hand is kept to a minimum. A dense and homogeneous concrete with a surface exhibiting low permeability is to be provided. It shall be textured in accordance with clause SC6.4.6.15.7(6) Texturing of surface.

(c) The supporting surface for the tracks of the paver, curing machine and any other equipment in the paving and curing train shall be in a smooth and firm condition.

(d) Once spreading commences, the concrete paving operation shall be continuous. The mechanical paver shall be operated so that its forward progress shall not be stopped due to lack of concrete. If disruptions occur for any reason, the superintendent may direct that a construction joint be formed before the recommencement of paving operations.

(e) Where an interruption to paving occurs, which is likely to result in a non-monolithic concrete mass, the contractor shall form a transverse construction joint in accordance with clause SC6.4.6.15.8(2) Transverse construction joints.

(f) Should subsequent testing at the location of an interruption indicate the presence of non-monolithic concrete, such concrete shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1) General – Removal and replacement of base, SC6.4.6.15.11(2) Removal and disposal of base and SC6.4.6.15.11(3) Replacement of base.

(4) Hand placing

(a) Hand placement shall only be used in areas where mechanical placement is impracticable or where it has been approved by the superintendent prior to commencement of work.

(b) Forms shall be so designed and constructed so that they can be removed without damaging the concrete and shall be true to line and grade and braced in a substantial and unyielding manner. Forms shall be mortar tight and de-bonded to ensure non adhesion of concrete to the forms.

(c) Concrete shall be delivered in agitator vehicles and shall be deposited uniformly in the forms without segregation. The concrete shall be compacted by poker vibrators and by at least two passes of a hand guided vibratory screed traversing the full width of the slab on each pass. Any build-up of concrete between the forms and vibratory screed shall be removed.

(d) If disruptions occur for any reason, the superintendent may direct that a construction joint to be formed before the recommencement of paving operations. The cost of forming such construction joints shall be borne by the Contractor.

(e) A dense and homogeneous concrete with a surface exhibiting low permeability, shall be provided. It shall be textured in accordance with clause SC6.4.6.15.7(6) Texturing of surface.

(f) Where an interruption to placing of concrete occurs, which is likely to result in a non-monolithic concrete mass, the contractor shall form a transverse construction joint in accordance with clause SC6.4.6.15.8(2) Transverse construction joints.

(g) Should subsequent testing at the location of an interruption indicate the presence of non-monolithic

concrete, such concrete shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1) General – Removal and replacement of base, SC6.4.6.15.11(2) Removal and disposal of base and SC6.4.6.15.11(3) Replacement of base.

(5) Alignment and surface tolerances

(a) Horizontal alignment tolerance

(i) The outer edges of the concrete base shall be square to the sub-base and shall not deviate from the plan position at any point by more than 10 mm.

(ii) Where an edge of a slab is to form a longitudinal joint line, the allowable horizontal alignment tolerances shall comply with clause SC6.4.6.15.8(7) longitudinal isolation joints.

(b) Tolerances and ride-ability

(i) The tolerance on thickness of the concrete base shall be zero below the specified thickness and in accordance with clause SC6.4.6.14.7(5)(b) for excess thickness.

(ii) The top surface of the base shall also not deviate at any measurement from a 3 m straightedge, laid in any direction, by more than 5 mm. Measurements for conformance shall be taken in accordance with the maximum lot size and minimum test frequencies in accordance with SC6.4.5 Construction management. Notwithstanding this requirement, the surface shall not pond water.

(6) Texturing of surface

Texturing of the concrete surface may be effected by use of a fine broom or hessian drag. The contractor shall submit to the superintendent details of the proposed texturing method and equipment.

(7) Curing

(a) The base shall be cured by the use of one of the following:

(i) Chlorinated rubber curing compound complying with AS 3799 Class C Type 1D or resin-based curing compound complying with AS 3799 Class B, Type 1D or Type 2, if an asphalt wearing surface is used, or

(ii) White pigmented wax emulsion curing compound complying with AS 3799 Class A Type 2, if no asphalt wearing surface is used, or

(iii) Bitumen emulsion Grade CRS/170 complying with AS 1160 for either asphalt wearing or no asphalt wearing surface.

(b) The contractor shall submit, for the information of the superintendent, a current certificate of compliance from an Australian laboratory, approved by the superintendent, showing an efficiency index of not less than 90 per cent when tested in accordance with Appendix B of AS 3799.

(c) The curing compound shall be applied using a fine spray immediately following texturing at the rate stated on the certificate of compliance or at a minimum of 0.2 litres per square metre, whichever rate is the greater. Bitumen emulsion shall be applied at a minimum rate of 0.5 litres per square metre. When applied with a hand lance the rates shall be increased by 25 per cent.

(d) The average application rate shall be checked by the contractor and certified to the superintendent by calculating the amount of curing compound applied to a measured area which is representative of a lot - and nominated by the Superintendent.

(e) The curing membrane shall be maintained intact for 7 days after placing the concrete. Any damage to the curing membrane shall be made good by handspraying of the affected areas.

(f) Equipment and materials for curing operations shall be kept on site at all times during concrete pours.

(8) Protection of work

(a) The Contractor shall protect the work from rain damage and shall provide, for the information of the superintendent, detailed proposals for procedures and equipment to be used for such protection.

(b) Neither traffic nor construction equipment, other than that associated with testing, sawcutting, groove cleaning or joint sealing, shall be allowed on the finished base until the joints have been permanently sealed and at least 10 days have elapsed since placing concrete, and the concrete has reached a

compressive strength of at least 20 MPa.

(9) Odd-shaped and mismatched slabs

(a) A slab is a portion of concrete base bounded by joints or free edges. A slab shall be considered to be odd shaped if the ratio of the longer dimension to the shorter dimension exceeds 1.6 or if the joint pattern produces an angle of less than 80 degrees between two adjacent sides. Slab dimensions shall be taken as the average dimension measured normal and parallel to the longitudinal joints. Slabs containing block-outs for drainage structures shall be considered as odd shaped.

(b) Where any joint meets a slab and is not continued across that slab, that slab shall be considered a mismatched slab.

(c) Unless otherwise shown on the drawings, odd shaped and mismatched slabs shall be reinforced with F82 reinforcing fabric placed with 50 mm to 60 mm cover to the surface of the base. Fabric shall be clear of all transverse and longitudinal joints by 50 mm to 100 mm.

(10) Terminal slabs

Terminal slabs shall be constructed adjoining bridge approach slabs and at changes from a rigid pavement to a flexible pavement. Terminal slabs shall be constructed to the dimensions and details shown on the drawings.

(11) Trial concrete base

(a) Before the commencement of paving, the contractor shall construct a trial section of concrete base on the carriageway to demonstrate to the superintendent the contractor's capability of constructing the concrete base in accordance with the specifications. This section shall be constructed so that it may be incorporated in the finished work.

(b) The trial base shall be constructed using the same materials, concrete mix, equipment and methods the contractor intends to use for the remaining base work. The contractor shall demonstrate the methods proposed to be used for texturing, the application of curing compound, the construction and sawing of joints and the placement of tie bars and dowels.

(c) The trial shall also be used to demonstrate that the contractor's allowances for concrete strength, compaction and slab thickness are adequate to achieve the minimum requirements specified.

(d) A trial length of between 20 m and 100 m for mechanical paving equipment or between 10 m and 30 m for hand placement is required. The maximum width proposed to be laid, shall be constructed in one continuous operation.

(e) Unless advised by the superintendent of any deficiencies in the trial concrete base, due to failure to comply with this sub-section, the contractor may proceed with placing the concrete base from a time ten working days after the completion of the trial concrete base or such earlier time as the superintendent may allow. In the event of deficiencies in the trial concrete base, the superintendent may order the contractor to construct a further length of trial concrete base which shall be treated as the first. If, after three trials, the base still is deficient in some way, the superintendent may require the contractor to justify to the satisfaction of the superintendent why the work should be allowed to continue using that method and/or equipment and/or materials and/or personnel.

(f) The superintendent shall have the right to call for a new trial section at any stage of work under the contract when changes by the contractor in the equipment, materials, mix, plant or rate of paving are deemed by the superintendent to warrant such a trial or when concrete as placed does not comply with this sub-section.

SC6.4.6.15.8 Joints

(1) General - joints

Joints shall be provided at locations indicated on the drawings or as approved by the superintendent.

(2) Transverse construction joints

(a) Transverse construction joints shall:

(i) be provided only at discontinuities in the placement of concrete determined by the contractor's paving operations;

(ii) not be placed closer than 1.5 m to a transverse contraction joint. Where necessary, the superintendent shall authorise a change in the spacing and/or skew of transverse contraction joints to ensure that sufficient clearance is obtained;

(iii) be constructed normal to the control line and to the dimensions and details shown on the drawings. The tie bars shall comply with clauses SC6.4.6.15.5(1) Material and SC6.4.6.15.5(5) Placing;

(iv) be smooth across the joint before texturing; and

(v) not deviate from a 3 m straightedge placed along the joint by more than 10 mm.

(b) Prior to the placement of adjacent concrete, the surface of the concrete shall be roughened to expose coarse aggregate. The roughened surface and the projecting reinforcement shall be washed clean and all excess water and loose material removed.

(3) Transverse contraction joints

(a) General

(i) Transverse contraction joints shall be continuous across the full width of the concrete base and shall be sawn unless otherwise approved by the superintendent.

(ii) Where the concrete base is to be overlaid with asphalt wearing course, the superintendent may approve the joint to be formed with a suitable plastic joint inducing system.

(iii) Transverse contraction joints shall be constructed normal to the control line and to the dimensions and details shown on the drawings. Where necessary, the joint may be skewed to a maximum 1 in 12 to accommodate construction joints and slab anchors.

(b) Saw-cutting

(i) The Contractor shall ensure that saw-cutting be conducted between 6 and 24 hours after initial paving so as not to cause excessive ravelling of aggregate adjacent to the cut and so as to prevent cracking of the concrete baseother than at the bottom of the 3 mm saw-cut. The contractor shall use the type of blade and equipment and the method of control best suited to the hardness of the concrete being sawn and shall have sufficient standby equipment available on site to maintain continuity of sawing.

(ii) The line of the transverse contraction joint shall be without any discontinuities. No edge shall deviate from a 3 m straight edge by more than 10 mm.

(iii) The surface of the transverse contraction joint shall not exhibit more than 5mm of vertical or horizontal edge ravelling. The length of edge ravelling shall not be more than 300 mm in any 1m length of joint on each edge. Saw debris shall be washed from the joint and pavement immediately after sawing.

(iv) Saw-cuts, which do not conform to the requirements of this clause, shall be rejected by the superintendent. Rejected saw-cuts may be repaired by a method approved by the superintendent.

(c) Cleaning

Immediately after any sawing, the saw-cut shall be cleaned of all debris. The cleaning method used shall not damage the saw-cut nor leave any substance deleterious to the concrete or to the adhesion of the joint sealants. The method shall incorporate a pressurised liquid or liquid/air jet. Cleaning liquid shall not be gravity fed from tanks.

(d) Temporary sealing

(i) Immediately after cleaning following the second saw-cut, if the transverse contraction joint is produced by a two cut operation, the joint shall be temporarily sealed by a continuous closed cell polyethylene backer rod of diameter shown on the drawings or as required by the superintendent.

(ii) The top of the sealant shall be neither higher than nor more than 10 mm below the concrete surface. The backer rod shall pass over any longitudinal joint seal already in place.

(iii) The temporary sealant shall be maintained by the contractor until the joint is sealed permanently.

Damaged or disturbed temporary sealants shall be removed, the transverse contraction joint is to be re-cleaned to the satisfaction of the superintendent and a new temporary sealant inserted.

(e) Permanent sealing

(i) General – permanent sealing

(A) Within 10 days of initial sawing and immediately on removal of the temporary sealant, the permanent sealant shall be placed in the joint.

(B) The permanent sealant shall be either a neoprene compression seal or an in situ cast silicone sealant. The contractor shall submit for the approval of the superintendent, a full technical description of the proposed sealant, including its operating parameters and the method of installation recommended by its manufacturer.

(ii) Neoprene compression sealants

(A) Neoprene compression sealants shall comply with all the requirements of ASTM 2628. Test methods used to determine compliance with these requirements shall include test methods Q462, Q463A and Q463B.

(B) At least four weeks before installation of the sealant, the contractor shall submit to the superintendent a certificate of compliance from a NATA registered laboratory showing that the sealant meets all the requirements of ASTM 2628.

(C) At the time of installation, the sides of the neoprene sealant shall be coated with a clear or concrete coloured lubricant compound approved by the superintendent and complying with ASTM D 2835. The sealant shall be inserted into the joint by using appropriate equipment and procedures which shall not damage the sealant during its insertion. The maximum increase in length of the sealant after installation shall be 5 per cent of original length. Any sealant exceeding 5 per cent extension shall be rejected. The sealant shall be located in the transverse contraction joint in the design orientation without twist or buckle.

(D) The sealant shall be continuous between formed longitudinal joints. Where such a discontinuity occurs, the sealant shall be angle butt jointed by a method approved by the superintendent. The top of the sealant shall be neither less than 5 mm nor more than 7 mm below the surface of the base and shall overlay any longitudinal sealants.

(iii) Silicone Sealants

(A) Silicone sealants shall be formed using a silicone joint sealant complying with the requirements listed in Table SC6.4.6.15.4 Silicone joint sealant requirements. At least 4 weeks before the installation of the sealant, the contractor shall submit to the superintendent a certificate of compliance, from a NATA registered laboratory, showing that the sealant meets all the requirements of Table SC6.4.6.15.4.

(B) The silicone joint sealant shall be grey in colour and shall be stored and installed in accordance with the manufacturer's written instructions. Installation of a silicone sealant shall take place only when the side walls of the groove have been grit blasted and are surface dry.

(C) Immediately before introducing the silicone sealant into the groove, any foreign or disturbed material shall be cleaned from the joint and from the top of the backer rod by dry air jet. The backer rod shall then be depressed to the depth such that the bottom of the silicone sealant shall be at the planned location and of the correct shape.

(D) If the backer rod is damaged in any way it shall be replaced for the full length of the joint.

(E) The method to be used for permanent sealing with silicone sealant shall be approved by the superintendent before permanent sealing commences. Notwithstanding any approval given by the Superintendent to a proposed method, the contractor shall be responsible for producing a permanent seal complying with all requirements of this specification.

Table SC6.4.6.15.4 Silicone joint sealant requirements

Test Method	Test	Requirements
ASTM-D-792	Specific Gravity	1.1 to 1.55
MIL-S-8802	Extrusion Rate	90 to 250 g per min
MIL-S-8802	Tack Free Time	30 to 70 min
ASTM D 2240	Durometer	10 to 25
Q461	Durability	Extension to 70% Compression to 50%
ASTM C794	Adhesion to Concrete	35N minimum average peel strength
ASTM C 793-7	Accelerated Weathering at 5,000 hours	No cracks, blisters or bond loss

(4) Transverse isolation joints

(a) Transverse isolation joints shall be provided at bridge approach slabs and at slab anchors where shown on the drawings and where directed by the superintendent.

(b) Transverse isolation joints shall be continuous across the full width of the concrete base normal to the control line and shall be constructed in accordance with the drawings.

(c) Transverse isolation joints shall not be placed closer than 2 m to other transverse joints. Where necessary, the superintendent shall authorise a change in the spacing and/or skew of adjacent transverse contraction joints to ensure that sufficient clearance is obtained.

(d) Joint filler shall consist of preformed jointing material of bituminous fibreboard and the joint sealant shall comply with the silicone sealant requirements of clause SC6.4.6.15.8(3) Transverse contraction joints. They shall be installed in accordance with the drawings and in a manner conforming to the manufacturers recommendations except that any reference to backer rods will not apply.

(e) The line of the isolation joint shall not deviate from a 3 m straightedge more than 10 mm.

(5) Longitudinal tied joints

(a) General – Longitudinal tied joints

(i) Longitudinal tied joints shall be provided at the locations shown on the drawings or where directed by the superintendent. The joints shall be parallel to the control line and/or to the dimensions and details shown on the drawings.

(ii) Longitudinal tied joints shall be formed or induced either by sawing or by machine insertion of a crack inducer ribbon.

(iii) The ties shall be 12 mm diameter deformed steel bars Grade 400Y, 1 m long and shall be inserted in accordance with clause SC6.4.6.15.5(5) Placing. Tie bars shall be located and spaced as shown on the drawings. All parts of any tie bar shall lie within 50 mm of its designed position. Tie bars shall be omitted within 500 mm of a transverse joint. The epoxy to be used when installing tie bars in existing concrete shall be hydrophilic epoxy resin. The setting system used shall develop an anchorage strength at least 85 per cent of the yield strength of the bar.

(iv) The line of longitudinal tied joints shall not deviate from the designed position at any point by more than 10 mm. The line shall also not deviate from a 3 m straight edge by more than 10 mm having made due allowance for any planned curvature.

(v) Where the longitudinal tied joint is formed or slip-formed, the joint face shall be corrugated in accordance with the details shown on the drawings.

(vi) Where the multi-lane width is greater than 18 m, a longitudinal isolation joint shall be constructed at each location shown on the drawings and in accordance with clause SC6.4.6.15.8(7) Longitudinal isolation joints.

(b) Sawn-induced joints

(i) Sawn longitudinal tied joints shall be provided to the dimensions shown on the drawings. Saw-cutting shall comply with clause SC6.4.6.15.9(3)(b) Saw-cutting.

(ii) Within 24 hours of sawing, the longitudinal tied joint shall be thoroughly cleaned of all debris and a neoprene backing rod, shall be inserted in accordance with the details shown on the drawings.

(iii) The sealant shall be coated with a lubricant adhesive compound approved by the superintendent. The compound shall have a colour compatible with the pavement colour. The sealant shall be inserted into the groove by means of suitable equipment which shall not damage the sealant during insertion. The maximum increase in length of the sealant after installation shall be 10 per cent of the original length, otherwise the sealant shall be rejected.

(iv) Joints in the sealant shall be kept to a minimum and shall be cemented together by an adhesive recommended by the manufacturer. The top of the sealant shall be neither less than 5 mm nor more than 7 mm below the surface of the concrete base, except where the sealant is depressed to lie under the transverse joint sealant.

(c) Ribbon-Induced Joints

(i) Ribbon induced longitudinal tied joints shall be provided to the dimensions and details shown on the drawings. The inducer ribbon shall be machine inserted so that the top of the ribbon does not protrude above the surface of the base, nor shall it lie below the surface of the base by more than 3 mm.

(ii) The inducer ribbon shall be a minimum of 0.5 mm thick. When placed, it shall be within 5º of the vertical plane. Any inducer ribbon that curls on placement when cut into the concrete base and is found to be curved in the transverse section by more than 3 mm its straight alignment, will be rejected.

(iii) At transverse construction joints, the inducer ribbon shall be carried through the joint sufficiently to allow a connection using strong stapling, or another method as approved by the superintendent. When a join, during paving, is necessary within the inducer ribbon - the inducer ribbon on the new spool shall be similarly joined to the tail of the inducer ribbon on the old spool.

(d) Treatment of sawn longitudinal tied joints prior to asphalt overlay

Where asphalt surfacing over sawn longitudinal tied joints is specified, the sealant shall be depressed to a depth below the concrete surface of not less than 10 mm and, following thorough cleaning, the joint shall be sealed flush with the concrete surface with a bituminous rubber compound, approved by the superintendent, which is to be compatible with the narrow groove.

(6) Longitudinal joint with kerb and/or channel

(a) Where kerbs and/or channel are to be constructed within the shoulder of a concrete base, they shall be formed directly onto the concrete sub-base and they may be cast either integrally with the concrete base or separately.

(b) Where constructed separately, they shall be tied to the concrete base by 12 mm diameter deformed steel tie bars grade 250S or 400Y, 1000 mm long at 1 m centres.

(c) The longitudinal joint shall be constructed parallel to the control line (parallel to the centre line for kerb ramps) and to the dimensions shown on the drawings. The tie bars shall be inserted in accordance with the drawings and clause SC6.4.6.15.5(5) Placing.

(d) The face of the longitudinal joint need not be scabbled however the joint does not need to be sealed.

(e) The line of the longitudinal joint shall be constructed to the tolerances specified for longitudinal tied joints in accordance with clause SC6.4.6.15.8 Longitudinal tied joints.

(f) The construction of kerb and/or channel shall be in accordance with kerb and channel sub-section SC6.4.6.9 Open drains regardless of method of construction except that the strength of the concrete used in the kerb and/or channel shall be 36 MPa.

(7) Longitudinal isolation joints

(a) Longitudinal isolation joints shall be provided where shown on the drawings and where directed by the superintendent.

(b) The line of the longitudinal isolation joint shall not deviate from the specified position by more than 10 mm. The line of the joint shall not deviate from a 3 m straight edge by more than 10mm.

(c) The joint filler shall consist of pre-formed jointing material of bituminous fibreboard and the joint sealant shall comply with the silicone sealant requirements of clause SC6.4.6.15.8(2) Transverse construction joints. They shall be installed in accordance with the drawings and in a manner conforming to the manufacturer's recommendations except any reference to backer rods will not apply.

SC6.4.6.15.9 Slab anchors

(1) General

(a) Slab anchors shall be constructed normal to the control line, to the dimensions and at the locations shown on the drawings.

(b) Slab anchors shall extend over the full width of the concrete base and the associated transverse expansion joint shall not be placed closer than 2 m to other transverse joints. Where necessary, the superintendent shall authorise a change in the spacing of transverse contraction joints to ensure that this minimum clearance is obtained.

(2) Excavation

(a) Excavation of trenches for slab anchors shall be to the dimensions and details shown on the drawings.

(b) All loose material shall be removed and the vertical faces trimmed to neat lines. The bottom of the trench shall be re-compacted, where required, to the degree of consolidation of the adjacent undisturbed material.

(c) The Contractor shall dispose of excavated material at locations approved by the superintendent.

(d) Where a slab anchor is required at the junction of an existing flexible pavement, a straight saw-cut to the full depth of the asphaltic concrete or bituminous seal shall be made in the flexible pavement along the joint line. Excavation of the trench shall then take place as described above without disturbance or damage to the existing flexible pavement. Any disturbance or damage to the flexible pavement shall be made good as directed by the superintendent.

(e) A subsoil drain shall be provided at the bottom of the trench, in accordance with subsection SC6.4.6.20 Subsoil, foundation and pavement drains and details shown on the drawings.

(3) Concrete

(a) Concrete for slab anchors shall be produced, transported and placed in accordance with the requirements for hand placed concrete base.

(b) Slab anchors shall be poured separately from the concrete base slabs and to the dimensions and details shown on the drawings - up to the top surface of the sub-base.

(c) A transverse isolation joint shall be provided on the downhill side of the slab anchor.

(d) Steel reinforcement in slab anchors shall be of the type and size shown on the drawings and shall be supplied and fixed in accordance with clauses SC6.4.6.15.5(1) Material and SC6.4.6.15.5(5) Placing.

(e) Bridge approach slabs, if not in the bridge contract, shall be constructed at bridge abutments to the dimensions and details shown on the drawings and in accordance with the requirements for the concrete base.

SC6.4.6.15.10 Conformance of concrete strength, compaction and thickness

(1) Concrete cylinders

(a) Test specimens

(i) Test specimens for determining the compressive strength of concrete shall be standard cylinders complying with AS 1012.8. The contractor shall supply a sufficient number of moulds to meet these requirements for the frequency of testing specified in this clause. The contractor will also arrange for a laboratory with appropriate NATA registration to conduct the sampling of fresh concrete and the making, curing, delivery and testing of specimens. Copies of test results shall be forwarded to the superintendent.

(ii) Samples of concrete for testing shall be taken in accordance with AS 1012.1. The selection of the

batches to be sampled shall be taken randomly. The specimens shall be moulded from each sample so that they are as identical as practicable.

(iii) The method of making and curing specimens shall be in accordance with AS 1012.8 with compaction by internal vibration.

(iv) The contractor shall mark the specimens for identification purposes.

(b) Frequency of moulding of test specimens

Test specimens shall be moulded at 7 days and 28 days or as directed by the superintendent - for the determination of the compressive strength. Each test specimen shall be moulded as follows:

(i) for each lot of up to 50 cubic metres of concrete placed at the one time - One pair of specimens;

A lot is defined as a continuous pour of up to 50 cubic metres of concrete placed.

(c) Inspection, capping and crushing of specimens

(i) Specimens required by this sub-section shall be tested at the NATA registered laboratory nominated by the contractor.

(ii) Specimens shall be inspected, capped and crushed in accordance with AS 1012.9.

(iii) Before crushing, the mass per unit volume of the seven day specimens shall also be determined in accordance with AS 1012.12.2, so that the relative compaction of cores taken from the same lot of concrete base can be determined.

(2) Compressive strength of concrete

(a) General

The compressive strength of the concrete represented by a pair of specimens moulded from one sample shall be the average compressive strength of the two specimens unless the two results differ by more than 3 MPa, in which case the higher result shall be taken to represent the compressive strength of the lot of concrete.

(b) Adjustment of test compressive strength for age of specimen

Should any specimen be tested more than 28 days after moulding the equivalent 28 day compressive strength shall be the test compressive strength divided by the factor applying to the age of the specimen at the time of the test shown in Table SC6.4.6.15.5 Concrete age conversion factors. For intermediate ages the factor shall be determined by interpolation.

Age of Specimen at time of test (days)	Factor
28	1.00
35	1.02
42	1.04
49	1.06
56	1.08
70	1.10
84	1.12
112	1.14
140	1.16
168	1.18
196	1.20
224	1.22
308	1.24
365 or greater	1.25

(c) Conformance for Compressive Strength

(i) If the 28 day compressive strength of test cylinders for any lot is less than 33 MPa or greater than 45 MPa, the lot represented by the test cylinders shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1) General – Removal and replacement of base, SC6.4.6.15.11(2) Removal and disposal of base and SC6.4.6.15.11(3) Replacement of base.

(ii) In case of non-conformance the contractor may elect to core the in situ concrete base for testing

of the actual compressive strength to represent the particular lot. The locations for testing shall be nominated by the superintendent. Such locations may be determined by the use of a nuclear density meter, or any alternative method approved by the Superintendent. Testing shall be carried out at the request of the contractor. Base concrete failing to reach the required in situ compressive strength shall not be re-tested for at least 72 hours after the determination of the value of the in situ compressive strength.

(iii) After testing for compressive strength of the sample concrete cores, as required, the superintendent shall consider the test results and shall, at his absolute discretion determine the compressive strength of the concrete to be either:

(A) The average of the 28 day compressive strength of the pair of specimens moulded at the time of placing; or

(B) The equivalent 28 day compressive strength of the core.

(iv) A lot is defined as a continuous pour of up to 50 cubic metres of base represented by a set of test specimens cast from a sample of the concrete used in its construction.

(v) Thickness measurements of the concrete base shall be determined and certified by a licensed surveyor. Measurements are to be taken at the edges or by coring. Audit checks using a suitable probe may be carried out whilst the concrete is being placed. The readings shall be rounded off to the nearest 5 mm.

(vi) Concrete base which is below the specified thickness shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1), SC6.4.6.15.11(2) and SC6.4.6.15.11(3) .

(vii) Base which is thicker than the design thickness will be acceptable provided the finish satisfies the requirements of Clause SC6.4.6.15.7 Placing and Finishing Concrete Base and that the finished surface base level complies with clause SC6.4.6.14.7 (5) (b)

(3) Relative compaction of concrete

(a) Test specimens

(i) Test specimens for determining the relative compaction of the concrete placed in the work shall be cores cut from the work. Cores shall be cut from the full depth of the concrete base to the requirements of AS 1012.14, with the following exceptions:

(A) the requirement that the concrete shall be at least 28 days old before the core is removed shall not apply. However concrete must be not less than 3 days old in the warm season and 6 days old in the cool season, before removal; and

(B) the nominal diameter of the cores shall not be less than 75 mm.

(ii) The location of coring shall be chosen to exclude joints, steel reinforcement or tie bars from the core. The locations are not intended to be random, but are intended to ensure that the whole of the concrete base conforms to the minimum requirements of this sub section. Cores shall be marked for identification by the contractor.

(iii) Cores shall be placed immediately either in a tank of lime saturated water or in an individual plastic bag and sealed to prevent water loss. Cores stored in plastic bags shall be kept in the shade.

(iv) Cores shall not be subjected to temperatures in excess of either ambient temperature or 23 ºC whichever is the higher and they shall not be subjected to temperature less than 10 ºC, until delivered to the testing laboratory.

(b) Frequency of coring

(i) The Contractor shall take a minimum of one core specimen from each lot of concrete base represented by standard cylinders moulded in accordance with clause SC6.4.6.15.10(1) Concrete cylinders.

(ii) In the case of hand placed concrete base, two cores shall be taken to represent a section of work. A section of work shall be confined between construction joints. Hand worked or placed base that is cast with machine placed concrete and not separated from the machine placed concrete shall be deemed to be part of the machine placed concrete, and be cored and tested as part of the

machine placed concrete base.

(c) Repair of core holes

(i) The Contractor shall clean and restore all core holes taken in the base with non-shrink cementitious concrete having a compressive strength of not less than that in the base and a maximum nominal aggregate size of 10 mm.

(ii) The surface of the restored hole shall be similar to the surrounding surface in texture and colour.

(d) Testing of cores for compaction

(i) The core specimens shall be wet conditioned in accordance with AS 1012.14 for not less than 24 hours immediately prior to testing for compaction. Testing to determine mass per unit volume shall be carried out on specimens at age seven days.

(ii) The relative compaction of a core specimen shall be the ratio, expressed as a percentage, of the mass per unit volume of the core specimen to the average mass per unit volume of the standard cylinders used to determine the seven day compressive strength from the same lot of concrete base. The mass per unit volume of both standard cylinders and cores shall be determined in accordance with AS 1012.12.2.

(e) Conformance for Compaction

(i) If the relative compaction is less than 97 per cent, the lot represented by the core shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1), SC6.4.6.15.11(2) and SC6.4.6.15.11(3).

(ii) Core specimens for compressive strength testing shall be wet conditioned, prepared and tested in accordance with AS 1012.14. Cores obtained for compaction shall not be re used for compressive strength testing.

(iii) The test strength shall be adjusted for age in accordance with clause SC6.4.6.15.10(2) Compressive strength and for length/diameter ratio in accordance with Table SC6.4.6.15.6 Correction factors by multiplying by the correction factor in Table SC6.4.6.15.6 Correction factors.

(iv) If the 28 day compressive strength of the core is less than 33 MPa, the lot represented by the compaction core shall be removed and replaced in accordance with clauses SC6.4.6.15.11(1), SC6.4.6.15.11(2) and SC6.4.6.15.11(3).

Table SC6.4.6.15.6 Correction factors

Length/Diameter Ratio	Correction Factor
2.00	1.00
1.75	0.98
1.50	0.96
1.25	0.93
1.00	0.89

SC6.4.6.15.11 Removal and replacement of base

(1) General – Removal and replacement of base

(a) Where directed by the superintendent, rejected base shall be removed and replaced in accordance with this clause. Rejected base, which extends more than 25 m longitudinally, shall be replaced by mechanical means unless the slabs are odd shaped or mismatched. Replacement shall be in full slab widths between longitudinal joints and/or external edges.

(b) At least 7 days before the commencement of concrete base removal, the contractor shall submit, for the approval of the superintendent, details of the proposed methods of carrying out the work which shall be such as to prevent damage to the adjoining concrete base and the underlying sub-base.

(2) Removal and disposal of base

(a) At each end of the section of concrete base to be removed, a transverse saw-cut shall be made for the full depth of the base layer. Such transverse saw-cut shall be normal to the control line and not closer

than 1.5 m to an existing contraction joint in the base. No over-sawing into the adjoining concrete base or underlying sub-base shall be permitted.

(b) Longitudinal saw-cuts shall be made along the existing longitudinal joints to define the edges of the base section to be removed. Such longitudinal saw-cuts shall not extend more than 250 mm past the transverse saw-cut at each end of the section to be removed and shall not extend into the underlying sub-base.

(c) No over-sawing shall be permitted on any internal saw-cuts made by the contractor to aid in the removal of the concrete base.

(d) The contractor shall dispose of the removed concrete base slabs at sites acceptable to the superintendent.

(e) Any slab, adjoining the removed slabs, damaged by the contractor's operations shall also be removed and replaced in accordance with this clause.

(3) Replacement of base

(a) Before construction of the replacement base, the sub-base shall be prepared and de-bonded in accordance with sub-section SC6.4.6.14 Mass concrete sub-base.

(b) All work involved in the replacement of the concrete base shall comply with this sub-section, including the following additional requirements:

(i) The joint faces on the adjoining slab at the transverse saw-cuts shall be deeply scabbled below the top 25 mm which shall be left smooth. Tie bars shall be provided to form a transverse construction joint in accordance with clause SC6.4.6.15.8(2) Transverse construction joints.

(ii) Transverse contraction joints shall be continuous across the full width of the base containing the replaced section. The length of the joint across the full width of the base shall be sealed with the same sealant as in adjacent work and in accordance with clause SC6.4.6.15.8(3) Transverse contraction joints.

(iii) The lower two thirds of the depth of the longitudinal joint faces shall be deeply scabbled and any concrete considered to be unsound by the superintendent shall be removed. A crack inducer ribbon shall be attached to the surface of any formed longitudinal joint in the replacement concrete base and tie bars provided to form a longitudinal tied joint in accordance with clause SC6.4.6.15.8(5) Longitudinal tied joints.

(iv) Tie bars placed into hardened concrete shall be set by the use of a hydrophilic epoxy resin. The setting system used shall develop an anchorage strength at least 85 per cent of the yield strength of the bar.

(v) Neither traffic nor construction equipment other than that associated with testing, saw-cutting, groove cleaning or joint sealing shall be allowed on the section of replaced concrete base until the joints have been permanently sealed and at least 10 days have elapsed since placing the replacement concrete base or it has reached a compressive strength of at least 20 MPa.

SC6.4.6.15.12 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.15.7 below:

Table SC6.4.6.15.7 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Aggregates** a. General	Mass of the total aggregates in concrete mix shall consist of at least 40% quartz sand	SC6.4.6.15.3(5)(a)
	b. Fine Aggregate (i) Grading	To be within the limits as per Table SC6.4.6.15.2 and shall not deviate from Proposed Grading by more than amounts in Table SC6.4.6.15.2	SC6.4.6.15.3(5)(b)

Item	Activity	Limits/Tolerances	Clause
	(ii) Wet Strength	Not less than 80kN for any fraction and/or constituent	SC6.4.6.15.3(5)(c)
	(iii) 10% Fines Wet/Dry Variation	Not to exceed 35% for any fraction and/or constituent	SC6.4.6.15.3(5)(c)
	(iv) Soundness	The loss in mass when tested with sodium sulphate to be less than 9% for any constituent	SC6.4.6.15.3(5)(c)
	(v) Particle Shape	The proportion of misshapen particles (2:1 ratio) to be less than 35%	SC6.4.6.15.3(5)(c)
	(vi) Fractured Faces	At least 80% by mass of the particles shall have two or more fractured faces	SC6.4.6.15.3(5)(c)
2.	**Concrete Quality** a. Cement Content	At least 270kg per yielded cubic metre of concrete	SC6.4.6.15.4(1)
	b. Flyash	Not greater than 50kg per yielded cubic metre of concrete	SC6.4.6.15.4(1)
	c.Compressive Strength	The minimum 28 day compressive strength shall be 36.0 Mpa	SC6.4.6.15.4(2)
	d. Shrinkage	Not to exceed 450 microstrain after 3 weeks of air drying	SC6.4.6.15.4(3)
	e. Consistency	Nominated slump shall be neither less than 30mm nor more than 40mm for mechanically placed concrete. It shall be neither less than 55mm nor more than 65mm for hand placed concrete.	SC6.4.6.15.4(4)
	f. Air content	Shall not be less than 4% nor more than 7% when discharged from the transport vehicle ready for placement	SC6.4.6.15.4(5)
3.	**Concrete Mixing and Transport**	After addition of cement to the aggregate, concrete shall be incorporated into the work within: (i) One and a half hours where transported by truck mixer or agitator. (ii) One hour where transported by non-agitating trucks.	SC6.4.6.15.6(2)
4.	**Concrete Placing**	Concrete shall not be placed when the air temperature in the shade is above 38ºC. The temperature of the concrete shall be neither less than 10ºC nor more than 32ºC.	SC6.4.6.15.7(1)
		Where the value of Rate of Evaporation exceeds 0.50kg per square metre per hour, the Contractor shall cease work.	SC6.4.6.15.7(2)
5.	**Alignment and Surface** a. Horizontal Alignment	The outer edges of the base shall not deviate from the plan position at any point by more than 10mm.	SC6.4.6.15.7(5)(a)

Item	Activity	Limits/Tolerances	Clause
	b. Surface Level	The level at any point on the top of the base shall not vary by more than +10mm or -0mm from that shown on the drawings or as directed by the superintendent. The top surface of the base shall not deviate from a 3m straight edge, laid in any direction, by more than 5mm.	SC6.4.6.15.7(5)(b)
6.	**Joints** a. Transverse Construction	The line of the transverse construction joints shall not deviate from a 3m straight edge placed along the joint by more than 10mm.	SC6.4.6.15.8(2)
	b. Transverse Contraction	(i) May be reduced locally to a skew of 1 in 12 to accommodate construction joints and slab anchors. (ii) No edge shall deviate from a 3m straight edge by more than 10mm. (iii) The surface of the transverse contraction joint shall not exhibit more than 5mm of vertical or horizontal edge ravelling. The length of edge ravelling shall not be more than 300mm in any 1m length of joint on each edge. (iv) Temporary sealing - the top of the sealant shall be neither higher than nor more than 10mm below the concrete surface. (v) Permanent Sealing The top of the sealant shall be neither less than 5mm nor more than 7mm below the surface of the base.	SC6.4.6.15.8(3)
	c. Transverse Isolation	The line of the transverse expansion joint shall not deviate from a 3m straight edge more than 10mm.	SC6.4.6.15.8(4)
	d. Longitudinal Tied Joints	(i) All parts of any tie bar shall be within 50mm of its designed position. (ii) The line of longitudinal tied joints shall not deviate from the designed position at any point by more than 10mm. The line shall also not deviate from a 3m straight edge by more than 10mm having made due allowance for any planned curvature. (iii) For sawn-induced joints, the maximum increase in length of the sealant after installation shall be 10% of the original length. The top of the sealant shall be neither less than 5mm nor more than 7mm below the surface of the base. (iv) For ribbon-induced joints, the inducer ribbon shall be a minimum of 0.5mm thick and when placed it shall be within 5 of the vertical plane.	SC6.4.6.15.8(5)

Item	Activity	Limits/Tolerances	Clause
	e. Longitudinal Isolation Joints	The line of the longitudinal isolation joint shall not deviate from the specified position by more than 10mm. The line of the joint shall not deviate from a 3m straight edge by more than 10mm.	SC6.4.6.15.8(7)
7.	**Slab Anchors**	Not placed closer than 2.0m to transverse joints (other than associated transverse expansion joints).	SC6.4.6.15.9(1)

SC6.4.6.16 Sprayed bituminous surfacing

SC6.4.6.16.1 Introduction

(1) Scope

This policy sub-section provides standards, advice and guidelines for the supply of all materials and the application of any or all of the following types of sprayed bituminous surfacing:

(a) prime
The application of a primer of field or refinery prepared cutback bitumen without aggregate to provide penetration of the surface (preferably from 5 to 10mm) and waterproofing;

(b) primerseal
The application of a primerbinder of field or refinery prepared cutback bitumen to provide surface penetration (preferably from 2mm to 5mm) and incorporation of a light cover of aggregate to provide a temporary wearing surface;

(c) seal or reseal
The application of a bituminous binder into which aggregate is incorporated to provide a durable wearing surface (including bitumen emulsion or polymer modified seals); and

(d) slurry surfacing
The application of a bituminous emulsion binder with or without polymer modifier and with or without continuous aggregate, mineral fillers, additives and water, properly proportioned to enrich the binder content and refresh the existing wearing course material. This is a preventive maintenance treatment and shall not be used in new construction.

The locations and required types of sprayed bituminous surfacings, including types of binders and aggregate sizes, shall be as shown on the construction drawings and/or as detailed in SC6.4.6.16 Attachment A Details of work.

For multiple application treatments, the binder and aggregate may be required to be laid in one or more separate applications indicated in SC6.4.6.16 Attachment B.

Requirements for adhesion agent in the bitumen and tolerances for binder application rates are set out in SC6.4.6.16 Attachment B Binder details.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note - A reference to drawings is a reference to construction drawings.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-section:
SC6.4.6.30 - Control of traffic

(b) Australian Standards:
AS 1160 - *Bituminous emulsions for the construction and maintenance of pavements*
AS 2008 - *Residual bitumen for pavements*
AS 2157 - *Cutback bitumen*
AS 2758.2 - *Aggregate for sprayed bituminous surfacing*
AS 3568 - *Oils for reducing the viscosity of residual bitumen for pavements*

(c) Queensland Department of Transport and Main Roads Technical Standards:
MRTS11 - *Sprayed Bituminous Surfacing (excluding Emulsion)*
MRTS12 - *Sprayed Bituminous Emulsion Surfacing*
MRTS13 - Bituminous Slurry Surfacing
MRTS17 - *Bitumen*

MRTS18 - *Polymer Modified Binder*
MRTS19 - *Cutter and Flux Oils*
MRTS20 - *Cutback Bitumen*
MRTS21 - *Bituminous Emulsion*
MRTS22 - *Supply of Cover Aggregate*

(d) Queensland state legislation:
Fire and Rescue Service Act 1990

(e) Other:
Austroads, *Guide to Pavement Technology Part 4K: Seals*
Austroads, *Bituminous Materials Sealing Safety Guide*

(3) Control of traffic
The Contractor shall provide for the control of traffic in accordance with the requirements of policy sub-section SC6.4.6.30 Control of traffic while undertaking the work and shall take all necessary precautions to protect the work from damage until such time as the new seal coat has developed sufficient strength to carry normal traffic without disturbance of the aggregate.

Where early use of the new seal is required to facilitate the movement of traffic, vehicles may be allowed to run on the work after initial rolling has taken place provided that vehicles are controlled to such slow speeds that no lateral displacement of aggregate occurs. Where necessary, the Contractor shall use patrol vehicles to ensure that traffic travels at an acceptable speed.

The Contractor shall take all necessary steps to avoid or minimise delays and inconvenience to road users during the course of the work. Where adequate detours or side tracks are included in the Contract or are otherwise available, traffic shall be temporarily diverted while the work is in progress.

If facilities for the diversion of traffic are not available, the Contractor may spray part width of the pavement in the one operation and make available to traffic the adjacent strip of roadway, except during the actual spraying operation when all traffic movement through the work shall cease. Traffic shall not be permitted to encroach upon the edge of the sprayed bituminous material until such time as it is covered with aggregate.

SC6.4.6.16.2 Materials

(1) Sampling and testing of materials
Sampling and testing of materials shall be arranged by the Contractor and carried out by a laboratory with appropriate NATA registration in accordance with the requirements of the relevant Queensland Department of Transport and Main Roads (DTMR) Specification.

(2) Bituminous materials and additives
Bituminous materials shall be in accordance with the relevant DTMR Specifications.

(3) Bitumen adhesion agent

(a) Bitumen adhesion agents.
Adhesion agents must conform to the following requirements:

(i) adhesion agent is to be added to bitumen at the rate of 5kg for every 1,000 Litres of bitumen CL170 and 10kg for every 1,000 litres of polymer modified bitumen; and

(ii) adhesion agents approved for use are Diamintol, or Bitumite EXP3995 if Diamintol is unavailable.

(4) Oils for reducing viscosity of bitumen
Cutter Oil shall conform to MRTS 19.

Delivery and storage procedures for cutter oil delivered in drums or in bulk shall ensure that all containers are free from any deleterious material prior to filling with cutter oil, and all drums are stored to ensure that entry of water through seals or welds in the drums is prevented.

(5) Aggregate

Aggregate shall conform to MRS22.

The Contractor shall obtain test results for each lot/stockpile of aggregate and certification of compliance from a laboratory with appropriate NATA accreditation, before aggregate from the lot is incorporated in the works.

SC6.4.6.16.3 Design of bituminous surfacing

(1) Before commencing sprayed bituminous surfacing work, the Superintendent will confirm the approved details of the proposed bituminous surfacing design for the work. Additional details are required to be submitted to the Superintendent prior to carrying out the work for check with the proposed bituminous surfacing design. These additional details include:

(a) test results for all nominated materials;

(b) aggregates source, geological type, nominated grading, average least dimension (ALD);

(c) pre-coating agent and bitumen adhesion agent types, proportions and manufacturer (if applicable);

(d) bitumen refinery source and certification of compliance;

(e) cutback bitumen refinery source of bitumen, type of cutter, source of cutter, cutter oil fraction, certification of compliance;

(f) polymer modified bitumen – refinery source of bitumen and manufacturer, class of polymer and fraction, certificate of compliance; and

(g) bitumen emulsion – refinery source of bitumen and manufacturer, grade of emulsion, certificate of compliance.

Design rates of application of binder and aggregate for bituminous surfacing shall be in accordance with *Guide to Pavement Technology Part 4K: Seals*. Design application rates shall be known as “nominated application rates” and materials as “nominated materials”.

SC6.4.6.16.4 Pre-coating of aggregate general

The aggregate pre-coating agent shall be applied to the aggregate in a manner and at a rate and time which will provide a complete, light, uniform, effective cover of all aggregate particles at the time of spreading.

Pre-coating of aggregate shall not be carried out when rain is imminent. If aggregate has been pre-coated and rain appears imminent, the aggregate shall be adequately covered to prevent the pre-coating material being washed from the aggregate particles.

The Contractor shall take precautions, such as covering stockpiles, to prevent settlement of dust, penetration of moisture or drying out of the pre-coating agent on the stockpiled aggregate.

Stockpiles pre-coated more than 14 days in advance of use shall be retreated unless otherwise approved by the Superintendent and shall not be used if less than 3 days old.

SC6.4.6.16.5 Application of sprayed bituminous surfacing

(1) General

The Contractor shall carry out sprayed bituminous surfacing to:

(a) provide a uniform application of binder with adequate adhesion to the underlying surface;

(b) provide a complete cover of interlocking aggregate particles; and

(c) achieve effective bond between binder and aggregate.

Details of equipment and methods to be used for sprayed bituminous surfacing shall be submitted to the Superintendent for approval prior to their use on the works.

(2) Plant

A mechanical sprayer shall be used to apply primer, primerbinder and binder. The sprayer shall have a current Sprayer Certificate issued by the Queensland Department of Transport and Main Roads.

The spray nozzles shall be of the make and type endorsed on the Sprayer Certificate. Any nozzles which may be damaged or become unduly worn or defective shall be replaced by satisfactory nozzles of similar type. A sufficient number of nozzles for this purpose shall be available at all times.

Mechanical spreading equipment shall be used to spread aggregate and shall be capable of achieving a uniform and accurate spreading rate.

Rollers shall be utilised in accordance with Clause SC6.4.6.16.4(9) Application and rolling of aggregate.

The Contractor shall remove from the site any plant or equipment considered by the Superintendent to be not fully operational or not in a satisfactory condition for carrying out work in accordance with this sub-section.

(3) Preparation of pavement surface

Before the application of primer, primerbinder or binder, the pavement surface shall be swept by the use of a mechanically operated rotary road broom or suction broom to provide a uniformly clean surface. If necessary, additional sweeping shall be done by hand, using stiff brooms. Sweeping shall, where possible, extend at least 300mm beyond each edge of the area to be sprayed.

Adherent patches of foreign material shall be removed from the surface of the pavement.

For the spraying of primer or primerbinder, the pavement surface shall be slightly damp to impede dust interfering with initial adhesion except where explicit instructions are provided with the seal design.

(4) Surface defects must be repaired prior to laying the wearing course. This may include crack filling, pothole repairs and repair of failed pavements.

Rut-filling and corrector must be applied where necessary to rectify any ruts and uneven surfaces prior to placing the wearing course.

Review of nominated application rates

The Contractor shall select the locations where each lot of aggregate is to be incorporated in the works.

The Superintendent shall review the bituminous surfacing design at each location based on the actual average least dimension (ALD) test result for the lot of aggregate instead of the nominated ALD value of the aggregate adopted at design. Due consideration must also be given to the surface texture of the prepared pavement surface and the likely degree of stone embedment, to establish if any additional minor adjustments to bitumen spray rates should be applied. The revised application rates shall be known as "target application rates".

The Contractor shall give the Superintendent notice of the Contractor's intention to commence sprayed bituminous surfacing. This notice shall confirm spray rates, aggregate size and ALD.

(5) Bitumen temperature requirements

Bitumen temperature requirements are as per MRTS 17, 18, 19, 20 and 21.

Table SC6.4.6.16.2 Cutback bitumen spraying temperatures

Grade	Temperature Range (ºC)
AMC 00	10 - 35
AMC 0	35 - 55
AMC 1	60 - 80
AMC 2	75 - 100
AMC 3	95 - 115
AMC 4	110 - 135
AMC 5	120 - 150
AMC 6	135 - 160
AMC 7	150 - 175

(6) Pavement temperature and weather conditions

The Contractor shall measure and record pavement temperatures at regular intervals during the course of the work. For this purpose, a spirit or mercury in glass thermometer or other suitable type of thermometer shall be placed in direct contact with the pavement and allowed to remain in position until the reading becomes steady. When a spirit or mercury in glass thermometer is used to measure pavement temperature, the bulb of the thermometer shall be covered from direct sunlight with a small heap of grit or similar material. Suitably calibrated infra-red thermometers may be used.

If the pavement is partly in sun and partly in shade, the temperatures for both conditions shall be taken and recorded.

Spraying primers, primerbinders and binders shall be undertaken only if the pavement temperature has been at or above 20ºC, 25ºC for PMB, 10ºC for emulsion for spraying for at least one hour before commencement of spraying and does not fall below 20ºC, 25ºC for PMB, 10ºC for emulsion for spraying during the period of spraying.

Spraying shall not be carried out on a wet pavement, while rain appears imminent or during high winds or dust storms.

(7) Incorporation of cutter oil, flux oil and adhesion agent

(a) Cutting back bitumen

The Contractor shall determine and record the proportion of cutter oil added to each sprayer load, using MRTS11 and based on the measured pavement temperatures.
The cutter oil, without being previously heated, shall be pumped into the sprayer, followed by the hot bitumen. The full sprayer load of cutback bitumen shall be circulated at a rate of at least 700 litres per minute for 20 minutes to ensure that the mixture is homogeneous.

If a part sprayer load of field cutback bitumen is unused on the date of mixing, and needs to be returned to the heater tanks, it shall be placed in an empty tank reserved for that purpose. No bitumen or cutter shall be added to the returned cutback bitumen unless the tank is fitted with an effective mechanical mixing system. When the returned cutback bitumen is subsequently used as part of a sprayer load, allowance shall be made for the cutter oil contained in the returned cutback bitumen.

(b) Fluxing bitumen

Where flux oil is to be included, it shall be added to the bitumen in the sprayer and the mixture circulated at a rate of at least 700 litres per minute for at least 20 minutes before spraying.

(c) Bitumen adhesion agent

Where bitumen adhesion agent is to be included, it shall be added to the bitumen in the sprayer and the mixture circulated twice at a rate of at least 1,000 litres per minute for at least twenty minutes before spraying. Spraying shall occur within 4 hours.

(8) Application of primer, primerbinder and binder

(a) General
The area to be sprayed with primerbinder or binder shall be limited to the area which can be covered with aggregate at the target application rate within ten minutes of spraying bitumen or cutback bitumen.

(b) Primer and primerbinder
Nominated and target application rates and quantities of primer and primerbinder shall apply to the whole material, including cutter oil, measured at 15ºC. Primer, Primerbinder and Binder application rates outside the tolerances indicated in SC6.4.6.16 Attachment B Binder details constitute a non-conformance.
After application of a primer, a period of at least forty eight hours, or such longer period as determined to be necessary for the primer to become completely dry, shall elapse before the binder for a seal is applied. All traffic shall be kept off the primed surface.

After application of a primerbinder, a period of at least fourteen days shall elapse before the binder for a seal is applied.

(c) Binder
The class of bitumen or grade of cutback bitumen shall be as specified in SC6.4.6.16 Attachment A Details of work.

Nominated and target application rates and quantities of binder shall be based on the volumes of bitumen measured at a temperature of 15ºC and shall not include any bitumen adhesion agent and/or cutter oil. If flux oil has been added to the bitumen, the quantity of flux oil shall be included as part of the binder. Binder application rates outside the tolerances provided in SC6.4.6.16 Attachment B Binder details shall constitute a non conformance.

Where bitumen adhesion agent and/or cutter oil have been added to the binder, the application rate of the total binder at 15ºC shall be adjusted to allow for the quantities of bitumen adhesion agent and/or cutter oil in the mixture.

The Contractor shall determine the hot application rate of total binder, including bitumen adhesion agent and/or cutter oil, using MRTS11.

Where refinery cutback bitumen is used as the binder, the target application rate of binder shall be increased by the Contractor to allow for the cutter oil in the mixture.

(d) Operation of the sprayer
Where the longitudinal edges of spray runs are not required to overlap, special type end nozzles must be used. Where an overlap is required, the overlap of spray between adjacent longitudinal runs shall be in the range 50-100mm for special type end nozzles. If intermediate nozzles are to be used to overlap adjacent longitudinal sprays the nozzles shall be set in the normal manner for intermediate nozzles and the overlap shall be in the range 250-350mm.

The spraying of primer, primerbinder or binder for each run of the sprayer shall commence on a protective strip of heavy paper weighing not less than 120g per square metre laid across and held securely to the pavement surface beforehand by addition of cover aggregate. The sprayer shall commence moving at a sufficient distance in advance of the protective strip to ensure that the road speed for correct application and correct alignment is attained at the commencement of spraying.

The sprayer shall maintain a uniform rate of application throughout the length of each sprayer run.

The spraying for each run shall terminate on a protective strip of paper laid across and held securely to the pavement surface beforehand. The width of paper at the commencement and/or termination of each run shall not be less than that endorsed on the Sprayer Certificate.
Spraying shall cease immediately if any defect develops in the spraying equipment and spraying shall not recommence until the fault has been rectified.

Where any blockage or partial blockage of nozzles occurs, spraying shall cease immediately. If the blockage is due to the condition of the binder being sprayed and is likely to re-occur, that load together with any binder from the same bulk tanker or supply unit shall not be used in the works.

Where a mechanical sprayer is not able to satisfactorily spray small areas or areas of irregular shape, such areas shall be sprayed by means of the hand spray equipment attached to the sprayer. The work shall be planned to minimise the area sprayed by hand spray equipment.

After each sprayer run, the quantity of binder sprayed shall be checked against the area covered and any necessary adjustments shall be made to ensure that the target application rate is achieved in subsequent runs. If the actual application rate of binder after three runs differs by more than 5% from the target application rate, the sprayer shall not be used until a new Sprayer Certificate has been obtained.

Areas not within 5% of the target application rate of primer, primerbinder or binder shall constitute a “non-conformance”.

(9) Application and rolling of aggregate

The application of aggregate shall proceed immediately after spraying is commenced and shall be completed within ten minutes of spraying bitumen or cutback bitumen. For polymer modified binder spreading and rolling shall start immediately after spraying and continue until adhesion is complete.
Wet aggregate shall not be used.

The Contractor shall apply the aggregate of the specified nominal size and at the target aggregate application rate. Sufficient loaded and measured trucks of dry aggregate shall be at the site to provide full cover for the area sprayed.
The aggregate shall be spread uniformly over the sprayed surface by means of suitable mechanical spreading equipment.

Any bare or insufficiently covered areas shall be re run by the mechanical spreader or covered by hand as necessary to give a uniform and complete coverage. Any aggregate spread in excess of the target aggregate application rate shall be removed before rolling is commenced if it is localised and can be efficiently removed by hand brooming.
After the aggregate has been applied to each section of the work, initial rolling shall be carried out with two or more dual axle smooth pneumatic tyred multi wheel rollers of minimum load of 1t per tyre and minimum tyre pressure of 550 kPa. A roller with a rubber surface drum providing equivalent compactive effort may be used in lieu of a multi-wheeled roller. Initial rolling shall continue until the aggregate is firmly embedded in the primerbinder or binder. Roller speed shall be 15-25 km/h subject to safe working conditions.

If the aggregate is not evenly distributed over the surface of the pavement, the surface shall be traversed with a light drag broom after the initial rolling. If the broom has any tendency to dislodge aggregate particles bedded in the primerbinder or binder, the Contractor shall defer or eliminate the drag brooming. Where drag brooming is eliminated, the Contractor shall substitute light hand brooming.

Backrolling shall then be carried out for a minimum period of 1 hour per 1,000 square metres sprayed for roads having a traffic volume of less than 500 vehicles per lane per day and 1 hour per 1,500 square metres sprayed for other roads, up to a maximum of 24 hours after the aggregate has been applied.

Where a bituminous surfacing is specified with separate applications of coarse and fine aggregate on a single application of binder, the coarse aggregate shall be applied first, rolled and any necessary brooming carried out as described above, before application of the fine aggregate and its subsequent rolling and brooming. In this case, the time limits for incorporation of aggregate shall apply only to the application of the coarse aggregate.

After final sweeping, and prior to removal of speed restriction and warning signs, the number of loose aggregate particles remaining on the surface of seals constructed with 10mm, or larger, aggregates not to exceed the values specified in Table SC6.4.6.16.3.

Table SC6.4.6.16.3 Maximum loose aggregate particles

Road type	Loose stones (particles/m²) max
Urban areas	20
Other medium to high traffic (> 250v/l/d)	30
Low traffic (< 250v/l/d)	40

Any remaining loose particles of aggregate shall be removed by light sweeping and/or vacuumed from the pavement and disposed of responsibly by the Contractor as per Table SC6.4.6.16.4 below or as directed to by the Superintendent.

Table SC6.4.6.16.4 Maximum time limits for sweeping or vacuuming

Traffic volume (vehicles/lane/day)	Maximum time limits
> 2,000	Within 8 hours of sealing
1,000 to 2,000	Within 24 hours of sealing
250 to 1,000	Within 48 hours of sealing
< 250	Within 5 days of sealing

Prior to leaving the work site, ensure that all services are uncovered and cleaned, if necessary. Remove from site all waste paper and rubbish arising from the sprayed sealing operations. Clean the stockpile site and store any excess material in a tidy heap or remove, depending on the requirements of the Superintendent.

(10) Work records

Particulars of the work performed shall be recorded by the Contractor on a spray record sheet. Details of primer, primerbinder, binder and aggregate applied shall be recorded immediately after every sprayer run. Each form shall be signed by the Contractor's representative as a true record of the work performed. The Contractor shall supply to the Superintendent a copy of each completed form.

(11) Protection

(a) New work

Protect the new work by providing warning signs as follows:

(i) provide signs to warn public of loose stones and absence of line marking including provision of temporary raised pavement markers;

(ii) maintain signs until loose aggregate has been removed and linemarking reinstated; and

(iii) if linemarking is to be undertaken by others, erect warning signs indicating the absence of linemarking to be maintained by the organisation responsible for linemarking.

(b) Services and road fixtures

The Contractor shall take all necessary precautions to prevent primer, primerbinder, binder, aggregate or other material used on the work from entering or adhering to gratings, hydrants or valve boxes, access chamber covers, bridge or culvert decks and other road fixtures.

Immediately after aggregate has been spread over the binder, the Contractor shall clean off or remove any sprayed surfacing material and leave the services and road fixtures in a condition equivalent to that existing when the Contractor commenced the sprayed surfacing work.

SC6.4.6.16.6 Nonconformance of materials and work

If any materials supplied or any section of sprayed bituminous surfacing work fail to conform to the requirements whether failure of the work is due to bad workmanship, defective materials supplied by the Contractor or materials made defective by the method of operation adopted, or any other cause then such failure or failures shall constitute a “non-conformance”.

The nonconforming section of sprayed bituminous surfacing work shall be either replaced or corrected as proposed by the Contractor, subject to the approval being obtained.

The rectified nonconformances, including any restoration work to any underlying or adjacent surface or structure,

which becomes necessary as a result of such replacement or correction, shall be the responsibility of the Contractor. Materials removed from the site by the Contractor shall be replaced with materials which conform to this sub-section.

SC6.4.6.16.7 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.16.5 below.

Table SC6.4.6.16.5 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Design of Bituminous Surfacing**	Contractor to provide details of design to Superintendent before proposed commencement of work.	SC6.4.6.16.3
2.	**Commencement of Work**	Contractor to give notice to the Superintendent of intention to commence work.	SC6.4.6.16.5(1)
3.	**Sweeping of Pavement Surface**	Sweeping shall extend at least 300mm beyond each edge of the area to be sprayed.	SC6.4.6.16.5(3)
4.	**Bitumen Heating** (a) Bitumen Temperature	When incorporated with cutter oil, bitumen shall be in temperature ranges as per MRTS.17 and 18 (06/09).	SC6.4.6.16.5(5)
	(b) Refinery Cutback Bitumen Temperature	At the time of spraying shall be in temperature range as per MRTS 20 (06/09).	SC6.4.6.16.5(5)
	(c) Retention of Temperature	Bituminous materials shall not be held at temperatures within the ranges of MRTS17,18 and 20 for periods in excess of 10 hours.	SC6.4.6.16.5(5)
5.	**Spraying Temperature** (a) Pavement Temperature	Bituminous surfacing shall not be undertaken if the pavement temperature has not been at or above 20°C, 25°C for PMB, 10°C for emulsion for at least one hour before commencement of spraying or if the pavement temperature falls below 20°C, 25°C for PMB, 10°C for emulsion during the period of spraying.	SC6.4.6.16.5(6)
6.	Cutting Back Bitumen	Circulation of hot bitumen and cutter oil mixture in the sprayer shall be at the rate of at least 700 litres per minute for 20 minutes.	SC6.4.6.16.5(7)
7.	Fluxing Bitumen or adding Bituminous Adhesion Agent	Circulation of fluxing oil or bituminous adhesion agent with hot bitumen shall be at the rate of at least 1,000 litres per minute for 20 minutes. Spraying to occur within 4 hours.	SC6.4.6.16.5(7)
8.	**Application of Bituminous Material** (a) Spray Area	Area to be sprayed shall be limited to area which can be covered by aggregate at target application rate within 10 minutes of spraying.	SC6.4.6.16.5(8)
	(b) Application Rates	Application rates and quantities shall apply to a temperature of 15ºC and have T1 tolerances of ±5% as set out in clause SC6.4.6.16.6 and T2 tolerances as set out in SC6.4.6.16 Attachment B.	SC6.4.6.16.5(8)
	(c) Primer	At least a 48 hour period shall elapse after spraying of primer before binder for a seal is applied.	SC6.4.6.16.5(8)
	(d) Primerbinder	At least a 14 day period shall elapse after spraying of primerbinder before application of binder.	SC6.4.6.16.5(8)

Item	Activity	Limits/Tolerances	Clause
9.	**Application of Aggregate** (a) Spreading Time	Application of aggregate shall be completed within 10 minutes of spraying bitumen or cutback bitumen on each section.	SC6.4.6.16.5(9)
10.	**Rolling** (a) Roller Numbers and Type	Initial rolling shall be carried out with two or more dual axle smooth pneumatic tyred multi-wheeled rollers. Minimum load of 1t per tyre and minimum tyre pressure 550KPa.	SC6.4.6.16.5(9)
	(b) Backrolling	(i) For traffic volume of <500 vehicles per lane per day, backrolling for minimum of one hour per 1,000 square metres sprayed.	SC6.4.6.16.5(9)
		(ii) For traffic volume >500 vehicles per lane per day, backrolling for minimum of one hour per 1,500 square metres sprayed.	SC6.4.6.16.5(9)

SC6.4.6.16 Attachment A: Details of work

Section Road Name From To	Prime Binder Type	Primer Seal		Seal or Reseal	
		Binder Type	Aggregate Nom. Size	Binder Type	Aggregate Nom. Size

Note —prime and primer seal binder type shall be indicated in this Attachment using the descriptive terms as follows:

Very Light Prime or Primer - equivalent cut back bitumen to grade AMCOO.
Light/Medium Prime or Primer - equivalent cutback bitumen to grade AMCO or AMC1.
Heavy Prime or Primer - equivalent cut back bitumen to grade AMC1 or AMC2.

SC6.4.6.17 Bituminous micro-surfacing

SC6.4.6.17.1 Introduction

(1) Scope

The work to be executed under this sub-section consists of the design, supply, mixing and placement of bituminous microsurfacing for surface correction and wearing surface applications on road pavements, carparks, cycleways and footpaths; or as a preventative maintenance treatment on roads with the objective of enriching the existing wearing course. The treatment must not be used in new road construction.

Bituminous microsurfacing must consist of a mixture of emulsified polymer modified bitumen binder, mineral aggregate, mineral filler, additives and water proportioned and mixed to form a slurry which is placed and spread evenly on the road surface. It must be capable of being spread in variably thick layers for surface correction and for wearing surface applications.

The size, nominal thickness, and extent of bituminous microsurfacing must be as shown on the drawings or as directed by the Superintendent.

For all new works on road and carpark pavements, this sub-section should be read in conjunction with sub-section SC6.4.6.16 Sprayed bitumen surfacing. For new works on road and carpark pavements, bituminous mircrosurfacing must be preceded by the application of a sprayed bituminous seal a minimum of 2 weeks prior to the application of the bituminous microsurfacing wearing course.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Terminology

Users of this specification should be aware that where terms are not specifically defined in the following section, AS1348 should be the default standard.

Bituminous microsurfacing	Is one of two types of bituminous slurry surfacing. It is distinguished from the other type, slurry seals, by the incorporation of polymer and other additives to the bituminous binder to improve the performance of the slurry surfacing. Bituminous microsurfacing is also commonly known under various proprietary names such as “cold overlay”, “microsealing”, “paveseal”, “microasphalt”, etc. The size of the bituminous microsurfacing is based on the nominal largest stone size in the mix. For the purpose of this sub-section, the size must be either Size 5 or Size 7.

(3) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy subsections to be read and applied in conjunction with this subsection are as follows:

SC6.4.6.16 Sprayed bitumen surfacing

SC6.4.5 Construction management

(b) Australian Standards:

AS1141.11.1	*Particle size distribution – Sieving method*
AS1141.12	*Material finer than 75 micrometre in aggregates (by washing)*
AS1141.22	*Wet/dry strength variation*
AS1141.23	*Los Angeles value*
AS1141.25.1	*Methods for sampling and testing aggregates - Degradation factor - Source rock*
AS1141.25.2	*Methods for sampling and testing aggregates - Degradation factor - Coarse aggregate*
AS1141.25.3	*Methods for sampling and testing aggregates - Degradation factor - Fine aggregate*

AS1141.42	*Pendulum friction test*
AS1160	*Bitumen emulsions for the construction and maintenance of pavements*
AS1289.3.7.1	*Determination of the sand equivalent of a soil using a power-operated shaker*
AS1348	*Glossary of terms - Roads and traffic engineering*
AS2008	*Residual bitumen for pavements*
AS2350	*Methods of testing Portland and blended cements*
AS2891.3.1	*Binder content and aggregate grading - Reflux method*

(c) International Slurry Surfacing Association Tests:
ISSA TB 100 - *Test method for wet track abrasion of slurry surfaces*
ISSA TB 109 - *Test Method for Measurement of Excess Asphalt in Bituminous Mixtures by Use of a Loaded Wheel Tester*
ISSA TB 114 - *Wet stripping test for cured slurry seal mixes*
ISSA TB 139 - *Method of classified emulsified asphalt/aggregate mixtures by modified cohesion test measurement of set and cure characteristics*
ISSA TB 144 - *Classification compatibility by Schulze-Breuer and ruck procedure*

SC6.4.6.17.2 Materials

(1) Sampling and testing of materials
Sampling and testing of materials must be arranged by the Contractor and carried out by a NATA registered laboratory for the nominated test methods.

(2) Binder
The binder supplied and used in the works must be an emulsified polymer modified bitumen, formulated to meet the performance requirements of the mix specified in clauses SC6.4.6.17.3(1) Mix properties and SC6.4.6.17.4(6) Surface texture.

Prior to emulsification, incorporation of polymer and additives, the bitumen must comply with AS2008.

The Contractor must provide the Superintendent with sufficient information to verify that the binder supplied is the same as that nominated in the mix design.

(3) Mineral aggregates
Mineral aggregates must consist of crushed rock or crushed gravel, or a mixture of crushed rock or crushed gravel and natural sand. It must consist of clean, hard, angular, durable particles, and free form clay, dirt, organic material or other deleterious matter.

The aggregate from each source must comply with the requirements given in Table SC6.4.6.17.1 Aggregate properties.

Table SC6.4.6.17.1 Aggregate properties

Property	Test Method	Requirement
Degradation Factor	AS1141. 25.1	50 minimum
Los Angeles Value	AS1141.23	30 maximum
Aggregate Wet Strength	AS1141.22	150kN minimum
Wet/Dry Strength Variation	AS1141.22	30% maximum
Polished Aggregate Friction Value	AS1141.42	45 minimum
Sand Equivalent	AS1289.3.7.1	60 minimum

When tested in accordance with AS1141.11 and AS1141.12, the aggregate (including mineral filler) must conform with the grading limits given in Table SC6.4.6.17.2 Grading limits for combined aggregate/filler.

Table SC6.4.6.17.2 Grading limits for combined aggregate/filler

Sieve Size	Percent Passing by Mass	
	Size 5	Size 7
13.2mm	100	100
9.5mm	100	100
6.7mm	100	85-100
4.75mm	90-100	70-90
2.36mm	50-70	45-70
1.18mm	30-50	28-50
600µm	20-35	19-34
300µm	12-25	12-25
150µm	7-18	7-18
75µm	4-10	5-15

The Contractor must nominate the source/s of aggregates to the Superintendent, and must submit NATA certified test reports on the quality and grading of the combined aggregate proposed to be used.

The Contractor must submit test results to the Superintendent for each lot/stockpile of aggregate a minimum of seven days prior to incorporation in the works.

(4) Mineral filler

Mineral filler must consist of hydrated lime, flyash, portland cement, or other material approved by the Superintendent.

The mineral filler must be dry, free from lumps and any deleterious material, with a minimum of 85% passing a 75µm sieve. In all other respects, the mineral filler must comply with the requirements of AS2350.

The quantity of filler added to the bituminous microsurfacing during placement must not vary by more than 1% of the total aggregate (by mass) from the filler content nominated in the mix design.

(5) Water

Water added to the bituminous microsurfacing must be potable and must be compatible with the component materials.

(6) Additives

Details of the type, source and nominal proportions of additives must be submitted to the Superintendent with the mix design.

SC6.4.6.17.3 Mix design

(1) Mix properties

The nominated mix design must satisfy the properties given in Table SC6.4.6.17.3 Mix properties.

Table SC6.4.6.17.3 Mix properties

Mix Property	Test Method	Requirement
Wear Loss	ISSA TB 100 6 day	800 g/m^2 maximum
Traffic Time	ISSA TB 139 30 minutes 60 minutes	12kg.cm minimum 20kg.cm minimum
Adhesion	ISSA TB 114 or ISSA TB 144	≥90% or 11 grade points minimum (AAA, BAA)

(2) Nominated mix

At least 7 days before commencing bituminous microsurfacing work, the Contractor must submit to the Superintendent for approval, details of the nominated bituminous mircrosurfacing mix design for the work including the target application rate (m^3 of mix/m^2 of road surface) and the corresponding nominal layer thickness, together with NATA certification and test results demonstrating that the nominated mix and its constituents meet the requirements of the specification.

The details of the nominated mix design must include the following:

(a) bitumen emulsion content of the mix, and the residual binder content of the emulsion;

(b) target combined aggregate/filler grading;

(c) proportions of constituent materials used;

(d) type and sources of aggregates, filler and binder; and

(e) all relevant compliance certificates.

(3) Approved mix

When a nominated mix has been approved by the Superintendent, it must be known as the “approved mix”. Work must not commence until a bituminous microsurfacing mix has been approved.

The combined aggregate/filler grading and the binder content of the approved mix will be termed the "approved grading" and the "approved binder content" respectively.

Any changes to the approved mix, its method of production or source of supply of constituents require written approval 21 days prior to proposed implementation.

SC6.4.6.17.4 Production and paving

(1) Requirements of production mix

Bituminous microsurfacing produced in the paving unit at the site must be known as the "production mix".

The production mix must comply with the requirements given in Table SC6.4.6.17.4 Maximum permitted variations from approved mix and must be confirmed by the Contractor as required in SC6.4.6.17.4(2) Sampling and testing of production mix.

The Contractor is responsible for taking samples for testing at a NATA registered laboratory to confirm compliance with Table SC6.4.6.17.4.

Table SC6.4.6.17.4 Maximum permitted variations from approved mix

Production Mix Properties	Maximum Permitted Variations from Approved Mix (by mass)	
	Size 5	Size 7
Grading*	Nil	Nil
Passing 9.50mm AS sieve and larger	Nil	± 7%
Passing 6.70mm	± 6%	± 6%
Passing 4.75mm	± 5%	± 5%
Passing 2.36mm and 1.18mm	± 4%	± 4%
Passing 0.600mm	± 3%	± 3%
Passing 0.300mm	± 2%	± 2%
Passing 0.150mm	± 1.5%	± 1.5%
Passing 0.075mm		
Residual Binder Content	- 0.5% + 1.0%	- 0.5% + 1.0%

Note—*these allowable variations must not fall outside the limits for design of nominated mix as given in Table SC6.4.6.17.2 Grading limits for combined aggregate/filler.

(2) Sampling and testing of production mix

(a) Lot definition

Compliance sampling and testing of bituminous microsurfacing must be undertaken on a lot by lot basis. For this purpose, 50m^3 or one day's production (whichever is the lesser), or such smaller quantity which is considered as representative of consistent production of the paving unit, will be considered as representative of consistent production of the paving unit.

(b) Responsibility of sampling

The Contractor is responsible for taking samples and must supply all facilities, equipment and labour for that purpose.

(c) Frequency of Sampling

For the testing of production mix, two 1.5kg representative samples of bituminous microsurfacing mustbe taken from each lot at random intervals. The samples must be taken from the discharge of the paving unit and the sample containers immediately sealed.

For the testing of the binder, two 2L samples of bitumen emulsion must be taken from each bulk delivery in accordance with AS1160.

(d) Testing

The samples of bituminous microsurfacing must be treated and tested at a NATA registered laboratory to confirm compliance with Table SC6.4.6.17.4 Maximum permitted variations from approved mix. Prior to testing for Residual Binder Content and Aggregate Gradation, as determined by AS2891.3.1, the samples must be dried to constant weight in an oven at 60ºC for a minimum of 15 hours.

Each delivery of emulsion must be tested for residual binder content in accordance with AS1160 Appendix D and accompanied by a certification of specification compliance traceable to the relevant batch at the supplier's storage tank.

The paving unit to be used must be calibrated for the component materials of the approved mix prior to the commencement of paving. Previous calibration documentation covering the same materials and approved mix must be acceptable provided that calibration has been carried out within the previous 12 months.

The documentation must include an individual calibration for each component material at various settings which can be related to the paving unit's metering devices.

No paving unit must be allowed on the work until the calibration has been verified and approved by the Superintendent.

(3) Preparation of pavement

The existing surface must be clean and free from any loose stones, dirt, dust and foreign matter. The surface must be swept beyond the edge of the area to be surfaced by at least 300mm. Any foreign matter adhering to the pavement and not swept off must be removed by other means. Any areas significantly affected by oil contamination must be cleaned to the satisfaction of the Superintendent.

The Contractor must take all necessary precautions to prevent the bituminous microsurfacing or other materials used on the work from entering or adhering to kerbs, gutters, driveways, gratings, hydrants, valve boxes, access chamber covers, bridge or culvert decks or other road fixtures. After the bituminous microsurfacing has been spread the Contractor must clean off any such material and leave such gratings, access chamber covers and other road fixtures, in a clean and satisfactory condition.

(4) Weather limitations

Bituminous microsurfacing must not commence if either the pavement or air temperature is below 10ºC and falling.

Bituminous slurry may be applied when both pavement and air temperatures are above 7ºC and rising, or above 10ºC.

Spreading must not proceed during rain or when rain appears imminent.

The Superintendent must require cease of works, if weather conditions are not appropriate.

(5) Spreading

The surface may be pre-dampened if necessary by fogging ahead of the spreader box. Water used for pre-wetting the surface must be applied so that the entire surface is damp with no apparent flowing water ahead of the spreader box. The application rate of the fog spray must be adjusted to suit temperature, surface texture, humidity and dryness of the surface being covered.

Bituminous microsurfacing must be mixed and applied using a purpose built paver. The mix must be of the desired consistency when deposited in the spreader box, and nothing more may be added other than minor amounts of water for the purpose of overcoming temporary build-up of microsurfacing in the corners of the spreader box.

The mixing time must be sufficient to produce a complete and uniform coating of the aggregate and the resulting mixture must be conveyed into the moving spreader box at a sufficient rate to always maintain an ample supply across the full width of the strike-off.

The strike-off must be adjusted to provide an application rate which will completely fill the surface voids and provide the nominal application rate of bituminous microsurfacing as scheduled.

After the bituminous microsurfacing has been spread, the Contractor must ensure that all kerbs, gutters, driveways, gratings, hydrants, valve boxes, access chamber covers, etc. are uncovered and left in a clean and satisfactory condition.

After the emulsion has broken and the mix is sufficiently stable, rolling must be carried out using pneumatic tyred rollers to produce a dense, even, homogeneous compacted surface where there is insufficient local traffic to achieve satisfactory compaction across the mat.

Bituminous microsurfacing must be capable of carrying slow moving traffic (<40 km/h) within 1 hour of application without permanent damage occurring, such as rutting or ravelling. When the time before the microsurfacing is capable of carrying traffic exceeds 1 hour, work must cease unless specifically approved by the Superintendent.

(6) Surface texture

The resulting surface after spreading must be uniform in appearance, and free of areas exhibiting segregation or

excessive or insufficient binder.

The surface texture must be demonstrated on a short test run for approval by the Superintendent. If the surface texture is acceptable to the Superintendent, then all subsequent work must be finished to an equivalent surface texture.

Where increased surface texture is required, a fabric skirt may be trailed behind the spreader box.

(7) Joints

Longitudinal joints in the wearing course must be straight and placed at either the edge or the centre of a traffic lane. If necessary, the edges and joints must be lightly screeded with a hand squeegee to achieve a smooth uniform appearance and to remove excess build-up of material.

(8) Shape and levels

Where a correction and wearing course have been placed, the finished surface level may not vary from the design level at any point by more than ±10mm. Additionally immediately adjacent to any kerb and/or gutter the finished surface level is not be below nor more than 10mm above the level of the lip of the adjacent gutter.

Notwithstanding the above, the deviation from a 3m long straight edge placed anywhere on the top of the finished surface may not exceed 10mm when assessed within 24 hours of work completion.

(9) Non-conformance of materials and finished surfacing

If any materials supplied fail to conform to the requirements in this sub-section or if any section of bituminous microsurfacing fails to conform to the requirements of this sub-section - whether failure of the work is due to bad workmanship, defective materials supplied by the Contractor or materials made defective by the method of operation adopted - then such failure or failures will constitute a “Notice of Non Conformance”. Such non-conforming sections of bituminous microsurfacing work must be either replaced or corrected.

The rectification of nonconformances, including any restoration work to any underlying or adjacent surface or structure, which becomes necessary as a result of such replacement or correction, is the Contractor’s responsibility. Materials removed from the site by the Contractor must be replaced with materials which conform to this sub-section.

(10) Control of traffic

The Contractor must provide for traffic in accordance with the requirements of sub-section SC6.4.6.30 Control of traffic while undertaking the work and must take all necessary precautions to protect the work from damage until such time as the new work has developed sufficient strength to carry normal traffic without damage.

The Contractor must take all necessary steps to avoid or minimise delays and inconvenience to road users during the course of the work. Where adequate detours or side tracks are included in the Contract or are otherwise available, traffic must be temporarily diverted while the work is in progress.

SC6.4.6.17.5 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.17.5 below.

Table SC6.4.6.17.5 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Spec Clause
1.	**Mineral Aggregate**	As per Table SC6.4.6.17.1	SC6.4.6.17.2(3)
2.	**Combined Aggregate/filler**	As per Table SC6.4.6.17.2	SC6.4.6.17.2(3)
3.	**Mineral Filler**	> 85% passing a 75 µm Sieve	SC6.4.6.17.2(4)
4.	**Mix Properties**		
	(a) Design properties	As per Table SC6.4.6.17.3	SC6.4.6.17.3(1)
	(b) Permitted variations	As per Table SC6.4.6.17.4	SC6.4.6.17.4(1)
5.	**Surface Preparation**	Sweeping must extend at least 300mm beyond edge of area to be surfaced	SC6.4.6.17.4(3)
6.	**Weather Limitations**	Microsurfacing must not commence if either air or pavement temperature is below 10°C and falling, and may only commence if both air and surface temperature is above 7°C and rising or above 10°C	SC6.4.6.17.4)4)
7.	**Shape and Levels**		
	(a) Finished Levels	Must not vary at any point by more than ± 10mm from design levels. Immediately adjacent to kerb and/or gutters, levels must not be below nor more than 10mm above design level	SC6.4.6.17.4(8)
	(b) Finished Shape	Deviation from the bottom of a 3m straight edge must not vary by more than 10mm	SC6.4.6.17.4(8)

SC6.4.6.18 Segmental paving

SC6.4.6.18.1 Introduction

(1) Scope

(a) This sub-section covers the construction of both clay and concrete segmental paving for road pavements, medians, traffic islands, driveways, cycleways, footpaths and other pedestrian areas.

(b) The work covered under this sub-section consists of the supply, placement and compaction of segmental pavers including the provision of a sand or crusher dust bedding course and joint filling sand, over bound or unbound base and/or subbase layer/s.

(c) This sub-section should be read in conjunction with the appropriate specifications for the construction of the base and subbase layers beneath the segmental paving, ie. SC6.4.6.12 Flexible pavements, SC6.4.6.14 Mass concrete subbase.

(d) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

Editor's note - A reference to drawings is a reference to construction drawings.

(2) Choice of paver type, shape, class and laying pattern

(a) The choice of concrete or clay segmental pavers, the paver class (for clay pavers), shape type (for concrete pavers), shape name, colour, thickness and laying pattern must be as per decision requirement for each area of application.

(b) Unless otherwise specified, concrete pavers for road pavements must be placed in herringbone laying pattern and must be in accordance with the requirements for the appropriate road application shown in Table SC6.4.6.18.1.

(c) Unless otherwise specified, clay pavers for road pavements must be Class 4, minimum 65 mm nominal thickness, and placed in a herringbone laying pattern.

(d) Paving for cycleways and other pedestrian areas must be carried out in accordance with SC6.4.3.3 Footpath treatment and SC6.4.4.7 Pathways and cycleways.

(e) Paving for road pavements, medians and traffic islands must be carried out in accordance with SC6.4.4.1 Geometric road design and SC6.4.4.2 Pavement design.

(f) Paving for driveways must be carried out in accordance with SC6.4.3.5 Driveways and SC6.4.4.8 Standard drawings.

(3) Terminology

Concrete segmental pavers are units of not more than 0.1sqm in gross plan area, manufactured from concrete, with plain or dentated sides, with top and bottom faces parallel and with or without chamfered edges. Concrete pavers are identified by shape as being one of the following types:

(a) **Shape Type A** - Dentated chamfered units which key into each other on four sides, are capable of being laid in herringbone bond, and by their plan geometry, when interlocked, resist the spread of joints parallel to both the longitudinal and transverse axes of the units; or

(b) **Shape Type B** - Dentated units which key into each other on two sides, are not (usually) laid in herringbone bond, and by their plan geometry, when keyed together, resist the spread of joints parallel to the longitudinal axes of the units and rely on their dimensional accuracy and accuracy of laying to interlock on the other faces; or

(c) **Shape Type C** - Units which do not key together and which rely on their dimensional accuracy and accuracy of laying to develop interlock.

Clay pavers are manufactured from clay, shale or argillaceous materials which may be mixed with additives. Clay pavers may have square, bevelled (chamfered), rounded or rumbled edges. They are generally rectangular in shape, with the length twice the width, plus 2mm.

Laying patterns of pavers are identified as being either Herringbone, Basket-weave, or Stretcher as shown in SC6.4.6.18 Attachment A Laying patterns. Each of these may be laid at either 90º or 45º to the line of edge restraints. A variation of Stretcher is the Zig Zag Running Bond, also shown in SC6.4.6.18 Attachment A.

(4) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.9 - Open drains kerb and channel
SC6.4.6.10 - Earthworks (construction)
SC6.4.6.12 - Flexible pavements
SC6.4.6.14 - Mass concrete subbase
SC6.4.6.19 - Stabilisation
SC6.4.6.28 - Minor concrete works.

(b) Australian Standards:
AS1141.11.1 - *Particle size distribution - Sieving method*
AS/NZS4455 - *Masonry units, pavers, flags and segmental retaining wall units*
AS/NZS4456.0 - *Methods of test - General introduction and list of methods*
AS/NZS4456.3 – *Methods of test - Determining dimensions*
AS/NZS4456.5 – *Methods of test - Determining the breaking load of segmental pavers and flags*
AS/NZS4456.9 – *Methods of test - Determining abrasion resistance*
AS/NZS4586 - *Slip resistance classification of new pedestrian surface materials.*

(c) Concrete Masonry Association of Australia specifications:
CMAA MA56-2010 - *Guide to permeable interlocking concrete pavements*
CMAA MA57-2010 - *Concrete segmental and flag pavements - guide to specifying*
CMAA T45-1997 - *Concrete segmental pavements - Design guide for residential access ways and roads*
CMAA T46-1997 - *Concrete segmental pavements - Detailing guide.*

(d) Clay Brick and Paver Institute specification:
CBPI Manual 1: 2003 - *Clay Paving Design and Construction.*

SC6.4.6.18.2 Materials

(1) General

(a) The Contractor must submit details of all proposed segmental paving materials, including bedding sand or crusher dust and joint filling sand. These details must be submitted to the Superintendent for approval supported with test results from a nominated NATA registered laboratory, confirming that the constituents comply with the requirements of this sub-section.

(b) No pavers may be delivered until the Superintendent has approved the type and quality of the pavers and noted the source of supply as compliant to the requirements of this sub-section.

(c) All pavers must have suitable “slip resistance” for pedestrian traffic and vehicular traffic with a classification “W” according to AS/NZS4586 for the Wet Pendulum Test. Where specific localities or levels of usage require a higher slip resistance classification, this classification must be indicated on the drawings. Such approval does not relieve the Contractor of any responsibility for supplying materials that comply with this sub-section.

(2) Concrete segmental pavers

(a) Concrete segmental pavers must comply with the requirements of relevant Concrete Masonry Association of Australia Specifications and AS/NZS4455 for each area of application.

(b) The material requirements for concrete pavers for each application, derived from CMAA MA57-2010 *Concrete segmental and flag pavements - guide to specifying*, are shown in Table SC6.4.6.18.1.

Table SC6.4.6.18.1 Material requirements for concrete segmental pavers

Pavement application		Minimum characteristic breaking load *kN	Work size minimum thickness mm	Dimensional deviation category (See Table SC6.4.6.18.3)	Maximum abrasion resistance (mean abrasion index) †		
Relevant Australian Standard		AS/NZS 4455.2 AS/NZS 4456.5	AS/NZS 4455.2	AS/NZS 4455.2 AS/NZS 4456.3	AS/NZS 4455.2 AS/NZS 4456.9		
Residential	Pedestrians only (eg paths, patios and outdoor areas)	2	40	DP0	§		
	Pedestrian and light vehicles only (eg driveways, parking spaces and the like)	3	40	DPB1	§		
	Pedestrian and commercial vehicles	5	60	DPB1	§		
					Pedestrian traffic volume		
					Low	Medium	High
Public space	Pedestrian only**	2	40	DPB1	7‡	5.5	3.5
	Pedestrian and light vehicles only	3	50	DPB2	7‡	5.5	3.5
	Pedestrian and commercial vehicles	5	60	DPB2	7‡	5.5	3.5
Trafficked segmental pavers	Minor and residential	6	60	DPB2	NA		
	Local access	6	60	DPB2	NA		
	Collector M	6	76	DPB2	NA		
Industrial	M	10	80	DPB2 or DPB3	7		

(Source: CMAA MA57-2010 *Concrete segmental and flag pavements - guide to specifying* - Table 1: Minimum Requirements for Dimensions, Breaking Load and Abrasion Resistance).

Note—

* At 28 days

† At 90 days

** where cleaning of pavers and flags is undertaken by mechanical means or where prevention of vehicle entry cannot be guaranteed, the minimum recommended pavers and flags are the 'Pedestrian and light vehicles only' for such pavement applications.

§ No abrasion criteria are specified for residential pavers. Abrasion resistance requirements for aesthetic or other purposes must be specified to the supplier/manufacturer.

NA Not applicable.

* Shape Type A pavers – dentated pavers that key into each other and by their plan generally interlock and resist relative movement of joints parallel to both the longitudinal and transverse axes of the pavers.
Examples of Type A shapes

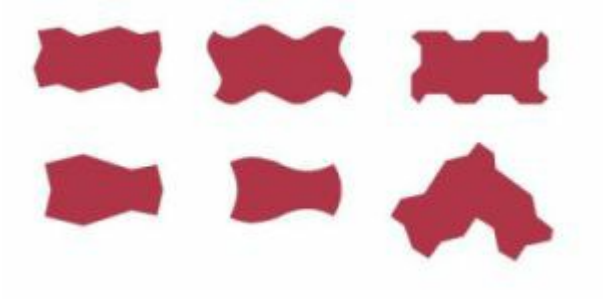

Table SC6.4.6.18.2 Maximum dimensional deviations determined by individual measurement

Category	Work Size dimensions, mm			
	Plan		Height	
	Standard deviation	Mean	Standard deviation	Mean
DP0	No requirement			
DPB1	2.0	± 3.0	3.0	± 2.5
DPB2	2.0	± 2.5	3.0	± 2.0
DPB3	Values declared by the supplier or by agreement between supplier and purchaser			
DPB4	1.5	± 2.0	2.0	± 2.0

Source: CMAA MA57-2010 Concrete segmental and flag pavements - guide to specifying - Table 2: Maximum Dimensional Deviations Determined for Pavers and Flags by Individual Measurement).

Note—all paving units will be categorised in accordance with AS/NZS4455.3 Method for Determining Dimensions.

(3) Clay segmental pavers
Clay segmental pavers must comply with the requirements of CBPI Manual 1:, *Clay paving design and construction* (chapter 3, Specifying clay pavers), and with the requirements of AS/NZS4455.

(4) Bedding sand or crusher dust

(a) The bedding material must be well-graded, consisting of clean, hard, uncoated grains uniform in quality, generally passing a 4.75 mm sieve. The bedding material must be from a single source or blended to achieve, when tested in accordance with AS1141.11, the following grading:

AS Sieve	**% Passing**
9.52mm	**100**
4.75	**95 - 100**
2.36	**80 - 100**
1.18	**50 - 85**

600µm	**25 - 60**
300	**10 - 30**
150	**5 - 15**
75	**0 - 10**

(b) The material must be of uniform moisture content when spread. It must be covered when stored on site to protect it from rain penetration.

(c) The bedding material must be free of deleterious soluble salts or other contaminants which may cause, or contribute to, efflorescence.

(5) Joint filling sand

(a) The joint filling sand must be well graded passing a 2.36mm sieve, and when tested in accordance with AS1141.11, having the following grading:

AS Sieve	**% Passing**
2.36mm	**100**
1.18	**90 - 100**
600µm	**60 - 90**
300	**30 - 60**
150	**15 - 30**
75	**5 - 10**

(b) The sand must be dry when spread. It must be covered when stored on site to protect it from rain penetration.

(c) The sand must be free of deleterious soluble salts or other contaminants.

(d) Material used for bedding is not suitable for joint filling.

(6) Concrete for edge restraints

(a) Concrete supplied and placed for the construction of edge strips must comply with sub-section SC6.4.6.28 Minor concrete works.

(b) Unless otherwise indicated on the drawings, or where the edge restraint is provided by kerb and/or gutter, the concrete used for edge restraints must have a minimum 28 day characteristic compressive strength of 32MPa for edge restraints to pavers on road pavements and 25MPa for edge restraints to pavers on footpaths, cycleways, medians and driveways.

SC6.4.6.18.3 Construction

(1) Subgrade preparation

(a) The subgrade must be formed to the required depth below finished surface level as shown on the drawings in accordance with SC6.4.6.10 Earthworks (construction).

(b) The finished subgrade foundation for the provision of subbase and/or base is subject to the approval of the Superintendent.

(2) Subbase

(a) As shown on the drawings, a subbase or working platform must be constructed in accordance with SC6.4.6.14.10 Subgrade Beams.

(b) The subbase must be constructed to the specified thickness, compaction and depth below finished surface level and to the design grade and crossfalls of the finished surface.

(c) The finished subbase is subject to the approval of the Superintendent.

(3) Base

(a) The base must be constructed to the specified thickness and depth below finished surface level, and to the design grade and crossfalls of the finished surface, as shown on the drawings in accordance with sub-section SC6.4.6.12 Flexible pavements.

(b) The base course must extend in width to at least the rear face of all new edge restraints.

(c) Notwithstanding the finished level tolerances contained within sub-section SC6.4.6.12 Flexible pavements for base of ±10mm of design levels, the level on the finished surface of the base course for road pavements to be overlain with segmental paving must be trimmed to within + 10mm or – 0mm of design levels. The deviation from a 3m long straight edge placed anywhere and laid in any direction on the top surface of the base course for all segmental paving must not exceed 10mm. Bedding material must not be used as a levelling material to compensate for base finishing outside the above tolerances.

(d) The finished surface of the base must drain freely without ponding.

(e) The finished base is subject to the approval of the Superintendent.

(4) Edge restraints

(a) Edge restraints in the form of kerb and/or gutter or edge strips must be constructed along the perimeter of all segmental paving as shown on the drawings. Concrete kerb and/or gutter and edge strips must be constructed in accordance with sub-section SC6.4.6.9 Open drains and SC6.4.6.28 Minor concrete works.

(b) Faces of edge restraints abutting pavers must be vertical.

(c) Edge restraints must be supported on compacted base and/or subbase of the thickness as shown on the drawings. Where not otherwise specified or indicated, the minimum thickness of compacted base beneath the edge restraints must be 100mm adjacent to road pavements and medians, and 50mm adjacent to footpaths, cycleways and driveways.

(d) Unless otherwise shown on the drawings, contraction joints, 20mm depth must be formed every 5m of edge restraint length.

(e) After the concrete has hardened and not earlier than 3 days after placing, unless otherwise directed by the Superintendent the spaces at the back of the edge restraint must be backfilled with earth, compacted in layers not greater than 150mm thick, then topsoiled to meet surrounding design levels.

(5) Bedding

(a) The bedding course must be spread in a single uniform layer and screeded in a loose condition to the nominated design profile and level. The bedding course must be laid such that a uniformly thick nominal 20-25mm layer is achieved following final compaction of the segmental paving.

(b) Any depressions in the screeding material exceeding 5mm must be loosened, raked and rescreeded before laying pavers.

(c) For the manual placing of paving units, the bedding material must be maintained at a uniform loose density. For mechanised laying, the bedding material must be uniformly and firmly, but not fully, compacted.

(d) Screeded material left overnight of subject to rain must be checked for level and rescreeded where necessary before pavers are placed. The material must not be screeded more than 2m in advance of the laying face at the completion of work on any day.

(6) Laying pavers

(a) Pavers must be uniformly placed on the screeded bedding to the nominated laying pattern. Pavers must be placed so that they are not in direct contact with each other and must have uniform 3mm nominal joint widths. The pavers must be mixed between various pallets to ensure that any colour variation from one pallet of pavers to the next is evenly distributed over the entire paved area.

(b) The first row must be located next to an edge restraint or an established straight line, and laid at a suitable angle to achieve the required orientation of pavers in the completed pavement.

(c) In each row, full units must be laid first. Edge or closer units must be neatly cut using a paver scour, or mechanical or hydraulic guillotine, and fitted subsequently. Cut pieces of pavers which are smaller in

size than one quarter of a full block must not be used.

(d) Access chambers, drainage gullies and similar penetrations through the pavement must be finished against the paving with a concrete surround or apron designed to suit and fit the laying pattern, otherwise complying with the requirements for edge restraints.

(e) Where pavers are placed over an isolation, contraction or expansion joint in an underlying concrete pavement, a joint must be provided in the pavers. The joint must consist of 10mm thick preformed jointing material of bituminous fibreboard.

(f) Any foot or barrow traffic must use boards overlaying paving to prevent disturbance of units prior to compaction. No other construction traffic is allowed on the pavement prior to compaction and provision of joint filling sand.

(g) On completion of subsequent bedding compaction and joint filling operations, all joints must have widths within the range 2-4mm.

(7) Bedding compaction

(a) After laying the pavers the bedding must be fully compacted and the surface brought to design levels and surface profiles by not less than two passes of a high frequency low amplitude plate compactor which covers at least 12 units. Compaction must continue until all pavers form a smooth surface with adjacent paver edges matching. The level difference between adjoining edges of any two pavers must be a maximum of 2mm, to avoid trip hazards, unless approved otherwise by the Superintendent for rough textured pavers.

(b) Any units which are structurally damaged during bedding compaction must be removed and replaced. The pavement must then be recompacted for at least 1m surrounding each replacement unit.

(c) The paving operations must be arranged so that the use of the plate compactor proceeds progressively behind the laying face without undue delay, and such that compaction is completed prior to cessation of construction activity on any day. Compaction must not be attempted within 1m of the laying face except on completion of the pavement against an edge restraint.

(d) The finished surface level must not vary from the design level at any point laid in any direction, by more than 6mm for all areas with Class 4 segmental pavements and 8mm for all other areas of segmental paving. Notwithstanding this, the finished surface of the segmental paving, including where the paving abuts an edge restraint other than a drainage inlet, must not deviate from the bottom of a 3m straight edge laid in any direction, except at grade changes, by more than 6mm for road pavements and 8mm for all other areas of segmental paving.

(e) The channels formed between abutting chamfered units must finish with their inverts not less than 5mm nor more than 10mm above adjacent drainage inlets.

(f) All compaction must be complete and the pavement must be brought to design profiles before spreading or placing sand filling in the joints.

(8) Filling joints

(a) As soon as practicable after bedding compaction, and in any case prior to termination of work on any day, dry sand for joint filling must be spread over the pavement and the joints filled by brooming.

(b) To ensure complete filling of the joints, both the filling sand and pavers must be as dry as practicable when sand is spread and broomed into the joints.

(c) The pavement must then receive one or more passes of a plate compactor and the joints then refilled with sand, with the process then repeated sufficiently to ensure that the joints are completely filled.

(9) Protection of work

Other than wheeled trolleys, forklifts and cluster-clamp vehicles, construction and other traffic may not use the pavement until bedding compaction and joint filling operations have been completed.

(10) Opening to traffic

(a) As soon as practicable after the filling of joints, construction vehicles may use the pavement, and should

be encouraged to traverse the greatest possible area of pavement to assist in the development of "lock-up".

(b) Excess joint filling sand must be removed prior to opening to traffic.

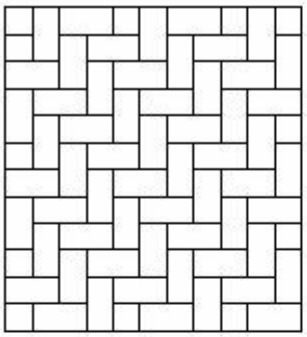
(c) The pavement must then be inspected by the Contractor at regular intervals up until the expiration of the defects liability period to ensure that all joints remain completely filled.

SC6.4.6.18.4 Limits and tolerances

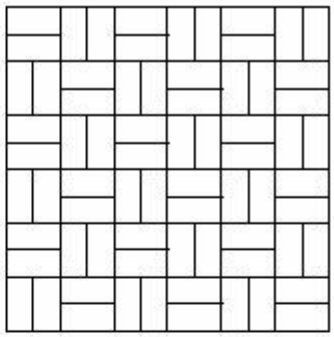
The limits and tolerances applicable to the various clauses in this Specification are summarised in Table SC6.4.6.18.3 below:

Table SC6.4.6.18.3 Summary of limits and tolerances

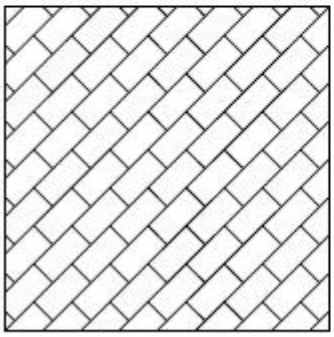
Item	Activity	Limits/Tolerances	Clause
1.	**Base**		
	(a) Surface Level	Finished level of base for road pavements to be within +10mm or -0mm of design levels.	SC6.4.6.18.3(3)
		Finished level of base other than for road pavements, to be within ±10mm of design levels.	SC6.4.6.18.3(3)
		The top surface of the base for all segmental paving must not deviate from a 3m straight edge, laid in any direction, by more than 10mm.	SC6.4.6.18.3(3)
2.	**Laying Paving Units**		
	(a) Joint widths	Within the range 2 -4mm.	SC6.4.6.18.3(6)
3.	**Completed Segmental Paving** (a) Surface level	Finished surface level of pavers must not vary from design levels by more than ±6mm for road pavements and ±8mm for other than road pavements.	SC6.4.6.18.3(7)
		Finished surface of pavers must not deviate from a 3m straight edge, laid in any direction, by more than 6mm for road pavements and 8mm for other than road pavements.	SC6.4.6.18.3(7)
	(b) Level adjacent to drainage inlets	Invert level of channels between abutting chamfered units must be not less than 5mm and not more than 10mm above the level of adjacent drainage inlets.	SC6.4.6.18.3(7)
	(c) Difference in level of adjacent pavers	≤2mm	SC6.4.6.18.3(7)



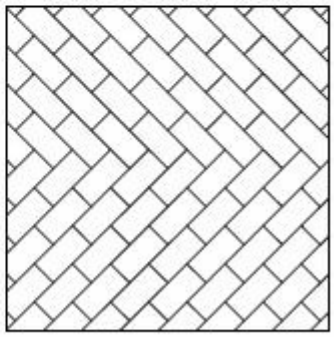
Herringbone



Basketweave



Stretcher



Zig Zag Running Bond

SC6.4.6.19 Stabilisation

SC6.4.6.19.1 Introduction

(1) Scope

This sub-section identifies the materials requirements for stabilised materials provided by stationary plant production as well as materials and process requirements for in-situ stabilisation.

The work to be executed under this sub-section consists of the supply and incorporation of stabilising binders with material in a nominated pavement course or subgrade layer (including materials for the selected material zone, and selected backfill), at specified locations in the work and the spreading, compaction, trimming and curing of such materials.

This sub-section provides the requirements for stabilisation of the types of pavement courses and subgrade zones or layers as shown in Table SC6.4.6.19.1.

Table SC6.4.6.19.1 Types of pavement courses, subgrade zones or layers and stabilising binder

Pavement Course Or Subgrade Zone Or Layer	Stabilising Binder
PAVEMENT COURSE	
Base and Subbase	Cement Blended Stabilising Agent Hydrated Lime (pugmill) Quicklime (in-situ) Foam bitumen (MRTS07C)
SUBGRADE ZONE OR LAYER	
Selected Material Zone	Cement Blended Stabilising Agent Quicklime (in-situ) Hydrated Lime (pugmill)
Other Subgrade Layers	Cement Blended Stabilising Agent Quicklime (in-situ) Hydrated Lime (pugmill)
Selected Backfill Zone	Cement Hydrated Lime (pugmill)

The pavement course or subgrade zone or layer to be stabilised shall be as specified in sub section SC6.4.6.12 Flexible pavements, or as indicated on the drawings.
Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

The Glossary of Austroads Terms, AP-C87-10

NSW Roads and Maritime Services Test Methods

Test method T432: Rate of slaking of quicklime, 2012

SC6.4.6.19.2 Inspection, sampling and testing

(1) Pre-construction compliance

The Contractor shall provide a certificate from a laboratory with appropriate NATA registration stating that the stabilisation mix(es) submitted and the mix constituents comply with the mix nominated in approved stabilisation mix design approved as part of the pavement design and that the stabilised material meets the requirements of sub section SC6.4.6.12 Flexible pavements if incorporated into the works as a pavement layer or alternatively SC6.4.6.10 Earthworks (construction) or SC6.4.6.4 Stormwater drainage.

(2) Construction compliance

Regular inspection, sampling and testing of pavement and subgrade materials shall be undertaken by the Contractor while stabilisation is in progress in accordance with this sub section.

SC6.4.6.19.3 Materials

(1) Unsuitable materials and shape correction

These shall be with unbound gravel of Type 1, Type 2, Type 3 or Type 4 in accordance with SC6.4.6.10 and SC6.4.6.12 New material shall not have a water soluble sulphate content exceeding 1.9 grams of sulphate per litre.

(2) Cement and stablising agent

The type of cement used as the stabilising agent or a constituent in a blended stabilising agent shall comply with AS3972.

Documentary evidence of the quality and source of the cement shall be furnished by the Contractor to the Superintendent upon request at any time.

If the Contractor proposes to use cement which has been stored for a period in excess of 3 months from the time of manufacture, the Contractor shall arrange a re-test, to ensure the cement still complies with AS3972, before the cement is used in the work. Test results shall be forwarded to the Superintendent for approval at least 2 days in advance of usage of the material.

The Contractor shall order gravel material with the cement content required to achieve the designed unconfined compressive strength (UCS) of the pavement. It is the Contractor's responsibility to ensure the material being used achieves the required UCS.

(3) Quicklime stabilising agent
Quicklime, consisting essentially of calcium oxide in a highly reactive form, shall have the following properties at the point of spread:

(a) available lime - the content of calcium oxide, determined by AS4489.6.1, shall not be less than 85%. Unless otherwise specified, the spread rate for quick lime shall be 20kg/m^3; and

(b) slaking rate - the active slaking time shall not be greater than 20 minutes and the temperature rise on slaking, determined from the average of four samples tested in accordance with Test Method T432, shall not be less than 40°C in 6 minutes.

The particle size distribution of the quick lime determined by AS1141.11 shall comply with the following requirements in Table SC6.4.6.19.2.

Table SC6.4.6.19.2 Particle size distribution of quicklime

AS Sieve	Per Cent Passing
13.2mm	100
9.5mm	96 - 100
4.75mm	70 - 100
2.36mm	0 - 90

(4) Hydrated lime stabilising agent

(a) Hydrated lime, consisting essentially of calcium hydroxide, whether used as the sole stabilising agent or blended with other additives, shall have the following properties:

(i) available lime - the content of calcium hydroxide, determined by AS 3583.12, shall not be less than 80%;

(ii) form - the material shall be in a dry powder form; and

(iii) residue on sieving - the residue on a 300 micron sieve, determined by (Particle Size) AS3583.14, shall not exceed 2%.

(b) The properties which characterise the particular hydrated lime to be used in the stabilising agent submitted as part of the mix design are:

(i) percentage of calcium hydroxide;

(ii) fineness percentage by mass passing the 45 micron sieve (AS 2350.9); and

(iii) source.

(5) Ground granulated blast furnace slag stabilising agent
The ground granulated blast furnace slag shall conform to AS3582.2.
The properties which characterise the particular ground blast furnace slag to be used in the stabilising agent submitted as part of the mix design are:

(a) fineness percentage by mass passing the 45 micron sieve (AS2350.9);

(b) relative strength (28 days) (AS3583.6); and

(c) source.

(6) Flyash stabilising agent
Flyash shall conform to AS3582.1.

The properties which characterise the particular flyash to be used in the stabilising agent submitted as part of the mix design are:

(a) fineness - percentage by mass passing the 45 micron sieve (AS2350.9);

(b) loss on ignition (AS3583.3); and

(c) source.

(7) Blended stabilising agents

The Contractor may utilise a blended stabilising agent. The Contractor shall obtain mill and batch information which will make the blended stabilising agent traceable to the supplier's test results.

Handling and storage requirements of the Supplier shall be complied with by the Contractor who shall also arrange for sampling of the agent as required by the Superintendent.

The mass of components of the nominated blended stabilising agent shall not vary by more than ± 3% from the blend percentages nominated in the mix design described in approved stabilisation mix design.

When a blended stabilising agent is produced from a combined grinding of components the following properties will characterise the particular stabilising agent blend:

(a) source of each component;

(b) fineness percentage by mass passing the 45 micron sieve (AS2350.9); and

(c) setting time (AS2350.4).

(8) Water (for curing)

Water shall be free from harmful amounts of materials such as oils, salts, acids, alkalis and vegetable substances. The water shall not contain more than:

(a) 600 parts per million of chloride ion, determined by AS3583.13;

(b) 400 parts per million of sulphate ion, determined by AS1289.4.2.1; and

(c) 1% by mass of undissolved solids.

Water accepted as potable and fit for human consumption will not require testing to confirm suitability.

(9) Foam bitumen

In accordance with MRTS07C.

SC6.4.6.19.4 Stabilisation processes

(1) General

The Contractor shall submit details of the proposed equipment (including the mixing plant) and stabilisation procedures to be used in the work 14 days prior to commencement of the work. This submission, hereafter called the work plan, is to include the following:

(a) the sequence of operations;

(b) widths of stabilisation passes;

(c) provision for traffic if appropriate;

(d) comply with statutory requirements for WHS;

(e) testing methods and frequency;

(f) comply with this specification;

(g) survey control methods; and

(h) curing methods.

Notwithstanding submission to the Superintendent of the Contractor's equipment and stabilisation procedures, the work shall meet all the sub-section requirements, and statutory requirements for work health and safety, and the Contractor shall perform such tests as specified as the work proceeds, to ensure compliance.

Stabilisation of pavement materials shall not proceed during wet weather or if rain is imminent and likely to occur during any stage of the stabilisation process so as to significantly influence the resultant moisture content and uniformity of moisture content in the mix.

(2) Application of stabilising agent

(a) Stationary mixing plant

Application rate of stabilising agent shall be monitored at the pug mill or equivalent plant utilised as approved by the Superintendent.

Application rate measured in kg/t of product shall be monitored and recorded for every 100t of production.

The achieved accuracy of application rate shall be ±10% of the nominated rate nominated in approved pavement design's stabilisation mix design.

The application rate shall not be allowed to exceed the nominated rate by more than 10%.

(b) In-situ

For environmental reasons in urban areas the incorporation of stabilising agent is to be a closed system process where stabilising agent is added and mixed into the pavement within the bowl of the specialist mixing equipment.

Where approved in rural areas spreading shall be carried out using the mechanical spreader nominated in the work plan and subsequently approved by the Superintendent. The approved pavement design's stabilisation mix design nominates the spread rate.

The actual spread rate shall be within ±10% of the nominated rate. The Contractor shall verify this by testing the spread rate for each lot or 500m^2 of pavement treated (whichever is less) in each application of binder. Spread rate testing shall be performed by weighing the contents of a suitable four sided tray placed on the pavement and between the wheels of the closed system stabiliser. The rate of stabilising agent spread shall be calculated by dividing the mass collected (kg) by the area of the tray (m^2).

Where spreading/stabilising vehicles are fitted with load cells, the Contractor shall ascertain the average spreading rate of the stabilising agent by dividing the mass of the stabilising agent spread per run by the area of the run. The Contractor shall record this data for each run and make it available to the Superintendent promptly. Such action will not cancel the Contractor's obligation to undertake prescribed testing of spread rate if required by the Superintendent.

Spreading shall not proceed during windy conditions which may cause loss of stabilising agent or cause nuisance or danger to people or property. Where open spreading is approved.

Traffic or equipment not involved in spreading or mixing of the stabilising agent shall not pass over the spread material until it has been mixed into the layer to be stabilised. Where open spreading is approved.

Any spillage of the stabilising agent on site or at any loading location related to the site shall be removed as soon as possible and within the same work shift of such spillage.

(3) Mixing

(a) Stationary mixing plant

The stationary mixing plant shall be purpose built for the process of mixing road making materials. All equipment shall be maintained and calibrated so as to provide a uniformly mixed product without segregation of the aggregate material.

The plant shall provide for the controlled and metered inclusion of water into the mix.

The stationary mixing equipment shall incorporate a delivery system for mix materials capable of producing a uniform mixture to design requirements. This performance shall be confirmed by monitoring of unconfined compressive strength of production, in accordance with AS1289.6.1.1, with a pair of test specimens tested for each 100 tonnes of production.

(b) In-situ

Mixing equipment shall be purpose built for the process of in-situ mixing of road making materials. It shall be capable of mixing to the depth specified for the layer to be stabilised and of distributing the stabilising agent uniformly through the full depth and over the whole area of the layer to be stabilised. Where directed a minimum of two passes of the mixing equipment is required. As mixing blades or tynes wear they shall be replaced so as to maintain mixing efficiency consistent with that demonstrated during the trial section. The mixing equipment will be capable of supplying a calibrated amount of water to the mixing bowl in such a manner as to provide a uniformly moist mix to a target moisture content.

The resultant mix shall be uniform over the full depth so that there are no lenses, pockets, lumps or granules of stabilising agent present in the layer or adjacent to it.

The procedure nominated in the Work Plan shall minimise disturbance of the distribution of stabilising agent spread in advance of the mixing process.

The Contractor shall carry out visual inspections during mixing to ensure uniform mixing is being achieved in the layer. Inspection results shall be recorded as cited in SC6.4.5 Construction management.

The Superintendent may require that additional passes by the mixing equipment be carried out to improve the visual uniformity of the mix and/or the moisture content.

(c) Paving equipment

For plant-mixed stabilising pavements, the mixture shall be placed by self-propelled paving machine purpose built for this work and with the capacity to place and spread the mixture in one pass at the required uncompacted thickness, width and shape. Other methods of paving may be considered by council where the use of a self-propelled paving machine is impractical.

(4) Field working period (allowable working time)

The time period from addition of water during the mixing process until the completion of compaction is nominated as the field working period.

The nominated field working period shall be provided in Stabilisation Mix Design for the stabilising agent approved as part of the pavement design. The Nominated field working period shall be based on laboratory tests determining the time from mixing until such time as the calculated Wet Density for standard compaction procedures decreases by more than 2 percentage points. This testing shall be undertaken utilising AS 1289.5.1.1 and samples of the materials representative of those to be utilised in the works. If the field working period is not specified as part of the pavement design, the maximum period between the commencement of mixing and the completion of compaction and trimming shall be 3 hours.

The Contractor will complete the compaction process within the Nominated field working period unless specific approval is provided by the Superintendent to an adjustment for site and seasonal conditions.

(5) Trimming and compaction

After mixing the layer shall be trimmed and compacted in accordance with sub-section SC6.4.6.12 Flexible pavements to produce a tight dense surface parallel with the finished wearing surface so that the levels do not vary from the design levels beyond the tolerance for primary trimming specified in clause SC6.4.6.19.4(7)(a) Levels and surface trim.

Subsequent secondary trimming may be undertaken on one or more occasions in preparation for primer seal and with the objective of meeting shape and level requirements. Secondary trimming shall involve cutting to waste. Work methods that lead to the development of laminations in the pavement will not be allowed and surface slurrying will not be accepted. The Contractor's survey control methods as stated in the work plan will be adequate to ensure that the pavement layer thickness is not reduced during secondary trimming to an extent such that it fails to comply with the requirement for layer thickness in accordance with the tolerance specified in clause SC6.4.6.19.4(7)(b) Layer thickness. When required by the Superintendent survey results shall be provided to confirm that the pavement layer thickness remains within tolerance after secondary

trimming.

Measurements with a 3m straight edge shall be taken at a minimum of ten randomly selected stations so as to represent each 200m lane length or part thereof. Deviation of the surface from the bottom of a 3m straight edge placed in any direction will meet the tolerance shown in clause SC6.4.6.19.4(7)(a). This testing will be undertaken immediately prior to sealing or prior to agreed practical completion for any work component.

The stabilised layer shall be compacted over the entire area and depth so that the relative compaction determined by AS 1289.5.1.1 is not less than as detailed in sub-sections SC6.4.6.12 Flexible pavements, SC6.4.6.10 Earthworks (construction) or SC6.4.6.4 Stormwater drainage as appropriate.

To provide true relative compaction assessments the lots shall be sampled and tested within the nominated field working period in accordance with AS1289.5.1.1.

The maximum wet density (standard compaction) will be determined by sampling immediately after the determination of field density and testing will be undertaken within 2 hours of sampling. A determination of maximum wet density (standard compaction) representing the full layer depth is required for each sampling location when calculation of relative compaction is undertaken.

The field density may be determined by in situ sand replacement testing or by single probe Nuclear Density Meter in direct transmission mode in accordance with AS1289.5.8.1.

(6) Joints

Joints are defined in this sub-section to comprise interfaces between work episodes that are separated in time by more than the nominal field working period for the nominated stabilisation mix design. A longitudinal joint shall be considered to be a joint generally parallel to the road centreline. A transverse joint occurs when a length of work is terminated and extended at a later time after a period which exceeds the nominated field working period.

All longitudinal and transverse joints shall be formed by cutting back into the previously stabilised and fully compacted sections. A minimum longitudinal overlap of mixing runs shall be 75mm. Transverse joints shall be overlapped by a minimum of 2m. The material disturbed during cutting back shall be remixed at full depth and incorporated into the new work. No longitudinal joints shall be allowed within 500mm of the centreline of a typical wheelpath.

The level and shape of the joints shall be within the limits specified in clause SC6.4.6.19.4(7) Tolerances.

(7) Tolerances

(a) Levels and surface trim

The surface level after primary trimming shall be within a tolerance of +30mm and +10mm of the levels shown on the drawings.

The surface level after secondary trimming shall be within a tolerance of +15mm and -15mm of the levels shown on the drawings.

The pavement surface after secondary trimming and immediately prior to sealing shall be of a quality such that deviation under a 3m straight edge does not exceed 12mm.

Ensure the final surface level is within ± 15mm of the design levels in the event only a single trim is carried out.

(b) Layer thickness

The final thickness of the stabilised layer at any point shall be within a tolerance of +20mm and 10mm of the nominated layer thickness.

The average thickness of the layer in a lot shall be determined from measurements of six randomly selected locations over any 200m length of a lot. The average thickness shall not be less than that

required to meet the specified final thickness tolerances after trimming.

The layer thickness shall be measured at the edges of the stabilising run after compaction commences. The layer thickness shall be measured relative to the finished design level.

(c) Width
The width measured at any point of the stabilised layer shall be not less than the specified width as shown in the drawings by more than 50mm.

The average width of the layer shall be determined from measurements at three sites selected at random by the Superintendent over any 200m length of a lot and shall be not less than the specified width.

(8) Curing
The Contractor shall submit to the Superintendent details of the proposed method of curing as part of the Work Plan.

The stabilised work shall be protected against rapid drying out by keeping it continuously wet or damp during the period prior to the provision of a subsequent layer or the application of a prime or primer-seal.

Water curing shall consist of frequent light uniform spraying (using fine spray jets) that will not produce significant run off or flooding on sections of the area. Conventional spray bars and high pressure nozzles are not permitted. Slurrying of the surface or leaching of the stabilising agent shall be avoided.

Under this sub-section provision for curing up to the period indicated in the approved Stabilisation Mix Design shall be the responsibility of the Contractor.

(9) Trial section of stabilised earthworks
Prior to the commencement of works submit a trial section of stabilised earthworks to demonstrate the methods proposed to conform with this sub-section.

This trial section is constructed so that it may be incorporated in the finished work with a length of approximately 50m.

Construct the trial stabilisation using the materials, equipment and methods for placing and finishing the same as would be used for the entire stabilisation works. Demonstrate the methods proposed to be used for the construction of joints.

In the event of deficiencies in the stabilisation the trial section may not be approved. The method, equipment, materials and personnel will require to be reviewed and an explanation submitted. A further length of trial stabilisation may be requested. Non-conforming trial sections of stabilised earthworks must be removed to ensure preventing damage to the remaining stabilised earthworks and underlying materials. Dispose of the removed materials at an approved location.

(10) Insitu lime stabilisation of subgrade

Lime stabilisation of subgrade material shall be carried out as a two day operation to a minimum depth of 250mm, except for natural subgrades of CBR 0.5% where stabilisation depth shall be a minimum of 300mm. The stabilising agent shall be spread using a purpose built spreader and the stabilising agent and water shall be incorporated into the material using a reclaimer/stabiliser. Alternatively, a reclaimer/stabiliser with a calibrated integrated spreader/applicator may be used to incorporate the stabilising agent and water directly into the material to be stabilised. Where a reclaimer/stabiliser with calibrated integrated spreader/applicator is used, quicklime shall not be used as the stabilising agent.

Day 1: a single lime pass at a rate of up to half the required rate shall be applied. Where quicklime is spread over the subgrade, it shall be slaked in accordance with the requirements in this document. In situations where hydrated lime is used, slaking is not required mixing the stabilising agent into the soil. The hydrated lime or lime slurry formed from the slaking of quicklime shall then be mixed into the material in accordance with the

requirements in this document. The depth of mixing shall not exceed 90% of the specified stabilisation thickness. The material shall be lightly rolled to seal the surface prior to the completion of work on that particular day.

Day 2: after the overnight amelioration period, the balance of the required lime shall be spread in accordance with the requirements in this document. Where quicklime is spread over the subgrade, it shall be slaked in accordance with the requirements in this document. In situations where hydrated lime is used, slaking is not required before mixing the stabilising agent into the soil. The hydrated lime or lime slurry formed from the slaking of quicklime shall then be mixed into the material in accordance with the requirements in this document. Notwithstanding this, a minimum of two mixing passes shall be completed.

Lime shall be spread at a maximum spread rate of 12kg/m2. The number of passes shall be calculated to comply with this requirement. The stabilising agent shall be uniformly spread over the insitu material at a controlled rate (mass per unit area, kg/m2). The total rate of spread shall be such that the stabilising agent spread rate for the compacted material is within the specified tolerances. Once the stabilising agent has been spread, no traffic, other than the construction plant employed for the stabilisation work, shall travel over it. After each spreading run at least one mixing run, and trimming and/or compaction as required, shall be completed. Further mixing operations between spreading runs shall comply with requirements in this document.

Quicklime shall be slaked with sufficient water to allow complete hydration such that the material remains friable after slaking and no further exothermic reaction occurs when further water is added to the lime. All through traffic shall be stopped during any slaking operation.

The entire stabilisation process shall not proceed in any of the following situations:

- during rainfall;
- when rainfall appears to be imminent;
- during periods when the wind is strong enough to cause particles of the stabilising agent to become airborne;
- during conditions that may result in the work causing nuisance or danger to people, property, the environment, or livestock;
- when the pavement temperature, measured 50mm below the surface, drops below 10°C; and
- when the air temperature, measured in the shade exceeds 40°C.

SC6.4.6.19.5 Limits and tolerances

The limits and tolerances applicable to the various clauses of this sub-section are summarised in Table SC6.4.6.19.3 Summary of limits and tolerances below.

Table SC6.4.6.19.3 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	Quicklime		
	a) Available Lime	>85% Calcium Oxide content	SC6.4.6.19.3(3) Quicklime
	b) Slaking Rate	Active Slaking time < 20 minutes, and temperature rise on slaking not less than 40ºC in 6 minutes (for an average of four samples).	SC6.4.6.19.3(3) Quicklime
	c) Particle Distribution	Fraction passing AS Sieve: 100% for 13.2mm Sieve 96-100% for 9.5mm Sieve 70-100% for 4.75mm Sieve 0-90% for 2.36mm Sieve	SC6.4.6.19.3(3) Quicklime
2.	Hydrated Lime		
	a) Available Lime	>80% Calcium Hydroxide	SC6.4.6.19.3(4) Hydrated Lime
	b) Particle Size	<2% residue on a 300 micron Sieve	SC6.4.6.19.3(4) Hydrated Lime

Item	Activity	Limits/Tolerances	Clause
3.	Blended Stabilising Agents	Blend percentages shall not vary by more than ±3% from those nominated in SC6.4.6.19 Attachment A (Stabilisation mix design)	SC6.4.6.19.3(7) Blended Stabilising Agents
4.	Water		
	a) Chloride ion content	<600 PPM Chloride ion	SC6.4.6.19.3(8) Water
	b) Sulphate ion content	<400 PPM Sulphate ion	SC6.4.6.19.3(8) Water
	c) Undissolved solids	<1% by mass of undissolved solids	SC6.4.6.19.3(8) Water
5.	Application of Stabilising Agent		
	a) Spread Rate or Incorporation Rate for in-situ plant.	Actual spread rate shall be within ±10% of the nominated rate	SC6.4.6.19.4(2) Application of Stabilising Agent
6.	Trimming and Compaction		
	a) Surface Level	After primary trimming be within +30mm and +10mm of levels shown on drawings After secondary trimming be within ±15mm of levels shown on drawings	SC6.4.6.19.4(7)(a) Tolerances
	b) Layer Thickness	Final thickness of layers shall not vary more than +20mm and -10mm of required thickness	SC6.4.6.19.4(7)(b) Tolerances
	c) Shape	Shall not deviate more than 12mm under a 3m straight edge immediately prior to first sealing	SC6.4.6.19.4(7)(a) Tolerances
7.	Joints		
	a) Longitudinal Overlap	> 75mm overlap of mixing runs	SC6.4.6.19.4(6) Joints
	b) Transverse Overlap	> 2m overlap of transverse joints	SC6.4.6.19.4(6) Joints
	c) Longitudinal Joints	Shall not be allowed within 0.5m of the centreline of a typical wheelpath	SC6.4.6.19.4(6) Joints
8.	Width		
	a) Width of Stabilised Layer	At any point, the width shall be not less than 50mm short of the width shown on the drawings with an average width always greater than that shown on the drawings.	SC6.4.6.19.4(7)(c) Tolerances

SC6.4.6.19 Attachment A: Stabilisation mix design

SC6.4.6.20 Subsoil, foundation and pavement drains

SC6.4.6.20.1 Introduction

(1) Scope

(a) The work to be executed under this sub-section covers the excavation, bedding, installation and backfilling of subsoil, sub-pavement, intra pavement, edge and foundation drains.

(b) Subsoil and foundation drains shall be constructed where and as shown on the drawings or as directed by the Superintendent.

(c) This sub-section should be read in conjunction with SC6.4.6.21 Subsurface drainage.

(d) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Order of construction

(a) Subsoil and sub-pavement drains
Subsoil drains shall be constructed as soon as possible after necessary earthworks are completed in the area of the drain. Where stabilisation of the subgrade is required, subsoil drains shall be constructed after completion of stabilisation, except where excessive ground water is encountered, they may be constructed prior to stabilisation of the subgrade.

Where a selected material zone is specified and excessive ground water is encountered, subsoil drains may be installed in two stages as follows:

(i) Stage 1: standard subsoil drains installed below the base of the cutting prior to placement of select material in the selected material zone; and

(ii) Stage 2: extension of subsoil drain to top of the selected material zone after placement of selected material.

(b) Intra-pavement drains
Intra-pavement drains shall be constructed after the completion of the layer below the pervious pavement material or 40mm open graded asphaltic concrete subbase and preceding the construction of the subsequent layers.

(c) Edge drains
Edge drains shall be constructed after the construction of the rigid pavement and before the placement and compaction of verge material.

(d) Foundation drains
Foundation drains shall be constructed after completion of clearing and stripping operations, and preceding the commencement of embankment construction.

(3) Terminology

Subsoil drains	are intended for the drainage of ground water and/or the pavement in cuttings.
Sub-Pavement Drains	are intended for the drainage of the pavement layers unless the subbase is open graded or pervious in nature in which case intra-pavement drains shall be provided.
Intra-Pavement Drains	are intended for the drainage of the pavement layers of a flexible pavement where the subbase comprises an open graded or pervious pavement material or open graded asphaltic concrete.
Edge Drains	are intended for the drainage of rigid pavements.
Foundation drains	are required for the drainage of seepage, springs and wet areas within and adjacent to the foundations.

(4) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with

this sub-section are as follows:
SC6.4.6.10 Earthworks (construction)
SC6.4.6.12 Flexible pavements
SC6.4.6.13 Asphaltic concrete
SC6.4.6.21 Subsurface drainage

(b) Australian Standards:

AS 1289.3.3.1	*Calculation of the plasticity index of a soil*
AS 1289.5.4.1	*Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS 1477	*PVC pipes and fittings for pressure applications*
AS 1289.5.6.1	(R2016) Methods of testing soils for engineering purposes Soil compaction and density tests - Compaction control test - Density index method for a cohesionless material

SC6.4.6.20.2 Construction

(1) Subsoil and sub-pavement drains

(a) Excavation

(i) Excavation shall be undertaken in accordance with the requirement of SC6.4.6.21 Subsurface drainage.

(ii) Trenches shall be trimmed to the required line and depth in accordance with the approved drain design specific to site conditions and as directed by the Superintendent.

(iii) The bottom of the trench shall be excavated to the same grade as the design pavement surface in the direction of the trench except where the grade of the design pavement surface in the direction of the trench is less than 0.25 per cent. In this case, the trench depth shall be increased to provide a minimum grade of fall in the trench of 0.25 per cent.

(iv) The bottom of the trench shall be excavated so that no localised ponding of water occurs. The bottom of the trench must not be more than 50 mm below the specified level of the invert of the pipe and ensure that the bottom and sides of the excavation are smooth with no protrusion that will damage the geotextile where required.

(v) If at any location the trench is excavated below the specified floor level, the trench shall be backfilled with non-porous subgrade material so that when the subgrade material is compacted to a relative compaction, determined by AS 1289.5.4.1, of at least 95 per cent (standard compaction), the bottom of the trench shall be at the specified floor level.

(vi) Where the drain is constructed in two stages, the excavation for Stage 2 shall be carried out after placement and compaction of the selected material zone or the stabilised subgrade layer. The Stage 2 trench shall be excavated to the same line and width as the Stage 1 trench and to a depth to provide a clean, full contact with the filter material placed in Stage 1. All excavated material shall be disposed to waste or incorporated into fills.

(vii) After the completion of excavation, the Contractor must present to the Superintendent the trench for inspection to ensure conformance with shape, grade line, filling and compaction and removal of any protrusions.

(b) Laying of pipe

(i) The 100mm diameter corrugated slotted plastic piping, complying with SC6.4.6.21 Subsurface drainage, shall be laid on a bed of filter material 50mm in thickness and shall be laid to the specified line and grade. The pipe shall not deviate from the specified line by more than 100mm at any point

(ii) The type of filter material shall be shown on the drawings as per the requirements of SC6.4.6.21 Subsurface drainage and shall be confirmed by the Superintendent prior to placement of material.

(iii) Joints in the pipeline shall be kept to the minimum number and, where required, shall be made using a suitable external joint coupling. The inlet end of the pipe shall be fitted with a cap.

(c) Backfilling

(i) The trench shall be backfilled with filter material to the level specified. The type of filter material shall be shown on the drawings as per the requirements of SC6.4.6.21 Subsurface drainage and shall be confirmed by the Superintendent prior to placement. The filter material shall be placed and

compacted in layers with a maximum compacted thickness of 300 mm. Tamping around and over the pipe shall be done in such a manner as to avoid damage or disturbance to the pipe.

(ii) The filter material shall be compacted for its full depth to a Density Index of not less than 70 per cent as determined by AS 1289.5.6.1.

(iii) The upper section of the trench, above the level specified for filter material backfill, shall be backfilled with selected free draining backfill material, conforming to the requirements of SC6.4.6.10 Earthworks (construction), compacted for its full depth to a relative compaction of not less than 97 per cent (standard compaction) as determined by AS 1289.5.4.1.

(iv) Where shown on the drawings or as directed by the Superintendent, a geotextile conforming with the requirements of SC6.4.6.21 Subsurface drainage, shall be provided at the interface between the filter material and adjoining materials. Cover the bottom and sides of the trench with sufficient free fabric to wrap around the completed drain. Conform to the shape of the trench with minimal wrinkles, folds or air voids between fabric and trench, but not stretched on the soil. Laps of 500mm shall be provided at joints in the fabric. The Contractor must take all reasonable care to ensure that the geotextile is not damaged during installation and backfilling operations. Ensure the period between initial laying out and final cover of the geotextile with drainage backfill layer does not exceed 14 days. Where possible place geotextiles just ahead of construction works and cover with materials within 48 hours. Any geotextile fabric exposed for longer than 14 days must be removed and replaced by the Contractor as directed by the Superintendent.

(v) Where the outlet section of pipes discharging through the fill batters, the trench shall be backfilled with the nominated filter material to a depth of 50mm above the pipe. The balance of trench shall be backfilled with earth backfill material of maximum particle size of 50mm and shall be compacted for the full depth to a relative compaction of 95 per cent (standard compaction) as determined by AS 1289.5.4.1.

(d) Outlets

(i) Outlets are to be provided at maximum intervals of 150m. Where possible, subsoil drains shall discharge into gully pits and other stormwater drainage structures. Where not possible, an outlet shall be constructed of unslotted plastic pipe of the same diameter as the main run to discharge below the edge of the road shoulder. An outlet structure in accordance with the drawings shall be constructed at the discharge end with appropriate treatment to address erosion of adjacent areas.

(ii) The outlet shall be made rodent proof in accordance with the requirements of SC6.4.6.21 Subsurface drainage.

(iii) The outlet shall be located so that erosion of the adjacent area does not occur, or shall be protected by the placement of selected stone in the splash zone of the outlet.

(e) Cleanouts

(i) Cleanouts are to be provided at the commencement of each run of subsoil drain line and at intervals of approximately 60m or as shown on the drawings.

(ii) Details of the required cleanout construction are shown on the drawings. The standard Cl caps as shown on the drawings shall be supplied by the Contractor.

(iii) Upon completion of backfilling, pump clean water into the cleanout at the commencement of each run until only clean water discharges at the outlet. The minimum rate of flow of flushing water at the inlet must be 100L/min.

(2) Intra-pavement drains

(a) Excavation

(i) A "V" shaped trench approximately 75mm deep shall be cut to the required line in the pavement layer immediately below the permeable pavement layer. No excavation is required below a 40mm open graded asphaltic concrete subbase layer.

(ii) The bottom of the trench is to be to the same grade as the roadway. The bottom of the trench shall be constructed so that localised ponding of water does not occur.

(iii) Where the pipe is to discharge through the fill batter a trench shall be constructed on a grade

suitable for the pipe to discharge its contents without scour. After laying the pipe the trench shall be backfilled with fill material and compacted for the full depth to a relative compaction of not less than 95 per cent (standard compaction) as determined by AS 1289.5.4.1.

(b) Laying of pipe

(i) Thick walled unplasticised PVC pressure pipe, complying with AS 1477, and having a nominal diameter of 58mm, and a minimum pipe wall thickness of 6.5mm, shall be used with crushed rock subbases having not more than 10 per cent of material passing the 9.5mm AS sieve and having layer thicknesses neither less than 150mm nor more than 200mm or open graded asphalt subbases having layer thicknesses neither less than 80mm nor greater than 100mm.

(ii) Where crushed rock subbases require pavement drains and have a depth exceeding 200mm, the type of pavement drain will need to be certified to have adequate crushing strength and a written approval from the Superintendent to the proposed pavement drain type will be required. Similar proposals shall require Superintendent and council approval for pavement drain in asphalt subbases greater than 100mm in depth.

(iii) All pipe shall be slotted except where otherwise shown on the drawings. Details of slot sizes and spacings shall be in accordance with SC6.4.6.21 Attachment A for thick walled unplasticised PVC pressure pipe.

(iv) Thick walled unplasticised PVC pressure pipe shall have square ends and shall be butt jointed.

(v) Where spigot and socket type pipes are used, the pipes shall be joined with the socket ends facing upstream.

(vi) The pipe shall be laid to the specified line and level. The pipe shall not deviate from the specified line by more than 100mm at any point.

(vii) The inlet ends of all pipes shall be fitted with caps.

(viii) All pipes shall be securely held to the layer under the free-draining subbase to prevent movement of the pipes during placement and compaction of the free draining subbase. At least 7 days before commencement of pipe laying, the Contractor shall submit details of the proposed method of securing the pipes to the layer under the free-draining subbase for the approval of the Superintendent.

(ix) Notwithstanding the Superintendent's approval to the use of a method of securing the pipes to the layer under the free draining subbase, if such securing method allows movement of the pipes, the method shall be discontinued and the Contractor shall propose an alternative securing method for approval by the Superintendent.

(x) Any additional costs resulting from the use of the alternative method of securing the pipes shall be borne by the Contractor.

(xi) The outlet length of pipe from the outside edge of the free-draining subbase to an outlet structure in the embankment batter shall be unslotted and the pipe joints in this length of pipe shall be sealed with suitable couplings or mastic.

(c) Backfilling

(i) Subbase material shall be spread, compacted and trimmed, where appropriate, as follows:

(A) for crushed rock subbase, in accordance with sub-section SC6.4.6.12 Flexible pavements; and

(B) for open graded asphalt subbase, in accordance with sub-section SC6.4.6.13 Asphaltic concrete.

(ii) Tipping, spreading and compaction of the subbase shall be undertaken in such a manner as not to damage the intra-pavement drain pipes. If any pipes are damaged as a result of the tipping, spreading and compaction of the subbase, the Contractor shall remove and replace the damaged pipes.

(iii) The cost of the removal and replacement of such damaged pipes shall be borne by the Contractor.

(iv) The thickness of the layer of subbase material enclosing the pipe shall be within the limits specified in clause SC6.4.6.20.2(b) Laying of pipe for the type of pipe used in the intra-pavement drain.

(d) Outlets

(i) Outlets are to be provided as shown on the drawings or at maximum intervals of 150m. Where possible intra-pavement drains shall discharge into gully pits and other stormwater drainage structures. Where not possible, each pipe shall be extended using a 60 degree bend and unslotted pipe to discharge through the fill batter and an outlet structure constructed on the discharge end in accordance with the drawings.

(ii) The outlet shall be made rodent proof in accordance with the requirements of SC6.4.6.21 Subsurface drainage.

(iii) The outlet shall be located so that erosion of the adjacent area does not occur, or shall be protected by the placement of selected stone in the splash zone of the outlet.

(iv) Joints in the pipeline shall be kept to the minimum number and, where required, shall be made using a suitable external joint coupling. The inlet end of the pipe shall be fitted with a PVC cap.

(3) Edge drains

(a) Excavation

(i) The verge material shall be trimmed to subgrade level and to the minimum width shown on the drawings. The bottom of the trench is to be constructed at the same grade as the roadway and in such a manner that localised ponding of water does not occur.

(ii) Where the grade of the roadway is less than 0.25 per cent the trench shall be excavated to provide a minimum grade of 0.25 per cent.

(iii) When the pipe is to discharge through the fill batter a suitable trench shall be excavated to provide the required grade.

(b) Laying of pipe

(i) Generally, 65mm diameter slotted corrugated plastic pipe enclosed in seamless tubular filter fabric, complying with SC6.4.6.21 Subsurface drainage, shall be used for edge drains.

(ii) Where any part of a shoulder consists of material other than concrete, slotted thick walled unplasticised PVC pressure pipe, complying with AS 1477, shall be used. Spigot and socket type pipes shall be joined with the socket ends facing upstream and the ends of each pipe shall be securely held against the vertical face of the rigid pavement. At least seven days before commencement of pipe laying, the Contractor shall submit details of the proposed method of securing the pipes against the rigid pavement for the approval of the council.

(iii) The pipe shall be laid on a prepared bed to the specified line and level. The pipe shall not deviate from the specified line by more than 100mm at any point.

(iv) Joints in the pipe shall be kept to a minimum number and shall be made using an external joint coupling approved by the Superintendent.

(v) The inlet end of the pipe shall be fitted with a cap.

(vi) The outlet section of a pipe from the vertical face of the rigid pavement to an outlet in the embankment batter shall be unslotted and the pipe joints in this length of pipe shall be sealed with mastic.

(c) Backfilling

(i) The pipe shall be covered with Type B filter material to the dimensions shown on the drawings.

(ii) Mechanical compaction of this filter material is not required, however after placement of the filter material it shall be soaked with water. Where necessary additional filter material shall be added and soaked to provide the final dimensions shown on the drawings.

(iii) Backfilling over the edge drain shall be done in such a manner as to avoid damage or disturbance of the pipe. Backfill material shall be selected material as required for verges and in accordance with the requirements of sub-section SC6.4.6.10 Earthworks (construction). Backfilling shall be compacted to a relative compaction of not less than 100 per cent (standard compaction) as determined by AS 1289.5.4.1.

(iv) Upon completion of backfilling, pump clean water into the cleanout at the commencement of each

run until only clean water discharges at the outlet. The minimum rate of flow of flushing water at the inlet must be 100L/min.

(d) Cleanouts

(i) Cleanouts are to be provided at the commencement of each run of edge drain line and at intervals of approximately 60m or as shown on the drawings.

(ii) Details of the required cleanout construction are shown on the drawings. The standard CI caps as shown on the drawings shall be supplied by the Contractor.

(e) Outlets

(i) Unless otherwise shown on the drawings outlets are to be provided at maximum intervals of 150 m. Where possible edge drains shall discharge into gully pits and other stormwater drainage structures. Where not possible, an outlet shall be constructed of unslotted plastic pipe of the same diameter as the main run to discharge below the edge of the road shoulder. An outlet structure in accordance with the drawings shall be constructed at the discharge end.

(ii) The outlet shall be made rodent proof in accordance with the requirements of SC6.4.6.21 Subsurface drainage.

(iii) The outlet shall be located so that erosion of the adjacent area does not occur, or shall be protected by the placement of selected stone in the splash zone of the outlet.

(4) Foundation drains

(a) Excavation

Excavation shall be undertaken in accordance with the requirements of SC6.4.6.21 Subsurface drainage and clause SC6.4.6.20.2(1) Subsoil and sub-pavement drains of this sub-section.

(b) Laying of pipe

(i) The 100mm diameter corrugated slotted plastic piping, complying with SC6.4.6.21 Subsurface drainage, shall be laid on a bed of filter material 50mm in thickness and shall be laid to the required line and grade.

(ii) The type of filter material shall be shown on the drawings as per the requirements of sub-section SC6.4.6.21 Subsurface drainage or as directed by the Superintendent.

(iii) Joints in the pipeline shall be kept to the minimum number and, where required, shall be made using a suitable external joint coupling. The inlet end of the pipe shall be fitted with a PVC cap.

(c) Backfilling

(i) The trench shall be backfilled with filter material in accordance with the provisions of clause SC6.4.6.20.2(3)(c) Backfilling.

(ii) The upper section of the trench, above the level specified for filter material backfill, shall be backfilled with suitable earth backfill material, compacted for its full depth to a relative compaction of not less than 97 per cent (standard compaction) as determined by AS 1289.5.4.1.

(iii) Where shown on the drawings or as directed by the Superintendent, a geotextile, conforming with the requirements of SC6.4.6.21 Subsurface drainage, shall be provided at the interface between the filter material and adjoining materials. Laps of 500mm shall be provided at joints in the fabric.

(d) Outlets

An outlet structure in accordance with the detail shown on the drawings and SC6.4.6.21 Subsurface drainage shall be constructed at the discharge end.

The outlet shall be located so that erosion of the adjacent area does not occur or shall be protected by the placement of selected stone in the splash zone of the outlet.

SC6.4.6.20.3 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.20.1 Summary of limits and tolerances below.

Table SC6.4.6.20.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Excavation**		SC6.4.6.20.2(3)(a)
	Trench Grade	0.25%	
2.	**Laying of Pipe**		
	• Alignment	Deviation <100mm from specified line at any point	SC6.4.6.20.2(3)(b)
3.	**Subsoil and Sub-Pavement Drain Backfill**		
	(a) Layer thickness	300mm max	SC6.4.6.20.2(3)(c)
	(b) Compaction (Relative)	70% Density Index	SC6.4.6.20.2(3)(c)
	Filter material	97% (Standard)	
	Backfill material		
4.	**Outlet Spacing**	150m max	SC6.4.6.20.2(3)(d)
5.	**Cleanout Spacing**	60m approx	SC6.4.6.20.2(3)(d)
6.	**Intra-Pavement Drain**		
7.	(a) Alignment	Deviation <100mm from specified line at any point.	SC6.4.6.20.3(b)
	Edge Drains		
	(a) Alignment	Deviation <100mm from specified line at any point	SC6.4.6.20.3(b)
	(b) Compaction (Relative) Backfill material	97% Standard	SC6.4.6.20.3(c)

SC6.4.6.21 Sub-surface drainage

SC6.4.6.21.1 Introduction

(1) Introduction

This is the general specification common and applicable to all types of subsurface drainage and must be read in conjunction with subsurface drainage sub-sections:

(a) SC6.4.6.20 Subsoil, foundations and pavement drains; and

(b) SC6.4.6.8 Drainage mats.

(2) Scope

(a) The work to be executed under this sub-section consists of:

(i) preparation for subsurface drainage construction;

(ii) siting of subsurface drainage facilities;

(iii) the supply of all materials associated with the provision of the subsurface drainage system;

(iv) all activities and quality requirements associated with the supply, placement and compaction of filter material;

(v) the provision of a detailed record of all subsurface drain installations; and

(vi) the marking on the ground of the location of all subsurface drains.

(b) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Supervision and construction guidelines.

(3) Extent of work

Details of the work are to be shown on the approved drawings.

(4) Temporary drainage during construction

(a) All drainage works carried out by the Contractor must provide measures of erosion and sedimentation in accordance with the requirements of the accepted project erosion and sediment control plan and/or *Best Practice Erosion and Sediment Control* and make adequate provision for runoff flows at drainage works under construction or at surrounding areas/structure.

(b) The Contractor must make adequate provision for runoff flows at subsurface drainage works under construction, to avoid damage or nuisance due to scour, sedimentation, soil erosion, flooding, diversion of flow, damming, undermining, seepage, slumping or other adverse effects to the Works or surrounding areas and structures as a result of the Contractor's activities.

(c) The Contractor's material and equipment must be located clear of watercourses or secured so that they will not cause danger or damage in the event of large runoff flows.

(5) Siting of work

(a) Before commencing construction of any subsurface drainage activity, the Contractor must set out on site the position of the work to the location and levels shown on the drawings, and must present this set-out for inspection by the Superintendent.

(b) The Superintendent may amend the locations or designed levels or the lengths to suit actual site conditions. Should the Superintendent require a change to the conditions of installation an appropriate variation must be ordered.

(c) Should the Contractor propose changes to the location, length, designed levels, conditions of installation or cover to suit the Contractor’s construction procedures, the Contractor must present the proposed set-out in addition to the designed set-out for consideration by the Superintendent. No changes shall be made unless the prior written approval of the Superintendent is obtained.

(6) Excavation

(a) In undertaking trench excavation the Contractor must provide any shoring, sheet piling or other stabilisation of the sides necessary to comply with statutory requirements.

(b) Where public utilities exist in the vicinity of drainage works the Contractor must obtain the approval of the relevant authority/corporation to the method of excavation before commencing excavation.

(c) Excavation by blasting, if permitted, must be carried out to ensure that the peak particle velocity measured on the ground adjacent to any previously installed structure does not exceed 25 millimetres per second. The Contractor must comply with other requirements concerning blasting operations in SC6.4.6.10 Earthworks (construction).

(d) Trenches must be excavated to the line, grade, width and depth shown on the drawings or as directed by the Superintendent. The bottom of the trench must be constructed so that no localised ponding can occur. All loose material must be removed by the Contractor.

(e) Any material at the bottom of the trench or at foundation level which the Superintendent deems to be unsuitable must be removed and disposed in accordance with SC6.4.6.10 Earthworks (construction) by the Contractor and replaced with backfill material in accordance with the requirements of this sub-section. The bottom of the excavated trench or foundation, after any unsuitable material has been removed and replaced, must be parallel with the specified level or grade of the pipe.

(f) The excavated material shall be used in the construction of embankments backfilling or spoiled in accordance with SC6.4.6.10 Earthworks (construction).

(7) Backfilling

Backfilling must be carried out in accordance with the requirements of the relevant subsurface drainage structures sub-sections.

(8) Outlet structures for subsurface drainage

(a) Subsurface drainage pipes must be connected to discharge into gully pits or to outlet structures as shown on the drawings or as directed by the Superintendent.

(b) Outlets must be spaced at a maximum interval of 150m.

(c) Outlets, including those discharging into gully pits, must be made rodent proof using galvanised wire netting unless otherwise indicated on the approved drawings.

(d) The outlet must be located so that erosion of the adjacent areas does not occur or must be protected by the placement of selected stone or similar treatment together with a marker post to indicate location and assist maintenance.

(e) Outlet pipes from curtain drains must be unslotted. At no point shall an outlet pipe be higher than the pipe at the end of the curtain drain.

(f) All concrete used in the construction of outlet structures must conform to the requirements of sub-section SC6.4.6.28 Minor concrete works.

(9) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

AS 3705	*Geotextiles - Identification, marking and general data*

AS 3706	*Geotextiles - Methods of test*
AS 3706.9	*Determination of permittivity, permeability and flow rate*
AS 3706.11	*Determination of durability - Resistance to degradation by light, heat and moisture*

(c) Other:

Austroads, *Guide to Pavement Technology - Part 4G Geotextiles.*

ASTM International, ASTM-D2434-68 – *Standard test method for permeability of granular soils (Constant Head)*

International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

SC6.4.6.21.2 Materials

(1) Corrugated plastic pipe

(a) Corrugated plastic pipe must be Class 1000 complying with AS2439.1 of 65mm or 100mm diameter as indicated on the drawings. All pipe must be slotted except where shown on the approved drawings.

(b) Joints, couplings, elbows, tees and caps must also comply with AS2439.1 and only the manufacturer's recommended fittings shall be used.

(c) The Contractor must obtain from the Manufacturer Test Certificate demonstrating compliance with AS2439.1.

(2) Other types of subsurface drainage

Where a Contractor wishes to use a subsurface drainage pipe other than corrugated plastic pipe, the Contractor must submit full details of the type of pipe, certification from the manufacturer of its suitability and quality and written acceptance by the council for its use in each particular application. Certification of the suitability of any pipe must address the crushing strength, flexural strength, jointing system and slotting details.

(3) Filter material

(a) General

The types of filter material covered by this sub-section shall include:

(i) Type A filter material for use in trench drains and Type B drainage mats;

(ii) Type B filter material for use in trench drains and Type B drainage mats;

(iii) Type C filter material comprising crushed rock for use in Type A drainage mats; and

(iv) Type D filter material comprising uncrushed river gravel for use in Type A drainage mats.

All filter material must consist of clean, hard, tough, durable particles. A sample of the proposed filter material must be submitted to the Superintendent for approval.

(b) Type A filter material

Type A filter material must be crushed rock complying with the following requirements in Table SC6.4.6.21.1.

Table SC6.4.6.21.1 Type A filter material

Test Method	Property	Requirement
AS 1141.11	Material passing AS sieve	Per cent by mass
	6.7mm	100
	4.75mm	85 to 100
	2.36mm	0 to 40
	1.18mm	0 to 5
	425µm	0 to 2

(c) Type B Filter Material

Type B filter material must be granular material complying with the following grading requirements in Table SC6.4.6.21.2.

Table SC6.4.6.21.2 Type B filter material

Test Method	Property	Requirement
AS 1141.11	Material passing AS sieve	Per cent by mass
	4.75mm	100
	2.36mm	95 to 100
	425µm	20 to 80
	300µm	0 to 30
	150µm	0 to 2
	75µm	0 to 0.1

In addition to the above grading requirements, Type B filter material must have a coefficient of saturated permeability, when compacted to its maximum dry density as determined by AS1289.5.5.1 and then tested in accordance with Test Method ASTM D2434 68, of at least 8m per day after 3 hours of flow.

Type B filter material must not vary from its original grading as a result of compaction processes by more than the following amounts listed in Table SC6.4.6.21.3.

Table SC6.4.6.21.3 Type B filter material variation

AS Sieve	Variation From Grading Before Treatment (per cent of mass)
2.36mm	± 3
1.18mm	± 1
425µm	± 1
300µm	± 1
150µm	± 0.5
75µm	± 0.1

(d) Type C Filter Material

Type C filter material must be crushed rock complying with the following requirements in Table SC6.4.6.21.4.

Table SC6.4.6.21.4 Type C Filter Material

Test Method	Property	Requirement
AS 1141.11	Maximum particle size	37.5mm
	Maximum passing the 9.5mm AS Sieve	5% by mass
	Maximum (D90:D10)*	3
AS 1141.22	Minimum wet strength	100kN
	Maximum 10% fines wet/dry variation	30%

Note—the D90 value must be determined by sieving the material using 75mm, 53mm, 37.5mm, 26.5mm, 19mm, 13.2mm and 9.5mm AS sieves, as appropriate, and then plotting the results on a graph of AS sieve size v percentage passing. The plotted points must be joined by straight lines and the D90 must shall be determined as the theoretical sieve size corresponding to 90 per cent passing.

D10 denotes the theoretical size of a sieve through which 10 per cent of the material would pass and must be determined from the same graph used to determine the D90 value.

(e) Type D Filter Material

Type D filter material must be uncrushed river gravel complying with the description of rounded aggregate in Table B1, Appendix B of AS2758.1 and the following requirements in Table SC6.4.6.21.5.

Table SC6.4.6.21.5 Type D Filter Material

Test Method	Property	Requirement
AS 1141.11	Maximum particle size	75mm
	Maximum passing the 9.5mm AS sieve	5% by mass
	Maximum (D90 : D10)	3
AS 1141.22	Minimum wet strength	100kN
	Maximum 10% fines wet/dry variation	30%

(4) Geotextile

Prior to placing geotextiles, documentary evidence that the geotextile and installation process conform to the requirements of this sub-section must be produced and submitted to the Superintendent.

(a) General

The geotextile, other than seamless tubular filter fabric, must consist of either a woven or a non-woven type which must be manufactured from synthetic materials other than polyamide. Rolls of geotextile shall be marked with product identification and supplied with data sheets and information in accordance with the requirements of AS 3705.

The geotextile must be bio stable and resistant to attack by alkalis, acids, dry heat, steam, moisture, brine, mineral oil, petrol, diesel and detergents when tested in accordance with the appropriate parts of AS3706.

The geotextile must be resistant to ultra violet light. No geotextile shall be left exposed to sunlight during storage and construction for a period longer than a total of 21 days. If exposure in excess of 21 days does occur, the geotextile must be tested in accordance with AS 3706.11 and if its characteristics have deteriorated to or below 90 per cent of the characteristics claimed by the manufacturer or the characteristics determined on unexposed geotextile, whichever is the better, it must be removed and replaced with a geotextile complying with this specification.

The geotextile material type, strength rating “G”, and minimum mass requirements must be as shown on the drawings.

The type, properties, functions, design and construction requirements for a particular application of geotextile installation must be compatible with recommendations provided by the Guide to Pavement Technology – Part 4G, as well as requirements indicated on the drawings.

In addition to the above mentioned requirements, geotextiles for curtain drains must consist of either polyester, polypropylene or polyethylene. The required rates of water flow are shown on Table 4.1 of Guide to Pavement Technology – Part 4G, under 100mm constant head determined using the perpendicular flow test to conform with AS3706.9.

(b) Seamless tubular filter fabric

Seamless knitted tubular filter fabric must be used to enclose all slotted pipes and must be manufactured from either polypropylene or polyester. The fabric must be free of imperfections in weave or yarn and have abrasion resistant and weave stability qualities such that it shall not form holes, ladder, deweave, tear or unravel more than 5mm from a cut end.

Fitting of the seamless tubular filter fabric must be in accordance with the requirements of SC6.4.6.21 Attachment A. Filter fabric that is excessively stretched, torn or otherwise damaged during fitting of the fabric, storage, transportation or pipe laying will be removed and replaced so as to eliminate any damaged lengths.

SC6.4.6.21.3 Recording of subsurface drainage information

(1) The Contractor must keep a detailed record of all subsurface drainage pipes and the completed subsurface drainage systems must be shown on the work as executed plans to be returned to the Superintendent upon completion of work.

In addition, the Contractor must prepare a subsurface drainage information sheet or sheets; at the completion of construction of each drain or drainage system and must submit the subsurface drainage sheet or sheets to the Superintendent within 5 working days of the completion of the drain or drainage system.

SC6.4.6.21.4 Limits and tolerances

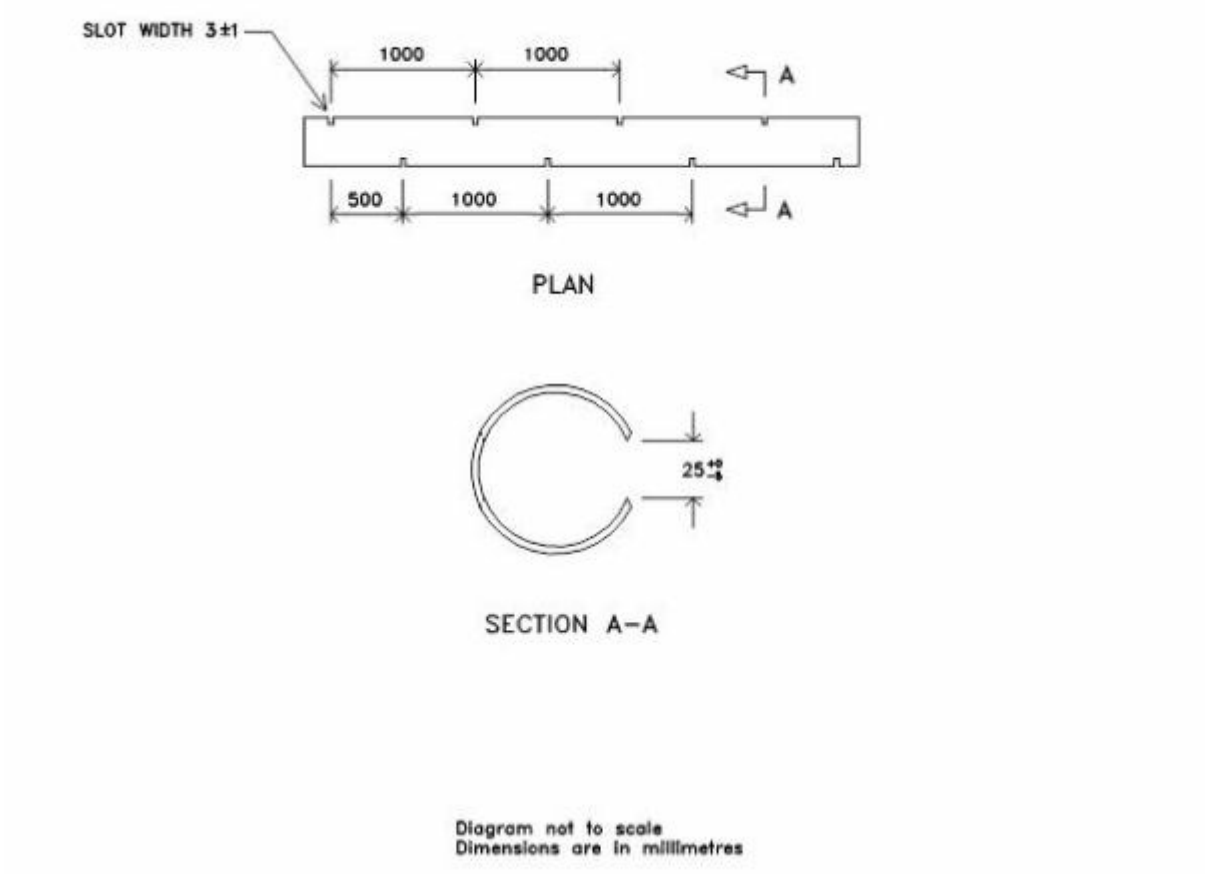
The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.21.6 Summary of limits and tolerances below.

Table SC6.4.6.4.21.6 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Excavation by Blasting** Peak particle velocity	25mm/s	SC6.4.6.21.1(6)
2.	**Outlets** Spacing	Max 150m	SC6.4.6.21.1(8)
3.	**Filter Material**		
	(a) Type A	Table SC6.4.6.21.1	SC6.4.6.21.2(3)
	(b) Type B	Tables SC6.4.6.21.2 and SC6.4.6.21.3	SC6.4.6.21.2(3)
	(c) Type C	Table SC6.4.6.21.4	SC6.4.6.21.2(3)
	(d) Type D	Table SC6.4.6.21.5	SC6.4.6.21.2(3)
4.	**Geotextile**		
	(a) Exposure to sunlight	<21 days If >21 days deterioration not to exceed 10% of claimed characteristics	SC6.4.6.21.2(4)

Attachment A

Figure SC6.4.6.21.1 Slotting details for thick walled PVC plastic pipe



1. Slotted pipes fitted with seamless tubular filter fabric

(a) Procedure for fitting seamless tubular filter fabric to slotted pipe

(i) Seamless tubular filter fabric must be fitted to slotted pipe immediately before the slotted pipe is to be laid in its final position in the work.

(ii) The filter fabric must be initially pulled over and onto a short length of smooth pipe of internal diameter between 20mm and 30mm greater than the external diameter of the slotted pipe to be enclosed by filter fabric. The short, larger diameter pipe must be referred to as the "mandrel".

(iii) The pipe to be enclosed by the filter fabric must be passed through the mandrel. The filter fabric must be slipped on to the pipe as the pipe emerges from the mandrel leaving enough overhang of the filter fabric to make a suitable joint with the filter fabric on the adjacent pipe. The filter fabric must be firmly held to the forward end of the pipe so that it cannot slip back along the pipe.

(iv) The pipe must be pulled right through the mandrel allowing the filter fabric to progressively slip over the pipe. The filter fabric shall be restrained from easily slipping off the mandrel thus ensuring the filter fabric is stretch fitted onto the pipe.

(v) When the end of the pipe emerges from the mandrel, the filter fabric must be clamped to that end of the pipe so that the filter fabric cannot slip down the pipe. The filter fabric must remain clamped to each end of the pipe to ensure the filter fabric remains stretch fitted onto the pipe when the pipe is placed in its final position in the drain. The filter fabric must be cut cleanly leaving enough overhang off the end of the pipe to make a fully covered join with the filter fabric on the adjacent pipe when the pipes are installed in the drain.

(b) Precautions to be taken when using slotted pipe fitted with seamless tubular filter fabric

(i) Slotted pipe fitted with seamless tubular filter fabric must not be dragged over the ground. If carried, the pipe must be lifted clear of the ground and the filter fabric must be protected from damage at all times.

(ii) Seamless tubular filter fabric which has been so damaged as to affect its filtering properties must be removed from the pipe and replaced with undamaged filter fabric.

(iii) If at any time during the installation of a slotted pipe it is found that the enclosed filter fabric has become loose on the pipe it must be restretched to its correct position. If restretching causes any damage to the filter fabric, the damaged filter fabric must be removed from the pipe and replaced with undamaged filter fabric.

SC6.4.6.22 Pavement markings

SC6.4.6.22.1 Introduction

(1) Scope

This sub-section provides standards, advice and guidelines for the removal, setting out, supply and application of pavement marking paint, thermoplastic pavement marking material, pavement marking tape and raised pavement markers. Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(d) Other:

Australian Paint Approval Scheme – Specification 0041/4 - Roadmarking paint, thermoplastic

Australian Paint Approval Scheme – Specification 0041/5 - Roadmarking paint, water borne

(3) Type of markings

Details of the various types of pavement markings and devices are in accordance with the requirements of the MUTCD, TRUM and GTPM.

Colours

White paint must have a colour equivalent to or whiter than Off White, Colour Y35 in AS2700.

Where yellow is used, the colour shall be equivalent to Y12, Wattle or Y14, Golden Yellow as detailed in AS2700 or any other colour deemed to lie between these two colours.

Where Green is used as a coloured surfacing on bicycle lanes, guidance on the application of green coloured surface treatments is contained within TRUM 1.34. The colour must be equivalent to Emerald, Colour G13; Traffic Green, Colour G16 or Shamrock, Colour G23 in AS2700. Where only one shade of each colour is specified, Traffic Green, Colour G16 is used.

(4) Types of materials to be applied
The materials shall be applied as follows:

(a) Pavement marking paint
Permanent markings on all wearing surfaces. Temporary markings, other than on the final wearing surfaces. Traffic islands and kerbs where specified;

(b) Thermoplastic pavement marking material
Permanent markings where explicitly indicated on the drawings;

(c) Pavement marking tape
Temporary markings on final wearing surfaces;
Temporary raised pavement markers (TRPMs);
Temporary markers fixed on any surface as a temporary marking.

(d) Reflective glass beads
To be applied to all painted and thermoplastic markings; and

(e) Raised pavement markers
Studs which may be retroreflective (RRPM) or non-retroreflective (NRPM) set into the roadway or attached to the road surface with adhesives, lane dividers, or pavement bars are installed as permanent as shown on the drawings.

(5) Material quality
The Contractor shall submit to the Superintendent NATA Registered Laboratory Test Reports, at least 7 days before work is scheduled to commence, on the quality of the materials, including paint, glass beads, raised pavement markers and thermoplastic material proposed for use.
Only materials conforming to the requirements of the referenced Specifications/Standards shall be used.

(6) Setting out
The Contractor shall set out the work "spotting" to ensure that all markings are placed in accordance with the drawings.
The locations of pavement markings shall not vary by more than 20mm from the locations shown on the drawings. Spotting for longitudinal lines is generally at 10m intervals with 3m intervals on curves of less than 50m radius.
The contractor must obtain approval from the administrator of the spotting prior to any application of pavement marking.

(7) Surface preparation
Surfaces which are to receive pavement markings shall be cleaned of all dirt, loose material and other contaminants. Pavement surfaces shall be thoroughly dry immediately prior to the application of pavement markings. Pavement marking shall not be carried out during wet weather or, if rain is likely to fall during the process.
In all cases, the reinstatement of longitudinal markings, particularly barrier lines and dividing lines, should occur as soon as possible after the new seal has been laid.
Where raised pavement markers are specified for pavements having a concrete wearing surface, the full area under each raised pavement marker shall be lightly scabbled to remove fine mortar material (laitance).
All painted markings whether installed by machine or hand are retroreflectorised by the application of drop-on glass beads (ballotini).

(8) Provision for traffic and protection of work
In accordance with MUTCD, Part 3 Works on Roads, and SC6.4.6.30 Control of traffic while undertaking the work and shall protect the pavement markings until the material has hardened sufficiently (no pick-up) so that traffic will not cause damage.

(9) Maintenance of pavement markings
The Contractor shall be responsible for the maintenance, and replacement if necessary, of raised pavement markers and all pavement marking during the contract period and the contract defects liability period.
Council requires all linemarking to be refreshed prior to to the end of the Defects Liability Period.

SC6.4.6.22.2 Pavement marking paint

(1) Materials

Paint shall comply with the requirements of AS4049.1 or AS4049.3. In this sub-section, the term “paint” shall mean “pavement marking paint”.

Glass beads shall comply with the requirements of AS2009 for drop-on beads.

(2) Mixing of paint

All paint shall be thoroughly mixed in its original container before use in accordance with the manufacturer’s recommendations to produce a smooth uniform product consistent with the freshly manufactured product.

(3) Application of paint and beads

All longitudinal lines shall be sprayed by an approved self-propelled machine. Line must have uniform thickness and intensity. Two coats of paint and glass beads shall be applied on longitudinal lines to new surfaces. The first coat shall be cured to “no pick up time” prior to the application of the second coat. The two sets of lines forming a one way or two way barrier line pattern shall be sprayed concurrently.

Hand spraying with the use of templates to control the pattern and shape shall be permitted for transverse lines, symbols, legends, arrows and chevrons.

The paint shall be applied uniformly and the wet film thickness shall be neither less than 0.35mm nor more than 0.4mm.

Glass beads shall be applied by air propulsion to the surface of all longitudinal lines at a net application rate of 1.3kg/sqm immediately after application of the paint. The actual application rate shall be set to overcome any loss of beads between the bead dispenser and the sprayed line.

Glass beads shall be similarly applied to all other paint markings at a net application rate of 0.3kg/sqm immediately after application of the paint by an applied method.

Pavement markings shall be straight or with smooth, even curves where intended. All edges shall have a clean, sharp cut off. Any marking material applied beyond the defined edge of the marking shall be removed leaving a neat and smooth marking on the surface of the pavement.

The lengths and widths of longitudinal lines and transverse lines must be within the tolerance specified in MUTCD/GTPM and MRST45.

The dimensions of arrows, chevrons and speed markings must be within the tolerances specified in MUTCD/GTPM as appropriate.

Arrows and speed markings shall be placed square with the centreline of the traffic lane.

Glass beads shall be uniformly incorporated in all coats of paint concurrently with the application of the paint.

Longitudinal line marking, when applied, must have a minimum retroreflectivity of 350mcd/lux/m2 measured between 10 and 20 days of wear.

(4) Field testing

The thickness of the wet film applied to the road pavement shall be checked by the method described in AS1580, comb gauge or test Q513 – (07/10).

The application rate of glass beads applied to the surface of the markings shall be checked by the method described in SC6.4.6.22 Attachment A Procedure for measurement of rate of application of spherical glass beads.

(5) Application rates

The minimum application rates for the paint and glass beads shall be as specified in Table SC6.4.22.1.

Table SC6.4.6.22.1 Application rates for paint and glass beads

Work type	Coverage (minimum per coat)	Wet application rate
Longitudinal lines – first coat Type B (drop-on beads)	> 300g/m^2	0.375L/m^2 ± 0.25
Longitudinal lines – second coat Type B (drop-on beads)	> 300g/m^2	0.375L/m^2 ± 0.25
Longitudinal lines – repaint Type B (drop-on beads)	> 200g/m^2	0.300L/m^2 ± 0.20
Longitudinal lines – second coat or repaint applying Type D beads	> 400g/m^2	0.500L/m^2 ± 0.25
Transverse lines – Type B (drop-on beads)	> 300g/m^2	0.375L/m^2 ± 0.25
Transverse lines – Type D beads	> 400g/m^2	0.500L/m^2 ± 0.25

Source: MRTS 45

The combination application rates for anti skid and glass beads shall not exceed the values specified above and in SC6.4.6.22.2(6) unless specified by the manufacturer.

Table SC6.4.6.22.2 Volume of glass beads (ml) required in 10 seconds of operation

Road Speed km/h	Line Widths			
	75mm	**100mm**	**125mm**	**150mm**
8	371	495	619	742
13	603	804	1006	1207
16	742	990	1238	1484

Note—

1. Tolerance of +10% shall be permissible when measuring the above volume.
2. When two or more glass bead dispensers are to be used, each dispenser shall be checked separately to make up the totals shown.
3. Glass beads weigh approximately 1.53g/ml.

(6) Anti skid

Transverse markings shall incorporate an anti skid treatment with a skid resistance greater than 45 BPN. The application of anti-skid shall comply with the manufacturer's requirements.

SC6.4.6.22.3 Thermoplastic pavement marking material

(1) Primer

A primer, of the type recommended by the manufacturer of the thermoplastic material, shall be applied to the surface immediately in advance of, but concurrent with, the application of thermoplastic material.

The primer shall be applied at the application rate recommended by the manufacturer and shall not be thinned.

(2) Application of thermoplastic material

Thermoplastic material may be applied by screeding, extrusion or profiling or as preformed material.

Thermoplastic material shall be applied to the pavement at a temperature between 180ºC and 200ºC unless a different temperature is recommended by the manufacturer.

The pavement surface to which thermoplastic material is applied shall be completely coated by the material and any voids in the pavement surface shall be filled.

(3) Application rate

Thermoplastic material shall be applied at the minimum thickness specified in Table SC6.4.6.22.3.

Location	Minimum application thickness (mm)
Longitudinal lines	2
Transverse markings	2

Editor's note - the term “thermoplastic material” shall mean “thermoplastic pavement marking material”.

Where specified, glass beads shall be applied immediately to the surface of the molten thermoplastic material at a rate of not less than 0.12kg/m2.

(4) Materials

Thermoplastic pavement marking material shall comply with the requirements of AS4049.2.

Glass beads shall be incorporated in thermoplastic material, in the proportion of 10% of the total mass, as part of the aggregate constituent and shall comply with the requirements of AS2009, Intermix type.

Glass beads for surface application shall comply with the requirements of AS2009, Drop-on beads.

Tack coat material shall be to the manufacturer's specification.

(5) Preparation of thermoplastic material on site

Immediately before application, the thermoplastic material shall be uniformly heated in a suitable oil bath kettle to the temperature recommended by the manufacturer. The thermoplastic material shall not be heated above the temperature recommended by the manufacturer. The thermoplastic material shall not remain molten for more than 6 hours for hydrocarbon resins and 4 hours for wood and gum resins. Should over-heating occur and/or the time expires for molten materials, then the thermoplastic material shall be discarded.

(6) Application of thermoplastic material and beads

Where the wearing surface of the pavement is smooth or polished, a tack coat of material may be required by the Superintendent and shall be applied in accordance with the recommendations of the thermoplastic manufacturer. The tack coat shall be applied immediately before the application of the thermoplastic material in accordance with the directions of the manufacturer of the thermoplastic material and the manufacturer of the tack coat material.

All longitudinal lines shall be sprayed by a self-propelled machine. The two sets of lines forming a one way or two way barrier line shall be sprayed concurrently. The thermoplastic material shall be applied uniformly and the cold film thickness shall be 2mm with a tolerance of plus or minus 0.5mm.

Glass beads shall be applied by air propulsion to the surface of all longitudinal lines at a net application rate of 0.3kg/sqm immediately after application of the thermoplastic material. The actual application rate shall be set to overcome any loss of beads between the bead dispenser and the sprayed line.

All transverse lines, symbols, legends and arrows shall be screeded. The screeded thermoplastic material shall be applied using a mobile applicator, and templates to control the pattern.

Preformed thermoplastic sheeting applied in accordance with manufacturer’s specifications is an approved process.

The thermoplastic material for transverse lines, symbols, legends and arrows shall be applied uniformly and the cold film thickness shall be 3.5mm with a tolerance of plus or minus 1.5mm. The surface finish shall be smooth.

Glass beads for other than longitudinal lines shall be uniformly applied to screeded markings at a net application rate of 0.3kg/sqm immediately after application of the thermoplastic material.

Pavement marking must be straight or with smooth, even curves where intended. All edges shall have a clean, sharp cut off. Any marking material applied beyond the defined edge of the marking shall be removed leaving a

neat and smooth marking on the wearing surface of the pavement.

The lengths of longitudinal lines shall not vary by more than 20mm from the lengths shown in MUTCD/GTPM. The widths of longitudinal lines shall not vary by more than 10mm from the widths shown in MUTCD/GTPM. The lengths and widths of transverse lines shall not vary by more than 10mm from the lengths and widths shown in MUTCD/GTPM.

The dimensions of arrows, chevrons and speed markings shall not vary by more than 50mm from the dimensions shown on the drawings or in MUTCD/ GTPM as appropriate. Arrows and speed markings shall be placed square with the centreline of the traffic lane.

(7) Field testing
The thickness of the cold film of thermoplastic material applied to the road pavement shall be checked by measurement, using a micrometer, of the thickness of thermoplastic material applied to a metal test plate. The application rate of glass beads applied to the surface of the markings shall be checked by the method described in SC6.4.6.22 Attachment A Procedure for measurement of rate of application of spherical glass beads.

SC6.4.6.22.4 Pavement marking tape

(1) Materials
Pavement marking tape shall be a strippable type of tape, such as “Staymark Detour Grade”, or equivalent tape approved by the Superintendent. Pavement marking tape must only be used on temporary works.

(2) Application of pavement marking tape
The method of application of pavement marking tape, including surface preparation, shall be in accordance with the manufacturer's recommendations.

(3) Removal of pavement marking tape
When directed by the Superintendent, the Contractor shall remove pavement marking tape in accordance with the manufacturer's recommendations.

(4) Temporary raised pavement markers (TRPMs)
Temporary raised pavement markers must comply with the requirements of AS1906.

Temporary raised pavement markers may be used to mark the temporary travelled path at short-term work sites, or to indicate the permanent travelled path on new work prior to the application of permanent pavement markings.

The use of temporary raised pavement markers may preclude the need for spotting where existing markings are to be reinstated after a reseal, and for respotting if proposed line markings were set out before the final seal on new works is applied. In these cases, the distance between TRPMs should be the same as would apply for spotting.

Temporary raised pavement markers should not take the place of spotting, as TRPMs may be broken off by traffic before final marking can be carried out. Once the longitudinal lines have been marked, the Temporary raised pavement marker flaps can be removed by cutting them off flush with the pavement surface.

SC6.4.6.22.5 Raised pavement markers

(1) Materials
Raised pavement markers, both reflective and non reflective, shall comply with AS1906.3 and shall have the dimensions shown on the drawings.
The adhesive used for attaching the raised pavement markers to the wearing surface of the pavement shall be a hot-melt bitumen adhesive or an equivalent product approved.

(2) Installation of raised pavement markers

The use of raised retroreflective pavement markers must be in accordance with the MUTCD, GTPM and TRUM 1.25 Fire Hydrant Indication System.

Raised pavement markers shall be fixed to the wearing surface of the pavement using a hot melt bitumen adhesive or an equivalent product. The adhesive shall be freshly heated to the manufacturer's instructions and thoroughly mixed.

The adhesive shall be spread uniformly over the underside of the raised pavement marker to a depth of approximately 10mm. The raised pavement marker shall be pressed down onto the pavement surface in its correct position and shall be rotated slightly until the adhesive is squeezed out around all edges of the marker. The raised pavement marker shall not be disturbed until the adhesive has set.

On rough surfaces, such as newly laid coarse sprayed bituminous seals, an initial pad of adhesive of diameter 20mm larger than the diameter of the base of the raised pavement marker, shall be provided. The adhesive shall be applied to fill the irregularities in the pavement surface to produce a flat, smooth surface flush with the upper stone level. The adhesive pad shall be allowed to set. Additional adhesive shall be applied to the pavement, as described above, and then the raised pavement marker shall be pressed down onto the adhesive pad on the pavement surface to ensure good adhesion.

When installed, raised pavement markers shall conform to the tolerances specified in Table SC6.4.6.22.4.

Table SC6.4.6.22.4 Tolerances - raised pavement markers

	Tolerance (mm)	Distance
Lateral position –	+ 25, - 50	from edge of line
• barrier/edge line	± 10	from edge of line
• broken line	± 10	from centre of line
• flush medians		
Longitudinal position –	± 10	1m from start of line
• broken line	± 100	1m from start of line
• new construction	± 300	1m from start of line
• replacement		

(1) General

The Contractor shall remove pavement markings, no longer required, from the wearing surface of pavements without significant damage to the surface.

Where required, existing pavement markings must be removed by the appropriate method stated in Table SC6.4.6.22.5.

The method of removal shall be submitted to the Superintendent for approval before commencement of the work.

Table SC6.4.6.22.5 Method of removal of existing pavement marking

Method of removal	Duration of result
Black paint	< 1 week
Emulsion and sand	< 2 weeks
Black cold applied resin or plastic	< 6 months
Chip seal	Permanent
Line grinder (asphalt only)	Permanent
Profiler (asphalt only)	Permanent
Abrasive blasting	Permanent

SC6.4.6.22.7 Surface treatments for bicycle lanes and school zone threshold

(1) Coloured surface treatments for bicycle lanes

Refer to the Traffic and Road Use Management Manual - Coloured Surface Treatments For Bicycle Lanes.

(a) The preferred colour is G13 Emerald (AS2700 S 1996). To accommodate different materials and varying conditions, an approximate colour match to one of the following three AS2700 S greens is permitted - G13 Emerald, G16 Traffic green or G23 Shamrock. Approximate colour match is determined in accordance with AS/NZS1580.601.1.

(b) A consistent green colour should be provided along a route or within a given locality.

(c) Where green surface colouring is used, it should be continuous through the required area and be bounded by the bicycle lane lines. Pavement markings, such as bicycle symbols and any directional arrows, should be placed over the coloured surface.

(d) A coloured surface treatment needs to do more than just provide a colour contrast. It must be designed to function like any other road surfacing, providing a sound, durable surface layer, which maintains the required texture and skid resistance for its design life.

(e) The design and specification of a coloured surface treatment for bicycle lanes should:

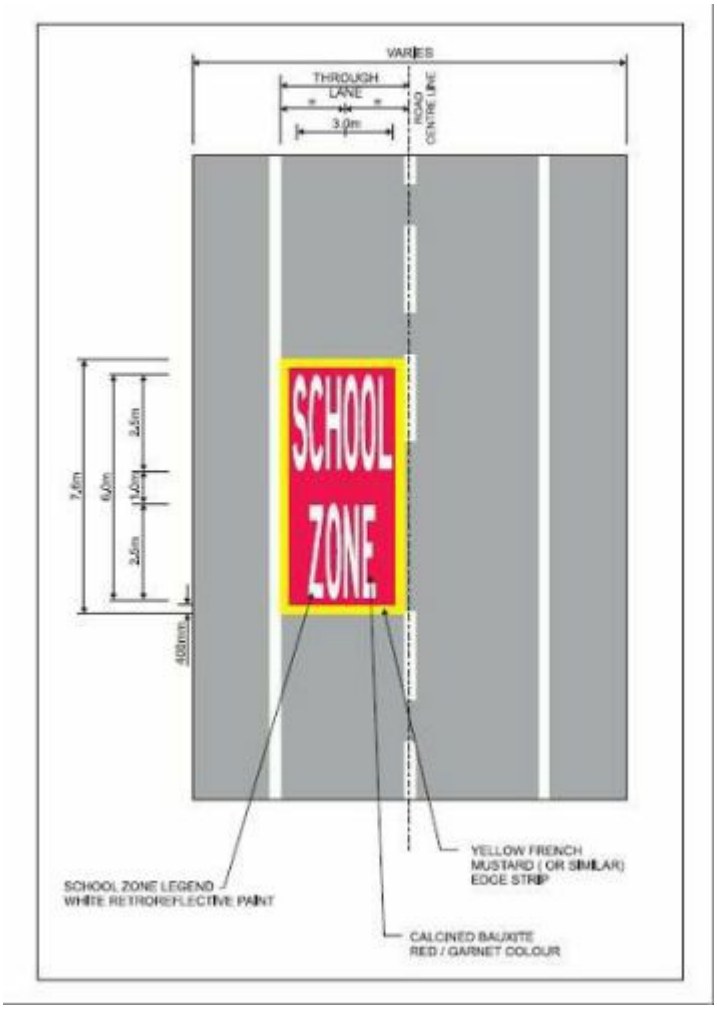
- ensure the suitability of the existing surface to support and bond with the colour treatment;
- provide a surface texture and skid resistance suitable for bicycle use, including in wet conditions; and
- limit differential skid resistance between the bicycle lane and adjacent traffic lanes.

(f) The Department of Transport and Main Roads is considering development of a formal specification for coloured surface treatments for Queensland. Until this is available it is recommended that advice on performance requirements, and the suitability of any product or service being considered for use, be sought from the Superintendent for approval before commencement of the work.

(2) Surface treatments for school zone thresholds

Refer to the Traffic and Road Use Management Manual - 3.23 Traffic and Road Use Management Manual - School Zones.

Threshold treatments may be provided at entrances to school zones to create a change in driver perception of the speed environment. A typical threshold treatment for a school zone is shown in Figure SC6.4.6.22.1.



Source:TRUM.

Figure SC6.4.6.22.1 Typical threshold treatment for a school zone

Advice on performance requirements, and the suitability of any product or service being considered for use, is to be sought from the Superintendent for approval before commencement of the work.

The pavement marking treatment (set out, type of material, preparation of surface, rate of application, method of application and maintenance) must be submitted to the Superintendent for approval before commencement of the work.

SC6.4.6.22.8 Limits and tolerances

The limits and tolerances applicable to the various clauses of this Specification are summarised in Table SC6.4.6.22.6 – Summary of limits and tolerances below:

Table SC6.4.6.22.6 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Location of Markings**	± 20mm from specified location	SC6.4.6.22.1(6)
2.	**Longitudinal Lines**		
	(a) Length	± 20mm from lengths shown in MUTCD/MRDGPM	SC6.4.6.22.2(3) SC6.4.6.22.3(3)
	(b) Width	± 10mm from widths shown in MUTCD/MRDGPM	SC6.4.6.22.2(3) SC6.4.6.22.3(3)
3.	**Transverse Lines**		

	(a) Length	± 10mm from lengths and widths shown in MUTCD/MRDGPM	SC6.4.6.22.2(3)
	(b) Width		SC6.4.6.22.2(3)
4.	**Arrows, Chevrons, Speed Markings etc.**	± 50mm from the dimensions shown in MUTCD/MRDGPM	SC6.4.6.22.2(3) SC6.4.6.22.3(3)
5.	**Application of Paint**		
	(a) Film Thickness	>0.35mm <0.40mm	SC6.4.6.22.2(3)
6.	**Application of Thermoplastic**		
	(a) Longitudinal Lines Cold Film Thickness	2.0mm ± 0.5mm	SC6.4.6.22.3(3)
	(b) Transverse Lines, Symbols, Arrows etc. Cold Film Thickness	3.5mm ± 1.5mm	SC6.4.6.22.3(3)
7.	**Glass Beads**		
	(a) Volume used in operation	0.3kg/sqm + 10%	SC6.4.6.22.2(3) SC6.4.6.22.3(3)

Attachment A: Procedure for measurement of rate of application of spherical glass beads

(1) **Scope**

The following procedure shall be adopted for field measurement of the rate of application of spherical glass beads on to wet paint or thermoplastic surfaces.

(2) **Spherical Glass Beads**

The glass beads shall comply with AS2009.

(3) **Measurement**

The method of field measurement shall be as follows:

(a) Turn off the paint or thermoplastic supply valves and operate the glass bead dispenser for exactly 10 seconds allowing glass beads to run into a plastic bag or tray.

(b) Pour the glass beads from the bag or tray into a suitable measuring cylinder calibrated in millilitres to measure the volume of glass beads collected. Level but do not compact the glass beads in the cylinder.

(c) Compare the volume of glass beads collected with the correct figure given in Table SC6.4.6.22.1 - Volume of Glass Beads (ml) required in 10 seconds of operation. Table SC6.4.6.22.1 - Volume of Glass Beads (ml) required in 10 seconds of operation shows the correct volumes of glass beads required to give a net application rate on the marked line of approximately 0.3kg/sqm for different line widths and road speeds. The glass bead volume figures given in Table SC6.4.6.22.1 - Volume of Glass Beads (ml) required in 10 seconds of operation are calculated for an actual application rate of 0.34kg/sqm.

(d) These figures are used for calibrating the machine because there is a loss of beads between the bead dispenser and the marked line; and

(e) The volume is measured with beads not compacted.

SC6.4.6.23 Guide posts

SC6.4.6.23.1 Introduction

(1) Scope

This policy subsection provides, minimum requirements for the setting out, supply of all materials and erection of guide posts in areas where street lighting is not provided to maintain safety of movement network.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-section:
SC6.4.6.30 - Control of traffic

(b) Australian Standards:
AS 1906.2 - *Retroreflective devices (non-pavement application)*
AS1580 -*Paints and related material*

(c) Queensland Department of Transport and Main Roads specification:
MRST14 *Road Furniture*

SC6.4.6.23.2 Materials

(1) General

Guide posts must be a proprietary metallic or flexible (driveable or non-driveable) post.

The surface of all posts must have a gloss or semi-gloss white finish. The surface shall be smooth and easily cleaned.

Proprietary posts must be minimum 1500 mm in length and must have one face of a minimum 80 mm width.

(2) Proprietary posts

Where a proprietary metallic or flexible guide post is proposed, the Contractor must supply details of the proposed guide post including the manufacturer's recommended installation procedure, technical specifications and test certificates for approval by the Superintendent.

(3) Delineators

Corner-cubed delineators, conforming to AS 1906.2 must be attached to each post. The delineators must conform to MRST14 *Road Furniture*.

SC6.4.6.23.3 Construction

(1) General

The Contractor must at all times conform to the requirements of sub-section SC6.4.6.30 Control of traffic.

Where the shoulder is in embankment or at natural surface level, the guide posts must be placed near the outer edge of the shoulder and at a uniform distance, minimum 1m, from the pavement edge line. Where the shoulder is located in a cutting, the guide posts must be placed on the road pavement side of the table drain, and minimum 1m from the pavement edge line, in such a manner that it does not impede the flow of water in the drain.

Guide posts must be erected at the locations shown on the Drawings. Underground services laid in proximity to the guide posts must be located prior to erection of posts all care must be taken not to damage such services.

(2) Erection of guide posts

Guide posts must be set vertically in the ground to a depth of approximately 500mm. In order to offset shoulder irregularities this depth must be varied so as to give uniform display of guide posts to a height of approximately 1000mm above ground level, with the tops evenly graded. Each guide post must be erected with the widest face at right angles to the centre line of the road.

Allowance must be made in the height of guide posts above the ground for the effects of superelevation and other road geometry in order to keep the guide posts within the range of the beam of vehicle headlights.

Backfilling must be compacted in layers of depth not more than 150mm for the full depth of the guide posts up to ground level. The density of the compacted backfilling must not be less than that of the adjacent undisturbed ground. Guide posts must be firm in the ground to the satisfaction of the Superintendent.

Proprietary guide posts, when installed in the ground in accordance with the recommendations of the manufacturer, must resist overturning, twisting and displacement from wind and impact forces. The Contractor must provide the manufacturer's instructions for anchorage.

If the guide posts are proposed to be installed on concrete pavements, the Contractor must provide the Superintendent details of fixing the guide posts to the concrete prior installation.

All necessary steps must be taken to prevent people and stock from stepping into the post holes during the erection of the guide posts.

(3) Delineators

"Corner Cubed" delineators, complying with AS1906.2, must be attached to each guide post using one way, anti-theft screws or rivets etc. In the case of proprietary posts, the delineators must be glued or otherwise fastened to the post in such a manner that they are not dislodged or rendered inactive under vehicular impact. The delineators must be mounted so that the top of the reflector is 100mm below the top of the guide post. The delineators must be so arranged that drivers approaching from either direction will see only red delineators on their left side and white delineators on their right side.

SC6.4.6.24 Signposting

SC6.4.6.24.1 Introduction

(1) Scope

This sub-section provides standards advice and guidelines for:

(a) the supply and erection of the regulatory, warning, guide, information and direction signs as described in Manual of Uniform Traffic Control Devices MUTCD.

(b) the supply and erection of sign support structures to support the signs, and

(c) the adjustment of existing signs and sign support structures.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:

SC6.4.6.28 - Minor concrete works

SC6.4.6.30 - Control of traffic

(b) Australian Standards:

AS 1163	*Cold-formed structural steel hollow sections*
AS 1214	*Hot-dip galvanised coatings on threaded fasteners (ISO metric coarse thread series)*
AS 1379	*Specification and supply of concrete*
AS/NZS 1554.1	*Welding of steel structures*
AS/NZS 1580.602.2	*Measurement of specular gloss of non-metallic paint films at 20 degrees, 60 degrees and 85 degrees*
AS 1580.108.2	*Dry film thickness - Paint inspection gauge*
AS/NZS 1734	*Aluminium and aluminium alloys - flat sheet, coiled sheet and plate*
AS/NZS 1866	*Aluminium and aluminium alloys - extruded rod, bar, solid and hollow shapes*
AS 2700	*Colour standards for general purposes*
AS/NZS 3678	*Structural steel - hot-rolled plates, floorplates and slabs*
AS/NZS 3679.1	*Structural steel - hot-rolled bars and sections*
AS 3990	*Mechanical equipment - Steelwork*
AS/NZS 4680	*Hot-dip galvanised (zinc) coatings on fabricated ferrous articles*

(c) Queensland Department of Transport and Main Roads Publications:

Manual of Uniform Traffic Control Devices (MUTCD)

Traffic and Road Use Management Manual (TRUM)

(3) Provision for traffic

The Contractor shall provide all necessary traffic safety measures in accordance with the requirements of sub-section SC6.4.6.30 Control of traffic while undertaking the work and shall organise the work to avoid or minimise delays and inconvenience to traffic.

Where a sign is erected before its intended use by traffic and is visible to traffic, the face of the sign shall be completely and securely wrapped in porous cloth sheeting or other opaque covering material approved by the Superintendent, until the Superintendent directs that the sign shall be uncovered.

SC6.4.6.24.2 Materials

(1) General

The Contractor shall advise the names of the proposed suppliers of signs and sign support structures for the Superintendent's concurrence. Only suppliers who have previously established or can now establish their competence to carry out the work in accordance with this sub-section shall be used.

The Contractor shall supply documentary evidence, satisfactory to the Superintendent that all materials and parts proposed for use comply with the requirements of the appropriate Australian Standard(s) as stated in this policy sub-section.

Details of the signs and sign support structures to be provided under the Contract shall be as shown on the drawings.

The dimensions, legend and background for each sign shall be in accordance with this sub section and the drawings.

(2) Sign blanks

Sign blanks shall be 1.6 mm thick aluminium sheet alloy. The aluminium alloy shall be Type 5251 or Type 5052 and Temper H38 or Temper H36 in accordance with AS 1734.

Sign blanks shall be free of cracks, tears and other surface blemishes and the edges shall be true and smooth. The dimensions of the sign blank shall be within plus or minus 1.5 mm of the dimensions specified and the finished sign shall be flat within a maximum allowable bow of 0.5 per cent of the maximum dimension of the sign blank in any direction.

Sign blanks shall be one piece except where the sign is of such a size as to require more than one full sheet of aluminium in which case a multipiece sign shall be allowed.

A multipiece sign shall be made up of the minimum number of pieces practical and sheets of the multipiece sign shall be butted together with a maximum gap of 1 mm at any point along the joint.

All joints shall be covered by a backing strip. The backing strip shall be riveted to each sheet with rivets, coloured to match the background material on the face of the sign, at a spacing not exceeding 200 mm. Backing strips shall be of the same material and colour as used for the sign blank and shall have a minimum width of 50 mm over the full length of the joint.

The aluminium extrusion used for mounting may be used as the backing strip for horizontal joints where it complies with the spacing requirements.

The face of each sign blank shall be chemically cleaned and etched or mechanically abraded. Where the sign blank is to receive a paint background, the face shall be spray painted with a compatible etch primer.

The back of each sign blank shall be uncoated and the surface finish shall be rendered dull and non reflective either by mechanical or chemical means and shall be free of scratches and blemishes.

Signs shall be supplied with square holes or aluminium extrusion backing for mounting purposes, at the centre spacings as shown on the drawings.

(3) Aluminium extrusion backing

The signs shall include special aluminium extruded sections for mounting purposes. The aluminium shall be Type 6063 T5 in accordance with AS 1866.

The aluminium extrusion shall be fixed at the centre spacings as shown on the drawings and shall be riveted to the sign blank with correctly coloured rivets at a spacing not exceeding 200 mm.

(4) Retro-reflective material for background and legend

Retro reflective material shall conform in colour and class to the requirements of AS 1743 and Table 1 in Section 1.2 of DTMR’s Traffic and Road Use Management manual for Class 1, Class 2 and Class 2A materials. Unless shown otherwise on the drawings, the material shall be Class 2.

(5) Non-reflective background material

(a) Background paint

Background paint shall be an approved long life industrial quality, two compound polyurethane paint. The paint shall exhibit high standards of adhesion, abrasion resistance, resistance to weathering and colour fastness under widely varying conditions of exposure. The paint shall be compatible with the etch primer used on the sign blank.

The paint shall be applied using conventional air spray application to give a uniform cover free of blemishes. A minimum dry film thickness of 38 microns is required when tested in accordance with AS 1580.108.2.

Background paint shall be as specified from one of the following colours:

(i) White Gloss

(ii) “Dark” Green Matt Colour No G61 as specified in AS 2700.

(iii) “Tourist” Brown Matt Colour No X65, Dark Brown, as specified in AS 2700.

(iv) “Dark Grey” Matt Colour No N64, Dark Grey as specified in AS 2700.

(b) Background sheet material
Adhesive cast vinyl sheet material or other equivalent material approved by the Superintendent may be used in place of background paint.

(c) The material shall be of uniform density and compatible with the material used for the legend both in application and durability.

The colours and gloss levels shall be uniform and conform to the requirements of clause SC6.4.6.24.2(5)(a) Background paint.

(6) Non-reflective material for legend

(a) Legend screening ink
Screening ink shall be a high quality, full gloss, non fade, non bleed and scratch resistant type of ink compatible with the material to which it is applied. Screening ink shall have durability at least equal to the material to which the screening ink is applied.

(b) Legend sheet material
Adhesive cast vinyl sheet material or other equivalent material approved by the Superintendent may be used in place of screening ink. The material shall be of uniform density and compatible with the material used for the background both in application and durability.

(c) Colours and finish
The requirements of clause SC6.4.6.24.2(5)(a) Background paint shall also apply to non reflective materials for legends but additional colours complying with AS 2700 may be specified.

(7) Rivets
Each rivet shall consist of a domed head and shank made of aluminium alloy and a steel mandrel which is discarded after securing the rivet.

A paint coating shall be applied to the domed head so that when the rivet is in position it will show the same colour as the material to which it is attached. Paint may cover the shank of the rivet, providing the coating thickness does not restrict the insertion of the shank into the standard drilled hole for that rivet.

The paint shall be an alkaloid enamel, which shall be applied after an appropriate treatment of the shank of the rivet to ensure long lasting adhesion.

(8) Reference markings
All signs shall be clearly and permanently stamped or engraved with an identification coding. The coding shall appear in ciphers of height neither less than 6 mm nor more than 10 mm on the rear of the sign and shall be carried out in such a manner that the front face of the sign is not damaged.

Manufacturers shall include coding information in the following format:

(a) sign reference number;

(b) manufacturer's name;

(c) month and year of manufacture; and

(d) manufacturer and class of retro reflective material.

(9) Sign support structures

(a) General
Sign support structures shall be fabricated from steel sections which shall comply with the requirements of AS 1163, AS 3678 and AS 3679.1.

Signs support structures shall be standard round galvanised posts of 50, 65 or 80 mm nominal bore or purpose designed steel structures as shown on the drawings and manufactured in accordance with the requirements of AS 1250.

Splices in members shall be restricted to a maximum of one splice per member. Splices shall be full penetration butt welds.

All welding shall be as shown on the drawings and in accordance with the requirements of AS 1554.1, Category GP.

(b) Protective treatment
Except for standard galvanised posts, all steel components including brackets shall be protected by hot dip galvanising after all fabrication processes are completed.

The steel components shall be finished by the hot dip galvanising process in accordance with AS/NZS 4680 to provide an average minimum coating thickness of 85 microns and a bright finished surface free from white rust and stains.

Bolts, nuts and washers and brackets shall be galvanised in accordance with AS 1214.

Splices in standard galvanised posts shall be painted by using an organic zinc rich primer, or inorganic zinc silicate paint, in accordance with the repair requirements in Appendix E of AS/NZS 4680.

Scratched and slightly damaged surfaces of galvanised coatings shall be renovated by using an organic zinc rich primer, or inorganic zinc silicate paint, in accordance with the repair requirements in Appendix E of AS/NZS 4680.

This method of renovation shall be restricted to areas not exceeding 2500 square millimetres on any one structure. Any structure with totally damaged coating areas exceeding 2500 square millimetres shall be regalvanised by the Contractor.

(c) Attachment of signs
Posts and other components shall be provided with the required sign attachment holes or fittings to suit the typical attachment systems as shown on the drawings. Sign panels shall be attached to each supporting member at each extrusion section or bolt hole in the sign panel.

The Contractor shall submit details of the proposed attachment systems for the Superintendent's approval.

SC6.4.6.24.3 Erection of new signs

(1) Setting out
The location of signs shall be as shown on the drawings or as directed by the Superintendent. The Contractor shall set out the work to ensure that all signs and support structures are placed in accordance with the drawings or as directed by the Superintendent.

Signs shall be aligned approximately at right angles to the direction of the traffic they are intended to serve. On curved alignments, the angle of placement should be determined by the course of approaching traffic rather than the orientation of the road at the point where the sign is located. Parking signs will generally be aligned at

45 degrees to the kerb line if not otherwise specified on drawings.

The Contractor shall submit details of and set out, for the Superintendent's inspection and approval, the proposed location and alignment of each sign support structure.

Work on the foundations of the sign support structure shall not commence until the Superintendent has approved the location and alignment of the sign support structure.

The Contractor is responsible in locating existing underground services in proximity of the signs prior to placement of footings and erection of signs to protect services from damage

(2) Clearing

The Contractor shall advise the superintendent of any trees and undergrowth within 3 m of the sign support structure and along a driver's line of sight to the front of the sign that are required to be cleared and removed. On receipt of this advice from the superintendent, council will inspect and advise what action is to be taken by the contractor.

(3) Sign structure footings

The footings for a simple pipe support or the footings for each post of a purpose-designed sign support structure shall be constructed in accordance with the drawings or as directed by the Superintendent.

The footings shall be neatly excavated to the depth and width shown on the drawings. The material from the excavation shall be disposed of in a responsible and legal manner.
When anchor bolt assemblies are specified they shall be accurately placed and firmly supported. Anchor bolt assemblies shall be provided with levelling nuts under the sign structure baseplates to allow adjustment of the structure after installation.

Steel reinforcement shall be placed as shown on the drawings.

Concrete in the footings of sign support structures shall comply with sub-section SC6.4.6.28 Minor concrete works and have a minimum compressive strength at 28 days of 20 MPa for pipe support footings and 32 MPa for purpose-designed support footings.

If ready mixed concrete is used, the concrete shall be mixed and delivered in accordance with AS 1379.

(4) Erection

All components shall be accurately positioned and supported during erection.

The top of each pipe support post shall extend sufficiently beyond the upper extrusion section or bolt holes on the sign panels to enable attachment of the signs. The top of each post shall be below the top edge of the sign panel.

For pipe support multi post installations, the tops of the posts shall be at the same level except where sign shape or the arrangement of sign panels dictates otherwise.

During erection, sign panels shall be suitably supported and braced and the sign face protected from damage. Signs damaged during erection shall be repaired to a standard equivalent to the original sign or replaced by the Contractor.

Galvanised coatings on purpose-designed support structures which are scratched or slightly damaged during erection shall be renovated by using an organic zinc rich primer, or inorganic zinc silicate paint, in accordance with the repair requirements in Appendix E of AS/NZS 4680. This method of renovation shall be restricted to areas not exceeding 2500 square millimetres on any one structure. Any structure with totally damaged coating areas exceeding 2500 square millimetres shall be regalvanised.

SC6.4.6.24.4 Adjustment of existing signs and support structures

Where shown on the drawings and where directed by the Superintendent, the Contractor shall adjust existing sign panels and sign support structures. The work shall include minor adjustments of existing sign panels and/or sign support structures or the work may extend to the dismantling of signs and sign support structures, relocation or replacement of sign support structures including footings and re erection of signs including all fittings.

SC6.4.6.24.5 Special requirements

(1) Street name, service and tourist signs

All street name, service and tourist signs shall comply with council's adopted signage system and with the details as shown on the drawings.

Proprietary signs shall be manufactured and installed in accordance with the requirements of Parts 1 and 6 of MUTCD to the following details:

(Sample only - to be completed by compiler)

(a) Colour:

(i) Legend - Blue, Non-reflective

(ii) Background - Yellow, Class 1 Retroreflective

(b) Lettering and Numerals:

(i) Font Type - Series D

(ii) Height – 100 mm

Details of council's logo shall be supplied to the Contractor by the council.

Details of the signs and legends are to be shown on the drawings.

The Contractor shall submit details of Manufacturer, all sign materials and sign attachment system to the Superintendent for approval by the council prior to commencement of sign manufacture.

SC6.4.6.24.6 Limits and tolerances

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.24.1 Summary of limits and tolerances below:

Table SC6.4.6.24.1 Summary of limits and tolerances

Item	Activity	Limits/Tolerances	Clause
1.	**Sign Blanks**		
	(a) Dimensions	± 1.50mm	SC6.4.6.24.2(2)
	(b) Bow	< 0.5% of maximum dimension	SC6.4.6.24.2(2)
	(c) Butt gap in multipiece sign	< 1mm	SC6.4.6.24.2(2)
	(d) Rivet spacing in backing strip	< 200mm	SC6.4.6.24.2(2)
	(e) Backing strip width	> 50mm	SC6.4.6.24.2(2)
2.	**Extrusion Backing**		
	(a) Rivet Spacing	< 200mm	SC6.4.6.24.2(3)
3.	**Background Paint**		
	(a) For matt coatings, gloss level	> 12% and < 15%	SC6.4.6.24.2(5)
	(b) For gloss coatings, gloss level	> 85% and < 95%	SC6.4.6.24.2(5)

Item	Activity	Limits/Tolerances	Clause
4.	**Reference Marking**		
	(a) Height of Coding	> 6mm and < 10mm	SC6.4.6.24.2(8)
5.	**Sign Support Structures**		
	(a) Protective Treatment thickness	> 100 microns	SC6.4.6.24.2(9)(b)
	(b) Paint coating over Splices in standard galvanised posts	> 100 microns	SC6.4.6.24.2(9)(b)
	(c) Damaged Surface of galvanised surfaces		
	(i) Coating with zinc rich paint	Area < 2500 sq. mm	SC6.4.6.24.2(9)(b)
	(ii) Regalvanise	Area > 2500 sq. mm	SC6.4.6.24.2(9)(b)
6.	**Clearing**		
	(a) Trees and Undergrowth to be cleared	< 3 metres from sign support structure	SC6.4.6.24.3(2)
7.	**Concrete in Foundations of Sign Support Structures**		
	(a) Strength	> 25 MPa at 28 days	SC6.4.6.24.3(3)

SC6.4.6.25 Non-rigid road safety barrier system

SC6.4.6.25.1 Introduction

(1) Scope

The work to be executed under this sub-section consists of the setting out, supply of all materials and erection of road safety barriers and terminals, in accordance with the requirements for non-rigid road safety barrier systems in TMR Road Planning and Design Manual (Chapter 8), at the locations shown on the drawings or as directed by the Superintendent.

This sub-section details the requirements for public domain non-rigid road safety barrier systems. Where a patented non-rigid road safety barrier system is specified and shown on the drawings, all materials shall be in accordance with the manufacturer's specifications and, it shall be constructed strictly in accordance with the manufacturer's instructions.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied to this sub-section are as follows:
SC6.4.6.30 Control of traffic
SC6.4.6.28 Minor concrete works

(b) Department of Transport and Main Roads Standards:
Road Planning and Design Manual (RPDM) 1st edition – (Chapter 8), Safety Barriers and Road Side Furniture – as amended.

(c) Australian Standards:

AS/NZS 1906.2	*Retroreflective devices (non pavement application)*
AS/NZS 3845	*Road safety barrier systems*
AS/NZS 4680	*Hot-dip galvanised (zinc) coatings on fabricated ferrous articles*

SC6.4.6.25.2 Materials

(1) Components

All steel components for public domain non-rigid road safety barrier systems, W beam and Thriebeam, shall be designed and constructed strictly in accordance with the RPDM (Chapter 8 – as amended) using crushable energy-absorbing materials and shall be of the type as shown on the drawings.

(2) Certification

Road safety barrier components shall not be erected until the Contractor has produced documentary evidence to the Superintendent that such safety barrier components conform to the requirements of this sub-section.

For galvanized steel components provide a manufacturers certificate of compliance certifying that the zinc coating mass conforms to AS/NZS 4680 or, for components of proprietary safety barrier systems or devices, to the manufacturer's recommendations.

SC6.4.6.25.3 Construction

(1) General

The Contractor shall at all times conform to the requirements of sub-section SC6.4.6.30 Control of traffic.

Construction of non-rigid road safety barrier shall comply with RPDM, except where explicit departures are approved on the drawings.

Road safety barriers shall be erected after the construction of the base on concrete pavements and after the placing of the initial layer of asphaltic concrete or sprayed seal on a flexible pavement, unless otherwise approved by the Superintendent.

The Contractor shall set out the work to ensure that all road safety barriers and terminal sections are located,

in accordance with the drawings or as directed by the Superintendent.

Underground cables and ducts laid in the road safety barrier area shall be located prior to the erection of posts and all care must be taken not to damage such cables and ducts.

The posts should be set to the full depth as shown on the drawings. If this is not possible due to the presence of an underground obstruction, an alternative method of setting the posts, as approved by the Superintendent, shall be used.

Posts shall stand vertical and the spacing shall be such that when the safety barrier is erected no post movement is necessary in order to align holes or for any other reason.

(2) Erection of steel posts

The safety barrier posts are to be located as shown on the drawings. The top of the post shall be 750mm, 845mm or 905mm as appropriate for W beam, Thrie beam or modified blockout Thrie beam respectively, above the ground level, unless otherwise shown on the drawings. On terminal ends, the level of the posts shall be such as to conform to the extended crossfall of the main pavement unless otherwise shown on the drawings.

When erected in position the posts shall be on a smooth line both horizontally and vertically with the tops of posts within ±10 mm of the heights specified in paragraph 1 of this clause.

Steel posts shall be erected by driving, or by other means, as directed by the Superintendent, in accordance with the requirements for foundation posts in the TMR RPDM. The open section of the post shall point in the same direction as adjacent traffic. The posts are to be firm in the ground and any movement at ground level shall not exceed 3mm in any direction when force tested in accordance with TMR guidelines

The posts shall not have any obvious deformation as a result of driving. Any damage which does occur to the posts is to be repaired within 24 hours using an organic zinc-rich primer in accordance with the repair requirements of Appendix E in AS/NZS 4680.

Any post which has been excessively damaged will be rejected by the Superintendent and shall be replaced by the Contractor at their own expense.

(3) Erection of road safety barrier rails

Steel blockout pieces shall be erected with the open section pointing in the same direction as adjacent traffic.

All rail laps shall be in the same direction as adjacent traffic such that approach rail ends are not exposed to traffic.

Stiffening pieces, 300mm long, shall be used on intermediate posts.

Road safety barrier rails and blockout pieces shall be handled and erected in such a manner that no damage occurs to the galvanising. Any minor damage occasioned to the galvanising shall be repaired within 24 hours using an organic zinc-rich primer in accordance with the repair requirements of Appendix E in AS/NZS 4680.

Any road safety barrier rails or blockout pieces that have been excessively damaged will be rejected by the Superintendent and shall be replaced by the Contractor at their own expense.

Road safety barrier rail attachment bolts and splice bolts are to be tightened initially such that the barrier can be erected. Adjustments are then to be made to the rails using the slotted holes provided to produce a smooth regular line, free of any kinks or bumps. The overall line of the top of the safety barrier rails is to visually conform with the vertical alignment of the road pavement.

When the alignment both vertically and horizontally is obtained the splice bolts are to be fully tightened. The bolt head (not the shoulder) should be in full bearing with the rail.

(4) End treatment of road safety barriers

Both approach and departure ends of the road safety barrier shall be constructed with leading and trailing terminal sections at locations shown and as detailed on the drawings.

An appropriate terminal end treatment shall be constructed, as detailed on the drawings, at the approach and end locations of road safety barriers as shown on the drawings. Consideration of alternate terminal end treatments will include sufficient clearance behind the safety fence to accommodate pedestrians and cyclists, where applicable.

The approach and departure ends of double sided road safety barriers shall have terminal sections as detailed on the drawings.

Non-rigid road safety barrier connections to rigid road safety barriers or bridge parapets shall be as detailed on the drawings.

(5) Delineators

Delineators complying with AS 1906.2 shall be fixed with brackets to the road safety barrier, to the details and at the locations shown on the drawings beginning at the first post and then in accordance with Table SC6.4.6.25.1 below.

Table SC6.4.6.25.1 Spacing of reflectors on barriers

Radius of Curve	Spacing of Reflectors on Barrier
m	every
30 - 90	3rd post
90 - 180	5th post
180 - 275	8th post
275 - 365	11th post
over 365 (including straight road)	16th post

The delineators shall be so arranged that drivers approaching from either direction will see only red reflectors on their left side, and white reflectors on their right.

(6) Connection to existing safety fencing

The Contractor is to inspect and document the condition of all existing barrier fencing and its suitability to meet current specifications and standards, prior to connection or incorporation into the subject works. All documentation of existing fencing is to made available to the Superintendent for future inspection, if requested.

If any existing safety fencing is deemed not to comply with current design and safety standards, it is to be replaced.

SC6.4.6.25.4 Limits and tolerance

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.25.2 Summary of limits and tolerances below:

Table SC6.4.6.25.2 Summary of limits and tolerance

Item	Activity	Limits/Tolerances	Clause
	Vertical Alignment	± 10mm	SC6.4.6.25.3(2)
	(a) Tops of steel posts.		
	(i) Post Movement	£ 3mm	SC6.4.6.25.3(2)
	Concrete Footings	-0mm or +50mm	SC6.4.6.25.3(3)
	(a) Diameter		

SC6.4.6.26 Landscaping

SC6.4.6.26.1 Introduction

(1) Scope

This sub-section sets out the standards and provides advice and guidelines for the construction of landscape works that will become a council asset.

Landscape works includes but is not limited to, site co-ordination, turfing, gardens, grass seeding, tree plantings, pathways, paved areas, concrete works, stormwater drainage and infrastructure.
This sub-section consists of:

(a) the vegetation of cut and fill batters, median areas, pathway verges, open drains and other areas within the site. Vegetation includes the initial surface preparation, topsoiling, fertilising, sowing of seed and may include surface protection works, hydroseeding, hydromulching and straw mulching; and

(b) the supply of plants, planting at locations fertilising, mulching, staking, watering and maintenance of plants.

Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents

All design and documentation, materials supplied and work carried out shall be in accordance with the following standards.

(a) Development manual planning scheme policy sub-sections to ne read and applied in conjunction with this policy sub-section are as follows:
SC6.4.6.10 - Earthworks (construction).

(b) Australian Standards:

AS 1160	*Bituminous emulsions for the construction and maintenance of pavements*
AS 1289	*Methods of testing soils for engineering purposes – General requirements and list of methods*
AS 1672.1	*Limes and limestones – Limes for building*
AS 2507	*The storage and handling of agricultural and veterinary chemicals*
AS 3000	*Electrical installations (known as the Australian/New Zealand Wiring Rules)*
AS 3700	*Masonry structures*
AS 3798	*Guidelines on earthworks for commercial and residential developments*
AS 3972	*General purpose and blended cements*
AS 4419	*Soils for landscaping and garden use*
AS 4454	*Composts, soil conditioners and mulches*
AS/NZS 4671	*Steel reinforcing materials*
AS 4843	*Synthetic weed blocking fabric*
AS 4970	*Protection of Trees on Development Sites*

(c) Other:

Electricity Act 1994
International Erosion Control Association (IECA), *Best Practice Erosion and Sediment Control*

(3) Terminology

For the purposes of this document the following definitions apply:

Defects liability period	refer to Section SC6.4.7 Acceptance of completed works.
Gardens, garden beds and garden areas	means a defined area of mulched “garden” containing various shrubs, trees, plants or hedges.

Litter	means bottles, paper, cigarette packets, cigarette butts, drink cans, ice cream sticks, plastic, rubber, glass, milk and fruit juice cartons, paper plates and the like. Litter also includes fallen branches, palm fronds, waste, household rubbish, condoms, sharps/syringes, leaves where leaves are unsightly or cause damage to lawn or garden areas, or other dumped material.
Maintenance period	equivalent to the defects liability period and includes the plant establishment period.
Plant establishment period	coincides with the defects liability period.
Planter box	means a transportable or in situ container designed specifically for containing a garden of trees and /or shrubs.
Sub grade	means the level at the underside of garden or turf top soil or the level at the underside of paving gravel base course.
Superintendent	means the nominated representative for council.

SC6.4.6.26.2 Works management

(1) Qualified personnel

Personnel shall be suitably qualified and competent in all aspects of landscape works and shall be familiar with all relevant Australian Standards. All maintenance work to new and existing trees shall be carried out under the supervision of an Arborist with formal qualifications (Level 5 Australian Qualification Framework) or at least 5 years recognised experience in Arboriculture.

(2) Design approval

The design of the landscape works will be prepared by a qualified Landscape Architect.

(3) Contractor inspections

Inspections must be certified and documented by a Registered landscape Architect (the supervising landscape architect). All approved works are required to be inspected by Townsville City Council.

(4) Council inspections

(a) Council may inspect the following:

(i) sub grade prior to placing fill;

(ii) sub grade prior to placing garden soil or turf soil;

(iii) sub grade prior to placing the gravel base course;

(iv) sub grade prior to placing paving or concrete works;

(v) installation of gypsum;

(vi) condition of plants after delivery to site and prior to planting, including planting holes prior to planting;

(vii) gardens prior to planting;

(viii) turf areas prior to laying turf;

(ix) areas to be hydro-mulched / seeded prior to treatment;

(x) concrete structures (formwork) prior to placing concrete;

(xi) block work and reinforcing prior to placing core fill concrete; and

(xii) other elements considered necessary by the Superintendent.

(b) Inspection of irrigation works shall be undertaken by the Superintendent and a council Irrigation Officer in association with the Landscape works and is detailed below:

(i) all mainline to be inspected prior to covering;

(ii) drip tube layout prior to covering;

(iii) 240v power conduit from Ergon POS to controller for correct depth prior to covering;

(iv) all envelopers (conduits) work under hard surfaces prior to covering;

(v) all envelopers (conduits) under hard surfaces must be continuous 100 mm PVC CL9, all conduit ends must be sealed with expanding foam prior to covering; and

(vi) water meter assembly installation prior to covering to ensure correct installation of thrust blocks and copper protection.

(5) Inspection results

(a) Work inspected that complies with the sub-section and/or the design plans will be accepted by council.

(b) Any work inspected that does not comply with the sub-section and/or the design plans, will not be accepted by council. Items not acceptable will be noted for rectification.

(c) The contractor is required to rectify these items prior to proceeding to the next construction phase and shall apply for a re-inspection by council on completion of the rectification work.

(6) A minimum of 24 hours notice by is required for notification of an Inspection. Failure by the Contractor to notify council of any inspections required, will result in the works being excavated at the Contractors cost to allow an inspection to be carried out.

(7) Inspection documentation.

Editor's note—this section relates to Inspection Test Plans and is currently under development.

SC6.4.6.26.3 Supply of materials

(1) Materials supply - general

(a) Substitutions

The Contractor shall notify the council immediately if an item is unavailable for inclusion in the works and shall provide alternative supply details if appropriate. Substitutions of any materials or products shall not be made unless approved by the Superintendent in writing.

(b) Material samples

In certain instances, council may request the Contractor to provide samples of materials to be installed or used for work under the development approval.

(c) Materials testing

In certain instances, council may request the Contractor to provide results of materials testing. Where applicable, testing requirements will be set out in the conditions of approval.

(d) Materials warranty

Where requested, the Contractor shall provide to council all relevant warranty details for the materials nominated in any conditions of approval.

(2) Supply of plants

(a) Plant specifications

(i) All plants supplied shall be in a healthy condition free from weeds, pests and diseases. Plants shall be well foliated, showing signs of active growth, true to type and of a form and shape considered typical for the species or variety.

(ii) Leaves shall be of normal size, shape, colour, and texture with no physical or insect damage or disease lesions.

(iii) The plant roots shall be fibrous, well developed and not root bound, with no kinking, knotting, girdling or spiralling and shall be free of any pests or diseases or any other root defects.

(iv) All plants supplied shall be hardened off and in a condition suitable for planting in the Townsville climate.

(v) Trees supplied (unless required to be multi-stemmed) shall have a single leading stem and shall

be self-supporting and unstaked.

(vi) Root bound plants, deformed plants and plants showing recent signs of root pruning will not be accepted.

(vii) At time of delivery to the site, each group of plant species shall be clearly and accurately labelled according to botanical nomenclature. Labels shall be water resistant and tied securely to one plant in every 20 for each species.

(viii) Plants which are above the minimum size requirements may be accepted for inclusion within the works.

(b) Container stock

Plants grown in containers shall have a root system firmly established with no large roots growing out of the container, shall be of such a size that the roots have penetrated to the bottom of the container and occupy 95-100% of the soil volume and/or have sufficient roots to hold the container soil together after removal of the plant from the container.

(c) Ex-ground stock plants

(i) Where plants are growing in ground prior to delivery to the site, the necessary root pruning and/or preparation procedures in accordance with accepted transplanting practice shall be commenced in sufficient time to ensure that, at the time of planting the plant is ready and will meet the specified requirements. Transplanting of ex-ground stock should be conducted under the supervision of a qualified (Level 3 Australian Qualification Framework) horticulturalist or arborist.

(ii) Refer to Table SC6.4.6.26.1 for minimum acceptable root ball sizes for ex-ground stock plants.

Table SC6.4.6.26.1 Acceptable root ball sizes

Small Trees		Large Trees	
Height of Tree (mm)	Root Ball Diameter (mm)	Approximate Tree Trunk Diameter (mm) (300 mm above ground)	Root Ball Diameter (mm)
600 - 900	300	40	500
900 - 1200	350	50	550
1200 - 1500	400	65	600
1500 - 1800	450	75	800
1800 - 2100	550	100	950
2400 - 2700	600	125	1200
2700 - 3000	650	150	1450
3000 - 3600	750	175	1600
3600 - 4200	800		
4200 - 5000	900		

(d) Substitutions

Substitutions of plants shall not be permitted unless approved in writing by council. In the event that a plant is unavailable the Contractor may request to provide a substitution. Substituted plants shall be of the same specified type, quality and size unless otherwise agreed to by council.

(3) Supply of imported soil mix

(a) Imported soil mix shall be organic soil, soil blend or top dressing in accordance with the Australian Standard AS 4419 Soils for landscaping and garden use.

(b) The Contractor shall note the requirements of AS 4419.

(4) Supply of turf

(a) Turf shall be the species nominated on the drawings and shall be supplied by a specialist grower of cultivated turf.

(b) The soil of the turf sod shall be an even thickness of 25 mm minimum.

(c) Turf shall be free from any matter toxic to plant growth and shall be free from roots, weed or weed

seeds.

(5) Supply of hydro seeding/mulching
The specific mix/blend of hydro seeding/mulching required shall be nominated on the drawings and supplied by specialist supplier of hydro seeding/mulch.

(6) Supply of mulch materials

(a) All mulch materials supplied shall be in accordance with the current relevant AS 4454 Composts, soil conditioners and mulches.

(b) Organic and inorganic mulch shall be of the type and quality as noted on the drawings.

(c) Organic mulch derived from vegetation cleared on site may only be used where it is free from deleterious materials such as rock, soil and weed material.

(7) Tree stakes and ties

(a) Unless otherwise noted on the drawings or approved by council, tree stakes shall be durable hardwood, straight, free from knots or twists and pointed at one end.

(b) Small plants may only require 1 stake where required.

(c) For trees up to 45 litre 2 stakes – 50 mm x 50 mm x 1800 mm long.

(d) For trees over 45 litre 3 stakes – 50 mm x 50 mm x 2400 mm long.

(e) Ties shall be 50 mm wide furniture grade hessian webbing or similar.

(f) Supply of proprietary items
Timber/concrete garden edging, soil conditioners, root barrier, furniture items, play equipment and other project specific items shall be supplied to the requirements and details noted on design and/or construction drawings.

(8) Supply of gypsum
Gypsum application rates shall be supply in accordance with AS 4454 and as required by soil types specific to the site.

(9) Supply of fertiliser
Fertilisers supplied shall be:

(a) delivered to the site in sealed bags clearly marked to show the manufacturer or vendor, weight, fertiliser type, N:P:K. ratio, recommended uses and application rates; and

(b) applied at the locations and frequencies in accordance with the manufacturer's recommendations.

SC6.4.6.26.4 Earthworks

(1) General
Earthworks relates to gardens, grass areas, pathways and paved areas and includes:

(a) site clearing;

(b) stripping of existing vegetation;

(c) stripping of existing top soil;

(d) excavation to sub grade level;

(e) filling to sub grade level; and

(f) cultivation of the sub grade surface.

(2) Quality management
All materials supplied and work carried out shall be in accordance with the current, relevant Australian Standards:

(a) AS 1289 - Methods of testing soils for engineering purposes; and

(b) AS 3798 - Guidelines on earthworks for commercial and residential developments.

(3) Existing services

Per sub-section SC6.4.6.11 Clearing and grubbing, the Contractor is required to locate all existing and newly installed services prior to commencement of any earthworks. Care shall be taken in areas to be excavated, filled or cultivated not to unearth or damage services. Any damage to services caused by the Contractor shall be reinstated by the Contractor at no cost to council.

(4) Site preparation

(a) Clearing/Demolition

(i) Clearing shall mean the removal of trees, shrubs, scrub and undergrowth and other vegetation above ground level and includes the removal of artificial obstructions such as fences, concrete slabs rubbish, timber, boulders, rubble and other man made products.

(ii) Clearing shall be carried out in accordance with sub-section SC6.4.6.11 Clearing and grubbing.

(b) Grubbing

Grubbing shall mean the removal from below ground level of trees, roots, stumps, rocks and artificial obstructions as defined and specified by sub-section SC6.4.6.11 Clearing and grubbing.

(c) Stripping of existing vegetation

Areas to be excavated or filled shall be stripped of all vegetation to a depth just sufficient to include the root zone (nominal 50 mm). All stripping of vegetation is to be in accordance with sub-section SC6.4.6.11 Clearing and grubbing and must not affect trees/vegetation to be retained, as per clauses SC6.4.5.2.1(18) and (19).

The striped material shall be removed from site or may be stockpiled on site for later reuse, if approved by council and in accordance with clause SC6.4.5.2.1(17) Stockpiling of materials.

(d) Existing topsoil

Existing topsoil excavated on site may be reused provided that the material conforms to the AS 4419 requirements and is approved for reuse by the Superintendent. The material may be stockpiled on site, in accordance with clauses SC6.4.5.2.1(16) and (17).

(5) Excavation (down to sub grade level)

(a) General

The existing surface of areas to be excavated shall be stripped of all vegetation prior to excavating. Care shall be taken not to unnecessarily expose subsoils through the area of construction by over excavation, to prevent any potential for the development of acid sulphate conditions.

(b) Excavation in gardens

(i) Garden beds shall be excavated down to subgrade level as required to suit the finished surface levels, the depth of garden mix soil and the depth of mulch.

(ii) The subgrade shall be shaped and graded evenly to fall towards subsoil drains (if present) and the topsoil shall be shaped to fall from the centre of the bed outwards in all directions.

(iii) Excavation in gardens shall be in accordance with council's approved standard drawings.

Editor's note— standard drawings for these works are under development.

(c) Excavation in grass areas

(i) Grass areas shall be excavated down to subgrade level as required to suit finished surface levels, the depth of turf top soil and the depth of turf.

(ii) The subgrade shall be shaped and graded evenly to fall towards subsoil drains (if any) and shall be graded evenly to follow the finished surface profile.

(iii) Excavation in grass areas shall be in accordance with council's approved standard drawings.

Editor's note—standard drawings for these works are under development.

(d) Excavation for pathways and paved areas (paving)

(i) Pathways and paved areas shall be excavated down to subgrade level as required to suit finished surface levels, the depth of the gravel base course, bedding sand, pavers or concrete. The subgrade shall be shaped and graded evenly to the falls shown on the drawings and/or to fall to stormwater pits or subsoil drains.

(ii) Excavation for pathways and paved areas shall be in accordance with council's approved standard drawings.

Editor's note—standard drawings for these works are under development.

(e) Excavation near existing trees
Excavation near existing trees shall be undertaken in accordance with clause SC6.4.5.2.1(19) Work adjacent to trees and protection of environmentally significant vegetation.

(f) Spoil

(i) Spoil material resulting from excavation shall be reused on site wherever practicable, provided that the material conforms to the specified requirements for its intended use (e.g. filling or top soil) as per AS 4419.

(ii) Spoil material to be reused may be stockpiled on site as per clause SC6.4.5.2.1(17) Stockpiling of materials.

(iii) After the excavation process has been completed, the sub grade surface shall be inspected for springs, soft soil areas and other structural weaknesses. Where such weaknesses are encountered the following remedial works may be required:

(A) excavation and replacement of unsuitable material;

(B) surface drainage blankets of sand; and

(C) subsoil drains.

(6) Filling (up to sub grade level)

(a) Existing surface treatment
The existing surface of areas to be filled shall be stripped of all vegetation prior to placing any fill. The existing surface shall then be scarified to a depth of 200 mm. If required, water shall be added to bring the existing surface up to optimum moisture content prior to placing any fill.

(b) Unsuitable existing surface
After the stripping process has been completed, the existing ground surface shall be inspected for springs, soft soil areas and other structural weaknesses in the naturally occurring soil. Where such weaknesses are encountered, the following remedial works may be required:

(i) excavation and replacement of unsuitable material;

(ii) surface drainage blankets of sand; and

(iii) subsoil drains.

(c) Acceptable types of fill material for gardens and grass areas
Fill material to garden and grass areas shall be either:

(i) "general purpose soil" to AS 4419 Clause 4.1; or

(ii) "natural soil" to AS 4419 Clause 4.3; or

(iii) spoil from on site excavations if approved by the Superintendent, with a maximum particle size 25 mm.

(d) Acceptable types of fill material for pathways and paved areas
Fill material to pathways and paved areas shall be:

(i) crusher dust, free from organic matter and lumps of clay; or

(ii) crushed rock gravel uniformly graded, nominal particle size 25 mm; or

(iii) other granular material approved by the Superintendent.

All material used shall have a linear shrinkage - 0 - 8%, Soaked California Bearing Ratio – 15 minimum.

(e) Fill in gardens
Gardens shall be filled up to sub grade level as required to suit the finished surface levels, the depth of garden mix soil and the depth of mulch. The sub grade shall be shaped and graded evenly to fall towards subsoil drains (if any).

(f) Fill in grass areas
Grass areas shall be filled up to sub grade level as required to suit finished surface levels, the depth of turf top soil and the depth of turf. The sub grade shall be shaped and graded evenly to fall towards subsoil drains (if any) or gully pits and to mirror the finished surface profile.

(g) Fill to pathways and paved areas
Path ways and paved areas shall be filled up to subgrade level as required to suit the finished surface levels, the depth of the gravel base course, bedding sand, pavers or concrete. The subgrade shall be shaped and graded evenly to the falls shown on the drawings and/or to fall to stormwater pits.

(h) Fill around existing trees
For informatin regarding placement of fill and compaction issues refer to AS 4970 Protection of trees on development sites and Clause SC6.4.5.2.1(18) Work adjacent to trees and protection of environmentally significant vegetation.

(7) Placing and compacting fill

(a) Fill material shall be placed and compacted in successive horizontal layers to the dimensions, levels, grades, and cross sections as shown on the drawings and so that the surface is always self-draining. Refer to Table SC6.4.6.26.2 for compaction standards. Care shall be taken to ensure that fill to garden areas is not excessively compacted.

(b) Each fill layer shall be scarified, and/or harrowed and processed to a finely divided condition, uniformly watered or aerated as the case may be, to obtain moisture content within the range of 80% - 90% of the optimum moisture content. The loose depth of the material in each layer shall be not more than 150 mm.

(c) Fill shall be placed in layers simultaneously on both sides of structures, culverts and pipe work to avoid differential loading. Fill shall not be placed against concrete or masonry structures, walls and the like until the concrete or masonry work has been in place for a minimum of 14 days.

(d) Existing works and structures shall be protected from damage due to compaction operations. Compaction by mechanical means shall not be carried out within 300 mm of paths, kerbs or structures. Compaction in these locations shall be carried out by hand or the size of compaction equipment shall be limited to ensure no damage is caused. Commence compaction of each fill layer at the structure and proceed away from it.

Table SC6.4.6.26.2 Fill compaction standards

Location	Compaction standard
Gardens and Grassed Areas.	85% Relative Dry Density Standard Compaction.
Pathways, Paved Areas and Structures.	95% Relative Dry Density Standard Compaction.

(8) Grading

(a) Runoff from impervious surfaces such as roofs, driveways and car parks, and overland flows from turf and garden beds is to be captured and allowed to infiltrate into subsoils by reshaping existing landforms through the use of swales, contour banks, soaks, percolation pits and basins, rain gardens and bioretention filters.

(b) To reduce runoff and erosion and encourage rainwater infiltration into soil, a landscape embankment is not to exceed grades of 1 in 5.

(c) The regrading of land is not to occur within the tree protection zone of existing trees to be retained.

(9) Cultivation

(a) Applies to gardens and grass areas (if directed or if noted on the drawings).

(b) Where shown on the drawings, the sub grade of Gardens and Grass Areas shall be cultivated prior to placing garden mix soil or turf top soil.

(c) The sub grade shall be thoroughly cultivated by ripping parallel to the final contours to loosen the compacted ground and to the depths nominated in Table SC6.4.6.26.3.

Table SC6.4.6.26.3 Cultivation depths

Location	Cultivation depth
Garden Areas	200 mm
Grass Areas	100 mm

(d) In areas of heavy clay natural soil, granulated gypsum shall be spread over the entire area of all gardens at a minimum rate of 2 kg per square metre and shall be thoroughly blended and incorporated into the subgrade during cultivation.

(e) In areas of heavy clay natural soil, granulated gypsum shall be spread over the entire area of all grass areas at a minimum rate of 2 kg per square metre and shall be:

(i) thoroughly blended and incorporated into the subgrade during cultivation if cultivation is to be carried out; or

(ii) spread prior to placing turf soil.

(f) Any soil additives and/or imported materials other than gypsum, that may be required to be applied to the natural soil shall be thoroughly blended with or spread over the subgrade.

(g) Cultivation shall not be carried out when the soil is wet or plastic.

(h) The Contractor shall ensure that no damage occurs to tree roots, underground services, kerbing and the like during the cultivation process. Cultivation by mechanical means shall not be carried out within the drip line of trees to be retained or within 300mm of pathways, paved areas and/or structures. Cultivation in these locations shall be carried out by hand. Refer to Clause SC6.4.5.2.1(19) Work adjacent to trees and protection of environmentally significant vegetation.

(i) After cultivation soil lumps shall have a maximum dimension of 50 mm. Stones exceeding 25 mm, clods of earth exceeding 50 mm, weeds, roots, sticks, rubbish and any other deleterious material brought to the surface during cultivation shall be removed. Any depressions caused by the removal of these materials shall be filled with top soil or on site spoil material approved by the Superintendent.

(j) After cultivation the surface shall be graded smoothly and evenly and trimmed to the required levels allowing for placing the specified depth of imported soil to achieve the finished surface levels as noted on the drawings. Care shall be taken to prevent areas of excessive compaction being caused by construction equipment.

(10) Backfilling trenches

(a) Backfill to trenches up to sub grade level under pathways and paved areas shall be clean sand or crusher dust compacted to 95% relative dry density standard compaction.

(b) Backfill to trenches up to sub grade level in gardens and grass areas shall be imported soil mix or material excavated from the trench or may be other on site material approved by the Superintendent.

(c) Trenches excavated in gardens within the imported garden mix soil shall be backfilled with imported garden mix soil mix as specified.

SC6.4.6.26.5 Vegetation of slopes and drains

(1) Execution and timing of work

(a) The work to be executed under this clause includes the vegetation of cut and fill batters, pathway verges, median areas, open drains and other areas within the site. Vegetation includes the initial surface preparation, topsoiling, fertilising and either sowing of seed or turfing as shown on the drawings.

(b) Exposed ground shall be vegetated before the area exceeds one hectare or lesser area in compliance

with council requirements.

(2) Materials

(a) Topsoil

The Contractor shall use topsoil stockpiled on site under the sub-section SC6.4.6.10 Earthworks (construction). Where imported topsoil is required it shall comply with AS 4419 and shall:

(i) be of a friable, porous nature;

(ii) be free of weeds and weed seeds, bulbs, corms and vegetable propagules;

(iii) contain no refuse or materials toxic to plant growth;

(iv) contain no stumps, roots, clay lumps or stones larger than 50 mm in size;

(v) have an organic content of at least 3 per cent by mass;

(vi) have a pH neither less than 5.5 nor more than 7.5; and

(vii) have a soluble salt content not exceeding 0.06 per cent by mass.

(b) Herbicide

Herbicide used shall be a glyphosate-based herbicide listed in SC6.4.6.26 Attachment A.

(c) Seed

(i) All seed used shall be of the species and varieties list in SC6.4.6.26 Attachment A and shall be sown at the application rates specified therein. The Contractor shall submit to the Superintendent the name/s of the proposed seed supplier/s within 2 weeks of the acceptance of the tender.

(ii) The Contractor's attention is drawn to the lead time that may be required to procure some native seed species. The native seed shall be delivered to the site in separate lots for each species and variety, clearly labelled to show species, variety and weight.

(iii) All seed must be accompanied by a "Certificate of Authenticity" which shall be furnished by the Contractor to the Superintendent upon request at any stage of the work. Grass and clover seed shall be pre-packed commercially with an accompanying certificate of germination.

(iv) The Contractor shall not take possession of the seed more than 7 days before sowing is to occur. The seed shall be stored in clean, air tight containers and kept away from direct sunlight. It shall not be exposed to the elements at any stage during storage.

(v) The Contractor shall replace at his own expense any exotic seed batch found not true to type.

(d) Turf

Turf shall consist of 25 mm depth of dense, well rooted, vigorous grass growth with 25 mm depth of topsoil. The type of grass turf to be used shall be selected from SC6.4.6.26 Attachment A and in accordance with the drawings. Unless specified, Kikuyu grass shall not be used. Turf shall be free of weeds, soil pests and diseases. The turf shall be supplied as rolls in long lengths of uniform width, not less than 300 mm, and shall be in sound unbroken condition.

(e) Fertiliser

Fertiliser shall be an organic type listed in SC6.4.6.26 Attachment A with Nitrogen: Phosphorus: Potassium (N:P:K) ratios of 8 : 3.6 : 2.

(f) Vegetable mulch

Vegetable mulch used in hydromulching shall consist of straw, chaff, wood fibre, paper pulp or similar material all finely shredded to a maximum dimension of 10 mm. Meadow hay or weeds shall not be used and paper pulp if used shall not exceed 50 per cent by mass of the total mulch.

(g) Water

Water used shall be potable.

(h) Binder

The binder used in hydromulching and strawmulching shall be Grade ASS, slow setting anionic bitumen emulsion, complying with AS 1160.

(i) Wetting agent

The soil wetting agent added in hydromulching or hydroseeding shall be listed in SC6.4.6.26 Attachment A and applied at the application rate specified therein.

(j) Pesticide
Pesticide used shall be a liquid or powder listed in SC6.4.6.26 Attachment A. The storage and handling of pesticides shall be in accordance with AS 2507.

(3) Vegetation of slopes 3 to 1 or flatter

(a) Preparation of surface

(i) Slopes shall be sprayed with herbicide applied at the rate specified in SC6.4.6.26 Attachment A to kill weed infestation. Sprayed areas shall remain undisturbed for two weeks.

(ii) The surface shall then be tyned to a depth of 200 mm to produce a loose surface and all large stones, rubbish and other materials that may hinder germination shall be removed before topsoiling.

(b) Topsoiling
Topsoil shall be uniformly applied to provide an average compacted thickness of 50 mm with a minimum compacted thickness of 30 mm at any location. The topsoiled area shall be cultivated to a depth of 50 mm to provide a roughened surface with soil lumps not exceeding 50 mm dimension.

(c) Mixing of seed
The Contractor shall give the Superintendent 2 days notice before each sowing operation. Seed shall be sown on the day of mixing with pesticide.

(d) Incorporation of pesticide
Immediately before sowing, all grass and native seed shall be treated with pesticide. The pesticide shall be thoroughly mixed as a dry powder with the seed at the rate specified in SC6.4.6.26 Attachment A to the equivalent mass of seed to be spread on 1 hectare of the surface in accordance with SC6.4.6.26 Attachment A.

(e) Sowing

(i) Sowing shall be carried out with an appropriate mechanical seeder. Where practicable, passes shall follow finished surface contours. Seed shall be sown at a depth of 5 mm or shall be raked or harrowed to provide 5 mm cover.

(ii) Seed and fertiliser shall be evenly distributed over the areas to be sown at the rates specified in SC6.4.6.26 Attachment A. Fertiliser shall be applied concurrently with the seeding operation.

(f) Turfing

(i) Turf shall be placed on the prepared topsoiled surface. Runs of turf shall butt hard against each other and be placed perpendicular to the direction of water flow. Turf seams shall then be topdressed with topsoil.

(ii) Four to six weeks after placement, the turf shall be lightly topdressed with topsoil to correct any undulations or unevenness in the established turf.

(g) Watering
The Contractor shall water areas to be sown to a moist condition and shall rewater areas to a moist condition without surface runoff on a daily basis for a minimum of 15 days after sowing, or as otherwise directed by the Superintendent, to promote and maintain growth.

(4) Vegetation of slopes steeper than 3 to 1

(a) General
Where required or directed by the Superintendent, slopes shall be vegetated by one of the following methods:

(i) topsoiling and hydromulching;

(ii) topsoiling, hydroseeding and straw mulching; or

(iii) hydroseeding.

(b) Preparation of surface

(i) Weeds shall be killed by spraying with herbicides as specified in SC6.4.6.26 Attachment A.

(ii) No more than 7 days before seeding all loose material shall be removed from fill batters and cut

batters, which are not stepped, by dragging a heavy steel chain of minimum weight of 30 kilograms per metre of length or by other methods approved by the Superintendent.

(c) Topsoiling

Where batters have been stepped, the steps shall be loosely filled with topsoil. Elsewhere, topsoil shall be uniformly applied to provide an average thickness of 50 mm with a minimum compacted thickness of 30 mm at any location.

(d) Hydromulching or hydroseeding

(i) The hydromulch or hydroseed shall comprise the materials shown in Table SC6.4.6.26.4. The materials shall be applied at the application rates shown in Table SC6.4.6.26.4.

(ii) Dry surfaces shall be watered by a fine spray before the application of the hydromulch.

(iii) During preparation of the hydromulch or hydroseed slurry, liquid form pesticide shall be added to the storage tank, to facilitate surface application, at a rate of 5 litres of pesticide to the equivalent volume of hydromulch or hydroseed slurry to be spread on 1 hectare of surface in accordance with Table SC6.4.6.26.4.

(iv) Storage tanks, containers and equipment to be used in hydromulching or hydroseeding of slopes shall be clean and free of contamination from previous operations.

(v) A slurry mixture shall be produced by addition of the specified materials in the tank and agitated to maintain a uniform consistency during application. It shall be applied uniformly over the whole surface.

(vi) Hydromulch or hydroseed shall not be applied under the following weather conditions at the site:

(A) when temperature is higher than 35 ºC;

(B) when winds exceed 15 km/hr;

(C) where, in the opinion of the Superintendent, the surface is too wet; or

(D) during rain periods or when rain appears imminent.

(vii) Application rates shall be in accordance with Table SC6.4.6.26.4.

Table SC6.4.6.26.4 Materials and application rates

Application Rate per Hectare		
Material	**Hydromulching**	**Hydroseeding**
i) Vegetable Mulch (kg)	2,500	Nil
ii) Water (L)	35,000	20,000
iii) Binder (L)	700	Nil
iv) Fertiliser	See SC6.4.6.26 Attachment A	
v) Seed	See SC6.4.6.26 Attachment A	
vi) Wetting Agent (L)	35	20
vii) Pesticide (L)	5	5

(e) Straw mulching

The mulch to be applied after hydroseeding shall comprise a matrix of straw and an anionic slow setting bitumen emulsion binder. Meadow hay shall not be used. The straw mulch shall be uniformly applied by a suitable blower unit at a rate of 250 bales (each of 20 kilograms) of straw per hectare of surface. The bitumen emulsion shall be incorporated as a spray into the air stream of the mulch blower at a rate of not less than 2,500 litres of bitumen emulsion per hectare of surface. The finished straw mat shall have a minimum thickness of 20 mm at any location.

(5) Vegetation of open drains

(a) Preparation of surface

The Contractor shall so execute the work that the excavation of open drains to the specified profiles is followed within 7 days by the vegetation of the surface as specified in this clause. Topsoil shall be spread to provide an average compacted thickness of 50 mm with a minimum compacted thickness of 30 mm at any location.

(b) Sowing
Before sowing, the surface shall be watered. Seed and fertiliser shall then be applied uniformly at the rates specified in SC6.4.6.26 Attachment A by one of the following procedures as directed by the Superintendent:

(i) mechanical sowing;

(ii) hydromulching or hydroseeding; and

(iii) by hand.

(c) Surface protection - general
Where shown on the drawings or directed by the Superintendent, one of the following protective treatments shall be applied immediately to all or part of the sown surface.

(d) Surface protection - spraying with bitumen emulsion
An anionic slow setting bitumen emulsion, conforming with Grade ASS of AS 1160, shall be sprayed over the surface at a rate of 1 litre of bitumen emulsion per square metre of surface.

(e) Surface protection - lining with organic fibre mat

(i) The channel surface shall be lined with an organic fibre mat listed in SC6.4.6.26 Attachment A. The runs of matting shall be laid along the direction of water flow. The matting shall be laid loosely on the soil surface and not stretched.

(ii) The upstream end of the matting shall be slotted into a trench 150 mm wide by 150 mm deep and pinned to the base of the trench at 200 mm centres. The trench shall be backfilled with soil and compacted by foot.

(iii) The pins shall be `U' shaped, 4 mm gauge wire, 50 mm wide and 150 mm long legs.

(iv) Adjacent runs of matting shall be overlapped 100 mm with the higher run lapped over the lower run. The matting shall be pinned along the sides of each run at 500 mm centres and along the middle of each run at 1 m centres. End overlaps shall be 150 mm wide with the higher run end lapped over the start of the lower run and pinned at 200 mm centres.

(f) Turfing

(i) Turf shall be as specified under clause SC6.4.6.26.5(2)(d).

(ii) Runs of turf shall butt hard against each other and be placed perpendicular to the direction of water flow in the drain, and pinned into position at 500 mm centres.

(iii) Seams of turf shall be topdressed with topsoil.

(g) Watering
The Contractor shall water treated areas in order to promote and maintain growth as specified under clause SC6.4.6.26.5(3)(g).

SC6.4.6.26.6 Garden construction

(1) Scope
The following work activities relate to the construction of garden beds, garden areas and mass planting areas:

(a) earthworks (excavation, filling and cultivation);

(b) supply and application of soil improvement additives;

(c) supply and placing garden mix soil;

(d) supply and placing mulch;

(e) supply and planting of trees, shrubs, ground cover plants and the like including stakes and other plant supports;

(f) supply and application of fertiliser;

(g) supply and installation of garden edging; and

(h) supply and installation of subsoil drains.

All garden construction shall be in accordance with the current relevant Australian Standards:

- AS 4419 - *Soils for landscaping and garden use*; and

- AS 4454 - *Composts, soil conditioners and mulches*.

(2) Co-ordination

The sequence for placing garden mix soil, installing irrigation, placing mulch and planting will vary according to the type of plants and irrigation system. The Contractor is required to liaise with other Contractors and the Superintendent to ensure the best possible method of construction is undertaken.

(3) Earthworks

Gardens may require Excavation or Filling to achieve the finished surface levels nominated on the drawings. After excavation or filling, all gardens may require cultivation.

(4) Garden bed dimensions

Planting bed dimensions are in accordance with the following:

(a) garden beds have an average minimum width of 1.2 m, provided that the bed is no less than 0.5 m wide; and

(b) root zone depths for plants are at least that of the root ball of the plant at planting.

(5) Soil condition

(a) Priority is to be given to using existing site soil as imported soil is a limited resource.

(b) Existing topsoil is conserved by either not disturbing the soil during construction or by stockpiling it prior to construction commencing, in accordance with SC6.4.5.2 Stockpiling of materials.

(c) Subsoil is to be cultivated to a minimum depth of 200 mm for garden beds and 100 mm for turfed areas unless this will adversely affect the roots of established trees.

(d) The minimum top soil depth is:

(i) 100 mm for non-irrigated turf areas;.

(ii) 200 mm for irrigated turf areas; and

(iii) 300 mm for garden beds.

(e) If additional soil is required to meet these minimum depths, soil is to meet AS4419 Soils for landscaping and garden use.

(f) The soil quality is sufficient to allow plants to grow effectively. Soil amelioration measures to improve the infiltration of existing soils, the soil's macropore and micropore balance and ensure a stable soil ecosystem, include the following:

(i) scarification of crusted topsoil layers;

(ii) aeration of topsoil layers;

(iii) deep ripping of subsoil layers;

(iv) using hand tools only within the tree protection zone of a tree identified for retention;

(v) the application of gypsum to sodic clay topsoils and subsoils;

(vi) installing a 50 mm layer of lucerne hay between the topsoil and mulch layer;

(vii) adding worms to the topsoil;

(viii) applying soil rhizobia in solution to the topsoil;

(ix) inoculating plants with Mycorrhizal fungi; and

(x) incorporating soil wetters, crystals and wettable foams.

(6) Soil improvement additives

Any soil additives to be applied shall be as required/recommended by soil test results.

(7) Placing imported soil in gardens

(a) Garden mix soil shall be an imported "Organic Soil".

(b) Garden mix soil shall be a minimum depth of 300 mm after consolidation.

(c) Garden mix soil shall be placed, spread and graded evenly in maximum 150 mm thick layers to finish at a level which allows the surface of the mulching material after consolidation to be flush with adjacent finished levels. Care shall be taken to prevent areas of excessive compaction being caused by construction equipment.

(d) Garden mix soil shall be graded evenly to form a gentle crowned appearance at the centre of the garden bed and/or shall conform to the finished levels detailed on the drawings.

(e) The surface of the garden mix soil shall be smooth and free from stones or lumps of soil prior to planting.

(8) Mulch material
Refer to clause SC6.4.6.26.3 Supply of materials.

(9) Placing mulch

(a) Mulch shall be placed as soon as practicable after planting and shall be placed progressively as planting proceeds along the length of the garden or planting area.

(b) Mulch shall be spread smoothly and evenly over the entire garden so that after initial consolidation the finished level of the mulch is flush with adjacent finished levels.

(c) Mulch shall be shaped around plants to slope into the plant and shall be kept a minimum of 50 mm clear of plant stems to avoid collar rot.

(d) Organic mulch
Organic mulch shall be placed to a depth not greater than 100 mm and as a minimum shall be maintained to a depth of 75 mm after consolidation.

(e) Inorganic mulch
Not less than 14 days prior to the placing of inorganic mulch, herbicide shall be applied to the entire area to be mulched and prior to placing the mulch.

(f) Inorganic mulch shall be placed to a minimum depth of 100 mm unless noted otherwise on the drawings for the type of mulch specified.

SC6.4.6.26.7 Planting

(1) General

(a) Planting shall be carried out in accordance with the best horticultural practices.

(b) Plants shall be installed at the spacings and locations detailed on the drawings to avoid existing services or to cover an area uniformly.

(c) In feature planting areas at least 25% of tree plantings are to be provided as larger advanced stock, with a minimum 25 litre pot size.

(d) The Contractor is required to locate all existing services prior to planting.

(e) Planting shall not be carried out if the soil is very wet or water logged or during periods of extreme weather conditions such as extreme heat, cold wind or rain.

(f) Plant supplies are to be healthy, attractive, and a general high standard of stock in order to ensure long-term viability of the specimen. The stock will be free from disease, pests and weeds and structural defects, as per clause SC6.4.6.26.3 Supply of materials.

(2) Planting procedure – container stock

(a) A planting hole with vertical sides shall be excavated to a width of twice the diameter of the root ball of the plant and to a minimum depth of 100 mm deeper than the height of the plant container.

(b) The depth of the planting hole shall allow for the clearance specified and shall be in relation to the finished surface level where applicable.

(c) The sub grade material at the bottom of the planting hole shall be loosened to a depth of at least 50% of the root ball depth and the compacted sides of the planting hole shall be loosened to prevent confinement of root growth to the hole. Additional excavation of the base of the planting hole may be

required to ensure that the plant has sufficient sub grade drainage.

(d) Plants shall be thoroughly watered in the pot prior to planting so that when removed from the pot the root ball is moist. Plants shall be removed from their pots without damage to the root system. Plants shall not be removed from pots until the planting hole is complete and ready for planting.

(e) The plant shall be placed in the centre of the hole with the stem vertical and shall be set at a height such that the top of the potting material is level with the surrounding soil. Plants placed on a slope shall be set in the centre of the hole with the top of the potting material level with the lowest side of the planting hole and the plant stem vertical.

(f) Fertiliser tablets or granules shall be placed in the planting hole at the time of planting in accordance with the manufacturers recommended rates of application. The fertiliser shall be placed around the plant at half the depth of the planting hole and shall be covered with backfill soil to ensure no direct contact with the plant roots.

(g) Plants other than container stock trees placed in gardens shall be backfilled with garden mix soil as specified for the entire planting hole. The garden mix soil shall be lightly tamped around the plant and thoroughly watered to eliminate air pockets.

(h) During planting care shall be taken to ensure that soil is not mixed with the mulch. Mulch that is contaminated with soil shall be replaced.

(i) Container stock trees shall be backfilled in 150 mm layers up to within 200 mm of the top of the planting hole. The backfill soil shall be tamped around the tree and thoroughly watered to eliminate air pockets. Backfill the top 200 mm with garden mix soil.

(j) In areas other than heavily planted borders, shrubs or tuft plants, each individual plant shall have a watering basin for the extent of the planting hole formed with garden mix soil around the base of the plant.

(k) Individual container stock trees located in irrigated grassed areas shall have a 150 mm high watering basin for the extent of the planting hole formed with garden mix soil around the base of the tree.

(l) Plants placed on a slope shall have a small horizontal terrace formed for the extent of the planting hole.

(m) Immediately after planting, the plants shall be watered to thoroughly water the root ball and the backfill. Watering shall be carried out progressively as planting proceeds to ensure that plants do not dry out and as a minimum, plants shall be watered within a maximum of 1 hour from planting.

(n) All identification labels, nursery ties and the like shall be removed from the plants immediately after planting

(3) Planting procedure - ex ground stock plants

Editor's note—content under development.

(4) Transplanting trees

(a) Trees to be transplanted will be noted on the construction drawings prior to the commencement of construction.

(b) Preparation of the tree prior to transplanting shall be carried out in accordance with accepted transplanting practice and any requirements provided by council to suit the particular species and project.

(c) Preparation of the tree for transplanting shall be commenced in sufficient time to ensure that at the time of planting the tree is adequately prepared and will meet the specified requirements.

(d) All transplanting work shall be carried out under the direction of a suitably qualified horticulturist or arborist.

(e) Planting of the transplanted tree shall be generally in accordance with the details shown on the drawings.

(f) The resulting excavation after the tree has been removed shall be backfilled with compacted fill material suitable for the location.

(5) Root barrier

(a) Locations and type of root barrier shall be noted on the drawings or shall be as directed by the Superintendent.

(b) Root barrier shall be installed as per the manufacturer's recommendations and with particular attention to the location of any underground services and service pits.

(c) Root barrier must be installed in all situations where it is likely that tree roots may interfere or adversely affect infrastructure - such as driveways, kerbs, pathways and other street furniture and buildings, e.g. where species such as Ficus are to be planted in reasonable proximity to pathways.

SC6.4.6.26.8 Staking, ties and guying

(1) Every container stock tree shall be staked and tied unless otherwise approved by the Superintendent. Tree stakes

(a) Stakes shall be:

(i) a minimum of 2 stakes per tree;

(ii) placed outside of the tree root ball;

(iii) driven into the ground a minimum one third of their length;

(iv) for smaller trees (trees up to 45 litre), at least 1.0 metre apart; and

(v) for columnar trees, spaced to avoid excessive root ball damage.

(b) Care shall be taken to avoid damage to the tree root system and any services when installing stakes.

(c) All stakes shall remain in place for the entire “maintenance period” unless otherwise instructed by the Superintendent.

(2) Ties

Ties shall be fixed securely with staples to the stakes in a figure eight pattern around the tree stem. As a minimum one tie at half the height of the main stem shall be provided with additional ties as necessary to stabilise the tree.

(3) Guying

(a) Trees requiring the installation of guying shall be noted on the construction drawings or shall be as directed by the Superintendent.

(b) Guying consists of a minimum of three heavy duty stakes of either steel or timber driven into solid ground, with heavy duty galvanised wire ties firmly fasten to the stakes and looped around the tree trunk with suitable wrapping to protect the trunk.

(c) Underground guying where required to be used, shall be positioned for stability purposes, placement of the guy wires shall away from the tree trunk to avoid girdling issues as the tree matures. Such tree guying practices shall be removed prior to Off Maintenance inspection and acceptance by council.

Editor’s note—underground guying is accepted where suitable for the tree in question.

SC6.4.6.26.9 Sub soil drains construction

(1) Sub soil drains in gardens may be required in areas of heavy clay soils and in roadway medians, roundabouts and the like. Sub soil drains shall be installed at the locations and to the details shown on the drawings.

(2) Pipes and fittings shall be perforated plastic Type 1 Class 200 to AS2439: Part 1. Sub soil drain filter fabrics shall be approved geo fabric material in accordance with the relevant Australian Standards.

(3) Pipe surround shall be a coarse washed river sand complying with the grading requirements given in Table SC6.4.6.26.5 and shall completely surround the perforated pipe.

(4) The subsoil drain pipe shall be laid to grade continuously to the outlets nominated on the drawings at a

minimum grade of 1:100.

(5) Sub soil drains may be inspected by the Superintendent prior to placing any garden mix soil or backfill.

Table SC6.4.6.26.5 Recommended grading for sub-soil drain sand

A.S. SIEVE	% PASSING
9.5 mm	100
4.75 mm	98-100
2.36 mm	70-100
1.18 mm	30-78
600 µm	2-15
300 µm	0-4
150 µm	0-1

SC6.4.6.26.10 Garden edging

(1) Supply and installation of timber, concrete or recycled plastic proprietary garden edging shall be in accordance with the details on the drawings and the manufacturer's recommendations where applicable. Timber or recycled plastic garden edging must have a minimum thickness of 30 mm.

(2) Supply and installation of concrete kerbing shall be as specified in clause SC6.4.6.26.15.

SC6.4.6.26.11 Planter boxes

(1) Planter boxes shall be constructed at the locations and to the details shown on the construction drawings.

(2) Planter box soil shall be an imported soil mix (Potting Mix). Refer to project specific specifications where applicable.

(3) Planter boxes must have appropriate drainage (see clause SC6.4.6.26.9 Sub soil drains construction) provided that it is connected to a lawful discharge point. The drainage discharge is not permitted to cause nuisance, such as staining or sediments, to adjacent areas.

SC6.4.6.26.12 Grass area construction

(1) General

The following work activities relate to grass areas construction:

(a) earthworks (excavation, filling and cultivation);

(b) supply and application of soil improvement additives;

(c) supply and placing turf soil;

(d) supply and lay grass turf;

(e) supply and lay grass seeding;

(f) supply and installation of hydro-seeding/mulching; and

(g) supply and application of fertiliser.

All grass area construction shall be in accordance with the current relevant Australian Standards:

- AS 4419 Soils for landscaping and garden use; and
- AS 4454 Composts, soil conditioners and mulches.

(2) Co-ordination

The sequence for placing turf soil, installing irrigation and placing turf will vary according to the type of plants and irrigation system.

(3) Earthworks

Grass areas may require excavation or filling to achieve the finished surface levels detailed on the construction drawings. Refer to clause SC6.4.6.26.4 Earthworks.

(4) Placing turf soil

(a) Turf soil shall be an imported soil mix Type 2 “Soil Blend”.

(b) Turf soil shall be a minimum depth of 100 mm after light compaction.

(c) Turf areas shall be graded to fall evenly between the finished surface levels detailed on the drawings and/or shall be graded to drain freely to stormwater inlets without causing ponding. As a minimum turf areas shall be graded to fall at 1:100.

(d) Turf soil shall be spread evenly and shall be lightly compacted to finish at a level which allows for the finished turf surface to be flush with adjacent surfaces such as paved areas, pathways mowing strips and the like. Care shall be taken to prevent areas of excessive compaction being caused by construction equipment.

(e) The surface of the turf soil shall be smooth and free from stones or lumps of soil prior to laying the turf.

(5) Turf material

(a) Turf shall be the species nominated on the drawings and shall be supplied by a specialist grower of cultivated turf approved by the Superintendent.

(b) Where turf areas are provided within centre medians, round-abouts and other identified areas of road reserve where edging/mowing may require traffic control, all turf is to be Empire Zoysia or approved similar turf and of a minimum width of 1.6 m to allow for clear mowing access.

(6) Laying turf

(a) Prior to laying turf, fertiliser shall be thoroughly mixed into the turf soil. Refer to Table SC6.4.6.26.5 for application rates.

(b) Areas to be turfed shall be divided into sections that can be prepared and completed (including adequate watering) in the same day.

(c) Turf shall be laid in straight lines in a stretcher bond pattern across the fall of the slope or parallel with the long side of level areas. Cross joints shall be staggered with a maximum gap of 5 mm between adjacent sections of turf.

(d) Immediately after laying the turf shall be rolled with a roller weighing not more than 90 kg/m of width.

(e) As soon as practicable after rolling turf shall be watered thoroughly with a fine spray to a depth of 150 mm. Watering shall continue as necessary to maintain moisture to this depth and to maintain the turf in a healthy condition.

(f) Where levels have deviated from the design levels after placing and watering the turf shall be lifted and the section regraded with turf soil to achieve design levels prior to replacing the turf.

(g) Turf shall be protected from pedestrian traffic until established and shall be protected from vehicle traffic at all times.

SC6.4.6.26.13 Hyrdo seeding/mulching

(1) General

(a) Excavation, filling, cultivation and placing imported soil mix for hydro seeding/mulching areas shall be as specified for turf areas.

(b) Details for hydro seeding/mulching supply and sowing shall be as noted on the drawings and/or as specified under separate cover.

(c) Organic mulches are to be applied to landscaped garden beds and trees which:

(i) meet AS 4454 Composts, soil conditioners and mulches;

(ii) are applied to a depth of 75 – 100 mm;

(iii) are of a coarse texture to allow water penetration to prevent nitrogen drawdown of the soil;

(iv) are aged prior to application;

(v) do not use plastic sheeting, typically used for weed suppression as it prevents rainwater from infiltrating soils and inhibits gaseous exchange between the soil and air; and

(vi) use a biodegradable mulch mat on any waterway embankment.

(d) Inorganic mulches, such as recycled concrete or brick cobbles, are limited to feature or themed landscapes, or in windy areas where organic mulches may be blown away.

(2) Supply of mulch materials

(a) Mulch materials supplied shall be free of deleterious and extraneous matter such as soil, weeds, seeds, rubbish, vermin, insects, pests, fungus, sticks, disease, declared plants or noxious weeds and shall be free of any matter toxic to plant growth or germination.

(b) All mulch materials supplied shall be in accordance with AS 4454 Composts, soil conditioners and mulches.

(c) Organic mulch
Organic mulch may be either:

(i) tea tree mulch from an approved supplier; or

(ii) wood chip produced by the chipping of native and other approved vegetation removed during the clearing and grubbing process on site (max 50 mm size); or

(iii) wood chip obtained from a council stockpile as directed by the Superintendent or his delegated site supervisor; or

(iv) other material as noted on the drawings.

(d) Inorganic mulch
Inorganic mulch shall be of the type and quality and noted on the construction drawings.

(3) Surface preparation

(a) Level sites
Prior to hydro seeding/mulching the area to be treated shall be graded to fall evenly between the finished surface levels detailed on the drawings and/or shall be graded to drain freely to stormwater inlets without causing ponding.

(b) Embankments and slopes (1 on 5 maximum slope)
Prior to hydro seeding/mulching the area shall be lightly cultivated across the slope to minimise surface run-off and erosion. After cultivation, soil crumb size shall not exceed 20 mm.

(c) The surface of the area to be treated shall be free from weeds, stones, roots, sticks or other deleterious material and have a general moisture content of around 10% just prior to applying the hydroseed/mulch.

(4) Irrigation
An approved temporary above ground irrigation system shall be installed to ensure establishment of the hydro seeding/mulching is achieved within the timer frame specified. Refer to SC6.4.6.27 Irrigation.

SC6.4.6.26.14 Paving construction
Refer to sub-section SC6.4.6.18 Segmental paving.

All areas of road reserve fronting a subject site must be assessed against, and treated in accordance with SC6.4.3.3 Footpath treatment policy where specified.

SC6.4.6.26.15 Concrete kerbs
This section contains specific details for construction of concrete kerb in landscape and open space situations. Concrete kerb is most commonly used for garden edge or as a restraint for softfall areas in playgrounds.

All concrete garden edge kerb or similar structure shall have minimum rectangular profile dimensions of 150 mm wide x 200 mm deep with edges rounded to a radius of 20 mm (minimum) and constructed in accordance with clause

SC6.4.6.28.2(2) Kerb and channel. Where the concrete garden edge kerb abuts grass areas, the surface of the kerb must finish level with the surface level of the grass area.

SC6.4.6.26.16 Concrete works

For all concrete works associated with Landscaping activities refer to sub-section 6.4.6.28 Minor concrete works.

SC6.4.6.26.17 Masonry work

This section covers the supply of all materials, placing and finishing of all masonry blockwork including concrete core-filling and clay brickwork. Masonry Work includes walls, retaining walls, free standing piers, structures and the like. All masonry work shall conform to the requirements of AS 3700.

(1) Materials

(a) Blocks - Hollow load bearing masonry blocks shall conform to the requirements of AS 3700 - Section 2, and shall have a characteristic unconfined compressive strength of 15 MPa unless nominated otherwise agreed.

(b) Masonry blocks shall be sound, dry, clean and crack free and shall have been cured for not less than 14 days before delivery. The correct type of block shall be used to make provision for all lintels, pilasters, bond beams, openings, etc.

(c) Clean out blocks shall be used in the first course of all reinforced cores and/or where cores are to be concrete filled.

(d) Cement - for mortar shall be Portland Cement Type A and shall conform in all respects with the requirements of AS 3972.

(e) Sand - for mortar shall be clean, sharp and free from organic impurities and excess fines and efflorescing salts.

(f) Water - used in mixing concrete shall be clean and free from injurious amounts of oil, acid, alkali, organic matter or other deleterious substances.

(g) Hydrated lime shall conform to the requirements of AS 1672.1.

(h) Admixtures - no air-entraining additives or other admixtures shall be incorporated in the mortar unless specifically approved by the Superintendent.

(i) Reinforcement - shall comply with AS/NZS 4671 as applicable.

(j) Clay bricks - and brickwork shall conform to AS 3700. Clay brick shall have a characteristic unconfined compressive strength of 40 MPa unless otherwise agreed.

(2) Mortar for blockwork

(a) All mortar for blockwork shall consist of a homogeneous mixture of the ingredients and shall be classified as M4 in AS 3700. The following proportions by volume shall be used unless the minimum compressive strength of mortar at 28 days has been nominated on the drawings. Cement 1: Lime 0 to 0.25: Sand 3.

(b) The mortar components shall be properly volume batched using calibrated volume boxes. Batching by shovel will not be permitted.

(c) Mortar shall be mixed in an approved mixing machine for not less than 3 minutes. Handmixing shall not be permitted unless specifically approved by the Superintendent. The dry ingredients shall be thoroughly mixed prior to the addition of water, which shall then be worked thoroughly through the mixture.

(d) Mortar shall be transported in a covered container such that excessive evaporation will be prevented. Retempering of mortar shall not be permitted.

(3) Core-fill concrete

(a) Core-fill concrete shall comply with the relevant requirements of AS 3600 Concrete Structures. Ready mixed concrete from an approved supplier shall be used. As a minimum and unless shown otherwise on the drawings, core-fill concrete supplied shall have the following properties in Table SC6.4.6.26.6.

Property	Design Value
Characteristic strenght F'c at 28 days	N 20
Norminal maximum size of aggregate	10 mm
Slump	230 mm +/-30 mm

(b) Testing of core-fill concrete supplied shall be carried out by the Concrete Supplier as part of the suppliers Quality Assurance System. The Contractor is required to provide the Superintendent with copies of the suppliers Test Certificates relating to the particular batch of core-fill concrete supplied.

Core-fill concrete supplied that does not meet the requirements of this specification shall be liable to rejection by the Superintendent. If directed by the Superintendent the Contractor will rectify any masonry wall which has been filled with rejected core-fill concrete.

(4) Laying blocks

(a) All work shall be carried out by experienced tradesmen to the general requirements of AS 3700 - Section 8. Blockwork shall be laid in lifts or not more than 2400 mm in height.

(b) All blocks shall be laid dry and wetting of the blocks shall not be permitted under any circumstances.

(c) Cutting of blocks shall be reduced to an absolute minimum by setting out to avoid irregular or broken bond.

(d) Blocks shall be stacked on planks or other supports free from contact with the ground and shall be covered at all times to ensure that the blocks remain dry.

(e) Blocks shall be laid in straight uniform courses of running bond unless noted otherwise on the drawings. Intersecting walls shall be bonded as shown on the drawings.

(f) The surface of the concrete footing, floor slab, beam, etc. on which the base course is to be laid shall be thoroughly cleaned prior to laying the base course to ensure all laitance is removed.

(g) The base course shall incorporate clean out blocks at every reinforced core, with the clean out opening on the inside face of the wall.

(h) Reinforcement starter bars shall be checked for alignment prior to laying the base course. Starter bars shall be vertical. Bending starter bars to allow the laying of the base course is not acceptable. Any starter bars out of position shall be rectified by the Contractor as directed by the Superintendent.

(i) For unreinforced and reinforced masonry walls, horizontal joints shall have full mortar coverage on the face shells and on the webs.

(j) For unreinforced masonry walls all vertical joints shall have full mortar coverage. For reinforced masonry walls all vertical joints shall be buttered only for the thickness of the face shells.

(k) All horizontal and vertical joints shall be 10 mm in width with a maximum mortar intrusion into the cores of 6 mm. Mortar droppings into cavities or cores shall be avoided.

(l) Tooling of the joints shall be done when the mortar is partially set but still sufficiently plastic to bond. All tooling shall be done with a V-shaped or round bar in a manner that will compact the mortar rather than drag it out. Raked joints shall not be permitted to encroach more than 5 mm in depth.

(m) If it is necessary to move a block after it has been set in place with mortar, then the block shall be removed from the wall, the mortar removed and the block shall be reset in fresh mortar.

(n) Capping blocks shall be fixed with a suitable flexible external grade adhesive as detailed on the drawings. Laying capping blocks in mortar only is not acceptable.

(o) Where new blockwork is to be laid on top of an existing masonry block wall, the existing core concrete shall be cleaned to expose all aggregate and treated using an adhesion enhancer such as bondcrete or approved equivalent before block laying is commenced.

(p) Extreme care shall be exercised to prevent mortar adhering to the face of blockwork. Acid shall not be used to clean down masonry walls.

(5) Reinforcement

(a) Steel reinforcement shall be supplied and bent in accordance with AS 3700. Rebending of reinforcement

with or without heating is not permitted unless approved by the Superintendent.

(b) Steel reinforcement shall be free from rust, oil, varnish, mud or any other coatings, cracks, scale blister and other defects and shall comply in all respects with AS/NZS 4671.

(c) All horizontal reinforcement shall be laid into the wall as the block laying progresses. Galvanised wire loops shall be cast into the horizontal joints prior to placing the reinforcement to ensure correct positioning of the reinforcement.

(d) Vertical reinforcement shall be placed after the wall has been laid and shall be placed in the core with the correct cover to the face of the blocks as detailed on the drawings. Unless noted otherwise on the drawings vertical reinforcement shall be placed in the centre of the core.

(e) Splice lengths for both horizontal and vertical reinforcement shall not be less than 45 bar diameters for plain round bars or 30 diameters for deformed bars or 450 mm, whichever is the greater.

(f) All reinforced block walls shall have vertical reinforcement in the core at the ends, corners, sides of openings, adjacent to control joints, at unbonded intersections and at the maximum centres between these points.

(6) Cast in elements

(a) The Contractor shall co-ordinate with all other trades as necessary to ensure that all conduits, fitments, penetrations and the like are incorporated in the masonry as detailed on the drawings and as specified.

(b) All bolts, anchors and other steel fittings shall be accurately set into the walls as the work progresses and positioned such that they shall be thoroughly embedded in mortar or core-filling concrete as required.

(c) Where items to be cast into the blockwork are found to be out of position and cannot be satisfactorily corrected, then the section of blockwork shall be completely demolished, and then reconstructed to allow correct positioning.

(7) Joints in blockwork

(a) Joints in blockwork shall be the type and at the locations detailed on the drawings. Joints with steel dowels shall have the dowels securely supported to ensure that the dowel remains in the correct position during the placing of core-fill concrete.

(b) Construction joints shall be located as detailed on the drawings or shall be located where agreed with the Superintendent to suit specific site requirements.

(c) Joint filling compounds shall be as detailed on the drawings and shall be installed in accordance with the manufacturers recommendations, with particular attention to the preparation of the blockwork surface to suit the application of the joint filling compound.

(8) Placing core-fill concrete

(a) Masonry walls shall cure for at least 3 days before core-fill concrete is placed.

(b) The cores to receive core-fill concrete shall be cleaned of all mortar protrusions by rodding from the top of the wall. All mortar droppings and foreign matter shall then be removed via the clean out openings at the base of the wall, the vertical reinforcement positioned and formwork fixed in place to seal the clean out block opening.

(c) Core filling shall not proceed until the reinforcement and cores have been inspected by the Superintendent. Clean out openings shall not be sealed until the inspection has been carried out.

(d) Core-fill concrete shall be thoroughly compacted into place as it is poured with the aid of small immersion vibrators or rodding. Block cores shall be topped up after settlement occurs.

(e) Core-fill concrete shall be placed for the full height of the blockwork in lifts of not more than 2400 mm in height. A minimum delay period of 1 hour and a maximum delay period of 3 hours shall be observed between lifts.

(f) Proprietary core plates shall be used to confine the core-fill concrete to the reinforced cores.

(g) Placing of core-fill concrete in bond beams shall be done in one continuous operation for the full length of the bond beam. Construction joints in bond beams other than control joints, are not acceptable.

(h) Extreme care shall be exercised to prevent slurry adhering to the face of blockwork. Acid shall not be used to clean down masonry walls.

(9) Mortar for clay bricks

(a) All mortar for clay bricks shall consist of a homogeneous mixture of the ingredients and shall be classified as M3. Refer to AS 3700.

(b) The following proportions by volume shall be used unless the minimum compressive strength of mortar at 28 days has been nominated on the drawings. Cement: 1, Lime: 1, Sand: 6.

(c) Mortar for clay bricks shall be generally in accordance with clause SC6.4.6.26.17(2) Mortar for block work.

(10) Laying clay bricks

(a) Clay bricks shall be fully bedded and fully faced. Bed joints shall be 10 mm nominal height.

(b) Clay brick masonry walls shall be laid with galvanised brick ties at 600 mm maximum centres each way and at 300 mm centres adjacent to openings in accordance with manufacturer's specifications.

(c) Laying of clay bricks shall be generally in accordance with clause SC6.4.6.26.17(4) Laying blocks.

(11) Protection of walls

(a) During construction and after the wall is laid and prior to placing core-fill concrete; under no circumstances shall masonry blocks be wetted or allowed to become wet.

(b) At the completion of a day's work and during wet weather the top and sides of all walls shall be covered to prevent rain penetrating the cores and wetting the blocks.

(c) During the construction of masonry walls and prior to the core-fill concrete having gained its full strength, the Contractor shall protect the wall by suitable means such as bracing to ensure that the wall is not damaged and to ensure the safety of workers on the site.

(12) Tolerances

(a) All masonry shall be built true and plumb such that the maximum "out-of-plumb" in a 3 m height does not exceed 10 mm.

(b) The bed joint at any level shall be within ± 3 mm.

(13) Surface finishes to masonry

(a) Surface finishes, such as painting, rendering or textured finishes shall be as detailed on the drawings or as nominated in the Finishes Schedule.

(b) Prior to applying any surface finish the substrate shall be free from dirt, dust, oil, grease, mould, fungi, efflorescence, release agents, bond breakers, scaling and laitance or any other contaminants or foreign material that may affect adhesion. Remove all traces of loosely adhering material by scraping, grinding, wire brushing or air blowing as necessary.

(c) Preparation of the surfaces to be treated, application of the surface finish and curing after application if required, shall be carried out in strict accordance with the manufacturer's recommendations. Particular attention shall be made to application during suitable weather conditions.

(d) Gap fill and/or sealant material used for joints or cracks in walls shall be checked for compatibility with the proposed surface finish.

(e) Anti-vandal coatings shall be used in circumstances where walls are exposed (i.e. not screened by soft landscaping) and prone to graffiti.

(f) Dissimilar materials adjacent to surfaces to be treated shall be masked to avoid contact, (e.g. capping and flashings).

(g) The Contractor shall provide the Superintendent with all warranty details of the surface finishes.

SC6.4.6.26.18 Stormwater drainage

All stormwater drainage shall be constructed in accordance with the relevant stormwater drainage guidelines contained in SC6.4.6.4 Stormwater drainage.

SC6.4.6.26.19 Infrastructure items

Supply and installation of infrastructure items such as timber decking, timber and steel fencing, seats, picnic sets, barbeques, play equipment and signage shall be as detailed on the drawings and constructed in strict accordance with the manufacturers' specifications. The Contractor shall provide the Superintendent with all warranty details. Concrete for footings, plinths and the like for infrastructure items shall be in accordance with clause SC6.4.6.26.16 Concrete works.

SC6.4.6.26.20 Electrical

The installation of electrical components shall comply with the requirements of AS 3000. Where required under the *Electricity Act 1994*, electrical installations shall be installed by a registered Electrical Contractor as defined by that Act. Refer to the electrical engineer's drawings and specifications for all requirements.

SC6.4.6.26.21 Summary of limited and tolerance

The limits and tolerances applicable to the various clauses in this sub-section are summarised in Table SC6.4.6.26.7 below.

Item	Activity	Limits/Tolerances	Clause
1.	**Topsoil**	>3% by mass	SC6.4.6.26.5(2)(a).
	a) Organic Content		
	b) pH	>5.5 <7.5	SC6.4.6.26.5(2)(a)
	c) Soluble Salt	<0.06% by mass	SC6.4.6.26.5(2)(a)
2.	**Turf**	Widths >300mm.	SC6.4.6.26.5(2)(d)
3.	**Vegetable mulch**	maximum size <10mm	SC6.4.6.26.5(2)(f)
	a) Material	<50% by mass of total mulch	SC6.4.6.26.5(2)(f)
	b) Paper Pulp		
4.	**Topsoiling**	Minimum compacted thickness	SC6.4.6.26.5(3)(b)

MATERIAL *(sample only - to be completed by compiler)*	**TYPE**	**MINIMUM APPLICATION RATE**
1. HERBICIDE *	"Roundup"	As per manufacturers recommendations
2. SEED		
a) Grass	Rye Corn (April-August) or	60 kg/ha
Japanese Millet (September-March		60 kg/ha
Hulled Couch		5 kg/ha
Red Clover (Inoculated)		5 kg/ha
White Clover (Inoculated)		5 kg/ha
"Elka" Perennial Rye		5 kg/ha
(b) Native	Acacia dealbata	4 kg/ha
Acacia buxifolia		1 kg/ha
Acacia decurrens		1 kg/ha
Acacia pravissima		1 kg/ha
Leptospermum lanigerum		1 kg/ha
Hardenbergia violacea		500 g/ha
Kennedia prostrata		500 g/ha
Acacia implexa		200 g/ha
Banksia marginata		200 g/ha
Bursaria spinosa		200 g/ha
Callistemon pallidus		200 g/ha
Dodonaea viscoca		200 g/ha
3. TURF GRASS (a) Medians (b) Verges/Footpaths (c) Other Areas	Couch Buffalo Couch	Refer to drawings " "
4. FERTILISER * (a) Vegetation of Slopes/Drains (b) Landscape Planting	Dynamic Lifter "Nitro" "Kokei" pellets	1000 kg/ha
5. WETTING AGENT *	"Aquasoil"	1 litre/1000 litres of mix water
6. PESTICIDE * (a) Liquid (b) Powder	"Lorsban 500 EC" "Lorsban 250 W"	5 litres 10 kg
7. ORGANIC FIBRE MAT *	"Sta-firma" (light grade)	-
8. MULCH	Composted/Pasteurized	100mm thick
* Material shall be as listed or equivalent as approved by council.		

SC6.4.6.27 Irrigation

SC6.4.6.27.1 Introduction

(1) Scope

(a) This sub-section sets out the standards for design, installation and construction of irrigation systems that will become a Townsville City Council asset.

(b) Irrigation systems that will be connected to an alternative water supply have additional requirements to this sub-section.

(2) Reference and source documents

All design and documentation, materials supplied and work carried out shall be in accordance with the following:-

(a) Australian Standards:

AS 1432	*Copper tubes for plumbing, gas fitting and drainage applications*
AS/NZS 1477	*PVC pipes and fittings for pressure applications*
AS 2032	*Installation of PVC pipe systems*
AS 2033	*Installation of polyethylene pipe systems*
AS 2053	*Conduits and fittings for electrical installations (all Parts)*
AS 2129	*Flanges for pipes and valves and fittings*
AS 2698.2	*Plastics pipes and fittings for irrigation and rural applications –Polyethylene rural pipe*
AS 2698.3	*Plastics pipes and fittings for irrigation and rural applications –Mechanical joint fittings for use with polyethylene micro-irrigation pipes*
AS 2845.1	*Water supply – Backflow prevention devices – Materials, design and performance requirements*
AS 2845.2	*Water supply – Backflow prevention devices – Registered air gaps and registered break tanks*
AS 2845.3	*Water supply – Backflow prevention devices - Field testing and maintenance of testable devices*
AS 3000	*Electrical installation (known as the Australian/New Zealand Wiring Rules)*
AS/NZS 3008.1.1	*Electrical Installations –Selection of cables - Cables for alternating voltages up to and including 0.6/1 kV - Typical Australian installation conditions*
AS/NZS 3500	*Plumbing and Drainage*
AS/NZS 3500.0	*Plumbing and drainage Part 0: Glossary of terms*
AS/NZS 3500.1	*Plumbing and drainage – Water services*
AS 3500.1.1	*National plumbing and drainage - Water supply – Performance requirements*
AS 3500.2.1	*National Plumbing and Drainage Sanitary plumbing and drainage - Performance requirements*
AS 3500.2.2	*National Plumbing and Drainage Sanitary plumbing and drainage - Acceptable Solutions*
AS/NZS 3808	*Insulating and sheathing materials for electrical cables*
AS/NZ 3879	*Solvent cements and priming fluids for PVC (PVC-U and PVC-M) and ASA pipes and fittings*
AS/NZS 4129	*Fittings for polyethylene (PE) pipes for pressure applications*
AS/NZS 4130	*Polyethylene (PE) pipes for pressure applications*
AS/NZ 4158	*Thermal-bonded polymeric coatings on valves and fittings for water industry purposes*

(b) Legislation:

Water Act 2000

Electricity Safety Act 2002

Work Health and Safety Act 2011

(c) Other:

Department of Energy and Water Supply, *Queensland Water Recycling Guidelines*, December 2005

(d) Authorities

The rules and regulations of the relevant local electricity supply authority.

The rules and regulations of the relevant local water supply authority.
The requirements of any other Authority having jurisdiction over the installation.

SC6.4.6.27.2 Irrigation pipework

(1) Standards
All pipes shall be supplied, installed and joined in accordance with the manufacturer's recommendations and all relevant, current Australian Standards.

(2) Class of pipe

(a) Main line pipes (pressurised) of nominal 80mm diameter and larger shall be minimum Class 12 uPVC rubber ring jointed (RRJ) or PN12.5 (Poly pipe).

(b) Main line pipes (pressurised) of nominal diameter less than 80mm shall be minimum Class 12 uPVC solvent welded joint (SWJ) or PN12.5 (Poly pipe).

(c) All lateral line pipes (non pressurised) shall be minimum Class 6 (uPVC) or PN6.3 (Poly pipe), except for lateral line pipe work under road pavements which shall be Class 12 (uPVC) or PN12.5 (Poly pipe).

(d) Supply line to a drinking fountain or a water tap shall be a minimum of 32 mm Class 12 uPVC or PN12.5 (Poly Pipe). Copper pipe is not acceptable.

(e) Copper pipe to a Water meter, drinking fountain and water tap assemblies shall be minimum Type B.

(f) All irrigation pipe work under pavements (road or otherwise) shall be encased in a conduit.

(3) Conduit crossings

(a) All conduits used to encase irrigation line pipes shall be 100mm Class 9 PVC SWJ Pipe as standard unless otherwise approved by the Superintendent. Storm water or waste water pipe used as conduit is not acceptable.

(b) Conduit crossing ends shall be sealed with duct tape to stop the ingress of soil and material from entering the conduit.

(c) Conduit crossings within road reserves and medians are to have the outer 50mm of conduit sealed with expanded foam, to stop the transportation of water through the conduit.

(d) Where underground bores or conduits crossings have been installed, a stainless steel tag shall be used to mark the start and finish of the conduit. The tag shall be a minimum of 38mm diameter and 1.6mm thick. It is to be nailed, glued or set into the surface of the crossing. The marker shall be engraved with the words "Irrigation Water", given a unique number and recorded on the as constructed drawings.

(4) Pipe fittings

(a) All fittings for uPVC pipe shall be minimum Class 18 PVC SWJ.

(b) All fittings for poly pipe shall be metric compression fittings, Plasson or Philmac.

(c) All fittings for low density pipe shall be barbed type, with all joints fitted with stainless steel cobra clamps – or approved equivalent.

(d) All threaded fittings, except sprinklers, shall be sealed using PTFE thread tape and Liquid Teflon.

(5) Pipe installation generally

(a) Interior of pipes shall be kept free of dirt and debris at all times.

(b) Where pipe work is left unfinished during installation, the open ends of pipes shall be sealed off with plastic secured to the end of the pipe or have end caps fitted.

(c) Pipes laid in a common trench shall be separated by a minimum of 100mm.

(d) Refer to SC6.4.4.8 Standard drawings SD-13.1, Figures 1 to 6 for pipe alignments for all irrigation works in road reserves.

(6) UPVC rubber ring jointed pipe – installation (i.e. Main line pipes of nominal 80mm diameter and larger).

(a) All uPVC rubber ring jointed pipe work shall be installed in accordance with the manufacturer's recommendations and AS 2032.

(b) All uPVC rubber ring jointed pipe work shall be laid in a minimum of 100mm sand bedding and surround.

(c) All connections and changes of direction horizontally and vertically in rubber ring joint (RRJ) pipe work shall be installed with concrete thrust blocks.

(d) Thrust block design and size shall follow pipe manufacturers recommendations ("Thrust Block Design – Pressure Pipeline Fittings" Iplex uPVC Design Manual). Thrust blocks shall be 15 MPA concrete in accordance with AS 2032. All thrust blocks are to be cast in situ against undisturbed ground and shall have neatly formed sides.

(e) The ends of pipes used for rubber ring joint (RRJ) connections shall have a smooth chamfer 15 degrees to the outer edge and shall be free of all burrs and rough edges. Rubber rings and lubricant used shall be in accordance with the pipe manufacturer's recommendations.

(f) Each pipe length shall be laid in the following direction; water flow runs from the socket end to the spigot end of the pipe, with the exception of ring mains.

(g) Trenches may be curved to avoid obstructions within the limits of the curvature of the pipe.

(7) UPVC Solvent welded joint pipe installation (i.e. main line pipes of nominal diameter less than 80mm or lateral line pipes).

(a) All uPVC Solvent welded joint pipe work shall be installed in accordance with the manufacturer's recommendations and AS 2032.

(b) All uPVC solvent welded joints shall be primed and cemented.

(c) Primer and solvent cement shall conform to AS/NZ 3879.

(d) Primer is to be "Priming Fluid (red)".

(e) Solvent is to be "Christy's PVC Red Hot Blue Glue" or approved Type "p" solvent cement.

(f) All pipes shall be primed before cementing the joint.

(g) Pipe ends shall be free of all burs and rough edges.

(h) All uPVC solvent welded joints shall not be subjected to water pressure for at least 24 hours after cementing the joint.

(i) All mainline uPVC solvent welded joint pipes shall be laid in a minimum of 100mm sand bedding and surround.

(8) Polyethylene pipe installation

(a) All polyethylene pipe work shall be installed in accordance with the manufacturer's recommendations and AS 2033.

(b) Poly pipe shall be laid with sufficient allowance for contraction and expansion of the pipe.

(c) Pipe ends shall be free of all burs and rough edges and shall be chamfered with the appropriate tool before jointing.

(d) Polyethylene tapping saddles are only to be used to connect sprinklers and dripper tube to polyethylene pipe work.

(9) Trenching

(a) All pipe work shall be laid in trenches, with the exception of:

(i) pipes which are installed in underground conduits; or

(ii) pipes which are installed above ground due to obstacles i.e. bridges, walls, etc.

(b) Trenches shall:

(i) be sufficiently wide to allow adequate working clearance;

(ii) be excavated in straight lines between bends or pits;

(iii) have vertical sides and be a constant depth for the full length of the trench; and

(iv) be of adequate depth to allow for pipe bedding and adequate cover to the pipe as specified.

(c) Trenches for multiple pipes shall be sufficiently wide to allow adequate working clearance and a minimum of 100mm separation between pipes.

(d) Pipes shall be firmly and evenly supported with bedding material or approved backfill material in the centre of the trench.

(e) Minor adjustment to the irrigation systems design layout will be permitted to clear underground obstructions.

(f) Trenching machinery shall be avoided within 1m of existing services. Hand trench to expose existing services, prior to connection or use of trenching machinery.

(g) Cover to pipes

The minimum and maximum depth of cover to pipes shall be as noted in Table SC6.4.6.27.1.

Table SC6.4.6.27.1 Depth of cover to pipes

Pipe	Minimum	Maximum
Main lines in road reserves (UPVC and Polyethylene)	600mm	750mm
Main lines all other locations (UPVC and Polyethylene)	400mm	600mm
Lateral lines - all locations	300mm	500mm
Drinking fountain and water tap supply lines. (except in land fill sites)	300mm	400mm
Drinking fountain and water tap supply lines in land fill sites	450mm	600mm
Dripper tube (turf)	75mm	100mm
Dripper tube (garden)	Surface	Surface

Note—depth of cover is defined as the distance from the top of the pipe to the finished surface level or from the top of the pipe to the underside of paving, concrete or road pavement. Refer to SC6.4.4.8 Standard drawings SD-18.1 for Typical Pipe Trench details.

(10) Pipe bedding

(a) A minimum of 100mm sand bedding and surround is required for:

(i) all main lines;

(ii) all uPVC Rubber Ring Jointed pipes;

(iii) all pipes under road pavements;

(iv) all pipes laid on solid rock;

(v) all pipes where rubble, rocks and/or debris is encountered in the trench;

(vi) all potable water lines; and

(vii) all electrical conduits.

(b) Bedding sand shall be clean sand with rounded grains free of any rocks, debris and organic matter and graded such that 100 per cent passes a 4.75mm sieve size.

(c) Pipe work, other than those listed in clause SC6.4.6.27.2(10)(a) may be laid without sand bedding, provided the trench is free of rubble, rocks and /or debris.

(d) Pipe work, other than those listed in clause SC6.4.6.27.2(10)(a), in locations where the natural earth contains rocks, debris and any materials that may damage pipes over time or where excessive ground movement is likely to occur shall be laid in a minimum of 75mm sand bedding and surround.

(11) Approved backfill to trenches

(a) Excavated material may be used as backfill, provided that the material is free of rubble, rocks, debris, organic material and any sharp or solid objects and/or materials that may damage the pipe over time.

(b) Where material excavated from the trench is unsuitable for backfill, clean sand, garden loam shall be used as backfill.

(c) Backfill to trenches shall be compacted with a wheel roll or plate compactor. Completed backfill is to be mounded 50mm higher than the surrounding surface for the full length of the trench, to allow for further consolidation.

(d) Backfill to trenches under road pavements and pathways shall be crusher dust material placed in 150mm compacted layers.

(e) On completion of backfilling operations, all excess material is to be either reused on site where possible or shall be removed from the site.

(12) Exposed pipes

(a) Any exposed pipe shall be constructed of stainless steel or lagged copper and shall comply with AS/NZS 3500 standards for exposed pipe.

(b) All above ground works are to conform to AS/NZS 3500.1, Section 5.7 "Support and fixing above ground".

(c) Bracing around the pipes is to be lined with an appropriate material to prevent damage to the pipe.

(d) Pipes are to be labelled “potable” or "non potable" in accordance with Australian Standards.

(13) Proximity to other services

Table SC6.4.6.27.2 lists the separation required between water pipes and electricity and gas services. Separation for all other services shall be as outlined in AS/NZS 3500.1 Section 5.3 entitled “Proximity to other services”.

Service	Separation
Electrical Cables with Warning Tape or Mechanical Protection (Water Pipes DN65mm and below)	100mm
Electrical Cables with Warning Tape or Mechanical Protection (Water Pipes larger than DN65mm)	300mm
Electrical Cables with no Warning Tape or Mechanical Protection	600mm
Consumer Gas Pipe with Marker Tape 150mm above complying with AS2648.1 (Water Pipes DN65mm)	100mm
Consumer Gas Pipe with Marker Tape 150mm above complying with AS2648.1 (Water Pipes larger than DN65mm)	300mm
Consumer Gas with no Marker Tape or Mechanical Protection	600mm

SC6.4.6.27.3 Control system

(1) Scope

This section covers the furnishing of all labour, materials and services in connection with the fabrication, factory testing, delivery and site installation of the irrigation controller and associated cabinets.

(2) Network requirements

(a) Townsville City Council operates an irrigation control system that consists of a Motorola Irrinet Supervisory Control and Data Acquisition (SCADA) System. This system is commonly known as the Irrigation Central Control (ICC). The ICC System communicates to irrigation controllers throughout the Townsville region over UHF wireless telemetry communication networks.

(b) All irrigation controllers shall be operated via the ICC System unless an alternative controller system is approved by the Superintendent

(c) Contractors are required to provide an approved irrigation controller to adequately service the proposed irrigation system. The Controller shall provide for the number of stations including master valve and fertigation control valve required for:

(i) the current irrigation system to be installed; and

(ii) defined future requirements of the controller.

(d) Irrinet M Slave, Irrinet M and Irrinet ACE controllers by Motorola are the approved irrigation controllers.

(e) All irrigation controllers must be capable of communicating with the ICC System across the telemetry communication network. Each controller must be fitted with an approved radio transceiver and antenna.

The transceiver must have the correct frequency configuration to communicate on the network.

(f) Each irrigation controller shall be allocated a logical address by Maintenance Services – Irrigation Design Unit for communications to the ICC System.

(g) All irrigation controller system components shall operate within the ranges specified by the manufacturer.

(3) Irrigation controller selection

(a) Irrigation controllers are to be selected from Table SC6.4.6.27.3.

Table SC6.4.6.27.3 Controller selection list

Controller Name	Power Type / Source	Valve Capacity
AC Irrinet M Slave 12 - 24	AC / 240 V Mains	12 to 24
AC Irrinet M Slave 36 - 48	AC / 240 V Mains	36 to 48
AC Irrinet M 12 - 24	AC / 240 V Mains	12 to 24
AC Irrinet M 36 - 48	AC / 240 V Mains	36 to 48
AC Irrinet ACE 24 - 48	AC / 240 V Mains	24 to 48
XR 1 - 4	DC / 6 V Solar	1 to 4

(b) AC powered irrigation controllers are the preferred option of the Superintendent. DC powered irrigation controllers are not acceptable unless approved by the Superintendent.

(4) Operating environment
Ambient conditions

(a) All equipment mounted inside cabinets and cubicles shall be suitable for operation in temperatures up to 60 °C. Measures shall be taken to ensure that high ambient temperatures and full load operation do not cause temperatures to exceed maximum allowed operating temperatures.

(b) Since all cabinets are to be mounted outdoors, particular consideration shall be given to minimise heating by direct solar radiation.

(5) Irrigation controller specification (general)

(a) General requirements

(i) The irrigation controller cabinet and component parts shall conform in all respects to the highest standards of design and workmanship and appropriate requirements of the latest applicable state or local codes.

(ii) When mounting accessories to the back panel, use fine threaded tapped screws.

(iii) The irrigation controller cabinet shall be completely wired, and assembled, with all devices and controls installed as shown in SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-29.1 so that the entire assembly is an operating unit ready for installation and the wiring of field devices.

(iv) Wiring shall meet the latest requirements of the AS 3000 and applicable workplace safety codes.

(b) Wiring

(i) All wire shall be 0.5mm²/PVC 105/ stranded, insulated for 600 V.

(ii) A "bootlace ferrule" shall be used on wires connected to terminals which have only a screw for securing the wire. Ferrules shall be properly crimped using a professional crimping tool.

(iii) All manufacturer terminal block wiring shall be restricted to the panel side of the blocks. The manufacturer shall connect no more than two wires to any terminal point. The field side of the terminal blocks shall be left completely free of wires and jumpers. Wiring on terminal blocks shall be so arranged that not more than one wire to the field side of any terminal point will be connected with the exception of the earth.

(iv) All multiple common connections shall be wired via bridging links on the terminal blocks.

(v) Horizontal and vertical wiring between the terminal blocks and the devices shall be enclosed in ducts except wiring between the ducts and the devices may run exposed for distances not exceeding 100mm. Duct loading shall not exceed 75 per cent rated fill at any point.

(vi) All exposed wiring shall be formed neatly with square corners and where possible, grouped in packs. Each pack shall be bound with plastic ties and be substantially supported throughout its full length. Cabled wire is not acceptable.

(vii) Splicing of wires on electrical circuits is not acceptable.

(c) Terminal blocks

Terminal blocks shall be provided for all wiring which exits the panel. All terminal blocks shall be mounted and of the colour as shown in SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-24.8.

(d) Consumer power

(i) The irrigation control cabinet shall be equipped with a (Clipsal 4CC6 or approved equivalent) enclosed consumer panel. Consumer power shall be wired direct into the consumer panel. The consumer panel shall enclose a neutral link and an earth bus with the panel structure connected to the bus so as to effectively earth the entire structure. A solder-less clamp type terminal lug shall be provided at the end of the earth bus for a 6mm² stranded earth cable to be attached from the external earth-stake.

(ii) Whenever the electrical diagrams indicate an earth for a circuit at the panel, a single wire for each circuit earthed shall be run independently to the earth bus and fastened thereto using a ring lug and a machine screw inserted in a tapped hole.

(iii) Earthing of the enclosure and back panel from the consumers panel shall be made using 4mm² stranded earth cable.

(iv) The consumer panel shall be wired with a main isolation switch an RCD/MCB and a suitably rated "Isatrol" mains filter unit, din-rail mounted within the consumer panel to provide power to the GPOs. One double GPO and one single GPO are to be mounted on the face cover of the consumer panel. Care shall be taken when positioning the GPOs not to cover the access screw holes to the consumer panel.

(v) Each device requiring 240 V AC power shall have an individual line plug and plug into an allocated GPO on the consumer panel.

(vi) Power will be supplied as a single phase voltage at 50 Hz and 240 V ± 10 per cent.

(vii) All 240 V connections are to be tool proof and either housed in the consumer panel or behind a protective cover.

(6) Irrigation controller specifications (specific)

(a) Irrinet M Slave, Irrinet M and Irrinet ACE.

(i) Each controller's maximum valve output is listed in Table SC6.4.6.27.3 including master and fertigation valves. The controller shall have as a minimum, two inputs from electronic pulse water meter and rain switch.

(ii) The general control voltage shall be 24 VAC for controller outputs used for water valve operation.

(iii) The 24 VAC power is via the PELV system with common tied to earth.

(iv) The irrigation controller cabinet layout, dimensions and wiring are shown in SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD 29.1.

(v) The irrigation controller cabinet shall be a B&R NI (NI06062/S) or (NI06063/S) with dual key lock (NI030) or approved equivalent as shown within SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-29.1. The controller pole, mast and cross arms shall be coated with 2PAK Epoxy Paint in Heritage Green colour.

(vi) Control equipment shall be selected from the Preferred Equipment list - Controller and Telemetry Components within SC6.4.4.8 Standard drawings SD-5.1 through SD 5.10 and SD-20.1 through SD-29.1, unless otherwise specified by the Superintendent.

(vii) All firmware incorporated in CPUs and other intelligent modules shall be the latest released

version.

(viii) The radio telemetry equipment involves the installation of the following equipment:

(A) TX-3600 GME Transceiver with blind front panel, programmed with Parks Services frequencies;

(B) YB6-61 Yagi Antenna, UNV2 mounting bracket and RG58 coax cable terminated with a N88 N type male connector;

(C) PS123 GME Power Supply or DC1224X Aeon UPS (for Irrinet M controllers);

(D) IS50NX Surge Arrestor flange mounted with N type female connectors;

(E) RG58 Coax Fly Lead terminated with N88 N type and BNC113 male connectors; and

(F) Data cable connecting controller to transceiver.

(ix) The transceiver shall be mounted on the door such that the indicator lights are visible when the door to the panel is opened. The antenna cable and data cable are to be feed from the controller via the cabinet ducting towards the door hinge and onto the door bracket. The transceiver shall be mounted in such a way to allow for its easy removal. The mounting bracket is to be securely fastened to the back of the door. All cabling on the door shall be neat and fastened in place by cable ties, SC6.4.4.8 Standard drawings SD-26.2, SD-26.4 and SD-5.10 refers.

(x) A Surge Arrestor shall be mounted on the cabinet earth lug and suitably earthed refer SC6.4.4.8 Standard drawings SD-27.1 and SD-5.10. The coax fly lead shall be connected from the transceiver BNC connector to the “Equipment” side of the surge arrestor. The coax cable from the antenna will enter the panel and be terminated on the “Antenna” side of the surge arrestor.

(xi) Before the transceiver is powered up a qualified radio technician shall fit the antenna coax plug and carry out a SWR / radio check and set the modulation level.

(xii) The “data cable” shall connect the controller to the transceiver and shall be secured and neatly run through the ducting.

(xiii) PS123 GME Power Supply 240 VAC to 12 VDC is to be mounted on the door bracket to supply power to the Transceiver and Interposing Relays refer SC6.4.4.8 Standard drawings SD-5.5.

(xiv) DC1224X Aeon UPS (uninterrupted power supply) 240 VAC to 12 VDC is to be mounted on the door bracket to supply power to the Irrinet CPU memory and Transceiver, refer SC6.4.4.8 Standard drawings SD-20.1 through SD-29.1.

(xv) A separate 24 V AC power supply shall be provided as shown within SC6.4.4.8 Standard drawings SD-5.1 through SD-5.10 and SD-20.1 through SD-29.1:

(A) Irrinet M, Irrinet M Slave and Irrinet ACE controllers require 1 Powertech 240 V/24 V 150 VA Transformer part No. MP3045 to be direct mounted to supply power to the controller and field solenoids.

(xvi) The controller shall have two conduits connecting the cabinet to the ground. The following conduit types and sizes shall be used:

(A) M.D. 50 mm electrical conduit (24 V Control Cable); and

(B) H.D. 25 mm electrical conduit (240 V Power Supply).

(xvii) A Mini-Clik II Rain Switch or approved equivalent is to be installed on the controller pole. Construction details are given in SC6.4.4.8 Standard drawings SD-29.1. The device is to be set on a 13mm setting.

(b) Piccilo XR

(i) The output control voltage used is a DC Pulse through a 2 wire circuit suitable for activating DC latching coils used for water valve operation - Hunter ICV with DC Coil option or approved equivalent. With the Piccilo XR output voltage adjusted to 18 V (from the factory default of 12 V).

(ii) The controller assembly is powered by a 6 volt sealed lead acid battery which is charged via a solar panel and regulating semiconductors. SC6.4.4.8 Standard drawings SD-4.2.

(iii) The irrigation controller cabinet layout, dimensions and wiring are shown in SC6.4.4.8 Standard drawings SD-4.1 through SD-4.4.

(iv) The Irrigation controller cabinet shall be a B&R NI (NI03021/S) with single key lock (NI030) or

approved equivalent as shown within SC6.4.4.8 Standard drawings SD 4.1 through SD-4.4. The controller pole, mast and cross arms shall be coated with 2PAK Epoxy Paint in Heritage Green Colour.

(v) Control equipment shall be selected from the Preferred Equipment list - Controller and Telemetry Components within SC6.4.4.8 Standard drawings 4.5, unless otherwise specified by the Superintendent.

(vi) All firmware incorporated in CPUs and other intelligent modules shall be the latest released version.

(vii) The radio telemetry equipment involves the installation of the following equipment:

(A) Qty 1, CD51 Whip Antenna (cut to wave length) with .5M of RG58 coax cable terminated by a SMA type male connector;

(B) Qty 1, Antenna Mounting Bracket; and

(C) the radio telemetry component is integrated within the XR Controller unit. So no external transceiver is required.

(viii) The antenna coax SMA male plug shall be connected into the XR Controller SMA socket mounted on the top of the unit.

(ix) Before the XR Controller is powered up a qualified radio technician shall fit the antenna coax plug and carry out a SWR / radio check on site.

(x) A Kyocera Mini Module Solar Panel as detailed in SC6.4.4.8 Standard drawings SD 4.5 shall be fastened to the top of the enclosure refer SC6.4.4.8 Standard drawings SD-4.3. An external grade silicon base sealant shall be applied to the solar panel perimeter to maintain the enclosure IP rating.

(xi) The regulator components shall be installed as detailed in SC6.4.4.8 Standard drawings SD-4.2 and tested by an electronics technician prior to final connection of the battery and XR units.

(xii) A 6 V 12 AH SLA Battery is placed inside on the bottom of the enclosure and connected to the terminal blocks. Refer SC6.4.4.8 Standard drawings SD-4.1 and SD 4.2.

(xiii) The controller shall have one 25mm conduit connecting the cabinet to the first electrical pit.

(7) Controller location

The final location of the controller shall be determined by taking into consideration all of the following factors:

(a) radio path tests (to be carried out by a qualified radio technician) to ensure reliable communications from the controller to the ICC System Base Station;

(b) the location shall be clear of large trees or structures that may interfere with the performance of radio communications, or solar panel. In newly planted areas the location shall make allowance for future tree growth;

(c) safe 24 hour access for maintenance by maintenance services personnel and equipment;

(d) the location shall allow access by motor vehicle and elevated platform (antenna servicing); and

(e) the Controller shall not be installed less than 3 m from a roadway unless approved by the Superintendent.

(8) Cabinet installation

The pre-assembled Controllers shall be installed in the ground as follows:-

(a) The pre-assembled Controller cabinet support post shall be embedded in a 200mm diameter x 600mm deep hole with a 400mm deep concrete footing (N25 concrete minimum). The concrete shall be poured up to the underside of the conduits entering the support post. Covering the conduits in concrete is not acceptable. The Cabinet shall be installed at a height of 1200mm from the finished ground level to the underside of the cabinet (1090 mm for XR controllers Refer SC6.4.4.8 Standard drawings SD-4.4).

(b) XR Controller Cabinet is to be orientated with the door side facing north to maximise the absorption of solar radiation into the solar panel, unless approved by the Superintendent.

(9) Controller cabinet and controller wiring

(a) All conduits shall be terminated at the controller cabinet with a suitable conduit adaptor. All conduits shall be sealed with an external grade Butyl Mastic sealant, such as “Selleys Butyl Mastic” or similar approved to a depth of 25mm into the conduit to prevent vermin entering the controller cabinet.

(b) Earth stakes shall be located in the electrical pit adjacent the controller. The location of the earth stake is to be indicated on the as constructed drawing.

(c) Earth stake connections are to be sealed with cold gal paint.

(d) All field wired cables entering the controller cabinet shall be made secured – in this instance only by the application of sealant to the conduit end inside the enclosure (see clause (9)(a) above). From this point on, the double insulation shall be removed from the cable for ease of wiring to the terminal blocks.

(e) All single insulated cables inside control cabinets shall be loomed together and cable tied in a neat orderly manner to the panel so that the connections into the terminal strip are not stressed.

(f) All cables inside the controller cabinet shall be of sufficient length to ensure that all cores will reach their termination point without any stress or joining of cables.

(g) All field cables inside the controller cabinet shall be of sufficient length to ensure that all cores will reach the upper and lower most termination points without any stress or joining of cables.

(h) All cables to be connected within the controller cabinet shall be terminated with a bootlace ferrule, CABOC BLP 150 or similar approved. Pin lugs are not acceptable.

(10) Field electrical wiring

(a) Cable types

(i) All electrical cabling shall conform to current Australian Standards.

(ii) All cables shall be Tyflo multi-core irrigation cables or similar approved with a minimum core size of 1.5 mm. Table SC6.4.6.27.4 details cable specifications.

Table SC6.4.6.27.4 Multicore cable specifications

Nominal core dia.	Conductor no. and size	Amp rating	Resistance Ohms/Klm	Number of cores
1.5 mm	7/0.50	16	13.6	3,5,7,9,13
2.5 mm	7/0.67	23	7.4	2,7
4 mm	7/0.85	30	4.6	2

(iii) All cables shall have an outer sheath of flexible 75□C PVC to AS/NZS 3808, over an Inner core of a sheath of HDPE, over a multi-strand plain copper wire.

(iv) Inner cores are to be readily available in 13 colours namely- Black, Blue, Green, Dark Brown, Brown, Grey, Light Blue, Orange, Pink, Red, Violet, White and Yellow.

(b) Cable installation

(i) A 7 core cable shall be run continuously from the controller to the water meter assembly solely for the operation of Master Valve, Pulse Meter and Fertigation. The black core shall be common, red core shall be Master Valve control, brown core shall be Fertigation control and run to the Fertigation Venturi Point and the blue and white shall be Pulse Meter and Pulse Meter common respectively.

(ii) An additional 20% of the total number of cables or 2 extra cores (whichever is the greater) shall be provided as spares. Designated spares shall run from the controller to the furthest most point from the controller in the cable run. The spares are to be marked at the controller. At the furthest point all spares shall be connected together and sealed with heat shrink so that a continuity test can be performed at the controller to confirm the total number of spares.

(iii) All extra low voltage cables shall be installed inside a conduit. The conduit size used shall be a minimum size of 50mm or 2.5 times the combined size of all the cables being installed, whichever is the greater.

(iv) The single insulation on the cable core shall not be cut or damaged when the outer sheath (double

insulation) is removed. All cables shall have the insulation removed from the cores using appropriate cable strippers. Use of a knife or other sharp blade is not acceptable practice.

(v) Cables shall be continuous between electrical inspection pits. Cable joints located between electrical inspection pits are not acceptable. Cable joints shall be kept to a minimum and shall only occur at valve take off points.

(vi) Where required each individual cable shall be joined using the appropriately sized insulated crimp links, to maintain a double layer of insulation at the joint after the heat shrink is installed, and shall be installed with a professional ratchet type crimping tool.

(vii) Bare conductors shall not be exposed.

(viii) Each individual cable joint shall be waterproofed by using ES-2 resign filled heat shrink three times the length of the insulated crimp link.

(ix) Multiple cables shall not be joined or heat “shrinked” together.

(x) All cut unused cables (spares) shall be sealed using ES-2 resign filled heat shrink.

(xi) Cable markers shall be attached to each cable at every electrical inspection pit indicating the individual cable number as shown on the design plan; refer SC6.4.4.8 Standard drawings SD-7.2. Cable markers shall be round 38mm diameter aluminium identification tags commercially available. Numbering shall be clearly stamped onto one side of the tag using a punch set with 13mm high numerals. Tags shall be fastened to the appropriate cable using a quality grade plastic cable tie attached at the mid-point of the cable loop.

(xii) The Black cable shall be used as the designated common.

(xiii) All spare cable in electrical inspection pits shall be left full length, individually sealed with heat shrink and grouped together.

(xiv) All continuous cable that passes through an electrical inspection pit shall have a loop of at least 1.5m in length and be neatly coiled and tied.

(xv) A draw wire is to be left in the conduit from the controller cabinet to the first electrical inspection pit.

(xvi) All electrical cable locations shall be recorded on the as constructed drawings.

(c) Electrical inspection pits

(i) Electrical inspection pits shall be heavy duty rectangular with rounded ends and fitted with a precast concrete lid, type P1 or P2.

(ii) The first electrical inspection pit shall be located a maximum of 1m from the Controller cabinet support base. A draw wire together with the electrical cables is to be installed in the conduits from the controller to the first electrical pit to allow for future works.

(iii) Electrical inspection pits shall be located adjacent to valve boxes and offset from the main irrigation line a maximum of 200mm as shown in SC6.4.6.27 Attachment A 17.2 (Plan View).

(iv) Electrical inspection pits shall be located at changes in direction and no more than 50m spacing.

(v) Electrical inspection pits shall be installed so that the top of the pit is flush with the finished surface level and matches the slope of the finished surface level.

(vi) All electrical inspection pit locations shall be recorded on the as constructed drawings.

(vii) All conduits shall enter at the end of an electrical pit. Side entry of conduits into electrical pits in not permitted.

(viii) All conduits shall enter an electrical pit at no greater than 45 degrees of the horizontal centre.

(ix) Electrical pits shall not be installed in drainage swales or places where water is collected during rainfall and irrigation.

(x) Electrical pits shall not be installed less than 3m from the road kerb, unless approved by the Superintendent.

(d) Electrical conduits

(i) All electrical conduit shall conform to current Australian Standards.

(ii) All conduit (extra low voltage electrical) buried in ground shall be Grey M.D.

(iii) All electrical conduits that are exposed above ground shall have a protective outer sheath of polyethylene pipe rating PN12.5. The sheath is to encase the conduit for the entire length of conduit above ground and for a depth of 150mm minimum below ground.

(iv) All electrical conduits that are exposed above ground shall be fixed in place so that they are vertical and shall be secured firmly to the accessory.

(v) Electrical conduit above ground shall be adequately secured to avoid damage by grass cutting operations.

(vi) All electrical conduit ends shall be neatly cut and free of burrs or rough edges.

(vii) The final 500mm of conduit entering an electrical inspection pit shall be M.D. corrugated flexible conduit which is to be connected to the M.D. PVC Conduit by a Socket. SC6.4.4.8 Standard drawings SD-17.2 (Electrical Pit), gives a typical construction drawing of the assembly.

(e) Electrical conduit trenching

(i) All electrical conduits shall be laid in trenches and bedded in sand.

(ii) Low voltage conduits (240 V) shall be installed with continuous electrical warning tape laid over the conduit for the entire length of the trench.

(iii) Low voltage conduit (240 V) shall not be installed in the same trench as irrigation lines.

(iv) Extra low voltage conduits (24 V) installed in the same trench as irrigation lines shall be bedded in sand and separated from the irrigation lines by a minimum distance of 100mm.

(v) Depth of cover to electrical conduits from finished surface level or from the underside of finished pavement level (e.g. pavers or concrete) shall be:

(A) 300mm minimum - for extra low voltage cables (24 V); and

(B) 600mm minimum - for low voltage cables (240 V). Refer SC6.4.4.8 Standard drawings SD-18.1.

(vi) Electrical conduits under roadways shall be a minimum 50mm M.D. Electrical conduit encased in a 100mm Class 9 PVC Pipe.

SC6.4.6.27.4 Water meter assembly

(1) Design and installation

(a) Water meter assembly components vary, as follows:

(i) For drinking fountains and water taps (potable water) the water meter assembly includes:

(A) isolation valve; and

(B) mechanical water meter (supplied by Townsville Water, a business unit of Townsville City Council).

(ii) For irrigation the water meter assembly includes:

(A) isolation valve;

(B) mechanical water meter (supplied by Townsville Water);

(C) master valve and electronic flow meter unit;

(D) RPZ back flow prevention device with two isolation valves;

(E) screen filter;

(F) lockable cover;

(G) cable and conduit; and

(H) protective bollards (depending on location).

Table SC6.4.6.27.5 Allowable water meter assembly component size combinations

Water Service	Townsville Water Water Meter	Irrigation Water Meter	Backflow	Master Valve
25mm	25mm	32mm Arad Multijet (1 pulse/10L)	25mm	25mm Hunter ICV*
32mm	32mm	32mm Arad Multijet (1 pulse/10L)	32mm	25mm or 40mm Hunter ICV*
50mm	50mm	Include in Master Valve (1 pulse/10L)	50mm	50mm Arad Hydrometer
80mm	80mm	Include in Master Valve (1 pulse/10L)	80mm	80mm Arad Hydrometer
100mm	100mm	Include in Master Valve (1 pulse/100L)	100mm	100mm Arad Hydrometer

*external master valve

(iii) All water meter assemblies with a 25mm and 32mm Water Service are to have a master valve external to the main assembly. Refer to SC6.4.4.8 Standard drawings SD-10.3 and SD-10.4.

(iv) Water meter assemblies with a water service sized, 50mm, 80mm and 100mm are to have a master valve as part of the main assembly. Refer to SC6.4.4.8 Standard drawings SD-10.1 and SD-10.2.

(b) Water meters

(i) All water meters and pipe work from the town mains to the water meter shall be supplied and fitted by Townsville Water.

(ii) The water meter type is selected by the following criteria:

(A) for drinking fountains and water taps a standard mechanical water meters shall be used.

(B) for irrigation refer to Table SC6.4.6.27.5 for water meter selection relative to the water service size.

(c) Master valves

(i) All irrigation systems shall be fitted with a master valve.

(ii) The master valve is to be selected by the following criteria:

(A) all water service assemblies sized 25mm and 32mm shall have an external master valve installed in a valve box and shall be fitted to the copper tail pipe of the backflow device. Refer to SC6.4.4.8 Standard drawings SD-10.3 and SD-10.4 for installation details; and

(B) all water service assemblies sized, 50mm, 80mm and 100mm shall be fitted with an assembly mounted master valve. The master valve is to consist of a flange mounted Arad Hydrometer including water (flow) meter module as detailed in Table 5 and 24VAC Solenoid actuator; or approved equivalent. Refer to SC6.4.4.8 Standard drawings SD-10.1 and SD-10.2 for installation details.

(d) Backflow devices design and installation

(i) Backflow prevention is to conform to AS 2845.1, AS 2845.2 and AS 2845.3.

(ii) The Backflow device shall be selected on the required size:

(A) 25mm, 32mm, and 50mm - Tyco Backflow System RP03 or similar to the following specification. The assembly shall be connected with the “ring and tail” to allow easy removal or replacement of the device in accordance with AS/NZS 3500.1. Main valve and internals shall be of stainless steel construction and to have pressure rating of 1600 kPa and a temperature rating of 90ºC. All internal parts and elastomers are to be accessible through a top entry point of the main valve to allow inline maintenance. Valve shall also be fitted with test points with BSPT threads to allow testing to AS 2845.3; and

(B) 80mm and 100mm - Tyco Backflow System RP03 or similar to the following specification. The main valve shall be constructed from ductile iron and coated with Rilsan Nylon 11 to AS/NZ 4158. All internals shall be constructed from stainless steel and to have pressure

rating of 1600 kPa and a temperature rating of 60ºC. Main valve body shall not form part of the wetted check valve sealing area or mechanism. All internal parts and elastomers are to be accessible through a top entry point of the main valve to allow inline maintenance. Valve connection shall be flanged to AS/NZS 4087. Valve shall also be fitted with test points with BSPT threads to allow testing to AS2845.3.

(iii) The velocity through the backflow device shall not exceed 2.2 m/s.

(iv) All backflow devices shall be reduced pressure zone (RPZ) rating.

(v) All backflow devices sized 25mm, 32mm, and 50mm shall be fitted with a locking mechanism, which prevents the two isolation valves and the three test cocks from unauthorised opening. The backflow device is to be lockable at a single point. A council standard series A padlock is to be fitted to the locking mechanism.

(e) Isolation valves

(i) All isolation valves fitted to the water service assembly shall be tested and approved to Australian Standards.

(ii) All isolation valves fitted to the water service assembly shall be selected on the following criteria:

(A) all water meter assemblies sized 25mm, 32mm and 50mm shall be fitted with brass ball valves; and

(B) all water meter assemblies sized 80mm and 100mm shall be fitted with resilient seated gate valves.

(f) Strainer

All water meter assemblies shall be fitted with a brass strainer immediately downstream of the isolation valve and upstream of the back flow device. Refer SC6.4.4.8 Standard drawings SD-10.1 to SD-10.4 for details.

(g) Water meter assembly installation

(i) The water meter assembly shall be supported by the appropriate size Support Stands as detailed in SC6.4.4.8 Standard drawings 10.5 and set into a concrete footing as detailed SC6.4.4.8 Standard drawings SD-10.1 to SD-10.4. A minimum distance of 300 mm from the underside of the assembly to the finished ground level is required.

(ii) A lockable stainless steel sheet metal cover shall be fitted over the water meter and master valve to prevent vandalism and weather damage. Water meter assembly covers shall be built from 316 Stainless Steel as detailed in SC6.4.4.8 Standard drawings SD-31.1 and SD-31.2 and for water meter assemblies sized:

(A) 25mm, 32mm, the cover shall be held in place using U-bolts; and

(B) 50mm, 80mm and 100mm the cover shall be fastened between each set of tightened flanges, using flange bolts.

(iii) Each cover shall be locked using a 40mm KA1 series lock.

(iv) A minimum of two recycled plastic bollards shall be provided at each water meter assembly as directed by the Superintendent, to protect the assembly from vehicle damage, except in garden beds.

Bollards shall be nominal 100mm diameter blue recycled plastic, embedded 450mm minimum into a 350 mm diameter concrete footing. The top of the bollards shall be 900mm above finished ground level.

(v) All cables running from the water meter to the ground shall be encased in a protective outer sheath of polyethylene pipe rating PN12.5. The conduit shall be firmly installed vertical to the ground so as not to be easily damaged by grass cutting operations.

(vi) Copper pipes shall be Type B.

(vii) All fittings to the backflow device shall be either copper of brass. PVC or Poly fittings are not acceptable.

(2) Valve assembly

(a) Design and installation

(i) The valve assembly includes:

(A) solenoid valve;

(B) ball valve;

(C) brass barrel union; and

(D) valve box.

(ii) Refer SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD-14.4 for standard details. Valves shall be connected to the main line via a tee.

(b) Solenoid valves

(i) Refer SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD-14.4 for solenoid valve assembly details.

(ii) Solenoid valves used shall be sized in accordance with Table SC6.4.6.27.6.

Table SC6.4.6.27.6 Approved solenoid valves

Manufacturer	Model	Size	Maximum flow rate (litres per minute).
Hunter	ICV	25mm	100
Hunter	ICV	40mm	250
Hunter	ICV	50mm	360
Hunter	ICV	80mm	700

(iii) Electronic solenoids for AC systems shall be 24 volt coils.

(iv) Electronic solenoids for DC systems shall be 12 volt 2 wire latching coils.

(v) Solenoid valves shall be wired in the following order:

(A) the first controller output shall be assigned to the master valve control;

(B) stations are to be wired to the controller outputs from output 2 on. Station 1 (Controller output 2) is to be located on one side of the site. The last station is to be located on the opposite side of the site. The controller outputs are to follow a logical geographical pattern from one side to another; and

(C) the same wire colour shall be maintained along the entire length of the cable run between the controller and each individual solenoid valve.

(vi) Only one valve shall be allocated per controller output.

(vii) Doubling up of stations on the same output is not allowed.

(viii) Valve boxes shall not be installed within 3m of the road kerb unless approved by the Superintendent.

(ix) The distance from a valve to the first sprinkler or first drip emitter shall not exceed 50m.

(c) Gate and Ball valves

(i) A Ball valve shall be installed on the upstream side of the Solenoid valve. A brass barrel union shall separate the Ball valve from the Solenoid valve to allow for ease of maintenance. Refer to SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD 14.4.

(ii) Ball valves shall be tested and approved to AS 3500.1.

(d) Valve boxes

(i) The valve assembly is to be located in a heavy-duty lockable valve box fitted with a stainless steel lock-down bolt in the lid.

(ii) Valve boxes shall be Heavy Duty Carson or similar approved.

(iii) Valve boxes used are to be of adequate size to ensure that there is sufficient space around the valve assembly to allow for ease of maintenance.

(iv) Valve boxes shall not require removal to facilitate maintenance of the valve assembly.

(v) All valve boxes shall be:

(A) supported on bricks so that the box does not rest on any pipes;

(B) installed so that the top of the box is flush with the finished turf surface level for turf areas, or 50mm to 100mm above the finished mulch surface level for garden areas;

(C) installed so that the clearance from the underside of the valve box lid to the top of the stem of the valve is; 150mm maximum – 50mm minimum for non drip valves and 75mm maximum – 50mm minimum for drip valves, refer SC6.4.4.8 Standard drawings SD-10.6, SD-14.3 and SD-14.4;

(D) installed so that the clearance from the underside of the valve housed within the valve box to the bottom of the box is at least equal to or greater than 50mm;

(E) the pipe holes shall be sealed with Geofabric around the openings to prevent the ingress of foreign material in the valve box;

(F) cutting of valve boxes for entry/exit of pipe work shall be keep to a minimum, boxes cannot be cut higher than 1/3 its height. Over cut boxes are not acceptable; and

(G) installed in association with its housed components so as not to require excessive cutting of the valve box to the satisfaction of the Superintendent.

(vi) All valve box lids shall be clearly marked with the identification of the contents using the follow key:

(A) IV = Isolation Valve;

(B) MV = Master Valve;

(C) A1 = Controller A Station 1 (Refer SC6.4.4.8 Standard drawings SD-8.1) for valve key; or

(D) 3 digit DTMF number as supplied by the Superintendent, for example “045” identifying the Irrinet System number.

(vii) Valve box lids shall be engraved by using a 50mm to 75mm high Signet 14474 / 14494 zinc Stencil Set or approved equivalent as a template. The engraving finish shall be evenly 1.5mm deep at its deepest point and between 4mm to 8mm wide by using an engraving power tool fitted with a spherical engraving bit. The finished engraving shall then be painted with a Signet 12205 White Marker or approved equivalent. Note excessively deep engraving will weaken valve box lids and is not acceptable.

(viii) No valve boxes shall be installed in drainage swales or places where water is collected during rainfall.

(ix) Stainless steel re-enforcing plates may be fitted to valve box lids to repair damaged threads only.

(x) Conduit connecting valve boxes with electrical inspection pits and other Valve Boxes is to be M.D. corrugated flexible conduit of a minimum 500mm and maximum 1500mm in length. SC6.4.4.8 Standard drawings SD-17.2 gives a typical construction drawing of the assembly.

(e) Valve nest enclosures

(i) Refer to SC6.4.4.8 Standard drawings SD-33.1 through SD-33.4 for valve nest enclosure details.

(ii) Valve nest enclosures may be installed where groups of more than three valves can be located together.

(iii) Allowance must be made for larger lateral pipe sizes to offset increased friction losses where longer lateral pipe lengths are required.

(iv) Allowance must be made for increase lateral sizes and quantity leaving the one location.

(v) Where three or more laterals leaving a valve nest cover share a common trench, bedding sand must be used to back fill trenches.

(vi) Lateral pipes leaving a valve nest cover must be run parallel in trenches (not twisted).

(vii) Valves inside a valve nest cover must be clearly identifiable via round 38mm diameter aluminium identification tags commercially available. DTMF numbering shall be clearly stamped onto one side of the tag using a punch set with 13mm high numerals. Tags shall be fastened to the appropriate solenoid valve using a quality grade plastic cable tie.

(viii) Electrical cables shall be cable tied to each solenoid valve control valve.

(ix) Enclosures shall be fitted with a pad lock and keyed to fit council “F” series.

(x) Solenoid valves shall be connected to a common copper manifold via individual brass barrel union and ball valve.

(xi) Copper manifolds (from 40mm to 80mm) must be of sufficient size to allow multiple stations to run simultaneously in program where required.

(xii) Copper manifolds connecting to PVC mainline shall be done via Cop-A-Mate flange or approved similar, installed 25mm above ground level.

(xiii) Copper manifolds connecting to Poly mainline shall be done via metric female compression fitting installed 25mm above ground level.

(xiv) Install Valve Nest Cover using 10mm 316 S.S dyna bolts fastened to 200mm diameter by 300mm deep concrete footings poured on site.

(xv) Top of concrete footings shall be installed level and 25mm above finished ground level.

SC6.4.6.27.5 Sprinklers, turf valves and drip irrigation

(1) Sprinkler design

(a) Sprinklers used shall be in accordance with Table SC6.4.6.27.7.

Table SC6.4.6.27.7 Approved sprinklers

Manufacturer	Model	Type
Hunter	PGP	Gear
Hunter	MPR	Rotating Nozzle**
Toro	570	Static
Rainbird	3500	Gear
Rainbird	5000 Plus	Gear
Rainbird	5505	Gear
Rainbird	6504	Gear

** Use on Toro 570 Body.

(b) Sprinkler uniformity shall not exceed a scheduling coefficient of 1.3 (5 per cent Window) SC6.4.4.8 Standard drawings SD-19.1, provides a definition of the scheduling coefficient and the process for calculation.

(c) Where possible, individual sprinkler stations shall be fitted with either all full circle sprinkler arcs or all part circle sprinkler arcs.

(d) All sprinklers on the same valve shall provide “matched precipitation”. The ratio of water supplied shall be even across all arcs of coverage. Sprinklers of different pressure and / or precipitation rate on the same station are not acceptable.

(e) The variation in flow between any sprinklers on a single station is not to exceed 10 per cent.

(f) All sprinklers are to be run at the manufacturer’s recommended pressure.

(g) All sprinkler heads on each individual station shall be the same type.

(h) Locations which are susceptible to low head drainage shall be fitted with either internal check valves, or Hunter or similar approved external check valves.

(i) No water shall be applied by design to locations where over spray is undesirable, (i.e. adjacent non-irrigated areas, roads, footpaths, private property etc.). The manufacturer’s published throw distance shall govern for design purposes.

(j) On roadway corners no water shall be applied by design to the road pavement whilst no unirrigated areas shall exceed 1m from the road edge. The manufacturers published throw distance shall govern. Examples of acceptable sprinkler layouts are given in SC6.4.4.8 Standard drawings SD-16.1.

(k) All static sprinklers are to be fitted with “fixed pattern” nozzles.

(l) Sprinklers are to be designed and installed in such a way that no electrical boxes, control cabinets, transformers, meter assemblies and the like are hit by direct water streams.

(2) Sprinkler installation

(a) No sprinklers shall be fitted until all main lines, lateral lines and risers have been flushed clean.

(b) Sprinklers shall be placed 150mm clear from walls, garden edges, pathways and the back face of concrete kerbs or concrete garden edges.

(c) Sprinklers shall be installed as detailed in SC6.4.4.8 Standard drawings SD-12.1 Figure 2, slightly above the finished surface level.

(d) Sprinklers shall be installed plumb unless placed on a slope in which case they shall match the slope of the surface.

(e) Where directed by the Superintendent sprinklers in grassed areas shall be installed with a sod of turf (300mm square) placed around them at the finished surface level to help stabilise the sprinkler.

(f) Sprinklers shall be connected to pipes (lateral lines) via either a tapping saddle or a BSP/F Tee and a flexible swing hose riser. All swing hose risers shall face downstream of the solenoid valve. Refer to SC6.4.4.8 Standard drawings SD-12.1 Figure 1.

(g) In locations where soils may be of a corrosive nature, 316 stainless steel bolt and nuts shall be used on all tapping saddles.

(h) The flexible swing hose riser used shall be either:

(i) 25mm safety yellow industrial hose, with nylon type elbows secured with stainless steel hose clamps; or

(ii) HR Products E-Z riser tube and E-Z riser elbows. (for sprinklers with 15mm and 20mm inlets).

The length of the flexible swing hose riser shall be no less than 500mm and no greater than 750 mm.

(i) Nozzle diffuser screws shall not reduce the wetted throw of a sprinkler by more than 20 per cent of the undiffused radius of a sprinkler.

(3) Bollard sprinkler installation

(a) Bollard sprinklers shall be installed where approved by the Superintendent in locations where sprinklers may be obstructed by plants or plant growth.

(b) Bollard sprinklers shall be assembled and installed as detailed in SC6.4.4.8 Standard drawings SD-12.2.

(4) Turf valves

(a) All turf valves shall be plasson.

(b) Turf valves shall be installed with an articulated riser connected to the main line via a tee coupling. Connecting turf valves to main line with tapping saddles is not allowed.

(c) Turf valves that are to be used as a hose watering point for garden establishment shall be installed in a valve box.

(d) Turf Valves Systems where sprinklers are directly inserted into the turf valves may be installed without a valve box flush with the soil surface.

(e) Turf valves located under valve box lids shall have the lid of the valve box clearly marked with an engraving tool and paint with the letters “TV”.

(5) Drip irrigation design and installation

(a) All drip irrigation systems shall be installed with an RPZ backflow device.

(b) The length of the drip tube shall be determined, based on all drippers along the line having sufficient pressure to operate 100 Kpa above the pressure compensation point as nominated by the dripper manufacturer. The maximum allowable inlet pressure shall be 300 Kpa.

(c) All drip tube used shall be Netafim Uni Ram 16 - 0.4m spacing @1.6lph or approved equivalent.

(d) The maximum spacing for drip tube is as shown in Table SC6.4.6.27.8.

Table SC6.4.6.27.8 Dripper spacing

SOIL TYPE	LOCATION	
	Grassed areas	Gardens
Loam and Clay Soil	400mm maximum	500mm maximum
Sandy Soil	300mm maximum	400mm maximum

(e) Refer SC6.4.4.8 Standard drawings SD-14.1 and SD-14.2 for typical drip irrigation details.

(f) Pressure compensation shall be fitted to each individual drip irrigation station. The devices used shall be retro fitted to the solenoid valve. The following two options are acceptable:

(i) Hunter Accu-Set pressure regulator, refer SC6.4.4.8 Standard drawings SD-14.3; and

(ii) inline pressure regulation device as specified by the Superintendent, refer to SC6.4.4.8 Standard drawings SD-14.4.

(g) A 120 mesh Disc Filtration system shall be installed immediately up stream of the solenoid valve in accordance with the manufacturer's specifications to ensure that the correctly sized filtration system is used. The following two filtration systems are acceptable:

(i) Netafim Tech Filter, (rated at 120 mesh by Netafim); and

(ii) Arkal 120 mesh Disc Filter fitted into a Netafim Tech filter housing, may be used during construction and for a period no greater than 1 month after installation of the drip tube.

(h) The filter, pressure regulator valve and solenoid valve assembly shall be installed in a valve box. Barrel Union/s shall be fitted to allow for easily removal of the filter, refer SC6.4.4.8 Standard drawings SD-14.3 and SD-14.4. The order of component installation from upstream to downstream is to be: Barrel Union, Filter, Barrel Union, Solenoid valve and Pressure Regulator. The fitting of these devices and the size of the valve box shall allow for:

(i) the filter cartridge to be easily serviced and changed; and

(ii) the pressure regulator to be easily adjusted and serviced.

(i) Drip tube shall be installed:

(i) in turf with 75mm cover to the finished surface level.

(ii) drip Tube laid on the surface shall be fitted with holding pins placed every 1.5m along the tube. Holding pins are to be constructed from 2.3mm minimum diameter Stainless Steel wire of 304 grade. Refer to SC6.4.4.8 Standard drawings SD-15.1 for details.

(j) Drip tube shall not be installed:

(i) directly into heavy clay or rocky soils where conditions may cause damage to the drip tube. In these soil types the drip tube must be installed between a 50mm surround of imported loan soil; and

(ii) in areas subject to significant vehicle traffic, where these condition would cause damage to the drip tube.

(k) All dripper lines shall terminate to a flushing manifold on the downstream side of the line. The head loss in the manifold shall be sized to lose no more than 1m based on twice the flow rate of the flow during normal operation. Each flushing line shall be fitted with a ball valve and 1 m of industrial vacuum and delivery hose. The ball valve shall be installed to provide easy operation. The ball valve shall be positioned in the valve box to prevent the industrial vacuum and delivery hose from kinking. The hose is to be held in place with a stainless steel hose clip. See SC6.4.4.8 Standard drawings SD-14.1 and SD-14.2 for component layouts. The valve box shall be sized as follows:

(i) 25mm ball valve – Carson or equivalent round valve box; and

(ii) 40mm and 50mm ball valves – Carson or equivalent rectangular valve box.

(l) All high point(s) in the dripper layout shall be fitted with a Bermad vacuum relief valve (Model ARV). The vacuum valve is to be installed in a valve box. A section of drip tube shall cross connect all drip tubes to the vacuum relief valve. The vacuum relief valve shall not be fitted to the supply manifold. See SC6.4.4.8 Standard drawings SD-14.1 and SD 14.2 for a typical installation.

(m) Netafim HCNL drip tube and/or Hunter adjustable check valves (or approved equivalent) shall be fitted if

the fall in the drip irrigation system exceeds 3m. Each side of the check valve shall be fitted with independent Flushing Valves and Vacuum Relief Valves. The check valves shall be set to 3m. The two methods for installation of the check valves are:

(i) check valves fitted to each drip tube; and

(ii) check valves fitted to both the supply manifold and the flushing manifold.

(n) Each drip irrigation station shall be fitted with operation indicators. The operation indicators consist of a Toro 570 100mm pop-up sprinkler fitted with an SST nozzle set to zero flow, sealed with silicon and installed level with the ground. The operation indicators are to be installed in a garden bed or next to a tree (not be a tripping hazard) and be visible from the drip valve assembly. Additional operation indicators shall be installed at the ends of each station and connected using a HR Products E-Z riser tube and 15mm E-Z riser elbows.

(o) Prior to the installation of the drip irrigation system the area to be drip irrigated shall be soaked with water and allowed to dry. Any resulting subsidence or soil shrinkage shall be filled with soil up to the finished surface level. The process of soaking with water and filling to a finished surface shall be repeated until the required surface level is achieved. Drip tubes may then be laid with the correct cover.

(p) On slopes the drip irrigation tubes shall following the contour lines of the area.

(q) “Snaking” of dripper lines shall be avoided.

(r) The minimum size of the header manifold is to be 25mm low density poly pipe.

(s) Drip tube shall be laid in straight runs inside roundabouts.

(t) No drip tube shall be installed within 150mm from walls, garden edges, pathways and the back face of concrete kerbs or concrete garden edges.

(u) Drip tube shall only be connected to low density poly pipe 25mm and 32mm using FI Tees and Netafim elbow adapters (3/4 inch to 17mm) with all low density pipe fittings clamped using Cobra stainless steel clamps or similar approved type. The use of quick start connectors is not approved by the Superintendent.

(v) Drip tube shall only be connected to PN 6.3 Poly Pipe using poly tapping saddles and Netafim elbow adapters (3/4 inch to 17mm). The use of grommet connectors is not approved by the Superintendent.

(w) In locations where soils may be of a corrosive nature, 316 stainless steel bolt and nuts shall be used on all tapping saddles.

SC6.4.6.27.6 Drinking fountain and water tap

(1) Drinking fountain

(a) A drinking fountain assembly includes:

(i) bowl - cast alloy, powder coated white;

(ii) turret - Ex 219 OD stainless steel tube powder coated "Heritage Green";

(iii) tap - BUB228C cam action Enware;

(iv) bubbler - Enware Type 61 push button bubbler with 3/8th - 1/2"x 3" male BSP tail;

(v) copper tube connection – 13mm Annealed Copper;

(vi) isolation valve;

(vii) precast concrete plinth base;

(viii) precast concrete pipe and aggregate backfill;

(ix) potable water supply line and water meter; and

(x) SC6.4.4.8 Standard drawings SD-32.1 contains the construction drawings for the fountain assembly.

(b) All pipe work to a drinking fountain shall comply with AS 3500. All pipe work installation to a drinking fountain, shall be carried out by a licensed plumber.

(c) The supply line to a drinking fountain shall be a “standalone” potable water line with its own water meter. Pipe work shall be a minimum 32mm PN12.5 Poly Pipe (from meter to isolation valve) laid in a trench with sand bedding and surround to the pipe and with 300 mm minimum cover over the pipe. Drinking

fountains and water taps may be installed on the same potable water line.

(d) The drinking fountain turret shall be installed on a precast concrete plinth base set on top of a 600 dia x 1.2m long reinforced concrete pipe embedded into the ground and backfilled with 20mm aggregate for drainage. Details of the base are given in SC6.4.4.8 Standard drawings SD-32.2. Alternately, the drinking fountain may be connected into an existing sewer drainage line.

(e) The Drinking fountain shall be isolated by a 15mm Ball Valve. The isolation valve shall be located a nominal 600mm from the drinking fountain adjacent the concrete plinth base and shall be installed in a circular valve box.

(f) The drinking fountain tap and bubbler shall be connected to the isolation valve with a flexible stainless steel hose.

(g) All bolts, screws and masonry anchor bolts fitted to the drinking fountain assembly shall be stainless steel.

(h) On completion and at commissioning of the drinking fountain the pressure shall be adjusted so the stream of water exiting the bubbler does not spill over the bowl.

(2) Water tap

(a) A water tap assembly includes:

(i) tap with vacuum breaker;

(ii) stainless steel support post;

(iii) concrete splash pad; and

(iv) potable water supply line and water meter.

(b) All pipe work to a water tap shall comply with AS 3500. All pipe work installation to a water tap shall be carried out by a licensed plumber.

(c) The supply pipe line to a water tap shall be a “standalone” potable water line with its own water meter. Pipe work shall be a minimum 32mm PN12.5 Poly Pipe (from the meter to copper tail pipe) laid in a trench with sand bedding and surround to the pipe and with 300mm minimum cover over the pipe. Water taps and drinking fountains may be installed on the same potable water line.

(d) Tap shall be a 15mm brass hose cock or similar approved connected to a 20mm copper tail pipe installed inside the support post.

(e) Support posts shall be 40mm x 40mm x 1.6mm stainless steel SHS fitted with a plastic cap and cast 350mm minimum into a 350mm dia x 450mm deep concrete footing.

(f) Splash pads shall be either:

(i) 600mm square x 100mm thick N25 concrete cast insitu; or

(ii) 600mm square x 50mm thick precast concrete.

(3) Fertigation

A fertigation point consisting of 25mm tested ball valve connected to the irrigation main line close down stream from the back flow assembly must be installed unless advised by the Superintendent. The fertigation point is to be housed in a round enclosure with the lid marked “FRT” for identification.

SC6.4.6.27.7 Effluent reuse systems

(1) Design and installation

(a) All works must comply with the *Queensland Water Recycling Guidelines*, current health and safety, environmental and related acts.

(b) Effluent reuse irrigation systems shall have:

(i) sprinklers fitted with lilac ID caps;

(ii) lilac coloured drip tubing;

(iii) lilac coloured valve box lids;

(iv) mainline and lateral pipe material (plastic) shall be lilac in colour or contain a lilac strip;

(v) all above ground pipe work shall be lilac coloured and/or clearly labelled “Recycled Water”, “Non Potable Water”; and

(vi) minimum separation of Pipe work for Potable and Recycles water systems shall be maintained at 300mm for below ground pipe work and 100mm for above ground pipe work.

SC6.4.6.27.8 Installations located in landfill sites

(1) Trenching in landfill sites

(a) When excavating in landfill sites or areas containing rock the trench shall be excavated to a minimum depth of 600mm.

(b) All trenching material removed from the trench shall be removed to the local refuse dump.

(c) All trenching spoil shall be totally removed from the surrounding surfaces and site and inspected by the Superintendent.

(d) Bedding sand shall be used to backfill to 200mm below finished soil level. The final 200mm shall be filled with an approved loam.

SC6.4.6.28 Minor concrete works

SC6.4.6.28.1 Introduction

(1) Scope

(a) This sub-section provide details for the supply and placement of concrete, including sprayed concrete, and ancillary requirements including excavation, preparation of foundations, forming up, placement of reinforcement and backfilling for work shown on the drawings but not having individual policy sub-sections. These works include kerb and channel, New Jersey type barriers, drainage pits and other supplementary structures, headwalls, box culverts, box culvert base slabs, driveways, footpaths, median toppings, retaining walls, footings, paving edge strips and works of a similar nature.

(b) The work also includes supply and placement of miscellaneous minor concrete work for water and sewerage construction such as valve chambers, thrust and anchor blocks, bulkheads, pumping stations, bedding, encasement and cast-in-situ access chambers.

(c) Requirements for quality control and testing, including maximum lot sizes and minimum test frequencies, are cited in SC6.4.5 Construction management.

(2) Reference and source documents
Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section are as follows:
SC6.4.6.6 - Pipe drainage
SC6.4.6.10 - Earthworks (construction)
SC6.4.6.12 - Flexible pavements
SC6.4.5 Construction management.

(b) Australian Standards:

AS1012.1	*Sampling of fresh concrete*
AS1012.3.1	*Determination of properties related to the consistency of concrete - Slump test.*
AS1012.8.1	*Method of making and curing concrete - Compression and indirect tensile test specimens*
AS1012.8.2	*Method of making and curing concrete - Flexure test specimens*
AS1012.9	*Determination of the compressive strength of concrete specimens*
AS1012.14	*Method for securing and testing cores from hardened concrete for compressive strength*
AS1141.14	*Particle shape, by proportional caliper*
AS1141.21	*Aggregate crushing value*
AS1141.23	*Los Angeles value*
AS1141.24	*Aggregate soundness – Evaluation by exposure to sodium sulphate solution*
AS1289.3.3.1	*Calculation of the plasticity index of a soil*
AS1289.5.1.1	*Determination of the dry density/moisture content relation of a soil using standard compactive effort*
AS1289.5.4.1	*Compaction control test - Dry density ratio, moisture variation and moisture ratio*
AS1379	*Specification and supply of concrete*
AS1478.1	*Chemical admixtures for concrete, mortar and grout – Part 1: Admixtures for concrete*
AS/NZS1554.3	*Welding of reinforcing steel*
AS/NZS1859	*Reconstituted wood-based panels*
AS2082	*Visually stress-graded hardwood for structural purposes*
AS/NZS2271	*Plywood and blockboard for exterior use*
AS2758.1	*Concrete aggregates*
AS3600	*Concrete structures*
AS3610	*Formwork for concrete*
AS3799	*Liquid membrane-forming curing compounds for concrete*
AS3972	*General Purpose and blended cements*

(c) Other:
NSW RTA, *Shotcrete design guidelines*

SC6.4.6.28.2 Excavation and foundations

(1) General

The foundation where specified, shall be formed at the required depth below the finished surface levels shown on the drawings. Rock foundations shall be neatly excavated to form a bed for the concrete, and shall be thoroughly scraped and cleaned. Soil foundation shall, as far as possible, be excavated neatly from the solid material to coincide with the under-surface of the concrete. Compaction requirements must meet the appropriate compliance standards as specified in sub-section SC6.4.6.10 Earthworks (construction).

All soft, yielding or other unsuitable material shall be replaced with sound material approved by the Superintendent, and the subgrade shall be compacted to provide a minimum relative compaction as specified in SC6.4.6.10 Earthworks (construction). If the subgrade is dry it shall be sprinkled with as much water as it will readily absorb, before the concrete is placed.

Preparation of the foundation is required in accordance with foundation type, as follows:

(a) concrete working base - remove projections above the plane surface, and loose material; and

(b) graded prepared subgrade - blind with sufficient sand to create a smooth surface free from hard projections. Wet the sand just before laying the underlay.

Editor's note—Provision of a vapour barrier for external slabs on ground prevents water loss to the subgrade and has the potential to reduce slab curling at edges and corners.

AS2870 Section 5.5 provides additional requirements and detailing of damp proof membranes for concrete slabs and footings exposed to either saline or acid sulphate soils. AS2870 Section C5.5 and CCAA T56 provide information on concrete exposed to saline soils.

Polymeric Film Underlay must be installed over the prepared foundation. Lap joints at least 200mm and seal the laps and penetrations with waterproof adhesive tape. Face the laps away from the direction of concrete pour. Take the underlay up vertical faces past the damp proof course where applicable, and tape fix at the top. Patch or seal punctures or tears before pouring concrete. Cut back as required after concrete has gained strength and forms have been removed.

The Contractor shall supply all necessary sheeting and bracing to safely support the excavation in accordance with statutory requirements. The excavation shall be kept free of water.

Prior to the construction of footings for cast-in-situ concrete walls on earth foundations, cover the latter with a mass concrete blinding slab. Unless otherwise specified, place precast concrete wall sections on a fresh mass concrete bedding layer while it is still in a plastic state. Ensure the following is adhered to:

(a) for earth foundation, place concrete not less than 50mm thick; and

(b) for rock foundation, place the concrete at least 50mm above the highest points of rock.

Place neither forms nor other materials on the bedding layer within 48 hours of the concrete being placed.

(2) Kerb and channel

Kerb and channel may be constructed in fixed forms, by extrusion or by slip forming, in accordance with AS2876.

The foundation, concrete quality, curing and testing details shall be in accordance with AS2876 except where placed on pavement courses, where the requirements of the respective pavement course must prevail. Kerb and channel will be constructed to the profile nominated on the drawings.

The top and face of the finished kerb and channel shall be true to line and the top surface shall be of uniform width, free from humps, sags or other irregularities. Kerb and channel shall have a steel float finish.

The level at any point on the surface of the kerb invert shall be within ±6mm of the design level. When a straight edge 3m long is laid on top of or along the face or invert of the kerb, the surface shall not vary more than 5mm from the edge of the straight edge, except at kerb laybacks, grade changes or curves or at gully pits requiring gutter depression. The drainage invert shall be free draining and shall not pond water.

Unless shown otherwise on the drawings, contraction joints, shall be formed every 5m of kerb invert length for a minimum of 50% of cross sectional area. The joint shall be tooled 20mm in depth to form a neat groove of 5mm minimum width.

Unless shown otherwise on the drawings, expansion joints, 15mm in width for the full depth of the kerb and channel, shall be constructed where the kerb invert abuts against kerb gully pits, both sides of kerb laybacks/ramps for vehicular or pedestrian access, retaining walls and overbridges. Expansion joints shall consist of a preformed jointing material of bituminous fibreboard.

Where kerb and channel is cast adjacent with a concrete pavement the same type of contraction, construction and expansion joints specified in the concrete base shall be continued across the kerb and channel.

All house stormwater outlets shall be provided and/or extended, to match the existing type and size of pipe, through the kerb as shown on the drawings providing correctly graded drainage outlet into channel. Pipework shall be in accordance with the requirements for UPVC pipes in sub-section SC6.4.6.6 Pipe drainage, or as directed by the Superintendent for other types of pipe.

At all driveway crossings, where shown on the drawings or where directed by the Superintendent, barrier kerb shall be discontinued to provide for vehicular or pedestrian access. At such locations, kerb laybacks/ramps must be constructed in accordance with the drawings and Standards. Footpath crossovers shall be constructed to meet the laybacks as shown on the drawings, or reinstated to match existing materials where not otherwise shown.

After the new kerb and channel has been constructed and not earlier than 3 days after placing, the spaces on both sides of the kerb and/or gutters shall be backfilled and reinstated in accordance with the drawings, or as instructed by the Superintendent.

Backfill material behind the kerb shall consist of granular material, free of organic material, clay and rock in excess of 50mm diameter, or material as approved by the Superintendent.

Backfill material behind the kerb shall be compacted in layers not greater than 150mm thick, to a relative compaction of 95% when tested in accordance with AS1289.5.4.1, for standard compactive effort. The whole of the work shall be finished in a neat and workmanlike manner, free draining and free from surface undulations and trip hazards.

Pavement material adjacent to new gutter shall be backfilled in accordance with the drawings or as directed by the Superintendent.

Where specified in drawings, kerb only work shall be pinned as detailed in Standard drawings.

(3) New jersey type barriers, driveways and footpaths

For New Jersey type barriers, driveways and footpaths a subbase of approved quality and of minimum 150mm compacted thickness, unless otherwise shown on the drawings, shall be placed over the subgrade. The surface shall then be checked for uniformity, line and level, and all irregularities shall be made good.

The subbase material shall be compacted to provide a minimum relative compaction as determined by AS1289.5.4.1 of 100% for standard compactive effort as specified in SC6.4.6.10 Earthworks (construction).

The finished subbase shall not deviate more than 15mm under a straight edge 3m long, subject to any necessary allowance on vertical curves.

(4) Drainage pits and other supplementary structures
Where the excavation is in sound rock, and the Superintendent so directs, part of the concrete lining of gully pits and other structures may be omitted, provided that a neatly formed pit of the required dimensions is constructed, and provided that the wall of the pit adjacent to and parallel with the road is constructed of formed concrete in all cases.

(5) Retaining walls, headwalls and wingwalls
In the case of rock foundations for retaining walls, headwalls and wingwalls, the excavation shall be carried into the rock for a minimum depth of 150mm. Where cut-off walls are to be provided, the depth of cut-off in rock foundations may be reduced to 100mm.

Prior to the construction of cast-in-situ concrete walls on earth foundations, the latter shall be covered by a mass concrete bedding layer at least 50mm thick and finished to a uniform surface. No forms or other materials shall be placed upon the bedding layer within a period of 48 hours after the concrete has been placed.

Unless otherwise specified, precast concrete wall sections shall be placed on a fresh mass concrete bedding layer while it is still in plastic state. In the case of soil foundations, the concrete shall be not less than 50mm thick, and where the foundation is in rock, the concrete shall be of such thickness as is required to provide a uniform surface at least 50mm above the highest points of rock.

SC6.4.6.28.3 Formwork

(1) General
Formwork shall be provided in accordance with AS3610 to produce hardened concrete to the lines, levels and shapes shown on the drawings or specified elsewhere. It shall have adequate strength to carry all applied loads, including the pressure of fresh concrete, vibration loads, weight of workers and equipment, without loss of shape. Forms shall be mortar tight and designed to allow removal without risk of damage to the completed structure. Joints in the formwork shall be perpendicular to the main axis of the shape of the concrete.

Where concrete is placed in earth excavations, side forms shall be provided to prevent contact between concrete and the insitu earth.

Design of formwork for high sections shall be such that it shall not be necessary to drop concrete freely from a greater height than 1.2m or to move concrete along the formwork after deposition.

Formwork material used shall be sound and suitable for the purpose intended and surface finish specified.

Provision shall be made for the accurate location and firm support of fittings, bolts, anchorages and formers of holes as shown on the drawings. Temporary fittings used for the support of the formwork shall be arranged to permit removal without damage to the concrete. The use of wires and or bolts extending to the surface of the concrete shall not be permitted except where shown on the drawings.

Forms for edges of concrete shall be filleted and for re-entrant angles chamfered as shown on the drawings.

Temporary openings shall be provided where necessary for cleaning out of formwork and inspection before concreting.

(2) Approval of formwork design
For box culverts and reinforced concrete retaining walls, detailed drawings, design calculations, description and/or samples of materials proposed for use shall be submitted for the Superintendent's concurrence before manufacture of the formwork is commenced.

(3) Provision for drainage
Where shown on the drawings, or where directed by the Superintendent, weepholes of 50mm diameter shall be provided in retaining walls and wingwalls.

(4) Construction

The type and quality of material selected for formwork and the workmanship used in construction shall be such that the surface finish specified shall be obtained. Construction shall be such that the erection tolerances shall be obtainable.

Timber for formwork shall be well seasoned, free from defects and, where in contact with fresh concrete, free from loose knots.

Timber forms for exposed surfaces shall be constructed from plywood or particle board with hardwood or approved softwood studs and wales. The plywood used for forms shall comply with AS2271, the hardwood shall comply with AS2082 and the particle board with AS/NZS1859.

Formwork for exposed surfaces shall be made from panels having uniform widths of not less than 1m and uniform lengths of not less than 2m, except where the dimensions of the member formed are less than the specified panel dimensions. Plywood panels shall be placed with the grain of the outer plies perpendicular to the studding or joists. Where form panels are attached directly to the studding or joists the panel shall be not less than 15mm thick. Form panels less than 15mm thick, otherwise conforming to these requirements may be used with a continuous backing of dressed material of 20mm minimum thickness. All form panels shall be placed in a neat, symmetrical pattern.

Forms for all surfaces which will be completely enclosed or permanently hidden below the ground may be constructed from dressed or undressed timber, steel, plywood or particle board.

Mild steel form surfaces in contact with concrete shall have all bolt and rivet heads counter-sunk and all welds ground back to even and smooth surfaces.

(5) Erection

(a) General

(i) Dimensions and position of forms shall be carefully checked after the forms are erected. Forms shall be aligned accurately and the location of all fittings, hold formers, etc. checked prior to placing concrete. Departure of the forms from the surfaces shown on the drawings shall not exceed 1/300 of the space between supports for any surface visible in the completed work and 1/150 for hidden work. For tolerances in plan position and levels, refer to clauses SC6.4.6.28.5(7) Finishing of unformed surfaces and SC6.4.6.28.5(10) Treatment of formed surfaces.

(ii) Joints as erected shall be mortar tight.

(iii) The interior surface of the forms shall be treated to ensure non-adhesion of the mortar. Commercial quality form oil or grease will be acceptable, but the oil or grease used on forms against surfaces to be exposed shall not stain or discolour the concrete surface. The coating shall be uniformly spread in a thin film and any surplus shall be removed prior to placing concrete. In the case of unlined timber forms, the timber shall be thoroughly wetted before oiling. Forms shall be treated before placing reinforcement to ensure that the form release agent will not contaminate the surface of the reinforcing steel or construction joints.

(iv) Formwork hardware shall be treated with a form release agent and so arranged that it may be removed from the concrete without excessive jarring or hammering.

(b) Approval by the Superintendent

(i) The formwork shall be inspected by the Superintendent, and the placing of reinforcement in the spaces formed, where specified, shall not commence until the formwork is approved by the Superintendent.

(ii) Placing of concrete shall not commence until the reinforcement, where specified, has been accepted by the Superintendent, and all dirt, chips, hardened concrete, mortar and all foreign matter removed from the forms.

(iii) When an inspection is requested by the Contractor, a notice of not less than 24 hours, excluding Saturdays, Sundays and public holidays, shall be given to the Superintendent.

SC6.4.6.28.4 Materials for concrete

(1) Cement

Cement shall be Type GP Portland Cement complying with AS3972.

When submitting details of the nominated mix in accordance with clause SC6.4.6.28.4(6) Testing of materials, the Contractor shall nominate the brand and source of the cement. On approval of the nominated mix by the Superintendent, the Contractor shall only use the nominated cement for the work.

Documentary or other acceptable evidence of the quality of the cement shall be furnished by the Contractor if required by the Superintendent.

If the Contractor proposes to use cement which has been stored for a period in excess of 3 months from the date of testing, a re-test shall be required at the Contractor's expense before the cement is used.

All cement shall be transported in watertight containers, and shall be protected from moisture until used. Caked or lumpy cement shall not be used.

(2) Water

Water shall be free from injurious amounts of materials harmful to concrete and to its reinforcement and neither salty nor brackish.

Water which is not potable for human beings shall not be used in reinforced concrete.

(3) Fine aggregate

Fine aggregates shall consist of clean, hard, tough, durable uncoated grains, uniform in quality, and shall conform to the requirements of AS2758.1 in respect of bulk density, water absorption (maximum 5%) material finer than 2 micrometres, impurities and reactive materials.

Fine aggregates shall be evenly graded within the absolute limits shown in Table SC6.4.6.28.1 Fine aggregate grading, and shall not deviate from the proposed grading by more than the amounts in Table SC6.4.6.28.1.

Table SC6.4.6.28.1 Fine aggregate grading

Australian Standard Sieve	Proportion Passing (% of Mass)	Deviation from Proposed Grading (% of Mass of Sample)
9.50mm	100	
4.75mm	90 - 100	±5
1.18mm	40 - 85	±10
300µm	8 - 30	±10
150µm	2 - 10	±5
75µm	0 - 4	±3

(4) Coarse aggregate

Coarse aggregate shall consist of clean, hard, durable, crushed stone, crushed river gravel, screened river gravel or metallurgical furnace slag and shall conform to the requirements of AS2758.1 in respect of particle density, bulk density, water absorption (maximum 2.5%), material finer than 75 micrometres, weak particles, light particles, impurities and reactive materials, iron unsoundness and falling or dusting unsoundness. In all other respects, the coarse aggregate shall comply with this sub-section. If required, coarse aggregate shall be washed to satisfy these requirements.

The percentage of wear shall be determined by AS1141.23, and the loss of weight shall not exceed 30%.

When required by the Superintendent, coarse aggregate shall be tested for conformance for any or all of the properties set out below:

(a) crushing value - AS1141.21
The aggregate crushing value shall not exceed 25%;

(b) soundness - AS1141.24
The loss of mass when tested with sodium sulphate shall not exceed 12%; and

(c) particle shape - AS1141.14
The proportion of misshapen particles (2:1 ratio) shall not exceed 35%.

Coarse aggregate shall be evenly graded within the absolute limits shown in Table SC6.4.6.28.2 Course aggregate grading and shall not deviate from the grading of the samples submitted under clause SC6.4.6.28.4(6) Testing of materials by more than shown.

Table SC6.4.6.28.2 Coarse aggregate grading

Australian Standard Sieve (mm)	Proportion Passing (% of Mass)			Deviation Proposed Grading (% of Mass of Sample)
	40mm Nominal	20mm Nominal	Extrusion Concrete	
	For Walls exceeding 150mm thickness	For all other structures		
53.0	100			±10
37.5	95 - 100			±10
26.5		100		±5
19.0	30 - 70	95 - 100		±5
13.2			100	
9.50	10 - 35	25 - 35		
4.75	0 - 10	0 - 10		
2.36	0 - 2	0 - 2		

(5) Admixtures
Chemical admixtures and their use shall comply with AS1478.1. Admixtures shall not contain calcium chloride, calcium formate, or triethanolamine or any other accelerator. Admixtures or combinations of admixtures other than specified below, shall not be used.

During the warm season, (October to March inclusive), a set retarding admixture approved by the Superintendent shall be used to control slump within the limits stated in clause SC6.4.6.28.5(4) Consistency. The dosage shall be varied to account for air temperature and haul time in accordance with the manufacturer's recommendations. A copy of the NATA endorsed Certificate of Compliance with AS1478.1 shall be submitted to the Superintendent, together with the proposed “dosage chart” in accordance with SC6.4.6.28.4(6) Testing of materials. If the Contractor proposes to vary the admixture between the warm and cool seasons such variation shall require approval by the Superintendent by providing the necessary certificate of compliance.

(6) Testing of materials
The Contractor shall submit to the Superintendent a copy of a NATA Certified Laboratory Test Report on the quality and gradings of the aggregates proposed to be used in the work.

The materials shall only be used after receipt of the Superintendent's notification of acceptance, and then only as long as the materials accord with the Specification.

SC6.4.6.28.5 Handling and treatment of concrete

(1) Measuring
All materials shall be measured by weight, except that:

(a) water may be measured by volume with an approved adjustable water-measuring and discharging device;

(b) cement may be measured by bags as packed by the manufacturer in which case batches shall be proportioned on the basis of one or more unbroken bags of cement, and for this purpose one bag of

cement shall be assumed to weigh 40kg. Bulk cement shall be weighed in an individual hopper and shall be kept separate from the aggregates until the components of the batch are discharged from the batching hopper; and

(c) measurement by volume for smaller works may be undertaken with the prior approval of the Superintendent.

(2) Measuring by weight, on-site mixing

Where concrete is to be mixed on site, and where mix control is likely to be less efficient than at a central batching plant, the weights of cement, fine and coarse aggregate shown in Table SC6.4.6.28.3 Materials in batch containing 1 bag (40kg) cement may be used as a guide to produce the classes of concrete specified. Small changes in the proportions of fine and coarse aggregate may be required to improve density or workability of the concrete. The use of proportions shown in Table SC6.4.6.28.3 shall not relieve the Contractor of his obligation to provide concrete of the specified compressive strength.

Table SC6.4.6.28.3 Materials in batch containing 1 bag (40kg) cement

MPa	Cement kg	Fine Aggregates kg	Coarse Aggregates kg	Total Aggregates kg
10	40	130	250	380
15	40	100	190	290
20	40	88	126	214

The proportions set out in Table SC6.4.6.28.3 make allowance for moisture contents of aggregates of 6% for fine aggregates and 1% for coarse aggregates. Where the moisture content of aggregates exceeds 8% or 3% respectively, the proportions of the mix shall be changed to compensate for the excess water in the aggregate.

(3) Measuring by volume, on-site mixing

Where measurement by volume is approved, the proportions of the materials shall be such as are required to produce a mix free of voids and having the specified strength at 28 days.

The nominal proportions given in Table SC6.4.6.28.4 Volume batching may be used as a guide for volume batching.

Table SC6.4.6.28.4 Volume batching

MPa	Parts by Volume		
	Cement	Fine Aggregate	Coarse Aggregate
10	1	3	6
15	1	2.25	4.5
20	1	2	3

The volumes of fine and coarse aggregates for each batch shall be measured in boxes or bins. The aggregates shall be measured loose (i.e. without compaction) in the boxes and shall be struck off level. Measurements by shovels or like methods will not be permitted. Batch proportions shall be so arranged that each batch contains 1 bag of cement. One 40kg bag of cement shall be assumed to have a volume of 27.5 litres.

(4) Consistency

A sufficient quantity of water shall be added to the mix so that the consistency of the concrete is such that it can be placed in the forms, compacted and worked into all corners without permitting the ingredients to segregate, or excess free water to collect on the surface. If required by the Superintendent, the Contractor shall determine the consistence of the concrete in accordance with AS1012.3.1. Except for extruded concrete, the nominated slump shall not exceed 80mm, plus the field tolerance of ±15mm.

In the case of concrete placed by an extrusion machine, the water in the mix shall be only sufficient to produce a slump of 10mm to 15mm.

(5) Mixing and delivery

(a) General

(i) Concrete may be mixed either at the site or at a central mixing plant. All concrete shall be mixed

with mechanically operated mixers. In an emergency, hand mixing may be permitted. Submit proposal for concrete mixing other than pre mixed concrete for approval by superintendent.

(ii) Any concrete which exhibits signs of segregation shall not be used.

(b) Machine mixing at site

(i) The mixing of concrete shall be done in a batch mixer which will ensure a uniform distribution of the materials throughout the batch.

(ii) The mixer shall be of such capacity that one or more whole bags of cement may be used per batch of concrete. The volume of the mixed material shall not exceed the manufacturer's rated capacity of the mixer.

(iii) The mixing time for each batch shall not be less than 1.5 minutes after all ingredients are assembled in the mixer, and prior to any portion of the batch being removed.

(iv) The entire contents of a batch shall be discharged from the mixer before any materials are placed therein for the succeeding batch.

(c) Mixing in an emergency

(i) In the case of breakdown of the mechanical mixing equipment, hand mixing in small quantities so as to complete a section of the work or reach a suitable construction joint is permitted.

(ii) Hand mixing shall be done on a water-tight platform of sufficient size to allow the mixing of at least two batches simultaneously. The amount of cement used shall be 10% more than the amount specified for machine mixed concrete.

(iii) The fine aggregate and cement shall first be mixed until a uniform colour is obtained, and then spread on the mixing platform in a thin layer. The coarse aggregate, which shall have been previously drenched with water, shall then be spread over the fine aggregate and cement in a uniform layer, and the whole mass turned over as further water is added with a rose sprinkler. After the water is added, the mass shall be turned at least three times, not including shovelling into barrows or forms, until the mixture is uniform in colour and appearance. Hand-mixed batches shall not exceed 25m^3 each.

(d) Ready-mixed concrete

(i) The concrete shall be mixed and delivered in accordance with the requirements of AS1379 relating to:

(A) mixing and delivery; and

(B) use of non-agitating equipment,

(ii) The water used for flushing the chutes and for cleaning shall be discharged in an area acceptable to the Superintendent. The chutes shall be long enough to permit delivery to the whole of the area enclosed by the forms.

(6) Placing and compacting concrete

No concrete shall be mixed or placed, without the approval of the Superintendent, while the air temperature is, or is likely to be within 24 hours, below 5°C or while the shade temperature exceeds 38°C. All concrete shall be placed in the dry. Prior to placing concrete the area shall be clean and moist but free from any ponding of water.

The concrete shall be mixed in the quantities required for immediate use and shall be placed in position as rapidly as possible. Any concrete which has developed initial set, or which does not reach the forms within 30 minutes after the water has been added (except when transported in agitator trucks) shall not be used.

The concrete shall be deposited in the forms, without separation of the aggregates. Concrete shall not be dropped freely from a height greater than 1.2m, or be deposited in large quantities at any point and moved or worked along the forms. Conveying equipment, including open troughs and chutes, where used, shall be made of metal, or have metal linings. Where used on steep slopes, troughs and chutes shall be equipped with baffles, or be placed in short lengths in such a way that the direction of flow of the concrete is changed. The concrete

shall be placed in horizontal layers in one continuous operation between the ends of the work and/or construction joints. Care shall be taken to fill every part of the forms and to work the coarser aggregate back from the face. The freshly placed concrete shall be compacted by continuous spading, slicing or by vibrator units. Vibrators shall not be left in one position for more than 30 seconds, and shall not be permitted to rest on reinforcement.

Exposed surfaces of the concrete shall be struck off and finished with a wooden float. Where shown on the drawings corners and edges shall be left neatly rounded or chamfered. Re-entrant angles shall be neatly filleted.

Concrete shall not be moved after it has been in the forms for more than 10 minutes.

In the case of concrete placed by an extrusion machine, small quantities of cement-sand slurry, comprised of two parts of plasterer's sand and one part of cement (by volume), together with sufficient water to bring it to a semi-fluid condition, shall be placed in the special receptacle in the machine, if the machine is so equipped and shall be fed onto the surface of the concrete at a rate sufficient to produce a smooth and uniform finish.

(7) Finishing of unformed surfaces

(a) Surfaces other than wearing surfaces

Unformed surfaces shall be compacted and tamped so as to flush mortar to the surface, screeded off and finally dressed with a wooden float to an even surface. Care shall be taken to drain or otherwise remove promptly any water which comes to the surface. A capping of mortar will not be permitted.

All future contact surfaces shall be left rough, with the coarse aggregate at the surface firmly embedded but not forced below the surface.

(b) Wearing surfaces

Where a concrete wearing surface is shown on the drawings the concrete shall be thoroughly compacted and the surface screeded off by a vibrating screed, or hand screeded where the distance between forms perpendicular to the direction of screed is no greater than 2m. Immediately following compaction and screeding the concrete shall be tested for high or low spots and any necessary corrections made. The surface shall be finished true and uniform and free from any glazed or trowelled finish and shall be finally dressed with a wooden template or float, or by the use of belting in an approved manner. The departure from grade shall not exceed 5mm in any 3m length.

Where an asphaltic concrete wearing surface is specified, the surface of the concrete, after being compacted, screeded and corrected, shall be dressed with a wooden float and finally broomed to produce a rough surface.

(c) Finished levels and location

The unformed surface of concrete structures not adjacent to road pavements shall not vary more than 25mm in plan position and not more than 25mm from the specified levels. In the case of barriers, drainage pits, culvert slabs and other structures adjacent to road pavements, the finished concrete shall not vary more than 10mm from the specified levels and alignment. Barriers, footpaths and similar shall not deviate from level or alignment by more than 5mm from a straight-edge 3m long, subject to any necessary allowances on vertical and horizontal curves.

(8) Curing and protection

All exposed surfaces of the freshly placed concrete shall be kept moist either by the use of plastic sheeting, damp sand or commercial curing compounds, in accordance with AS3799, for a minimum period of 3 days. During this time the work must be adequately protected from the effects of excessive surface evaporation, rain, running water, vandalism and other causes likely to damage the concrete. All costs involved in making good or replacing any work that has been damaged due to the above mentioned factors shall be borne by the Contractor.

Curing for concrete shall generally be in accordance with the appropriate surface exposure classification in AS3600.
If it is proposed to use a liquid membrane-forming curing compound submit the following information:

(a) certified test results for water retention to AS3799 Appendix B;

Editor's note—It is likely that polyvinyl alcohol (PVA-based) products will not comply with water retention requirements.

(b) evidence of compatibility with concrete, and with applied finishes including toppings and render, if any, including methods of obtaining the required adhesion.

For visually important surfaces, evidence that an acceptable final surface colour will be obtained.

(9) Removal of forms

All forms shall remain in place, after placement of concrete, for minimum periods specified hereinafter. These periods may be extended by the Superintendent if the air shade temperature falls below 10 °C during the periods specified.

Mass retaining walls, headwalls, wingwalls, gully pits, sumps, and similar drainage structures	48 hours
Footpaths, driveways and similar	17 hours
Sides of reinforced concrete walls when height of each day pour is:	
• under 0.6m	1 day
• 0.6m to 3m	2 days
• 3m to 6m	3 days
• 6m to 9m	5 days
Supporting forms under deck slabs of culverts	10 days

To permit the satisfactory finishing of barriers, forms shall be removed in not less than 12 hours nor more than 48 hours after placing concrete, depending upon weather conditions.

Care shall be taken in removing forms so that the concrete will not be cracked, chipped or otherwise damaged. The use of crowbars or other levering devices exerting pressure on the fresh concrete to loosen the forms will not be permitted.

No superimposed load shall be allowed on any part of a structure until the concrete has reached at least 70% of the design strength.

Hole formers such as pipes and bars shall be removed as soon as the concrete has hardened sufficiently for this to be done without damage to the concrete.

(10) Treatment of formed surfaces

All concrete surfaces shall be true and even, free from stone pockets, depressions or projections beyond the surface. All arrises shall be sharp and true, and mouldings shall be evenly mitred or rounded. Care shall be exercised in removing forms to ensure this result. Formed concrete surfaces shall be presented for inspection by the Superintendent within 1 day of stripping of formwork and finishes in accordance with the classes of surface finish in AS3610 as follows:

(a) Non-visible surfaces - Class 4.

(b) Visible surfaces - Class 2.

As soon as the forms are removed from mass or reinforced concrete work, all rough places, holes and porous spots shall be repaired by removing defective work and filling with stiff cement mortar having the same proportions of cement and fine aggregate as used in the concrete, and shall be brought to an even surface with a wooden float.

Any tie wires or other fitments extending to outside surfaces, shall be cut back after removal of forms, to a depth of at least 40mm with sharp chisels or cutters. All cavities caused by removal of fitments or tie wires shall be wetted and carefully packed with cement mortar, as above.

The surfaces of bolt cavities, tie wire holes, and all defects in concrete shall be coated prior to the placing of mortar, grout, or fresh concrete, with an approved bonding agent, in lieu of wetting with water. The method of

application of such agent and the conditions in which it is to be used shall generally be as laid down by the manufacturer.

The formed surfaces of concrete structures not adjacent to road pavements shall not vary more than 25mm in plan position and not more than 25mm from the specified levels. In the case of drainage pits and other structures adjacent to road pavements, the finished concrete shall not vary more than 10 mm from the specified levels and alignment.

(11) Joints

Submit proposed methods, timing and sequence of sawing joints for approval by superintendent a minimum of 7 days prior to works commencing.

Where horizontal construction joints are found to be necessary in walls, or cast-in-situ drainage structures the joints may be made at the base of walls and at other locations in the walls where approved by the Superintendent. In order to provide for bond between the new concrete and the concrete which has already set, the surface on which the new concrete is to be placed shall be thoroughly cleaned of loose material, foreign matter and laitance. The surface shall be roughened or keyed and saturated with water. After any excess water has been removed, the surface shall be thinly coated with a neat cement grout.

Retaining walls shall be provided with vertical expansion joints as shown on the drawings. The expansion joints shall consist of jointing material of approved quality, and of thickness shown on the drawings, and a depth sufficient to fill the joint. The jointing material shall be neatly cut to fit the surface of the concrete.

Where barriers are extruded or cast in place, narrow transverse vertical grooves, 20mm deep, shall be formed neatly in the surface of the freshly placed concrete to produce contraction joints for the control of cracking. The contraction joints, shall be at intervals of 3m.

In barriers, unless shown otherwise on the drawings, expansion joints, 15mm in width for the full depth of the barrier, shall be constructed at intervals not exceeding 15 m and where the barrier abuts against gully pits. Expansion joints shall consist of a preformed jointing material of bituminous fibreboard.

In footpaths, median toppings and driveways, unless otherwise shown on the drawings, expansion joints, 15mm in width for the full depth of paving, shall be constructed at intervals not exceeding 15m and where the pavement abuts against gutters, pits and structures. Expansion joints shall consist of a preformed jointing material of bituminous fibreboard.

All unreinforced paving shall be provided with narrow vertical grooves, 20mm deep to induce contraction joints for the control of cracking. The joints shall be formed in the freshly placed concrete in a neat regular pattern to form “slabs” no bigger than $2m^2$. The ratio of the longest side to the shortest side shall not exceed 1.6.

(12) Strength of concrete

When tested in accordance with AS 1012.9, the concrete shall have a characteristic compressive strength not less than that shown on the drawings or if not shown shall have a compressive strength not less than that specified in Table SC6.4.6.28.5 Concrete strength requirements for the particular class of work. The cement content restrictions shown in Table SC6.4.6.28.5 refer to Portland cement. Where General Purpose Blended cements are utilised the acceptable minima are indicated in brackets.

The characteristic strength shall be determined from the average of not less than two specimens, moulded from each class of concrete being used in the work, and selected to represent the whole of the concrete placed at the time of moulding.

In general, two pairs of test specimens shall be moulded for each $15m^3$ of concrete, or part thereof, one pair being intended for the 7 day test if required and the other pair for a 28 day test.

Table SC6.4.6.28.5 Concrete strength requirements

Use	Charac-teristic Strength MPa	Minimum Portland Cement per 3 metre (Minimum GB Blended Cement)	Coarse Aggregate Nominal Size	Characteristic Cylinder Strength Required	
				7 days	28 days
		kg	mm	MPa	MPa
Foundations, mass retaining walls	20	270 (330)	40	15	20
Mass concrete footings, pitching, linings etc.	20	270 (330)	20	15	20
Miscellaneous minor concrete work	20	270 (330)	20	15	20
Reinforced concrete culverts, drainage structures, driveways footpaths, headwalls, base slabs, sign structures. Large footings, retaining walls	32 50	320 (380) 350 (455)	20 20	24 36	32 50
Extruded concrete Safety Barriers	25 40	270 (330) 330 (380)	14 20	15 24	20 40

Note—the total cement and Portland cement quantities indicated as minima are aimed at providing suitably durable concrete for exterior public works under normal circumstances.

The strengths specified at 28 days shall be increased by multiplying by factors as shown in Table SC6.4.6.28.6 Concrete age conversion factors for tests at ages in excess of 28 days.

Table SC6.4.6.28.6 Concrete age conversion factors

*Age of test specimen in days of date of testing	Factor
28	1.00
35	1.02
42	1.04
49	1.06
56	1.08
70	1.10
84	1.12
112	1.14
140	1.16
168	1.18
196	1.20
224	1.22
308	1.24
365 and greater	1.25
*For intermediate ages the factor shall be determined on a pro-rata basis	

If the test specimens fail to achieve the specified characteristic strength, the Contractor may, with the approval of the Superintendent, arrange for cores to be taken from the work. If the average strength of such cores complies with the specified requirements nominated in Table SC6.4.6.28.5 Concrete strength requirements, the concrete will be accepted.

If cores taken fail to satisfy the strength requirements, the concrete shall be removed.

(13) Sampling concrete

Equipment and facilities shall be provided by the Contractor for the taking and storage of samples of any materials or concrete being used, or intended to be used in the work.

Concrete test specimens shall be cylinders 300mm long and 150mm diameter, moulded concurrently in the presence of the Superintendent or Superintendent's representative, in accordance with AS1012.8, from samples taken in accordance with AS1012.1.

SC6.4.6.28.6 Reinforcement for concrete

(1) Fibre reinforced concrete

Footpath/Bikeways/Driveways.
The concrete shall be reinforced with a mixed dose of High Performance Polymer and Discreet Graded Fibrillated filament fibres. These fibres shall be provided as a coarse filament in an engineered contoured sinusoidal profile of not less than 600 denier and discreet graded fibrillated filament fibres of not greater than 6 denier. These fibres are to be manufactured from virgin polypropylene and added to the concrete by the concrete company, at the rate of 4.6kg/m^3. The 4.6kg consists of 3.8kgs of HPP and 0.8kgs of discrete Graded Fibrillated filament fibres.

Two bags of "Novomesh" HPP as supplied by Tapex Concrete Fibres Qld or approved equivalent added per m^3, will be deemed suitable for council's use. Where footpaths/bikeways are not subject to wheel loads one bag of fibres per m^3 will suffice.
Any alternate product must have prior written approval obtained from council.

(2) Steel reinforcement

Steel reinforcement shall comply with AS/NZS4671 *Steel reinforcing materials*.
The type and size of bars shall be as shown on the drawings.

If changes are proposed to reinforcement shown on the drawings, submit details to superintendent for approval 2 days prior to commencing works.
Steel reinforcement shall be free from loose or thick rust, grease, tar, paint, oil, mud, millscale, mortar or any other coating, but shall not be brought to a smooth polished condition.

Damaged galvanising must be repaired in accordance with AS/NZS4680 Section 8 and notification of repairs made to the superintendent for approval.

The Contractor shall supply evidence satisfactory to the Superintendent that steel reinforcement complies with AS/NZS4671. Test certificates shall show the results of mechanical tests and chemical analysis.

Where the material cannot be identified with a test certificate, samples shall be taken and testing arranged by the Contractor. The samples shall be selected randomly and consist of three specimens each at least 1.2m in length. The cost of all samples and tests shall be borne by the Contractor.

Plastic bar chairs or plastic tipped wire chairs shall be capable of withstanding a load of 200kg mass on the chair for one hour at 23 ± 5°C without malfunction. The Contractor shall demonstrate that the proposed chairs conform with these requirements.

(3) Bending

Reinforcement shall be formed to the dimensions and shapes shown on the drawings. It shall not be bent or straightened in a manner that will injure the material, and bars with kinks or bends not shown on the drawings will not be accepted. Heating of reinforcement for purposes of bending will only be permitted if uniform heat is applied. Temperature shall not exceed 450°C and the heating shall extend beyond the portion to be bent. Heated bars shall not be cooled by quenching.

(4) Splicing

(a) General

All reinforcement shall be furnished in the lengths indicated on the drawings. If splicing is required, it shall be in accordance with the provisions of AS/NZS4671.

The cost of any test ordered in connection with splices not shown on the drawing shall be borne by the Contractor.

(b) Lapped splices

Laps in reinforcing bars, wire or fabric shall be as shown on the drawings. Laps not shown on the drawings shall be as follows for unhooked bars:

(i) Plain bars, Grade 250 40 bar diameters.

(ii) Deformed bars, Grade 400 35 bar diameters.

(iii) Hard-drawn wire 50 bar diameters.

Splices in reinforcing fabric shall be so made that the overlap, measured between outermost transverse wires of each sheet of fabric is not less than the spacing of those wires plus 25mm.

(5) Marking

Bars of identical shape shall be made up in bundles of three and securely tied together by soft iron wire. Each bundle shall have a stout metal label of not less than 40mm diameter attached to it. Each metal label shall be punched with the appropriate marking in accordance with the steel list shown on the drawings. If called for on the drawings the marking shall incorporate a prefix, and bars with different prefixes shall be stored separately.

(6) Storage

Reinforcement shall be stored above the surface of the ground and shall be protected from damage and from deterioration by exposure.

(7) Delivery and receipt of reinforcement

Unless the Contractor elects to have the reinforcement inspected at the site, no reinforcement shall be delivered to the site until all tests and inspections have been satisfactorily completed and permission to deliver has been granted by the Superintendent.

The Contractor shall give 10 working days' notice to the Superintendent for carrying out inspection and testing. The Superintendent will carry out the inspection and testing with reasonable expediency, but the Contractor shall not be entitled to an extra as a result of any delays in this connection.

(8) Placing

Reinforcement shall be accurately placed as shown on the drawings and shall be securely held by blocking from the forms, by supporting on concrete or plastic chairs, or metal hangers, and by wiring together at all intersections or at 0.5m centres, whichever is the greater distance, using annealed iron wire of diameter not less than 1.25mm. Steel shall not be supported on metal supports which extend to the surface of concrete, on wooden supports, or on pieces of coarse aggregate. Reinforcement shall have the minimum cover shown on the drawings or otherwise approved by the Superintendent.

The Superintendent may approve the use of tack welding instead of wire ties on reinforcing wire. All welding of reinforcing steel shall be in accordance with AS1554.3. Tack welding of cold-worked and hard grade bars shall not be permitted.

The reinforcement in each section of the work shall be approved by the Superintendent before any concrete is deposited in the section and adequate time shall be allowed for inspections and any corrective work which may be required. Notice for inspection shall not be less than four normal working hours.

Splices shall be staggered where practicable and when not shown on the drawings they shall be arranged as directed by the Superintendent.

Bars forming a lapped splice shall be securely wired together in at least two places, unless welded.

The clear cover of any bar, including stirrups, to the nearest concrete surface shall be as shown on the drawings. Where not so indicated it shall be as stated below:

(a) concrete normally in contact only with air:

(i) slabs: 40mm;

(ii) other than slabs: 45mm; and

(b) concrete in contact with earth or fresh water:

(i) slabs of box culverts: 50mm; and

(ii) other than culverts: 50mm.

(9) Cores, fixings and embedded items general

Cores, fixings and embedded items identified on shop drawings showing the proposed locations, clearances and cover, and indicating proposed repositioning of reinforcement must be presented for inspection by the superintendent.

If cutting or coring of hardened concrete is proposed, provide details to the superintendent for approval.

For adjoining elements to be fixed to or supported on the concrete, provide for the required fixings. If required, provide for temporary support of adjoining elements during construction of the concrete.

If in external or exposed locations, galvanize anchor bolts and embedded fixings, or propose alternative materials such as stainless steel.

Fix cores and embedded items to prevent movement during concrete placing. In locating cores, fixings and embedded items, reposition but do not cut reinforcement, and maintain cover to reinforcement.

Isolate embedded items so that water cannot track to concrete providing minimum cover to reinforcement.

SC6.4.6.28.7 Backfilling

(1) General

Backfilling at barriers, paving, etc., and minor concrete works shall not commence until after the concrete has hardened and not earlier than three days after placing.

No superimposed load on any part of what will become a load bearing structure within 21 days after placing concrete shall occur unless the structure is effectively and independently supported to the satisfaction of the Superintendent (approval must be sought at a minimum of 3 working days prior to loading upon evidence of early strength) or until the Contractor can demonstrate that 85% of the design strength of the concrete has been achieved.

Selected backfill shall be placed against retaining walls and cast-in-place box culverts for a horizontal distance equal to one-third of the height of the wall. It shall consist of granular material, free from clay and stone larger than 50mm gauge. The Plasticity Index of this selected backfill material shall not be less than 2 or more than 12 when tested in accordance with AS1289.3.3.1. The material must be placed in layers not exceeding 150 mm and must be compacted to provide a relative compaction as specified in sub-section SC6.4.6.10 - Earthworks (construction).

(2) Treatment at weepholes

Drainage adjacent to weepholes shall be provided by either a layer of broken stone or river gravel consisting of clean, hard, durable particles graded from 50mm to 10mm such that:

(a) the maximum particle dimension shall not exceed 50mm; and

(b) no more than 5% by mass shall pass the 9.5mm A.S. sieve.

The broken stone or river gravel, enclosed in a filter fabric suitable for drainage without scour, shall be continuous in the line of the weepholes, extend at least 300mm horizontally into the fill and extend at least

450mm vertically above the level of the weepholes.

Alternatively the Contractor may provide a synthetic membrane of equivalent drainage characteristics at no extra cost to the Principal. It shall be stored and installed in accordance with Manufacturer's instructions. The use of a synthetic membrane shall be subject to the Superintendent's approval.

SC6.4.6.28.8 Sprayed concrete

(1) References

NSW RTA – *Shotcrete Design Guidelines*.

(2) General

Sprayed concrete is concrete pneumatically applied at high velocity on to a surface. Application may be either a wet or dry process. A sound homogeneous product shall be provided with surface finish reasonably uniform in texture and free from blemishes.

The minimum depth of sprayed concrete to be applied shall be 75mm.

Sprayed concrete lining in open drains shall be coloured to match the adjoining rock colour.

Sprayed concrete shall have a minimum cement content of 380kg/m3 as discharged from the nozzle and shall have a minimum compressive strength of 25MPa at 28 days when tested by means of 75mm diameter cores taken from in-place sprayed concrete.

Cores shall be secured, accepted, cured, capped and tested in accordance with AS1012.14. Equipment and facilities shall be provided by the Contractor for the taking of cores from the work. The Contractor shall arrange for a laboratory with appropriate NATA registration for the curing and testing of the cores. Copies of test results shall be forwarded to the Superintendent.

The cost of all work and material required in the taking, handling, delivery and testing of cores shall be borne by the Contractor.

At least 14 days prior to applying any sprayed concrete the Contractor shall submit to the Superintendent details of his proposed procedure, plant, materials and mix proportions. Materials shall comply with AS3600.

(3) Test panels

Not less than 7 days before applying concrete, the Contractor shall prepare at least three test panels for each mix proposed, in conditions similar to those in the works and in the presence of the Superintendent. The test panels shall be made by applying a 75mm thickness of sprayed concrete to a hardboard panel approximately 750mm square. The sprayed concrete shall be applied to the panels in the same manner, using materials including steel reinforcing fabric, equipment, pressures and curing that will be used in the Works. The panels shall be submitted to the Superintendent for examination.

The Contractor shall cut four 75mm diameter cores from one test panel for each proposed mix approximately 48 hours after the panel has been sprayed. The cores shall be tested as for cores from in-place sprayed concrete. One core shall be compression tested at 3 days, one core at 7 days and the remaining two cores at 28 days.

Should any of the cores reveal defects such as lack of compaction, dry patches, voids or sand pockets or should the test panel exhibit an unacceptable surface finish, the Contractor shall modify the mix design and/or method of placement and prepare fresh test panels for testing and inspection.

Sprayed concrete shall not be applied to the Works until the Contractor produces test panels for the approval of the council.

(4) Surface preparation

Earth surfaces shall be graded, trimmed and compacted and shall be dampened prior to applying the sprayed concrete. The Contractor shall take any precautions necessary to prevent erosion when the sprayed concrete is applied.

Rock surfaces shall be cleaned of loose material, mud and other foreign matter that might prevent bonding of the sprayed concrete onto the rock surface. The rock surface shall be dampened prior to applying the sprayed concrete.

Corrugated steel pipes shall be cleaned of loose material, mud and any other foreign matter.

The Contractor shall remove free water and prevent the flow of water which could adversely affect the quality of the sprayed concrete.

(5) Application of sprayed concrete

Application shall begin at the bottom of the area being sprayed and shall be built up making several passes of the nozzle over the working area. The nozzle shall be held so that the stream of material shall impinge as nearly as possible perpendicular to the surface being coated. The velocity of discharge from the nozzle, the distance of the nozzle from the surface and the amount of water in the mix shall be regulated so as to produce a dense coating with minimum rebound of the material and no sagging. Rebound material shall be removed after the initial set by air jet or other suitable means from the surface as work proceeds and disposed of.

Spraying shall be discontinued if wind causes separation of the nozzle stream.

Concrete shall not be sprayed in air temperatures less than 5 °C.

Construction joints shall be kept to a minimum. A joint shall be formed by placing or trimming the sprayed concrete to an angle between 30° and 45° to the sprayed concrete surface. The joint edge shall be cleaned and wetted by air-water jet before recommencing concrete spraying.

When spraying around reinforcement, concrete is to be sprayed behind the reinforcement before concrete is allowed to accumulate on the face of the reinforcement.

Adjoining surfaces not requiring sprayed concrete shall be protected from splash and spray rebound. Splash or rebound material on these adjoining surfaces shall be removed by air-water jet or other suitable means as work proceeds.

(6) Curing

Curing shall commence within one hour of the application of sprayed concrete and may be by water or by colourless wax emulsion curing compound complying with AS3799 and applied in accordance with manufacturer’s specifications.

In water curing, the surface of the sprayed concrete shall be kept continuously wet for at least 7 days.

SC6.4.6.28.9 Summary of limits and tolerances

The limits and tolerances applicable to the various clauses in this Specification are summarised in Table SC6.4.6.28.7 – Summary of limits and tolerances below:

Item	Activity	Limits/Tolerances	Clause
1.	**Foundation**		
	(a) Relative Compaction	³95% RDD(standard compactive effort) within 0.3m below subgrade	SC.6.4.6.28.2(1)
2.	**Barriers, Footpaths etc.**		
	(a) Finished Subbase	To be trimmed and compacted so that the levels do not vary more than 15mm under a straight-edge 3m long.	SC6.4.6.28.2(2)

Item	Activity	Limits/Tolerances	Clause
	(b) Relative Compaction of Subbase	³100% (standard compactive effort)	SC6.4.6.28.2(2)
3.	**Formwork**		
	(a) Position of Forms	Forms shall be aligned accurately so that departure of the forms from the surfaces specified on the drawings shall not exceed 1/300 of the space between supports for any surface visible in the completed work and 1/150 for hidden work.	SC6.4.6.28.3(5)
4.	**Fine Aggregate**		
	(a) Grading	To be evenly graded within the absolute limits and shall not deviate from the grading of sample aggregate as per Table SC6.4.6.28.1.	SC6.4.6.28.4(3)
5.	**Coarse Aggregate**		
	(a) Percentage of wear	Loss of weight shall not exceed 30%	SC6.4.6.28.4(4)
	(b) Crushing Value	Crushing value shall not exceed 25%	SC6.4.6.28.4(4)
	(c) Soundness	The loss of mass when tested with sodium sulphate shall not exceed 12%	SC6.4.6.28.4(4)
	(d) Particle Shape	The proportion of misshapen particles (2:1 ratio) shall not exceed 35%	SC6.4.6.28.4(4)
	(e) Grading	To be evenly graded within the absolute limits and shall not deviate from the grading of sample aggregate as per Table SC6.4.6.28.2.	SC6.4.6.28.4(4)
6.	**Aggregate Moisture Content**	Where moisture content of fine aggregate exceeds 8%, or moisture content of coarse aggregate exceeds 3%, the proportion of mix shall be changed.	SC6.4.6.28.5(2)
7.	**Consistency**	In accordance with AS1012.3, Method 1 the slump shall not exceed the nominated slump ±15 mm.	SC6.4.6.28.5(4)
		In the case of concrete placed by extrusion machine, the slump will be between 10mm and 15mm.	SC6.4.6.28.5(4)
8.	**Ready-Mixed Concrete**		
	(a) Mixing & Delivery	The time taken from the introduction of water until the concrete is completely discharged shall be not more than 1.5 hours. Where non-agitating equipment is used the concrete shall be completely discharged not more than 30 minutes after the addition of water.	SC6.4.6.28.5(5)
9.	**Placing & Compacting of Concrete**	Concrete shall not be placed without the approval of the Superintendent if the air temperature within 24 hours is likely to be below 5°C or the shade temperature is likely to exceed 38°C.	SC6.4.6.28.5(6)
10.	**Finishing of Unformed/Formed Concrete Surfaces**		
	(a) Wearing Surface	to be finished true and uniform so that departure from designed grade shall not exceed 5mm in any 3m length.	SC6.4.6.28.5(7)(b)
	(b) Finished Surfaces		

Item	Activity	Limits/Tolerances	Clause
	(i) Not Adjacent to Roads	≤25mm Plan position	SC6.4.6.28.5(7)(c)
		≤25mm Level	SC6.4.6.28.5(10
	(ii) Adjacent to Roads	≤10mm Alignment	SC6.4.6.28.5(7)(c)
		≤10mm Level	SC6.4.6.28.5(10)
	(iii) Culvert Inverts	≤25mm Alignment	SC6.4.6.28.5(7)(c)
		≤10mm Level	SC6.4.6.28.5(10)

SC6.4.6.29 Boundary fencing

SC6.4.6.29.1 Introduction

(1) Scope

The work to be executed under this sub-section includes setting out, clearing of fence line, supply of material and erection of fencing and gates, in accordance with the drawings or as directed by the Superintendent.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections:

SC6.4.6.11 - Clearing and grubbing

SC6.4.6.28 - Minor concrete works

(b) Australian Standards:

AS 1289.5.4.1 - *Compaction control test - Dry density ratio, moisture variation and moisture ratio.*

AS 1725.1 – *Chain link fabric fencing - Security fences and gates.*

AS 2423 - *Coated steel wire fencing products for terrestrial, aquatic and general use.*

(c) Queensland Department of Transport and Main Roads publication:

Manual of Uniform Traffic Control Devices (Queensland) (MUTCD)

SC6.4.6.29.2 Materials

(1) General

All materials shall be supplied by the Contractor and shall be of dimensions, manufacture and quality in accordance with the requirements of this policy and all galvanised wire fencing products shall conform to AS 2423.

For each type of material to be supplied, the Contractor shall submit to the Superintendent for approval the source, manufacturer, and also the type if applicable.No materials shall be used until approved by the Superintendent.

(2) Galvanised posts, braces and rails

All posts, bracing and rails shall be galvanised iron pipe in accordance with AS 1725.1. The pipes shall be to the dimensions shown on the drawings.

All pipe joints shall be welded. All welds shall be satisfactorily cleaned and painted with a cold galvanising compound to the satisfaction of the Superintendent.

(3) Chain wire

Galvanised chain wire mesh, 1200 mm high, 1450 mm high or 1830 mm high for Manproof Fencing shall be of 3.15 mm diameter wire woven to a 50 x 50 mm square mesh. Chain wire shall be supplied in lengths of not less than 30 m. The zinc coating shall be uniform, continuous, free from imperfections and thoroughly adherent. The coating shall be applied to the wire before the mesh is woven. The weight of the zinc coating shall not be less than 290 g/sq m of wire surface.

Where specified, the chain wire shall be coated in black PVC after galvanising.

(4) Wire netting

Wire netting shall be standard quality galvanised 1.40mm diameter wire, 40mm mesh, 1.05m wide for normal use and 1.60mm diameter wire, 50mm mesh, 0.90m wide where used in creek crossings.

(5) Gates

Gates shall be of galvanised tubular steel construction, 3.6m in width by 1.5m or 1.2m (as specified) in height,

and shall be fitted with substantial hinges, catch, drop bolts and locking chains unless otherwise shown on the drawings or directed by the Superintendent.

Where required, gates shall have stout and well supported rabbit-proof mesh to a height of at least 900mm above ground level.

(6) Reinforced concrete posts

(a) Strainer posts
Concrete strainer posts shall be approximately 150 x 150 square in section and lengths as shown on the drawings. Each post shall be provided with 12mm dia holes to suit the spacing of the wires shown on the drawings for the particular type(s) of fencing to be erected.

The posts shall be reinforced longitudinally with not less than four reinforcing bars each 12mm diameter. All posts shall have suitable stirrup reinforcement to control diagonal cracking. Longitudinal reinforcement shall have 25mm minimum cover. End cover on reinforcement shall be 25mm.

(b) Intermediate posts
Intermediate Posts shall generally conform to the requirements for Strainer Posts, except that the longitudinal reinforcing bars may be 9mm dia.

(7) Prestressed concrete posts

(a) Strainer posts
At least four longitudinal high carbon deformed high tensile strands (or equivalent) of 5mm diameter, shall be provided. The strands shall be tensioned to a stress of 800 MPa minimum prior to placing concrete. Cross sectional dimensions of the posts shall be as shown on the drawings.

Concrete shall have a minimum compressive strength of 32 MPa at 24 hours. In lieu of holes for wires, grooves may be provided to suit the spacing of the wires shown on the appropriate drawings for the particular types of fencing to be erected. The grooves shall be at least 5mm deep and 5mm wide at the surface of the post.

(b) Intermediate posts
Intermediate posts and strainer stays shall generally conform to the requirements for Strainer Posts except that two only high tensile, high carbon deformed strands shall be required.

Cross sectional dimensions shall be as shown on the drawings.

(8) Steel posts (rural fencing)
Steel posts shall be "STAR" pattern. Posts shall be drilled to suit the spacing of the wires shown on the Drawing(s), and shall be black varnished or galvanised. The total weight of 300 posts each 1.65m long shall be at least 1 tonne.

(9) Galvanised pipe posts (rural fencing)
Galvanised pipe posts shall be used where shown on the drawings. The pipes shall be of the dimensions shown on the drawings and shall be of first grade quality in accordance with AS 1725.

(10) Wires

(a) Plain wire
Plain wire shall be standard galvanised drawn annealed steel wire of diameters shown on the drawings.

(b) High tensile plain wire
High tensile wire shall be galvanised and of diameters shown on the drawings.

(c) Barbed wire
Barbed wire including barbs shall be 2.5mm diameter galvanised drawn annealed steel wire, with clusters of four barbs spaced at 90mm maximum. Alternatively barbed wire may be of 1.6mm diameter high tensile steel wire, with clusters of barbs spaced at 90mm maximum.

(d) Cable wire
Cable wire shall consist of three pairs of 2 x 3.15mm galvanised iron wire tightly twisted around posts and located as shown in the drawings.

(e) Tie wire
The wire shall be 2mm diameter galvanised wire.

(11) Concrete backfilling
All concrete backfilling of post holes specified on the drawings shall be of minimum 20 MPa 28 day compressive strength and shall conform to the requirements of sub-section SC6.4.6.28 Minor concrete works.

SC6.4.6.29.3 Construction

(1) General
Fencing shall be erected prior to the commencement of other work on a particular section of the work, unless directed otherwise by the Superintendent.

All fencing shall be erected in a workmanlike manner, and when completed shall be sound, strong and of neat appearance.

For a clear width of one metre on either side of the fence line, and for the full length of the line, all logs, boulders, stumps, roots, undergrowth and rubbish shall be removed and disposed of by the contractor in accordance with SC6.4.6.11 Clearing and grubbing. Trees within this area shall be removed only as directed by the Superintendent and approved by council's authorised officer.

If trees on or adjacent to the fence line are to be retained the arrangement of the fencing at the trees shall be as directed by the Superintendent.

Wire shall not be strained around or against any trees to be left in the fence line, and strainer posts are to be provided on both sides of each tree.

Where minor irregularities occur in the ground the vertical alignment of the fence shall not follow these irregularities, but shall be aligned to a uniform grade between definite changes in the natural slope of the ground.

All boundary fencing is to be erected on the common boundary line (where practicable) which has been surveyed and marked with pegs by a registered cadastral surveyor. The placement of the proposed fence (including footings), relative to the marked boundary line, is to be such that no (or minimal) loss of accessible land results for either property owner once the fence is erected. Any deviation of the proposed fence line away from the marked property boundary is to be mutually agreed to by all parties prior to erection of the fence.

The Contractor shall maintain the fencing at all times in a condition secure against the ingress or egress of stock, and shall take such precautions as are necessary to prevent people or stock from stepping into holes excavated for the construction of fencing.

Where old fencing is to be replaced by new fencing, all holes left after removal of the old fencing shall be backfilled and rammed firmly in layers of maximum depth 150mm.

The Contractor shall be held responsible for any loss, damage, or injury to buildings, goods, crops, livestock, property of any kind or persons due to negligence on the Contractor's part.

(2) Chain link fencing

(a) Erection of posts
All posts shall be erected vertically and set in concrete blocks approximately 250mm diameter and 600mm deep except for end, corner, strainer and gate posts which shall be set in concrete blocks approximately 250mm diameter and 900mm deep unless otherwise shown on the drawings. Concrete shall have a minimum compressive strength of 20 MPa at 28 days and shall conform to the requirements

of sub-section SC6.4.6.28 Minor concrete works.

Galvanised weather caps shall be fitted to all galvanised posts.

Strainer posts shall be used at ends of fencing, angles, intersections with other fencing, gates and at intermediate points. Distances between strainer posts shall not exceed 120m.

(b) Erection of wire

All wire shall be spaced as shown in the drawings. Wire shall be securely fastened and strained to an even tension between strainer posts.

Where specified, or shown on the drawings, chain wire mesh shall be erected on the outside of the posts and fastened with two turns of tie wire to each cable wire on both sides of each post and at intervals of not more than 900mm between posts and to each post midway between cable wires.

(3) Stock-proof fencing

(a) Erection of posts

All posts shall be erected vertically. Reinforced concrete posts shall be erected in neatly cut holes sunk in earth, or in rock where this is encountered. Steel posts, except where placed in rock, shall be driven with suitable driving equipment, care being taken not to damage the tops of the posts during driving.

Where prestressed posts are proposed to be used, they shall be either erected as for reinforced concrete posts or shall be driven. Where driven, the Contractor shall use a suitable post driver which shall be equipped with two sets of guiding rollers, to hold the post vertical and in position during driving.

A steel cap with a plywood cushion shall be used to protect the top of the post during driving.

If the post cannot be driven for the full depth specified, or if it becomes significantly damaged, or cannot be driven vertically, it shall be removed. The same post if undamaged, or a new post, shall be erected as described for reinforced concrete posts.

Posts shall be sunk to the depths shown in Table SC6.4.6.28.1 Post depth in ground.

Table SC6.4.6.29.1 Post depth in ground

Type of Post	Depth	
	Earth	Rock
Concrete Corner Posts and Strain Posts	900	*600
Concrete Intermediate Posts	600	*450
Steel Posts	450	450

Note —*permitted only in cases where posts of the correct length are provided (see below), otherwise the depth of sinking shall be the same as for earth.

Cutting of concrete posts will not be permitted, and in order to take advantage of the lesser depth of sinking permitted in rock, it will be necessary to use posts manufactured in lengths to suit the depth of sinking. Where rock is encountered, steel posts shall be sunk in drill holes of sufficient diameter to permit them to be refilled with cement mortar consisting of one part of cement to two parts of clean sand.

Earth shall be backfilled around intermediate posts in layers of maximum depth 150mm for the full depth of the hole and up to ground level. The relative compaction of the rammed material shall be not less than that of the original undisturbed ground.

Where concrete posts are placed in rock, the space around the posts shall be tightly filled with cement mortar consisting of one part of cement to two parts of sand, or concrete where this is available.

Strainer posts shall be used at ends of fencing, angles, intersections with other fencing, gates and at intermediate points. These posts shall be backfilled with approved concrete to their full depth.

Distances between strainer posts shall not exceed 120m in the case of fencing using steel intermediate posts, and 90m in the case of fencing for the retention of cattle (for which only concrete posts are permitted). Junctions with existing fencing shall be made in an approved manner.

(b) Erection of wires

All wire shall be placed as shown on the drawings. Wires shall be securely fastened and strained to an even tension between strainer posts with an approved wire strainer. Where barbed wire is to be used, it shall be tied in position at the top of intermediate posts, and where additional barbed wires are called for they shall be secured to the sides of the posts as shown on the drawings.

Where concrete posts are used and the barbed wires are secured either to the tops or sides of the posts by tie wire, the tie wire shall be stretched tight and shall fit snugly against the sides of the posts to prevent movement of the barbed wire.

Where prestressed posts are used, wires shall be securely tied so that they seat firmly in the grooves.

All joints in wires shall be as shown on the drawings.

(4) Crossing of watercourses and depressions

The crossing of all watercourses and depressions, shall be made secure by longer posts, suitably strutted as directed by the Superintendent. Additional cable wire and chain wire/wire netting shall be provided as necessary to make the fence stock proof.

The fence shall allow the passage of floodwater without the accumulation of debris. If directed by the Superintendent, flood gates shall be provided in accordance with clause SC6.4.6.29.3(6) Flood gates.

(5) Connections to existing fences

Existing cross fences shall be connected to the new fence using a strainer post with braces in each direction of strain (including cross fence) and the wires in both fences properly fastened to the post.

(6) Flood gates

(a) General

Suitable provision for the passage of flood waters past the fence shall be made at all watercourses. In all cases flood gates shall be of the type indicated on the drawings, or as directed by the Superintendent, and shall be erected so as to prevent the accumulation of flood debris, while remaining stock-proof or rabbit-proof.

(b) Small watercourses

Flood gates, in accordance with the drawings, shall be provided in small gullies at the locations indicated on the drawings or as directed by the Superintendent. The opening of each flood gate shall provide a waterway area at least twice that of the culvert opposite to which it is placed, or as otherwise directed by the Superintendent.

(c) Large gullies and creeks

Flood gates, in accordance with the drawings, shall be provided in gullies and creeks at the locations indicated on the drawings, or as directed by the Superintendent.

A 9mm galvanised wire rope shall be carried over the gully in one span, threaded through a strainer post and tied back to an anchor at an adjacent concrete intermediate post. Turnbuckles are to be provided at each end to tension the wire rope. Netting shall be suspended from the wire rope and shall be overlapped and securely tied. The netting shall be of sufficient length to lie on the ground for a distance of not less than 1.0m on the downstream side.

Ballast, of sound timber securely tied to the netting, shall be provided at the downstream end of the netting.

The sides of the gully shall be trimmed, as necessary, to ensure that the flood gate shall be stock-proof

or rabbit-proof. The flood gate shall have sufficient movement of the suspended portion under the flow of flood waters to prevent damage to the fence and the accumulation of debris against it. Each strainer post shall be stayed in three directions, as shown on the drawings.

(7) Erection of gates

Where gates are specified or shown on the drawings, they shall be erected so that they swing away from the road. Double gates shall be supplied if directed by the Superintendent, otherwise a single gate only shall be supplied.

At the location of gates the surface shall be levelled and shall be nearly horizontal. The area where the gates swing shall be similarly levelled.

The gates shall be hung as indicated in the drawings.

(8) Where required, existing fencing is to be removed as shown on the drawings.

No fencing is to be removed if there is a risk of egress or ingress of stock. If the existing fence is a rabbit-proof fence, then the contractor shall ensure that at night and weekends and other such times when work is not in hand that the whole of the fence is maintained in a rabbit-proof condition, even if temporary fencing is required.

All material removed in demolishing existing fencing shall be disposed by the Contractor as provided by clause SC6.4.6.29.3(9) Removal and disposal of surplus material and rubbish.

(9) Removal and disposal of surplus material and rubbish

All surplus material, offcuts, timber, roots and other debris resulting from the fencing contract shall be removed or otherwise disposed of to the satisfaction of the Superintendent.

The contractor shall not burn any timber, vegetation or refuse on site unless specifically approved by council's authorised officer.

(10) Cattle grids

Cattle grids shall be erected in accordance with the drawings.

The cattle grid shall be evenly bedded on a continuous layer of compacted sand or other granular material approved by the Superintendent. The bedding material shall be compacted so that the relative compaction as determined by AS 1289.5.4.1 is not less than 95 per cent.

Cattle grids shall be installed on raised abutments with approach ramps where possible. Alternatively, a cattle grid may be placed over an excavated pit, in which case adequate drainage shall be provided.

Crossfall for single lane cattle grids shall be level and for two lane cattle grids each section shall have a crossfall conforming to the crossfall of the approach road.

The cattle grid construction shall include all activities associated with the cattle grid including any adjustments to the fencing as shown on the drawings.

Advance signposting, in accordance with MUTCD, shall be provided on each approach to the cattle grid in accordance with sub-section SC6.4.6.24 Signposting.

SC6.4.6.30 Control of traffic

SC6.4.6.30.1 Introduction

(1) Scope

This sub-section provides standards, advice and guidelines for work necessary to provide for the safe movement of traffic and the protection of persons and property through and/or around the work site.

The extent of work includes the design, construction, maintenance and removal of temporary roadways and detours, the provision of traffic controllers, signposting, roadmarkings, raised pavement markers, lights, barriers and any other items required. All temporary traffic arrangements required by works are included under this sub-section except where specified otherwise.

Control of traffic shall be in accordance with Manual of Uniform Traffic Control Devices (MUTCD), this sub-section, and the drawings.

(2) Reference and source documents

Documents referenced in this sub-section are listed in full below whilst being cited in the text in the abbreviated form or code indicated.

(a) Development manual planning scheme policy sub-sections to be read and applied in conjunction with this sub-section one as follows:

SC6.4.6.4 - Stormwater drainage
SC6.4.6.5 - Drainage structures
SC6.4.6.6 - Pipe drainage
SC6.4.6.9 - Open drains
SC6.4.6.10 - Earthworks (construction)
SC6.4.6.11 Clearing and grubbing
SC6.4.6.12 - Flexible Pavements
SC6.4.6.13 - Asphaltic concrete
SC6.4.6.16 - Sprayed bitumen surfacing

(b) Australian Standards:

AS 1742 – *Manual of uniform traffic control devices*
AS 1742.3 - *Manual of uniform traffic control devices – Traffic control for works on roads*
AS 1743 - *Road Signs - Specifications*
AS 1744 - *Standard alphabets for road signs*
AS/NZS 1906 - *Retroreflective materials and devices for road traffic control purposes*
AS/NZS 4602 - *High visibility safety garments*

(c) Austroads publications:

Guide to Road Design - Part 3 Geometric Design
Guide to Traffic Management – Part 6 Intersections, Interchanges and Crossings
Guide to Road Safety – Part 9 Roadside Hazard Management

(d) Queensland Department of Transport and Main Roads publication:

Manual of Uniform Traffic Control Devices (Queensland) (MUTCD).

(e) Other:

International Erosion Control Association (IECA), *Best Practice Erosion and Sediment control council*

(3) Traffic guidance scheme

The Contractor shall construct the work with the least possible obstruction to traffic.

Two weeks before undertaking work which would involve any obstruction whatsoever to traffic the Contractor shall submit, for the Superintendent's approval, a Traffic guidance scheme in accordance with Part 3 of the MUTCD.

The Traffic guidance scheme shall include:

(a) design drawings for any temporary roadways and detours in accordance with clause SC6.4.6.30.2(3) Design drawings, showing pavement, wearing surface and drainage details;

(b) details of arrangements for construction under traffic in accordance with Part 3 of MUTCD;

(c) a signpost layout plan showing:

  (i) location, size and legend of all temporary signs;

  (ii) temporary regulatory signs and temporary speed zones, and

  (iii) all traffic control devices such as temporary traffic signals, linemarking, pavement reflectors, guideposts, guard fence and barrier boards; and

(d) working times when traffic control measures are in place to minimise disruption to traffic during periods of peak flows.

The Contractor shall obtain all necessary approvals for temporary traffic arrangements except where specified otherwise.

Where the Traffic guidance scheme involves Regulatory traffic control signs or devices and/or where a disruption to traffic (including pedestrian) to the existing road is likely to be significant, the contractor must undertake consultation with all stakeholders and where identified, must include changes to bus routes and the establishment of temporary bus stops, relocation of any taxi ranks and parking bays for people with disabilities, establishment of any work zones on the roadway amd arrangements for the safe movement of pedestrians past the work site as part of the application to council for approval.

In the case of an intersection with a State controlled road approval from the Department of Transport and Main Roads (DTMR) must also be obtained.

The Traffic guidance scheme shall be in accordance with the requirements of this sub-section and the drawings.

Special consideration to the safety of pedestrians and workers shall be given in the preparation of the Traffic guidance scheme. Particular care shall be taken when requiring reversal of traffic flows or the separation of unidirectional flow by medians or other physical separation.

An approved copy of the Traffic guidance scheme must be kept on site at all times. This must be used to check the arrangement and maintenance of traffic control devices.

For staged works and complex traffic guidance schemes, the Contractor shall conduct a regular safety audit during the construction phase including risk assessments for the workers safety as recommended in *Guide to Road Safety – Part 9 Roadside Hazard Management.*

For non-complex traffic guidance schemes such as short term and mobile works not involving full or part road closure or works involving relatively simple part-roadway closures, the Contractor is required to carry out risk assessments considering factors such as traffic volume and speed, road geometry and width and general behaviours of road users. A fully protected work site will be required if identified risks cannot be tolerated.

(4) Side roads and property accesses

The Contractor shall provide safe and convenient passage for vehicles, pedestrians and stock to and from side roads and property accesses connecting to the roadway. Work that affects the use of side roads and existing accesses shall not be undertaken without providing adequate alternative provisions to the prior satisfaction of the Superintendent.

Where interuptions to access is required, they are to be kept to a minimum and the contractor must advise the property owners of any interruption to access by way of a letter drop at least 24 hours before the intended interruption. The contractor shall repeat this advice verbally to the property owner where possible before proceeding with the access closure. All interuptions to access must have the the approval of the superintendent.

(5) Traffic controllers

The Contractor shall advise the Superintendent of the names of proposed traffic controllers with a signed declaration that they are appropriately trained in the duties of traffic controllers in accordance with the MUTCD.

In situation where restricted sight distance is identified by the Superintendent, an additional traffic controller shall be placed at the tail end of the queue.

(6) Approved clothing for work personnel

All personnel shall wear high visibility clothing to the requirements of the MUTCD.

(7) Temporary speed zoning

Where a temporary speed limit has been approved by the council, or in the case of a gazetted or State controlled road the District Manager of DTMR, the Contractor shall arrange for the supply of appropriate temporary speed zoning signs, including posts and fittings, for erection. Where and when directed by the Superintendent, the Contractor shall erect these signs, cover the signs when the speed zone is not in use and remove the signs when the speed zone is no longer required as part of the provision for traffic. A diary recording operation times of the speed zone shall be kept by the Contractor.

(8) Plant and equipment

During the day plant and equipment working in a position adjacent to traffic and having a projection beyond the normal width of the item, for example, a grader blade, shall have a fluorescent red flag attached to the outer end of the projection. During poor light conditions or at night, an additional traffic controller with an illuminated red wand shall direct traffic around such plant and equipment.

At night, where traffic is permitted to use the whole or portion of the existing road, all plant items and similar obstructions shall be removed from the normal path of vehicles to provide a lateral clearance of at least 6 m where practicable, with a minimum clearance of 1.2 m.

Plant and equipment, within 6 m of the normal path of vehicles, shall be lit by not less than two yellow steady lamps suspended vertically from the point of the obstruction nearest to a traffic lane and one yellow steady lamp at each end of the obstruction on the side furthest away from the traffic lane.

SC6.4.6.30.2 Temporary roadways and detours

(1) Approval

The design of all proposed temporary roadways and detours; to be undertaken in accordance with this policy sub-section

(2) Design standards

The standard of alignment and grading adopted shall be in accordance with specific provisions of this policy and shall otherwise be in accordance with the *Guide to Road Design – Part 3 Geometric Design*

Intersections shall be designed in accordance with the Guide to Traffic Management – Part 6 Intersections, Interchanges and Crossings.

Design drawings, geometric standards, design speed, wearing surface type and pavement design of the proposed temporary roadways and detours shall be submitted by the Contractor with the Traffic Guidance Scheme.

(3) Design drawings

Design drawings submitted for approval should show:

(a) alignment and grading at a horizontal scale of 1:2000 for rural roads and 1:500 for urban roads. Where the temporary road rejoins the existing road, levels showing the full cross section shall be extended along the existing road for a minimum length of 200 m;

(b) a sight distance diagram if opposing traffic is to use a single carriageway;

(c) intersections, and any other locations where traffic may be required to make turning, merging or diverging movements, at a scale of 1:500;

(d) pavement marking details;

(e) sufficient cross sections to indicate the feasibility of making connections between various parts of the work;

(f) sufficient dimensions, especially lane widths, to make clear the geometry and clearances of the proposed works;

(g) a north point or some other location method to orientate the plan;

(h) roadside furniture;

(i) drainage structures (existing/temporary and proposed); and

(j) pavement and surfacing type.

(4) Drainage

Drainage structures and drains shall be constructed in accordance with the following sub-sections:

(a) SC6.4.6.4 - Stormwater drainage;

(b) SC6.4.6.6 - Pipe drainage;

(c) SC6.4.6.5 - Drainage structures; and

(d) SC6.4.6.9 - Open drains.

Drainage proposed in accordance with clause SC6.4.6.30.1(2) Traffic guidance scheme shall be able to cope with upstream rainfall run off resulting from all rainfall intensities up to that expected for a once in five year frequency, without overflow over the road.

Pavements shall be designed and constructed to not pond water on the wearing surface or shoulders. Temporary formations to be constructed shall not dam water.

(5) Construction of earthworks and pavement

Temporary roadways shall be constructed in accordance with the following specifications:

(a) *Best Practice Erosion and Sediment Control*;

(b) SC6.4.6.11 Clearing and grubbing;

(c) SC6.4.6.10 Earthworks (construction); and

(d) SC6.4.6.12 Flexible Pavements.

(6) Surfacing

The wearing surface width shall extend across the full width of the traffic lanes plus the width for each shoulder, or as otherwise demonstarted.

The wearing surface shall be carried onto any existing connecting roadway so as to finish square to the existing roadway centreline.
Surfacing shall be constructed in accordance with:
SC6.4.6.16 - Sprayed bitumen surfacing; and
SC6.4.6.13 - Asphaltic concrete

(7) Road safety barrier

Corrugated steel road safety barrier shall be erected on all temporary embankments where the vertical height between the edge of the shoulder and the intersection of the embankment slope and natural surface exceeds 2m.

Road safety barrier shall be erected in accordance with:
SC6.4.6.25 - Non-Rigid Road Safety Barrier Systems.

(8) Opening to traffic

Temporary roadways and detours (including portable or temporary traffic signals sites) shall not be open to traffic until they have been inspected, approved and authorised in writing.

All signposting, pavement marking, guardfence and portable or temporary traffic signals shall be completed before the opening of temporary roadways to traffic.

The opening of temporary roadways shall be arranged so that sections of existing roadway being replaced are not disturbed for a minimum of 48 hours in the event of temporary roadway failure and there is a warrant to redirect traffic back onto the existing roadway. The determination to redirect traffic shall be by the Superintendent.

The redirection of traffic back onto the existing roadway shall be the responsibility of the Contractor.

Unless otherwise approved by the Superintendent, traffic shall be switched to a temporary roadway or detour only where the Contractor's usual workforce will be on site for a minimum of 2 days thereafter.

(9) Maintenance

The Contractor shall be responsible for the maintenance of temporary roadways and detours and shall ensure the road surface is kept safe for traffic. Any potholes or other failures shall be repaired without delay.

(10) Removal

Upon completion of the work the temporary roadways and/or detour arrangements shall be removed and the area restored to a condition equivalent to that which existed prior to the commencement of the work.

SC6.4.6.30.3 Arrangements for traffic

(1) Construction under traffic

Where a temporary roadway or a detour is not provided or available then, subject to the approval of the Superintendent, construction under traffic may be permitted provided a minimum of 3.5 m lane width is available for through traffic on a two lane roadway and where 3.5 m lanes are available in both directions for through traffic when working on multilane roads.

The carriageway/s shall be restored to a safe and trafficable state for through traffic prior to cessation of work each day in accordance with the approved Traffic guidance scheme.

Full details of temporary signposting, traffic control devices and traffic control methods, in accordance with the appropriate arrangement diagrams in MUTCD, are to be submitted for the Superintendent's approval at least 5 working days before undertaking any work which would involve construction under traffic.

(2) Opening completed work

The Contractor shall give the Superintendent at least 5 working days written notice confirming the date of opening completed work to traffic. The procedure for opening shall be determined through consultation between the Superintendent, the Contractor and the council.

The Contractor shall be responsible for the removal of all temporary traffic control devices no longer required for the safety of traffic, when the works or part thereof are opened to traffic.

SC6.4.6.30.4 Traffic control devices

(1) Arrangement of traffic control devices

The arrangement and placement of traffic control devices shall be carried out in accordance with the approved Traffic guidance scheme, and MUTCD. The arrangement diagrams illustrate the more common examples of the arrangement of traffic control devices and set out the minimum requirements.

All temporary traffic control devices, when no longer required, shall be covered and/or removed without delay in order to maintain unambiguous safe guidance to traffic.

(2) Maintenance of traffic control devices

All traffic control devices shall be maintained in accordance with MUTCD so that they are in good order and in the correct positions day and night. They shall be neat and clean, and signs shall be clear and legible at all times.

To ensure the preceding clause is complied with, the Contractor shall inspect the site at least once every 24 hours for the maintenance of all traffic control devices.

The Contractor may need to be contacted outside normal working hours to arrange for adjustments or maintenance of traffic control devices. The Contractor shall notify the Superintendent and the council in writing, the names, addresses, and means of communicating with personnel nominated for this purpose.

(3) Adequate traffic control devices

Where the Contractor fails to provide and maintain adequate traffic control devices specified in this sub-section, the Superintendent shall arrange to have such items provided and maintained.

(4) Regulatory traffic control signs and devices

A regulatory traffic control sign or device shall be in accordance with the MUTCD, and shall require approval by the council, or in the case of a gazetted or State controlled road, the District Manager of DTMR, before its erection. This approval should be obtained through the Superintendent, refer to clause SC6.4.6.30.1(6) Temporary speed zoning.

(5) Signs

Signs shall be designed and manufactured in accordance with AS 1743. Details of each letter shall be as shown in AS 1744.

The reflective material used on signs shall be Class 2 material complying with AS 1906.1 except where otherwise specified.

(6) Supplementary signs

Signs supplementary to the MUTCD are shown in SC6.4.6.30 Attachment A Supplementary temporary warning signs to MUTCD. Approval must be obtained from DTMR prior to their use.

(a) Heavy Machinery Crossing
This temporary sign, shown as Sign SW5-22, if approved, may be used in lieu of W5-22, trucks entering.

(b) Cycle Hazard Grooved Road
This temporary sign, shown as Sign ST1-10, if approved, may be used in addition to T1-10 of AS 1742.3 where the road is grooved and is a hazard to cyclists.

(c) Tar Spraying Possible Short Delay
This temporary sign, shown as Sign ST3-1, if approved, may be used in addition to T3-1 for bituminous surfacing works.

(7) Flashing arrow signs

Flashing arrow signs shall comply with MUTCD.

(8) Barrier boards

Barrier boards shall comply with MUTCD.

Trestles supporting the barrier boards may be manufactured of timber, metal or other suitable material and shall be yellow. The trestles shall provide firm supports for the barrier board and be kept in place by sandbags suitable devices. The bases of the trestles shall not protrude beyond the ends of the boards.

(9) High visibility mesh fencing

High visibility mesh fencing shall be constructed where shown on the drawings, Traffic Guidance Scheme or as directed by the Superintendent.

High visibility mesh fencing shall be constructed in accordance with MUTCD, containment fences.

The mesh fencing shall be approximately 1 m in height and of a red-orange colured flexible material as approved by the Superindendent.

(10) Temporary post-mounted delineators
In addition to the requirements of MUTCD, temporary post mounted delineators shall be provided in conjunction with high visibility mesh fencing which is erected parallel to and in close proximity to traffic.

(11) Cones and bollards
Traffic cones and bollards shall comply with MUTCD and be placed in accordance with the arrangement diagrams in MUTCD.

Unless cones are firmly fixed in position they shall be used only while work is in progress, or in locations where there is an employee in attendance who shall reinstate any of the cones which have been dislodged by traffic. Otherwise they shall be removed and bollards or barriers substituted.

Cones and bollards used under night conditions shall be reflectorised in accordance with MUTCD.

(12) Traffic warning lamps
Traffic warning lamps shall comply with MUTCD and shall be installed in accordance with MUTCD. The Contractor shall ensure that warning lamps are in good working order, correctly aligned and positioned with respect to the direction of traffic flow each night, before the site is left unattended.

(13) Temporary pavement markings
All pavement markings shall be reflectorised and consist of painted lines, roadmarking tape and/or raised pavement markers in accordance with the relevant Australian Standards or as otherwise approved by the Superintendent and shall be provided in accordance with MUTCD.

Where the adjoining roadway is edgelined, temporary roadways shall be similarly edgelined.

(14) Temporary linemarking
Where temporary linemarking is required on the final wearing surface, only pavement marking tape shall be used.

Where the pavement linemarking has become ineffective in the opinion of the Superintendent, remarking shall be undertaken within 48 hours of direction by the Superintendent.

Where a single carriageway is opened adjacent to or used in lieu of an existing dual carriageway length, pavement arrows indicating the direction of flow of traffic shall be placed at not more than 500 m or at a spacing nominated by the Superintendent. The arrows shall be removed if the section is then reincorporated as dual carriageway.

Immediately before or after placement of new markings all superseded pavement markings shall be obliterated or removed to the satisfaction of the Superintendent.

On a final surface, obliteration by painting shall not be permitted.

(15) Raised pavement markers
Where raised pavement markers have become ineffective in the opinion of the Superintendent, they shall be replaced within 24 hours of direction by the Superintendent.

All superseded raised pavement markers shall be immediately removed from the pavement by the Contractor.

Attachment

SC6.4.6.30 Attachment A Supplementary temporary warning signs to MUTCD

(1) Black letters and border on yellow reflectorised ground.

(2) Dimensions are in mm.

SC6.4.7 Acceptance of completed works

SC6.4.7.1 Release of the plan of survey

SC6.4.7.1.1 Introduction

The Release of the plan of survey sub-section details the requirements that must be met prior to the release of the Plan of Survey.

(1) Principles

Prior to the release of the Plan of Survey the developer must:

(a) comply with all conditions of the development permit; and

(b) ensure that all required fees, bonds, contributions, infrastructure charges and outstanding rates are paid.

Works will not be accepted on maintenance until the formal Plan of Survey has been released.
Where exceptional circumstances exist and an early release of the Plan of Survey is agreed to by the Director Planning and Development, the developer is required to bond any outstanding work.

(2) Terminology

Terms in this policy have the same definition as in the *Planning Act 2017*, unless otherwise defined.

DEHP	*Department of Environmental and Heritage Protection*
Plan of Survey	Includes all surveys undertaken by a cadastral surveyor as defined by the *Surveyors Act* 2003 and for the purpose of: • subdividing one or more lots; or • dedicating land to public use; or • redefining a lot by resurvey; or • amalgamating two or more lots to create a smaller number of lots; or • defining an area for an easement, lease, profit a prendre or covenant; or • any other purpose that the Registrar may require the registered proprietor to undertake.
On maintenance date	The date the works have been inspected and are complete, relevant conditions of the Development Permit have been satisfied, council has accepted maintenance responsibility for agreed public infrastructure and the developer commences the defects liability period.
Off maintenance date	The date the works are fully accepted by council following an inspection by council, which considers that all works are satisfactory, and the defects liability period concludes.
Maintenance period	The period of time between when council accepts the works on-maintenance until council accepts the works off-maintenance. This includes any establishment periods and the defect liability period, the period of time during which the developer is required to repair defects that occur. A defect is an imperfection, fault of deficiency in the works and does not include general wear and tear of items or damage due to misuse.

SC6.4.7.1.2 Release of plan of survey requirements

The following must be received or completed prior to the release of the Plan of Survey.

(1) Certification

(a) The developer must submit one print of each drawing, excluding council Standard Drawings:

(i) as originally approved by council;

(ii) including amendments incorporated in the construction of the development; and

(iii) overprinted with a certificate from a Licensed Surveyor or Registered Professional Engineer of

Queensland (RPEQ) as detailed below.

(b) An RPEQ and/or a Registered Landscape Architect must certify that the completed works comply with the development approval, the specific outcomes of the applicable regulations and good engineering practice.

The RPEQ and/or Registered Landscape Architect must also certify the 'as constructed drawings by including the following statement on each drawing:

"I/We (Name) of (Firm) hereby certify that the works as shown on the 'as constructed' drawings reflect any changes that were made during the course of construction (signed with RPEQ No and dated)".

(c) A Registered Surveyor must certify that the locations, surface and invert levels of all works and infrastructure presented on the as constructed drawings and digital submissions have been surveyed and are true and accurate representations of the works by including the following statement on each as constructed drawing:

"I/We (Name) of (Firm) herby certify that this drawing accurately describes and records the nature and the location of the works depicted hereon as they have been constructed for the purposes of the development (signed and dated)".

(2) As constructed drawings

One signed hard copy and digital copies of the as constructed drawings (AutoCAD DWG and a copy converted to PDF A1 format correctly scaled to A3 size) must be submitted and approved by council. As constructed information must be provided for all completed works, and must include the following information.

(a) Lot

(i) The lot layout as approved and as shown on the Plan of Survey.

(ii) Approved street names.

(b) Earthworks

(i) As constructed contours or where allotments are under 2000m^2 spot levels will be adequate to verify a minimum as constructed surface gradient of 1 in 250.

(ii) Denote location, extent and depth of fill.

(iii) The maximum depth of fill on each lot must be indicated.

(iv) Flood lines as adopted by council.

(v) Street names as approved by council and noted on the Plan of Survey.

(c) Infrastructure

(i) Pavement and kerb and channel information (e.g. edge of pavement and kerb and channel alignment and depths of pavement, kerb type, road surface type and depth, road pavement details, type and depth, road cross sections).

(ii) Stormwater drainage information, including:

(A) pipe alignments denoting sizes and invert levels at each end;

(B) manhole location; and

(C) inlet pit types to be denoted.

(iii) Major overflow paths and trunk drainage channels located and clearly shown.

(iv) Invert levels and offsets of the junction points and manhole connections where roof water drainage systems have been used.

(v) Sewerage 'as constructed plans', including all required details, lodged and approved.

(A) Location of maintenance structure (MH, MC, JU and end of PCS or house drain connection point); and

(B) Material type and sizes.

(vi) Details of all water mains, fittings of consequence and markers, including relevant dimensions,

included on as constructed plans, which are to be lodged and approved.

(vii) Location and dimensioning of subsoil cleanout points.

(viii) BOS data to detail location of house drain connection point - building envelop upgraded.

Editor's note: -

a) The accuracy of as constructed plans locating house connections is essential.

b) Council's Inspector, while on site, may take measurements that will permit some cross checking of as constructed plans. Should these checks indicate discrepancies, then reopening of the work will be required for checking measurement of the work.

(3) Ongoing operational requirements

Where requested, applicants are required to identify the ongoing operational requirements in a relevant Maintenance Plan, as detailed in Section SC6.4.2 Development application guidelines.

(4) The on maintenance inspection

The on maintenance inspection must be satisfactorily completed prior to the release of the Plan of Survey. The Consulting Engineer must undertake and report on the following prior to requesting the on maintenance inspection.

(a) Lodgement

(i) Demonstrated full compliance with all conditions of relevant Development Approvals.

(ii) Building approval for all buildings/structures, where required by the *Building Code of Australia* (BCA).

(iii) Plan of Survey submitted in accordance with approved proposal plan and any approved amendments, or where the Plans of Survey differ from the approved proposal plan, details of any changes must be provided with the application.

(iv) A Supervision Certificate from the Consulting Engineer and request to have the works accepted on maintenance.

(v) Infrastructure Agreements, if required, must be in place for the provision of and/or connection to trunk infrastructure.

(vi) Approval by other authorities, e.g. evidence of NBN Agreement, Certificate of Acceptance or Letter of Supply from Ergon.

(b) Sewer

Sewerage works

(i) Pressure test all sewers and manholes to ensure the requirements of the specification are met.

(ii) Check by internal examination (closed circuit television) that all sewers are straight, clean and to grade.

(iii) Check that all manholes are sound, smooth and clean and benched as per the required standard.

(iv) Check that house connection jump up construction complies with council's standards.

(v) Performance testing of pumping equipment. This testing will require the connection of the electricity supply and water to the pump station.

(vi) Obtain licences for overflows to the sewerage system from DEHP.

All sewerage works including pump stations, rising mains, trunk mains and the proposed sewers must have been inspected and certified by the supervising engineer as being 100 per cent complete and in full working order. Sewer systems must be installed, tested and operational. (Bonding of pump stations may be accepted; refer to SC6.4.7.3 Sewer pump-out agreements.

(c) Water

(i) Water reticulation

(A) Pressure test and supervise the swabbing (if necessary) and sterilisation of the water mains.

(B) Check location of hydrants and valves to ensure they are in their correct location.

(C) Check that all valves and hydrants are working satisfactorily (include lid arrangement as per SD-350).

(D) When water mains have been constructed, mains must be commissioned in accordance with council requirements.

(ii) All works associated with water supply on site must be 100 per cent complete, and all water mains must be tested and live. Reservoirs and associated pump stations must be commissioned prior to the lodgement of survey plans unless otherwise approved by council.

(d) Earthworks

(i) All allotment preparation work and earthworks on allotments must be 100 per cent complete in accordance with the requirements of SC6.4.6.10 Earthwork construction, with finished surface levels, the degree of compaction achieved and geotechnical assessments required on any of the allotments submitted and approved by council. All works within allotments must be fully completed and no further disturbance required on the allotments. Appropriate erosion and sediment control measures must also be in place for all disturbed areas.

(ii) Where specific revegetation works have been bonded for future completion, the earthworks and top soiling must be complete prior to the release of the Plan of Survey.

(iii) All survey pegs placed.

(e) Roads

(i) Roads must be completed and fully sealed.

(ii) Pavement line markings completed at major intersections.

(iii) All traffic control devices, including traffic islands to be completed.

(iv) All traffic signage to be in place and completed compliant with Manual of Uniform traffic control devices (MUTCD) requirements.

(v) Traffic signals, if present, to be installed, completed and fully functional, compliant with the relevant requirements and legislation.

(vi) Retaining walls within road reserve to be completed and maintenance requirements documented.

(vii) Fences and noise abatement/screening walls to be completed and maintenance requirements documented.

(f) Stormwater

(i) Stormwater drainage works must be installed with all erosion controls in place and able to function without detriment to the system. Allotments must be provided with the nominated flood immunity. All stormwater systems must be constructed, including kerb and channel. Downstream drainage easements must have been executed in favour of council, necessary drainage and other easement documentation must have been submitted, and required reserves for drainage, parkland, etc. must have been provided.

(ii) This excludes large water sensitive urban design (WSUD) measures such as bio-retention basins and wetlands, where the acceptance of the asset and ongoing maintenance requirements is to be in accordance with SC6.4.3.9 Water sensitive urban design guidelines.

(iii) Performance testing of pumping equipment must be passed satisfactorily. This testing will require the connection of the electricity supply and water to the pump station.

(g) Services

Evidence must be provided of street lighting, telecommunications and electrical supply works commitments. Satisfactory evidence must be provided to council of a negotiated agreement with service providers for telecommunications and NBN Co infrastructure, reticulation of electricity and the provision of street lighting, and gas service providers for provision of gas (if gas is provided).

(h) Payments and Bonds

(i) The full payment of fees and bonds, including the maintenance bond and any bonds for incomplete works. The maintenance bond will be a minimum 5 per cent of the value of the works as certified by the RPEQ and accepted by council, and must be lodged with council until the development is accepted as off maintenance.

(ii) All outstanding rates paid.

(iii) All infrastructure charges required by the conditions of the development permit must be paid.

(iv) Accompanied by the prescribed form and fee of an amount in accordance with council's fees and charges current at the time of payment.

(i) Land

The developer must covenant that all transfers of land and interests in land to council are free of encumbrances and registered in the Title's Office at the same time as the Plan of Survey is registered at no cost to council.

SC6.4.7.1.3 Bonds

To enable early release of the Plan of Survey it will be necessary to bond all outstanding works and requirements. Security bonds for incomplete works will be subject to a minimum value of $15,000.

(1) Standard bond conditions

(a) Estimates

(i) To verify the maintenance bond estimates, council must be supplied with a schedule of the works together with the appropriate estimated rates and amounts for all the items.

(ii) To verify the incomplete works bond estimates, council must be supplied with a schedule of the incomplete works together with the appropriate estimated rates and amounts for the incomplete works.

(iii) Such estimated prices must be fair and reasonable.

(b) Conditions

(i) The amount of the security for incomplete works must be for an amount of not less than one hundred and fifty per cent (150 per cent) of the certified cost of the works remaining to be completed as at the date of the release of the subject Plan of Survey.

(ii) Incomplete works must be itemised, valued and certified by an RPEQ.

(iii) All bonds submitted must be clearly identified as to the particulars of the site and the purpose of the bond.

(iv) Insurance and indemnity certificates must be current and valid to cover the period outstanding works are being completed.

(c) Acceptable security

(i) Cash bonds.

(ii) Unconditional bank guarantees.

(A) A bank guarantee must include:

- a binding contractual relationship between council and the guaranteeing bank;
- specific requirements for renunciation of the guarantee; and
- a requirement of adequate notice of renunciation.

(B) Bank guarantees must not have expiration dates.

(2) Incomplete works bond

(a) Incomplete works condition

In addition to the standard bond conditions:

(i) Where council consents to the early release of a Plan of Survey in line with the minimum requirements listed in Section 3, the developer will be required to lodge a security (bond) and an undertaking to complete the works within an agreed timeframe. These works must be completed to the satisfaction of council and the security submitted in a format as detailed in this sub-section. Security bonds for incomplete works will be subject to a minimum value of $15,000.

(ii) Outstanding works must be itemised, valued and certified by an RPEQ.

(iii) Potential purchasers of lots must be advised of the arrangements.

(b) Required information

The RPEQ must provide the following information:

(i) certification of the value of incomplete works;

(ii) detailed schedule of the scope and cost of the incomplete works for auditing purposes;

(iii) certification that all external and internal works can be completed and accepted on maintenance within the timeframes detailed elsewhere in this Policy sub-section;

(iv) certification that the contract has been let for the construction of the remaining internal and external works and the name of the Contractor;

(v) proposed finish dates for remaining internal and external works; and

(vi) security lodgement form completed clearly indicating that the purpose of the bond is for incomplete works.

(3) Revegetation bonds

Revegetation bonds may be required where conditioned by a development permit. At the time of on maintenance council may accept the drains and earth batters within a subdivision whereby the vegetation is not in accord with the objectives of this and other SC6.4 Development manual planning scheme policy sub-sections, subject to the following requirements.

(a) Revegetation performance bond

(i) A bond for the incomplete revegetation must be included as a performance bond for incomplete works along with all other bonds for incomplete works upon that subdivision.

(ii) The bond for the revegetation works must be 150 per cent of the approved estimated cost of the revegetation works to allow for the typical seasonal weather encountered in the region, due to the risk of erosion and scouring in areas of exposed earth.

(iii) The revegetation performance bond will be considered for acceptance on and off maintenance separate to the general subdivision works.

(b) Revegetation maintenance bond

(i) The revegetation performance bond will be reduced to a revegetation maintenance bond upon achievement of a minimum scour protection, which is deemed as 40 per cent vegetal coverage, which includes 15 per cent of the total area having the specified species. The revegetation maintenance bond must be equal to the approved estimate of the value of the works required to achieve the specified grass coverage by the off maintenance date.

(ii) The acceptance of revegetation on maintenance will correspond with the reduction of the performance bond for revegetation works. The acceptance of the revegetation works off maintenance and release of the revegetation maintenance bond will require the specified grass coverage to be completed but will not occur prior to the remainder of the development being accepted off maintenance.

(4) Sewer pump station bonds

(a) Where a sewage pump station is a pump station identified by council in the Priority Infrastructure Plan (PIP) and that sewage pump station is identified as minor trunk infrastructure, then consideration will be given to the release of the Plan of Survey prior to the completion of the works associated with that pump station.

(b) The pump station must be located upon land that is or will be under the control of the council upon the registration of the subject Plan of Survey.

(c) The working drawings and specifications must have been completed and approved by council for construction.

(d) The Consultant Engineer acknowledges that with respect to the nominated works that they are working for council and not the developer, and that the specifications nominate council as the Principal of the Contract.

(e) The tenderers must have been reported to council and council must have approved the successful tenderer.

(f) The Contract must have been let, and a submitted works program must indicate that the trunk

infrastructure is programmed to be completed prior to when the commencement of dwelling construction is envisaged, including provision for a normal wet season.

(g) The developer must enter into a Deed of Agreement with council, as detailed in SC6.4.7.3 Sewer pump-out agreements that includes provision for a pump-out service and a security for this pump-out. The template in Attachment A of SC6.4.7.3 Sewer pump out agreements may be used for the Agreement.

SC6.4.7.1.4 Early release of the plan of survey

(1) Justification for early release

Council may elect to release plans of survey prior to satisfaction of the development permit on the basis that critical works are provided and security is afforded for the outstanding works. This process requires the developer to request the early signing in writing at the time of lodging a survey plan and payment of a fee, demonstrating how conditions of the development approval are satisfied or secured.

Early approval and dating of the Plan of Survey does not discharge the developer from obligations to satisfy the conditions of development approval, and the development may be subject to enforcement action for non-compliance with the development permit(s) and/or the undertaking given to complete the outstanding works.

The aim of this clause is to enable the developer to have the Plan of Survey released from the council as early as possible while at the same time ensuring that the allotments being constructed will be fully serviced at the time that the Plan of Survey is registered and subsequent sales of the allotment takes place.

(2) Early release of survey fees

A fee for the early release of the Plan of Survey in accordance with council's schedule of fee's and charges at the time of payment will also be required as payment separate to the incomplete works bond.

(3) Minimum requirements

Council will not sign any Plans of Survey where the relevant works or matters are incomplete, unless the following are completed:

(a) Early Plan of survey on maintenance inspection

An on maintenance inspection must be satisfactorily completed in accordance with SC6.4.7.1.2(4) and as detailed below, however some minor defects may be outstanding, with minor defects defined as those not impacting on public safety and/or the ability of council to operate and maintain the infrastructure.

(b) Earthworks

All allotment preparation work and earthworks on allotments to be 100 per cent complete in accordance with the requirements of SC6.4.6.10 Earthworks (construction), with finished surface levels, the degree of compaction achieved and geotechnical assessments required on any of the allotments submitted and approved by council. All works within allotments must be fully completed and no further disturbance required on the allotments. Appropriate erosion and sediment control measures must also be in place for all disturbed areas.

(c) Sewerage

All sewerage works including pump stations, rising mains, trunk mains and the proposed sewers have been inspected and certified by the supervising engineer as being 100 per cent complete and in full working order. Sewer systems must be installed, tested and operational. (Bonding of pump stations may be accepted; refer to SC6.4.7.1.3(4)). Conduit inspection must be undertaken in accordance with SC6.4.2.2.6 Conduit assessment.

(d) Water

All works associated with water supply on site are 100 per cent complete, and all reticulation has been pressure tested, sterilised, completed and connected to an existing supply. All water pumping stations must be certified by an RPEQ as being 100 per cent complete and in full working order.

(e) Roads

Roads must be completed to the point where the pre-seal inspection has been carried out by council's inspectors and the pavements are approved for application of bitumen or asphalt.

(f) Stormwater

(i) Stormwater drainage works must be installed with all erosion controls in place and able to function without detriment to the system. Allotments must be provided with the nominated flood immunity. All stormwater systems must be constructed, including kerb and channel. Downstream drainage easements must have been executed in favour of council, necessary drainage, other easement documentation must have been submitted, and required reserves for drainage, parkland, etc. must have been provided.

(ii) This excludes large WSUD measures such as bio-retention basins and wetlands, where the acceptance of the asset and ongoing maintenance requirements is to be in accordance with SC6.4.3.9 Water sensitive urban design guidelines.

(g) Services

Evidence must be provided of street lighting, telecommunications and electrical supply works commitments. Satisfactory evidence must be provided to council of a negotiated agreement with service providers for telecommunications and broadband infrastructure, reticulation of electricity (e.g. Letter of Supply) and the provision of street lighting and gas service providers for provision of gas (if gas is provided).

(h) Payments and bonds

(i) The full payment of fees and bonds, including the maintenance bond and any bonds for incomplete works. The maintenance bond will be 5 per cent of the value of the works as certified by the RPEQ and accepted by council, and must be lodged with council until the development is accepted as off maintenance.

(ii) All outstanding levied rates are paid.

(iii) All infrastructure charges required by the conditions of approval must be paid.

(iv) Accompanied by the prescribed form and fee of an amount in accordance with council's fees and charges current at the time of payment.

(i) Land

The developer must covenant that all transfers of land and interests in land to council are free of encumbrances and registered in the Title's Office at the same time as the Plan of Survey is registered at no cost to council.

(j) As constructed plans

As constructed plans must be submitted in accordance with SC6.4.7.1.2(2) showing all works completed to date, including as a minimum, the requirements above in parts (a) – (i). All works not shown on the as constructed drawings at the time of submission for early release of Plan of Survey, will be required to be bonded in accordance with the requirements of this section.

(4) Timing

All incomplete works must be completed and ready for council inspection within 1 month of council releasing the Plan of Survey. Should the developer not be able to meet this requirement they must submit justification to council detailing exceptional circumstances. The RPEQ must submit for the approval of council, a program of works to certify that the incomplete works can be completed within 1 month (or longer as agreed by council).

(5) Sewer pump stations

Early release of the Plan of Survey may be considered if council developed sewer pump stations are almost complete. See SC6.4.7.1.3(4) for more information.

SC6.4.7.2 On maintenance/final completion/off maintenance requirements

SC6.4.7.2.1 Introduction

This sub-section provides guidance and advice for the requirement for on maintenance/final completion/off maintenance to facilitate the release of the plan of survey (see SC6.4.7.1 Release of the plan of survey).

SC6.4.7.2.2 Lodgement

(1) Requirements for on maintenance:

(a) building approval for all buildings/structures, where required by the *Building Code of Australia* (BCA);

(b) a supervision certificate from the Consulting Engineer and request to have the works accepted on maintenance;

(c) a workmanship guarantee from the Contractor;

(d) submission to and acceptance by council of as constructed information. The RPEQ must certify the "as constructed" drawings by including the following statement on each drawing:

I/We (Name) of (Firm) hereby certify that the works as shown on the as constructed drawings reflect any changes that were made during the course of construction (signed with RPEQ No and dated);

(e) a Registered Surveyor must certify that the locations, surface and invert levels of all works and infrastructure presented on the as constructed drawings and digital submissions have been surveyed and are true and accurate representations of the works by including the following statement on each relevant as constructed drawing:

I/We (Name) of (Firm) hereby certify that this drawing accurately describes and records the nature and the location of the works depicted hereon as they have been constructed for the purposes of the development (signed and dated);

(f) infrastructure agreements, if required, must be in place for the provision of and/or connection to trunk infrastructure;

(g) approval by other authorities, e.g. evidence of NBN Agreement, or Certificate of Acceptance from Ergon;

(h) the works must remain on maintenance for a minimum period of 12 months;

(i) the works subject of other approvals for which the works of this approval are dependent must also have been accepted on maintenance; and

(j) where on maintenance can be achieved within 1 month of the release of the plan of survey then the date for the on maintenance will be backdated to the date of the release of the plan of survey. Otherwise, on maintenance will be from the date that all requirements have been satisfied.

SC6.4.7.2.3 Sewer

(1) Requirements for on maintenance:

(a) pressure test all sewers and manholes in accordance with WSA to ensure the requirements of the specification are met;

(b) check by internal examination (closed circuit television) that all sewers are straight, clean and to grade. Conduit inspection must be undertaken in accordance with SC6.4.2.2.6 Conduit assessment;

(c) check that all manholes are sound, smooth and clean and benched as per the required standard;

(d) check that house connection "jump up" construction complies with council's standards;

(e) performance testing of pumping equipment. This testing will require the connection of the electricity supply and water to the pump station;

(f) certified results of pressure tests on all mains;

(g) certified results of field tests on pumping equipment;

(h) operations manual, performance specifications and maintenance requirements for all pump stations; and

(i) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications.

SC6.4.7.2.4 Water

(1) Requirements for on maintenance:

(a) pressure test and supervise the swabbing and sterilisation of the water mains (if necessary);

(b) check location of hydrants and valves to ensure they are in their correct location;

(c) check that all valves and hydrants are working satisfactorily(include lid arrangement as per SD-350;

(d) when water mains have been constructed, mains must be commissioned in accordance with council requirements;

(e) certified results of pressure tests on all mains;

(f) certified results of field tests on pumping equipment;

(g) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications; and

(h) no concrete footpaths installed over water main where property connections are yet to be constructed.

SC6.4.7.2.5 Earthworks

(1) Requirements for on maintenance:

(a) all survey pegs placed; and

(b) compaction results of each layer of earthworks on roads and on each allotment where depth of fill exceeds 0.5 m. The maximum depth of fill on each lot must be indicated on the as constructed drawings. Allotment fill must be in layers no greater than 200 mm and compacted a minimum standard of 95% standard compaction for residential subdivision and 98% standard compaction for commercial subdivision. The fill material must be free of vegetation and organic material.

SC6.4.7.2.6 Roads

(1) Requirements for on maintenance:

(a) roads must be completed and fully sealed;

(b) all tests and hold point documentation completed and finalised;

(c) pavement line markings completed, including passing and turning lanes at major intersections;

(d) where a double coat bitumen seal has been used, copies of bitumen spray sheets and calculated average spray rate and aggregate spread rate are required;

(e) where asphaltic concrete surfacing has been used, test results on samples of the material supplied to the site must be taken at the Asphalt Plant together with field tests to confirm asphalt depth and percentage of voids filled;

(f) all traffic control devices, including traffic islands, to be completed;

(g) all traffic signage to be in place and completed in accordance with *Manual of uniform traffic control devices'* requirements;

(h) traffic signals, if present, to be installed, completed and fully functional in accordance with the relevant requirements and legislation;

(i) retaining walls within road reserve to be completed and maintenance requirements documented;

(j) fences and noise abatement or screening walls to be completed and maintenance requirements documented;

(k) compaction results of subgrade and each course of pavement; and

(l) grading, Atterberg limits and a California Bearing Ratio (CBR) test of each course of pavement material in accordance with SC6.4.5.3 Quality management system.

SC6.4.7.2.7 Stormwater

(1) Requirements for on maintenance:

(a) stormwater drainage works must be installed with all erosion controls in place and able to function without detriment to the system. Allotments must be provided with the nominated flood immunity. All

stormwater systems must be constructed, including kerb and channel. Downstream drainage easements must have been executed in favour of council, necessary drainage and other easement documentation must have been submitted, and required reserves for drainage, parkland, etc. must have been provided;

(b) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications. Conduit inspection must be undertaken in accordance with SC6.4.2.2.6 Conduit assessment;

(c) performance testing of pumping equipment. This testing will require the connection of the electricity supply and water to the pump station;

(d) certified results of field tests on pumping equipment;

(e) operations manual, performance specifications and maintenance requirements for all pump stations; and

(f) certification from the Consultant that the pipes and fittings used are as per the drawings and specifications.

This excludes large water sensitive urban design (WSUD) measures such as bio-retention basins and wetlands, where the acceptance of the asset and ongoing maintenance requirements is to be in accordance with SC6.4.3.9 Water sensitive urban design guidelines and SC6.4.6.1 Water sensitive urban design construction and establishment guidelines.

SC6.4.7.2.8 Landscaping and irrigation

(1) Introduction

This clause outlines the conditions and timeframes associated with acceptance by council of landscape and irrigation works (Works) constructed as part of a Development Permit.

(2) Principles

(a) the establishment period will be included within the maintenance period;

(b) council will accept works on maintenance that have reached practical completion and have met the relevant conditions of the Development Permit, but may still require time to establish;

(c) the establishment date will be used to determine satisfactory establishment;

(d) council will accept responsibility for maintenance of hard landscape assets from the on maintenance date;

(e) the Developer will remain responsible for maintenance of soft landscape assets during the maintenance period;

(f) the Developer is responsible for all defects in the works until the off maintenance date; and

(g) council will accept responsibility for maintenance of soft landscape assets from the off maintenance date.

(3) Terminology

In addition to the terms previously defined in SC6.4.7.1.1(2) the following terms and definitions apply to this clause, specific to landscape and irrigation works:

Contractor	A person or company who has entered into a contract with the developer to supply and install infrastructure, landscaping and/or an irrigation system.

Establishment period	The period of time between when council accepts the works on-maintenance until when council accepts the works as established (the established date). Works are deemed established when: (i) all the defects identified at the on-maintenance and practical completion; (ii) defects identified at inspection have been rectified unless agreed otherwise; (iii) all turfed areas have "taken root" and there are no obvious gaps between strips of turf; (iv) all turfed areas have been rolled and/or topdressed to fill any depressions; (v) all plants are showing signs of healthy, new growth, and that the planting design intent is starting to take shape; (vi) generally, the landscape works indicate that they are being maintained in accordance with the Development Permit; and (vii) revegetation areas have achieved specified cover.
Hard landscaping	Structures, paths and facilities such as playground equipment constructed from building materials (but excluding irrigation systems).
Maintenance period	The period of time between when council accepts the works on-maintenance until council accepts the works off maintenance. This includes any establishment periods and the defect liability period. This is to be: (i) a minimum of 12 calendar months; and (ii) include the establishment period and the defect liability period.
Off maintenance date	The date the works are fully accepted by council following an inspection by council, which considers that all works are satisfactory, and the defects liability period concludes. This date must be: (i) after the established date; (ii) after all defects have been remedied; (iii) at least 12 months after the on maintenance date; (iv) after an inspection by council which considers that all works are satisfactory.
Soft landscaping	Trees, plants, grass and vegetation generally and any irrigation system associated with such vegetation.

(4) Ownership and responsibilities

The ownership of the works transfers to council on the earlier of:

(a) the date when the land on which the works are constructed is transferred to council; or

(b) the on maintenance date.

(5) Typical timelines

(a) Construction

(i) achieve practical completion;

(ii) conduct inspections to determine the on maintenance date; and

(iii) release Plan of Survey if applicable.

(b) 0 weeks

(i) on maintenance date.

(c) 12 weeks

(i) normal established date;

(ii) landscape inspection to be carried out; and

(iii) if works are unsatisfactory, establishment date will be deferred.

(d) 52 weeks

(i) normal off maintenance date;

(ii) landscape inspection to be carried out; and

(iii) if works are unsatisfactory the off maintenance date will be deferred.

(6) Landscape works on maintenance/practical completion

(a) Requirements for on maintenance:

(i) maintenance inspection;

(ii) the Registered Landscape Architect must certify as constructed drawings by including the following statement on each drawing:

I/We (Name) of (Firm) hereby certify that the works as shown on the "as constructed" drawings reflect any changes that were made during the course of construction;

(iii) all asset transfer documentation is submitted and approved by council including the following:

(A) Open Space Asset Data Collection Form – This form contains the asset information relating to the construction of new assets; or

(B) Asset Change Form – This form contains information about minor changes to existing assets; and

(C) warranty details for all items with a value greater than $500.00. This information is required by council to assist in future warranty claims;

(iv) plantings, gardens and turfed areas must be exhibiting a "strike", but compliance with full establishment requirements is not essential at on maintenance;

(v) the defects liability period for soft landscape works shall be concurrent with the defects liability period for any associated irrigation system; and

(vi) the defects liability period for landscape works shall not commence until:

(A) the associated irrigation system has been commissioned; and

(B) all requirements of the Special Conditions of Approval have been met.

(7) Landscape works defects liability period

(a) Establishment

(i) All soft landscaping will be subject to a 12 week landscape establishment period. The landscape establishment period is included in the 12 month maintenance period. The Developer is responsible for establishing the works during the establishment period until the established date as advised by council.

(ii) The developer may be required to undertake additional works during the establishment period such as additional watering, formative pruning, topdressing, turfing, replenishment of mulch and replacement of plants.

(iii) At the conclusion of the landscape establishment period a landscape establishment inspection may be conducted, and if the landscaping establishment is not satisfactory additional works may be requested and/or the maintenance period may be extended.

(b) Landscape maintenance period requirements and responsibilities

(i) Council is responsible for maintenance of hard landscaping during the maintenance period.

(ii) The developer is responsible for maintenance of soft landscaping during the maintenance period until the off maintenance date.

(iii) Water costs

(A) The developer is responsible for the cost of water during the maintenance period.

(B) Council is responsible for cost of water from the off maintenance date.

(iv) Vandalism, theft and damage caused by unexpected events or third parties

(A) For soft landscaping, the developer is responsible for rectification works to remedy vandalism, theft and damage caused by unexpected events during the maintenance period.

(B) For hard landscaping, the council is responsible for rectification works to remedy vandalism, theft and damage caused by unexpected events during the maintenance period.

(v) Extended maintenance periods

(A) In addition to provisions detailed, where negotiated as conditions of the development approval, extended maintenance period beyond the 12 month period may apply.

(B) Where the landscape maintenance period is extended as a condition of development approval or due to provisions within this policy, this extension may concurrently apply to any irrigation system associated with the landscape works.

(vi) General maintenance activity requirements

(A) All maintenance activities must be undertaken in accordance with council's public open space maintenance specifications. Any maintenance activities that deliver a level of service above and beyond council's specification is at the discretion and cost of the developer.

Editors Note - council's Public open space maintenance frameworks are currently under development.

(B) Maintenance activities include, but are not limited to mowing, top dressing, litter collection, watering, pruning, fertilising, weeding, mulching, pest and disease control.

(C) All maintenance work to new and existing landscaping shall be carried out in accordance with the best horticultural practices.

(vii) Watering requirements

(A) All soft landscaping shall be watered regularly (either by hand watering or by irrigation) to ensure the continuing healthy establishment and growth of all plants taking into account soil type, plant type and size, prevailing weather conditions and seasonal variations.

(B) Watering methods are to be suitable for watering the root ball of newly planted plants during the critical first several weeks of establishment.

(C) Watering shall not cause displacement of mulch or erosion of garden mix soil.

(viii) Weeding, pest and disease control

(A) Gardens and turf shall be regularly weeded. Six weeks prior to the end of the defects liability period ("off maintenance"), the area shall be inspected for weed growth and treated with an appropriate selective herbicide. All chemicals shall be used in accordance with the manufacturer's recommendations.

(B) Plants shall be regularly inspected for pest and diseases throughput the defects liability period. Any pest or disease detected shall be reported to the Superintendent. Acceptable horticultural techniques shall be employed by the Contractor to manage any infestations as directed by the Superintendent. 12 weeks prior to the end of the defects liability period ("off maintenance"), the area shall be inspected for pests and disease and treated with an appropriate pest and disease control.

(ix) Planting and tree maintenance

(A) All maintenance work to new and existing trees shall be carried out by an arborist with formal qualifications or at least 5 years recognised experience in Arboriculture. The works shall be carried out in accordance with the AS 4373 *Pruning of Amenity Trees* and shall not proceed without the written approval of the Superintendent.

(B) Stakes and ties and guying shall be checked for firmness and support and shall be adjusted as necessary to prevent any damage to the bark or roots of the tree. Stakes and ties or guying shall be removed when the tree is self-supporting and/or as directed by the Superintendent.

(x) Planting, trees, turf and hydroseed failure and replacement

(A) Plants and trees lost through vandalism, theft or that have died shall be replaced by the Contractor on a monthly basis.

(B) Plants, trees, and turf supplied by the Contractor that have failed to become established during the defects liability period or are diseased and/or dying shall be removed and replaced by the Contractor twelve weeks prior to the end of the defects liability period ("off maintenance") and at no cost to council. If the loss is significant, it will be at the discretion of the Superintendent if an extension on the defects liability period for the failed landscaping is warranted.

(C) Areas of hydro seeding/mulching that have failed to become established or have died during the defects liability period shall be removed and retreated by the Contractor at no cost to council. If the area is of significant size it will be at the discretion of the Superintendent if an extension to the defects liability period for the failed area is warranted.

(8) Landscaping inspections during the defects liability period

In addition to the requirements outlined in SC6.4.7.2.8(2) Principles, the following requirements apply to landscaping works:

(a) any work inspected that does not comply with the specification and/or the design plans or has not been adequately maintained in accordance with SC6.4.7.2.8(2) will not be accepted by council and will be noted for rectification. The contractor is required to rectify these items as soon as is practical and as a minimum before the next scheduled inspection; and

(b) failure by the Contractor to rectify unacceptable items prior to the next inspection may result in the defects liability period for those items being extended by the number of weeks that have lapsed prior to the rectification work being completed.

(9) Landscaping off maintenance/final completion

(a) Final inspection and completion

(i) Soft landscaping shall be inspected by the Superintendent for acceptance ("off maintenance") at the end of the defects liability period, subject to any special conditions of approval.

(ii) In addition to the requirements outlined in SC6.4.7.2.8(2), the final inspection and completion requirements apply as detailed below.

(b) Final acceptance criteria (Gardens)

The acceptance criteria for gardens shall be:

(i) gardens shall be free from weeds, stones, roots, sticks, rubbish and other deleterious material;

(ii) gardens shall be free of disease and pests;

(iii) mulch shall be to the minimum thickness specified;

(iv) plants shall be as specified; and

(v) plants shall be placed at the spacings nominated and in the quantities nominated as detailed on the drawings or as specified.

(c) Final acceptance criteria (plantings)

The acceptance criteria for plants shall be:

(i) plants shall exhibit signs of healthy active growth;

(ii) plants shall show no signs of yellowing or wilting;

(iii) plants shall be well formed;

(iv) plants shall be free of disease and pests;

(v) plants shall have healthy root systems and shall not be root bound; and

(vi) plants are true to cultivar, type or form as specified.

(d) Final acceptance criteria (turf)

The acceptance criteria for turf areas shall be:

(i) the achievement of an even green colour with a dense sward over the entire area with no open joints;

(ii) turf shall exhibit signs of healthy active growth;

(iii) turf shall be free from weeds, stones, roots, sticks, rubbish and other deleterious material; and

(iv) turf shall be free of disease and pests.

(e) Final acceptance criteria (hydro seeding/mulch)

The acceptance criteria for hydro seeding/mulch areas shall be:

(i) the achievement of an even green colour over the entire area and exhibiting healthy active growth with acceptable vegetative cover. Of this cover 95% shall be the nominated dominate grass species with the remaining 5% made up of annual and perennial grasses;

(ii) free from weeds, stones, roots, sticks, rubbish and other deleterious material;

(iii) free of disease and pests; and

(iv) the area shall not be mowed for at least 5 days prior to the inspection.

(f) Final inspection documentation

(i) Following the final inspection (off maintenance) council will issue a site inspection report (defects list). Any items not acceptable to council will be noted for rectification.

(ii) The Contractor is required to rectify these items and apply for a re-inspection when all rectification items have been completed.

(iii) A certificate off final completion will be issued by council following the rectification of all defects noted at the off maintenance inspection.

(10) Irrigation works on maintenance/practical completion

(a) Requirements for on maintenance:

(i) all as constructed drawings and documentation nominated in SC6.4.7.2.8(2) is submitted and approved by council;

(ii) all asset transfer documentation including the following:

(A) Irrigation Asset Data Collection Form – This form contains the asset information for the construction; or

(B) Irrigation Asset Change Form – This form contains information about minor changes to existing assets;

(C) Irrigation Network Controller Setup Request Form – This form is used to provide information to the infrastructure Services Irrigation Technician who will configure the telemetry network. The form shall be submitted to council a minimum of 4 working days prior to commissioning of the system;

(D) Irrigation Program Setup Request Form – This form is used to provide information to the infrastructure Services Irrigation Technician who will setup the irrigation controller program. The form shall be submitted to council a minimum of 4 working days prior to commissioning of the system. After the program has been set up, the Infrastructure Services Irrigation Technician will issue a copy of the program to the Contractor;

(E) Warranty details for all irrigation components with a value greater than $500.00 excluding GST. This information is required by council to assist in future warranty claims; and

(F) Plumbing and Drainage Application Forms 1, 2 and 7 are to be completed by a licensed plumber and submitted to the Hydraulic and Building Services Unit of the Townsville City Council. The Backflow Test Certificate must be lodged with Hydraulic and Building Services Unit of the Townsville City Council. A copy of the Backflow Test Certificate must also be supplied to Infrastructure Services; and

(iii) commissioning of the irrigation system shall not proceed until all of the above documentation is submitted and approved by the council.

(11) Irrigation defects liability period

(a) A defects liability period applies to all irrigation systems installed by contractors. The defects liability

period shall be undertaken in accordance with this policy and any special conditions of approval.

(b) If applicable the defects liability period for the irrigation system shall be concurrent with the Defects Liability Period for any associated landscaping works.

(c) The defects liability period for an irrigation system shall not commence until:

(i) all of the documentation nominated in SC6.4.7.2.8(10)(a) above is submitted and approved by council;

(ii) all requirements of the special conditions of approval have been met;

(iii) if applicable the associated landscaping works are accepted “on maintenance”;

(iv) the irrigation system has been commissioned; and

(v) the site has been jointly inspected by the council and contractor and the irrigation system is free of defects at the time of inspection.

(12) Irrigation inspections during the defects liability period

During the defects liability period, council may require access to the site to undertake the following tests:

(a) main lines pressure test – the main line is pressurised to test for leaks. All valves are shut and the pressure is taken over a determined length of time;

(b) sprinkler pressure test – the sprinkler pressure is taken at the nozzle using a pitot pressure gauge and is then compared to manufacturer recommendations;

(c) dripper pressure test – measurement at flushing valves are taken and the pressure gauged to make sure it conforms to the manufacturer recommendations. The inlet pressure is then tested under the same conditions to check it does not exceed 300Kpa; and

(d) lateral pressure loss test – the first and last sprinklers of the lateral line are pressure tested. The variation in flow is then calculated and compared with the limits nominated in the specification.

(13) Irrigation off maintenance/final completion

(a) Final inspection and completion
Final completion shall be managed in accordance with this policy and any special conditions of approval.

(i) Following the final inspection, council will issue an irrigation inspection defects list detailing items that do not comply with the specification and/or design plan.

(ii) The contractor is required to rectify these items and apply for a reinspection when all rectification work has been completed.

(iii) After reinspection of the rectification work, and if the work is satisfactory to council an Irrigation Inspection Report (Defects List) will be issued with the status noted as “Ready to proceed to off maintenance”.

(iv) A Certificate of final completion will be issued by the Superintendent when the Contractor has met all obligations under the Contract.

SC6.4.7.2.9 Quality assurance documentation

(1) Requirements for on maintenance

(a) Copies of the Test Certificates from a National Association of Testing Authorities (NATA) registered laboratory; and

(b) A single quality control document must be submitted, including but not be limited to:

(i) pavement levels;

(ii) compaction tests;

(iii) pavement materials tests;

(iv) concrete tests;

(v) asphalt tests;

(vi) sewer pressure tests;

(vii) water pressure tests;

(viii) water bacteriological tests;

(ix) landscaping soil tests;

(x) playground and fitness equipment certification;

(xi) softfall under surfacing certification;

(xii) structural certification (forms 15, 16 and 21);

(xiii) electrical safety, testing compliance certification; and

(xiv) backflow certificate.

SC6.4.7.2.10 Defects liability period

The defects liability period for all works is a minimum of 12 months from the date of the release of the formal plan of survey or from the date of acceptance on maintenance, whichever is later, at which time the bond will be refunded subject to the off maintenance requirements being completed to the satisfaction of council. If for any reason during the maintenance period, a defect of substantial proportions is discovered then council reserves the right to extend the defects liability period for a further 12 months from the date of correction of the defects, or as negotiated e.g. infrastructure is required to be reconstructed after a significant failure due to deficiency in design/construction.

SC6.4.7.2.11 Bonds and fees advice

(1) Requirements for on maintenance

(a) A works inspection fee (at the rate applicable at the time of payment) must be paid prior to the works being accepted.

(b) A reinspection fee (at the rate applicable at the time of payment) will be applicable where an additional inspection is required due to works being incomplete or unsatisfactory at the initial inspection. The reinspection fee must be paid prior to the additional inspection being conducted.

(c) A maintenance bond (5% of the value of the works as determined and certified by a Registered Professional Engineer of Queensland (RPEQ) or Registered Landscape Architect) and supporting Schedule of Works with costs certified by the RPEQ or Registered Landscape Architect must be lodged with council. The bond must be in favour of council and in the form of cash or an unconditional bank guarantee (non-expiring). If the security is in the form of a bank guarantee, the guarantor must be a bank or financial institution acceptable to council.

(d) In the event of a default by the developer relating to defects, council may undertake whatever action required to secure compliance with the conditions of approval and may apply the security for that purpose. The security (or balance) will be returned to the developer upon satisfaction of the conditions of approval relating to maintenance responsibility.

SC6.4.7.2.12 On maintenance inspection and final inspection and compliance check

(1) Requirements for on maintenance:

(a) The developer must provide council at least 5 business days' notice, requesting the works be checked for compliance with the approvals and be accepted on maintenance.

(b) A report must be submitted, showing the scope of works, date and outcome of works inspected by the supervising Registered Professional Engineer of Queensland or supervising Registered Landscape Architect.

(c) Council must be satisfied with the results of an on maintenance inspection and compliance checks against the development approvals. Council will issue an On Maintenance Certificate, identifying the relevant works and any defects applicable.

(d) Prior to requesting an on maintenance inspection, the developer must correct any defects arising from faulty workmanship, materials or design identified in the On Maintenance Certificate or during the maintenance period (or extended period following rectification of such defects).

(e) The on maintenance date may be backdated to the date of the initial on maintenance inspection date or the release of the plan of survey (whichever is the latter), if all outstanding requirements were met within 4 weeks of identification.

SC6.4.7.2.13 Off Maintenance

(1) The works will become off maintenance subject to:

(a) rectification of all defects identified at on maintenance or during the maintenance period;

(b) council being satisfied with the results of an off maintenance inspection and compliance check against development approvals conducted by council officers following the end of the maintenance period;

(c) the development will only be accepted off maintenance in its entirety and all works must be performing satisfactorily at this stage;

(d) the developer, or their representative, must arrange with council an inspection of all defects 1 month prior to the work being due off maintenance;

(e) the whole of the works must be inspected at the off maintenance inspection. The consulting engineer is responsible for thoroughly inspecting the development and any necessary remedial work prior to the off maintenance inspection; and

(f) acceptance of the works off maintenance does not discharge the developer from their obligation to provide a development free of defects. Any defect that is discovered after the acceptance off maintenance, which attributed to the failure to deliver a development in accordance with the conditions of the development permit, must be repaired at the developer's expense.

SC6.4.7.3 Sewer pump-out agreements

SC6.4.7.3.1 Introduction

(1) Purpose

In accordance with SC6.4.7.1 Release of the plan of survey, council may consider early sealing of the survey plan for a development if:

(a) incomplete or non-commissioned trunk infrastructure is preventing the developer providing infrastructure from being fully commissioned; and

(b) the non-delivery of this trunk infrastructure is impacting on council's process for signing of the survey plan.

(2) Scope

This sub-section sets out the circumstances in which a sewage pump out agreement may be entered into, and the mandatory requirements that will be included in such an agreement under the *Sustainable Planning Act 2009.*

(3) Reference and source documents

This section shall be read in conjunction with the following standards and legislation:
Environmental Protection Act 1994
Local Government Act 2009
Plumbing and Drainage Act 2002
Sustainable Planning Act 2009
Water Supply (Safety and Reliability) Act 2008
WSA 02-2002 2.3 *Sewerage Code of Australia*
WSA 04-2005 2.1 *Sewerage Pumping Code of Australia*

SC6.4.7.3.2 Sewage pump-out deed of agreement requirements

(1) A Deed of Agreement relating to the incomplete or non-commissioned trunk infrastructure must be entered into. The agreement must ensure that all risks associated with the temporary pumping out and disposal of sewage are adequately addressed by the developer. The following sections must be addressed within the Deed of Agreement at a minimum:

(a) Timing

The trunk infrastructure must be programmed to be commissioned prior to when the completion of dwelling construction is envisaged.

(b) Supply of electricity

(i) Sewer pump stations must be provided with a continuous and reliable electrical supply. Details of the provision of power supply must be provided with the sewage pump station design.

(ii) Alternatively, if temporary power supply is proposed to be supplied by a generator, details of this arrangement must be included as part of the agreement.

(c) Lawful effluent disposal and access arrangements

Access arrangements for pump stations and/or other wastewater maintenance holes required for the pump-out service must be specified, and the wastewater maintenance hole or licensed septic disposal facility designated. The disposal of all sewage must be as directed by Townsville Water from time to time by a registered operator following agreed transport routes, for the duration of the agreement, and under the supervision of a suitably qualified engineering consultant.

(d) Developer's provision of pump-out service
A minimum standard for the developer's provision of a pump-out service must be specified.

(e) Management of odour complaints, fish kills and wastewater spills
Details of management of overflow/spills or environmental harm must be included in the Deed of Agreement and actions undertaken in accordance with the *Environmental Protection Act 1994.*

Click here to obtain a copy of the following form.

SC6.4.7.3.3 Template agreement

Council's Template Agreement for Sewage Pump-Out may be used to assist in the preparation of the Deed of Agreement (see SC6.4.7.3 Attachment A).

SC6.5 Economic impact assessment planning scheme policy

SC6.5.1 Introduction

Short Title - The planning scheme policy (PSP) may be cited as the Economic impact assessment PSP.

SC6.5.1.1 Purpose

(1) The purpose of this planning scheme policy is to provide applicants with direction on how to undertake an economic impact assessment which council request to inform the proper assessment of a development application. Particularly, the policy provides direction on the standard information requirements expected to be incorporated within an economic impact assessment report.

An economic impact assessment report may be required to demonstrate compliance with the Townsville City Plan particularly for significant in-centre or out-of-centre development of a commercial nature. It is likely to be required where there is potential conflict with the Townsville City Plan, or for impact assessable development of a commercial nature in any zone.

SC6.5.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016.*

SC6.5.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan.

SC6.5.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 – Definitions, is to be interpreted in accordance with Part 1.3.1 terminology.

SC6.5.2 Planning scheme policy details

SC6.5.2.1 Terms of Reference for an economic impact assessment report

(1) Council intends to protect the economic viability and the intended role and successful functioning of centres. An economic impact assessment report will need to demonstrate that the proposed development will meet the relevant performance outcomes in the planning scheme codes and the intentions expressed in the strategic framework. Where the development is inconsistent with the planning scheme the assessment may form part of the basis for determining whether sufficient grounds exist to approve such a development.

(2) The standard requirements for the preparation of an economic impact assessment report should typically provide the following information:

(a) an outline of the purpose of the study;

(b) a description of the methodology used;

(c) a description of the proposed size, function and tenancy mix of the proposed development, together with details of any pre-commitment;

(d) the identification of the proposed development's trade area, supported by the reasoning and methodology behind the identification of the area;

Note—Refer to section SC6.5.2.2 Trade Area of this policy for guidance on identification of trade areas.

(e) an examination of the population growth prospects and socio-economic characteristics of the trade area, including socio-economic factors such as expenditure potential;

(f) the identification of any approved or proposed development that may affect the proposed development or be affected by the proposed development;

(g) the identification of the location, size, nature, function and tenancy mix of competitive business, commercial or centre uses likely to be affected by the proposed development;

(h) evidence that any feasible alternative, appropriately zoned location/s have been investigated and discussed so that reasoning behind the selection of the preferred site is clear;

(i) an estimation of the demand, or likely future demand, for business, commercial or centre floor space in

the trade area;

(j) an estimation of the market share of the proposed development;

(k) where an out-of-centre development is proposed, demonstration as to why the proposed development is required, including why the development cannot be accommodated within the existing centres;

(l) commentary on changes to the supply/demand balance upon approval of the proposed development, including whether the proposal represents an excess of supply for the community;

(m) a calculation of the quantitative economic impact upon competitive centres likely to be affected by the proposed development including a description of the consequent effects on the competitive centres;

(n) the identification of the impacts the proposed development would have on the successful trading of other centres (including the period of time) and the identification of the impacts on the Townsville hierarchy and functionality of activity centres;

(o) the changes, if any, to the range of services that existing centres will continue to provide; and

(p) a summary of the overall need for the proposed development including a description of the community benefits.

(3) The economic impact assessment report referred to in (1) above must be prepared by a suitably competent person.

Note — For the purpose of this section of the planning scheme policy, a competent person is an appropriately qualified and experienced economist or economic analyst with appropriate and proven technical experience in providing advice about the economic impacts of development.

SC6.5.2.2 Trade Area

For developments that are trade area based, the definition of the trade area should have due consideration to the following:

(1) the existing centres hierarchy and other relevant competition;

(2) the nature, scale and functionality of the proposed development;

(3) the nature of the potential users of the development (e.g. residents, workers, students, other businesses);

(4) typical travel routes of potential users of the development; and

(5) the attracting capacity of any neighbouring uses.

A map(s) of the trade area should be included in the economic impact assessment report, which clearly defines the trade area boundary, identifies relevant existing centres, identifies the site of the proposed development and includes key transport corridors. The economic impact assessment report should include a justification of the proposed trade area boundary.

SC6.6 Emerging community planning scheme policy

SC6.6.1 Introduction

Short Title - The planning scheme policy (PSP) may be cited as the Emerging community PSP.

SC6.6.1.1 Purpose

The purpose of this planning scheme policy is to provide applicants with direction on how to undertake structure planning for a greenfield development area contained within an emerging community zone. Such a structure plan is likely to be required to demonstrate compliance with the zone code and reconfiguration of a lot code.

The provision of this planning scheme policy may also be relevant to other large scale development within the city.

SC6.6.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016.*

SC6.6.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in Parts 6 and 9. The Emerging community planning scheme policy specifically relates to the assessment of any development application for a material change of use or reconfiguring a lot within the Emerging community zone.

SC6.6.1.4 Terminology

Terms used in this planning scheme policy are as defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 - Definitions is to be interpreted in accordance with Part 1.3.1.

SC6.6.2 Planning scheme policy details

SC6.6.2.1 Structure planning framework

A structure plan prepared under this planning scheme policy will address the following aspects at a minimum:

(1) type of development and land uses proposed;

(2) scale, density and height of development;

(3) servicing of the development by transport and other infrastructure;

(4) how the proposal addresses the relevant planning scheme overlays; and

(5) integration of the development with the local context.

SC6.6.2.2 Structure plan contents

A structure plan should identify the major elements of the locality surrounding a development that can impact on the planning and design of the site. It does not constitute an approval for land outside the development site but ensures the continuation of corridors, networks and linkages.

The major components of the development are to be designed with consideration of this broader context. It must be clear how the proposed development will integrate with the surrounding community and with the existing parks, centres, service and infrastructure networks and the movement system (road network, public transport facilities and pedestrian and cyclist paths) in the area. Where necessary, the structure plan will identify upgrades to infrastructure which are required to achieve the development outcomes proposed in the structure plan.

(1) Preparing a structure plan:

The steps that should be followed and information provided when preparing a structure plan are outlined below. Separate maps and reports may be provided for each step.

(a) Step 1—Site context:

Prior to preparing the structure plan an assessment of the site and its context must be undertaken and a site description of the land prepared, supported by a map containing the following features as a minimum:

(i) topography—contours and levels;

(ii) the street network, intersections and treatments, and public transport routes and stops;

(iii) existing and approved land uses on surrounding sites (including subdivision layouts) and including the location of nearby schools, activity centres, employment generators and other community facilities; and

(iv) the existing and proposed park network and pedestrian and cyclist paths.

(b) Step 2—Constraints mapping (identification):

Land may possess attributes or be subject to constraints which affect the development on the site. State planning regulatory provisions and overlays must be considered as part of the constraints mapping process.

(c) Step 3—Constraints analysis, land use allocation and infrastructure provision:

The site context mapping (step 1) and identification of constraints (step 2) will inform a further detailed analysis of the conditions on the site. This process will seek to 'ground truth' the sites constraints. It will involve technical investigation to identify specific constraints and their implications on future development of the land. The outcomes of the constraints analysis will determine which land is able to be developed for urban purposes and will also provide guidance to suitable uses of the land.

The design response should consider:

(i) the proposed layout and land use mix are integrated appropriately with surrounding land;

(ii) constraints are reflected on the structure plan and are in accordance with their relevant values;

(iii) an appropriate and well-designed proposed transport network;

(iv) the development incorporates appropriate provision for infrastructure (water, sewer, stormwater, parks and community services) for the land and demonstrates how the infrastructure is able to be coordinated with adjoining development where applicable; and

(v) where needed, land uses buffers to other uses or values.

(d) Step 4—Documenting the structure plan:

The structure plan for the land may include the following, as relevant to the land:

(i) the vision and principles for the structure plan area;

(ii) appropriate controls for land use and density, connectivity, open space and public realm and built form and design;

(iii) identification of specific precincts with individual characteristics and development outcomes, as relevant to the land and the site constraints;

(iv) levels of assessment where this is proposed to be altered through a preliminary approval; and

(v) any alternative code provisions where these are proposed to be altered through a preliminary approval. Any proposed code is to be constructed to be consistent with the format of codes within the Townsville City Plan.

SC6.7 Flood hazard planning scheme policy

SC6.7.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Flood hazard PSP.

SC6.7.1.1 Purpose

The purpose of the planning scheme policy is to:

(1) provide background information on the derivation of the Flood hazard overlay identified as overlay maps OM-06.1 and OM-06.2; and

(2) provide applicants with additional information and guidance in meeting the requirements of the Flood hazard overlay code.

SC6.7.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016.*

SC6.7.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan and applies to the whole of the local government planning scheme area. Flood hazard PSP specifically relates to the assessment of Flood hazard overlay code.

SC6.7.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 – Definitions, is to be interpreted in accordance with Part 1.3.1 Definitions.

SC6.7.2 Background information

SC6.7.2.1 Flood mapping

The flood hazard overlay maps show flood hazard derived from numerous sources and include:

(1) Detailed flood modelling studies identified in SC6.7.2.1.1 of this planning scheme policy; and

(2) Interim flood assessment overlay mapping completed by the Queensland Reconstruction Authority and amended for local constraints by Townsville City Council.

SC6.7.2.1.1 Flood modelling studies

Flood modelling studies are complex technical investigations requiring a detailed understanding of catchment hydrological processes and floodplain hydraulic controls. Computer simulations are used to quantify runoff from rainfall and evaluate flow patterns and flooding extents around floodplains. There are numerous flood modelling studies which have been completed for the Townsville local government area. Results from these flood modelling studies have been combined to provide the Flood overlay maps.

At the commencement date of the planning scheme, the flood modelling studies that have contributed to the Flood overlay maps are:

(1) Alligator and Whites Creek Flood Study (Alligatorcreek);

(2) Althaus Creek Flood Study - Baseline Flooding Assessment (AlthausCk);

(3) Townsville Flood Hazard Assessment Study (Arcadia, NellyBay and PicnicBay);

(4) Balgal Beach Infrastructure Master Planning Report (BalgalBeach);

(5) Black River Flood Study - Baseline Flooding Assessment (BlackRiver);

(6) Bluewater Creek Flood Study (Bluewater);

(7) Captains Creek Flood Study - Baseline Flooding Assessment (CaptainsCreek);

(8) Deeragun Flood Study - Baseline Flooding Assessment (Deeragun);

(9) Douglas/Annandale Flood Study - Baseline Flooding Assessment (DougAnnan);

(10) Gordon Creek Flood Study - Baseline Flooding Assessment (GordonCreek);

(11) Horseshoe Bay Flood Study - Baseline Flooding Assessment (HorseshoeBay);

(12) Little Bohle River Flood Study - Baseline Flooding Assessment (LittleBohle);

(13) Lousia Creek Flood Study - Baseline Flooding Assessment (LousiaCreek);

(14) Lower Bohle Flood Study - Baseline Flooding Assessment (LowerBohle);

(15) Townsville State Development Area - Flood Modelling (LowerStuart);

(16) Middle and Upper Bohle Flood Study - Baseline Flooding Assessment (MiddleBohle and Upper Bohle);

(17) North Ward Flood Study - Baseline Flooding Assessment (NorthWard);

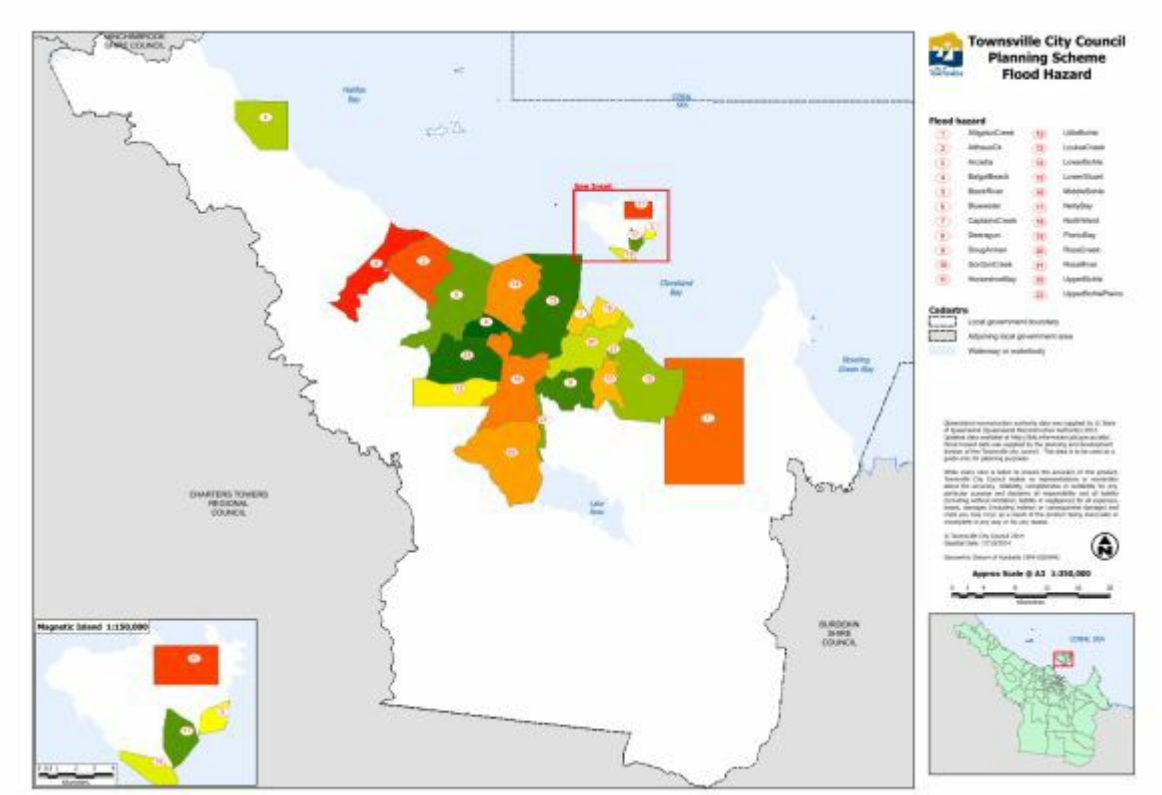
(18) Ross Creek Flood Study - Baseline Flooding Assessment (RossCreek);

(19) Ross River Flood Study - Baseline Flooding Assessment (RossRiver); and

(20) Upper Bohle Plains Flood Study - Baseline Flooding Assessment (UpperBohlePlains).

The area of applicability for each of the flood modelling studies identified in the aforementioned have been graphically presented on Figure SC6.7.1– Flood modelling study areas.

Flood modelling studies are under constant development due to the construction of infrastructure and the acquisition of new data. This information is available on Townsville City Council's website and contains digital copies of the latest and current flood modelling studies.



Click here to view PDF high resolution map.

Figure SC6.7.1 - Flood modelling study areas

SC6.7.2.2 Flood hazards

The Flood hazard overlay maps OM-06.1 and OM-06.2 have the following flood hazard ratings identified:

(1) high flood hazard;

(2) medium flood hazard;

(3) low flood hazard; and

(4) medium flood hazard – further investigation.

SC6.7.2.2.1 High and medium flood hazard

Both the high flood hazard and the medium flood hazard areas mapped on the Flood hazard overlay maps OM-06.1 and OM-06.2 are based on the 1% AEP flood. A velocity-depth criterion is used to distinguish between high flood hazard and medium flood hazard areas. High flood hazard areas are characterised by faster flowing and/or deeper floodwaters.

Figure SC6.7.2 – Flood hazard categorisation on 1% AEP flood (below) - shows the velocity depth criteria for designating the high flood hazard and the medium flood hazard areas from the 1% AEP flood. Velocity and depth information for the 1% AEP flood has been determined from flood modelling studies (refer SC6.7.2.1.1).

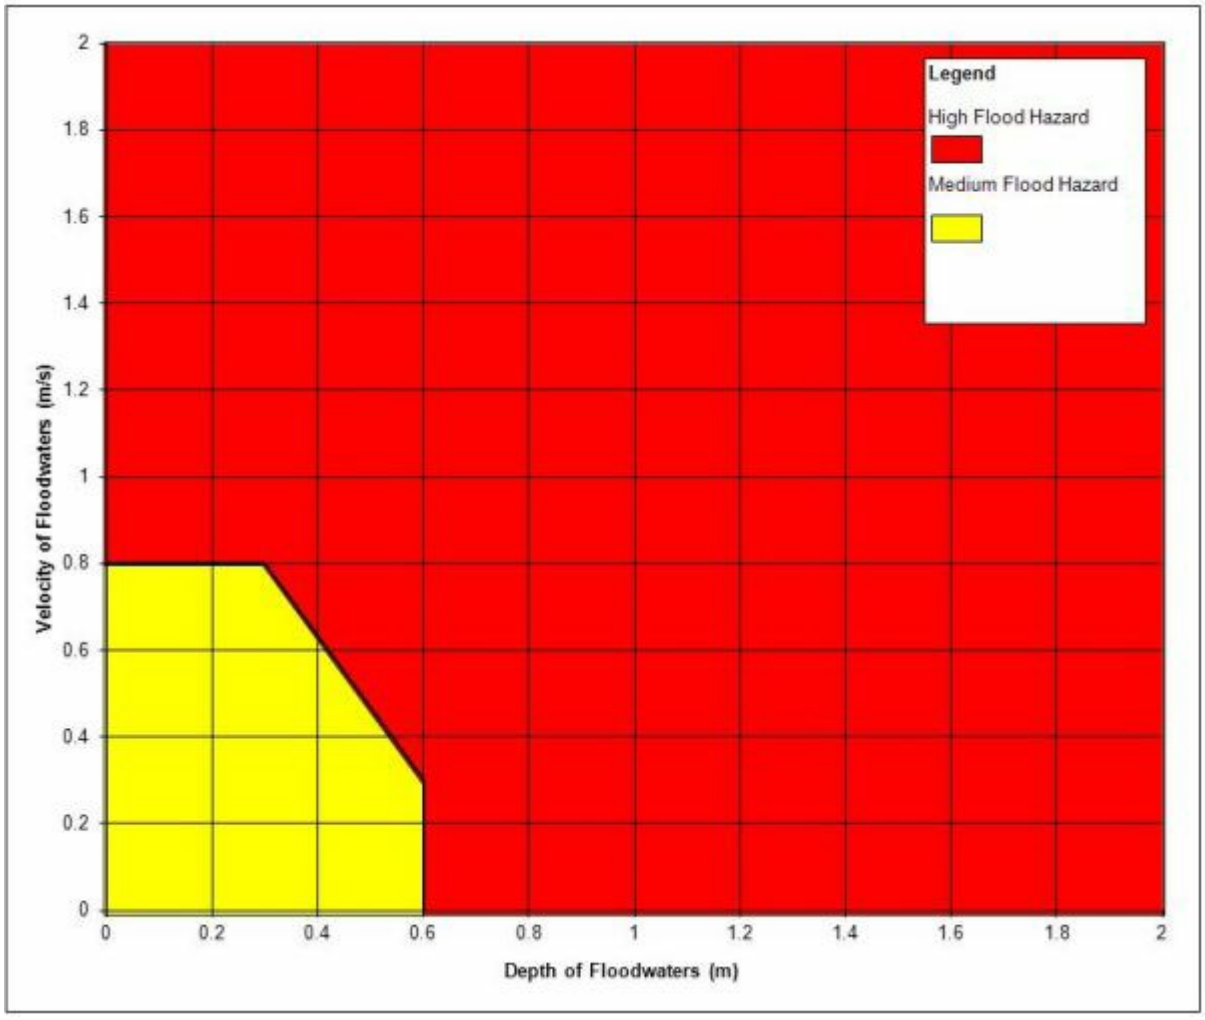


Figure SC6.7.2 - Flood hazard categorisation on 1% AEP flood

SC6.7.2.2.2 Low flood hazard

Areas of the floodplain outside the 1% AEP flood extent are still susceptible to flooding in rarer, more extreme flood events. Within the Flood hazard overlay maps OM-06.1 and OM-06.2, the low flood hazard area is identified as areas inundated by the probable maximum flood outside the combined extent of the high and medium flood hazard areas. The extent of the probable maximum flood has been determined from flood modelling studies (refer SC6.7.2.1.1).

SC6.7.2.2.3 Medium flood hazard - further investigation

Areas identified as medium flood hazard – further investigation on the Flood hazard overlay maps OM-06.1 and OM-06.2 are areas outside the extent of flood modelling studies and have been mapped by the Queensland

Reconstruction Authority. The Interim flood assessment overlay mapping produced by the Queensland Reconstruction Authority has been reviewed and amended by Townsville City Council to reflect local conditions. This information is less reliable than the other areas mapped on the flood hazard overlay maps OM-06.1and OM-06.2. Limited information is available on the flood characteristics in these areas as there is no information about flood depths, levels or velocities.

Within areas identified as medium flood hazard – further investigation, assessable development is likely to require further detailed flooding investigation, involving:

(1) development of a base-line flood study in accordance with Attachment 1 - Guidelines for preparation of flood studies and reports at a scale suitable to represent relevant floodplain process and site specific features;

(2) assessment of the potential impacts on flooding of the proposed development;

(3) identification of suitable measures to mitigate any adverse impacts on flooding; and

(4) demonstration of how the proposed development layout reduces the risk of flooding.

SC6.7.2.3 Defined flood level

Most development applications for which the Flood hazard overlay code is triggered will require details of the defined flood event (DFE). The DFE is the 1% AEP flood, which is spatially represented by the combined extent of the high flood hazard and the medium flood hazard areas mapped on the Flood hazard overlay maps OM-06.1 and OM-06.2.

For development which is accepted subject to requirements, it is most likely that existing information from flood modelling studies for the DFE will be adequate to address the acceptable outcomes of the Flood hazard overlay code. Information on the DFE derived from the flood modelling studies can be obtained from council's website.

SC6.7.3 Application requirements

This section provides information for a development application, guidance and advice for addressing assessment benchmarks.

SC6.7.3.1 Addressing assessment benchmarks

SC6.7.3.1.1

Development that is accepted subject to requirements and triggers the Flood hazard code only has to address the acceptable outcomes for performance outcomes 1 and 2 of the code.

Performance outcome 1
Development in medium and high hazard areas is designed and located to minimise susceptibility to and potential impacts of flooding.

Other than in the medium hazard - further investigation, council will be able to make available the height of the flood level for any particular location, upon request, where flood modelling studies have been undertaken (refer SC6.7.2.1.1).

In some areas, storm tide hazard areas will also co-exist with flood hazard areas. In these instances, the floor levels and other design responses will need to be sufficient to comply with both the Coastal environment overlay code, the Flood hazard overlay code and the *Building Regulation 2006*. Typically, floor levels will need to be based on the highest of either the defined flood level or the defined storm-tide level as depicted in Figure SC6.7.3.1.1.1-Floor control levels for both flooding and storm tide (below).

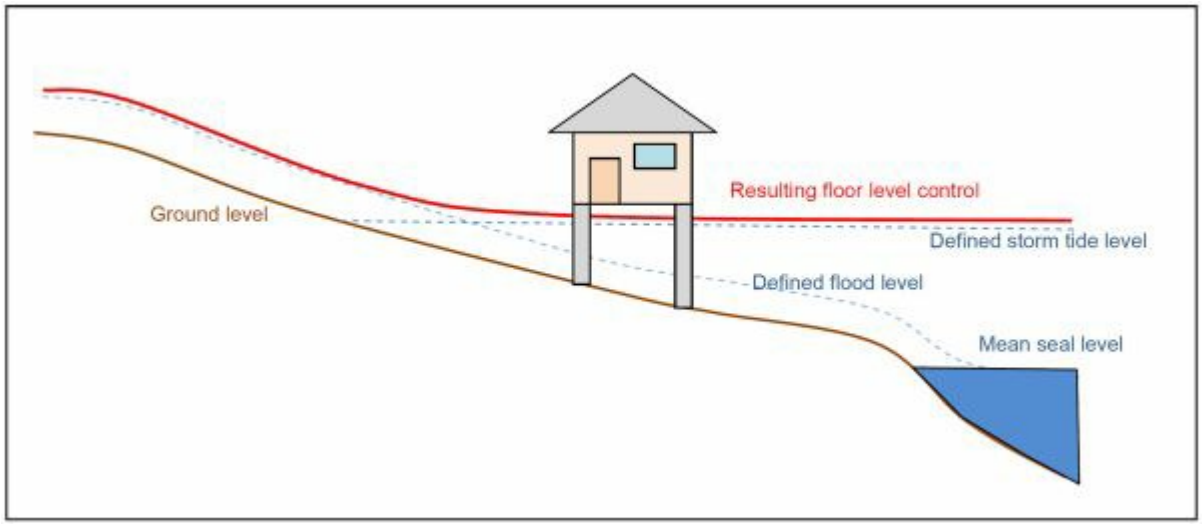

Figure SC6.7.3.1.1.1 - Floor control levels for both flooding and storm tide

Performance outcome 2

Development in high hazard areas does not significantly impede the flow of flood waters through the site or worsen flood flows external to the site.

The delineation of the high flood hazard areas on Flood hazard overlay maps OM-06.1 and OM-06.2 allows for clear identification of areas where performance outcomes 2 is applied.

Performance outcome 3

Development does not intensify use in high hazard areas, in order to avoid risks to people and property.

The delineation of the high flood hazard areas within Flood hazard overlay maps OM-06.1 and OM-06.2 allows for identification of areas where performance outcome 3 applies. Where flood flows are potentially altered by the development, a flood study will likely be required and the revised extent of the high flood hazard area will need to be mapped.

Performance outcome 4

Siting and layout of development maintains the safety of people and property in medium hazard areas.

Other than in the medium hazard – further investigation, council will be able to make available the height of the flood level for any particular location, upon request, where flood modelling studies have been undertaken (refer to SC6.7.2.1.1).

Alternatively, council's online flood mapping service can be used to obtain the height of flood levels for any particular locations.

Where flood flows are potentially altered by the development, a flood study will likely be required and the revised extent of the medium flood hazard area will need to be mapped.

Performance outcome 5

Signage is provided within high and medium flood hazard areas to alert residents and visitors to the flood hazard.

Signage will need to clearly state the nature of the flood hazard, with regards to inundation depths and flow velocities. Signage should also be able to function during a flood event and be practically visible.

Performance outcome 6

Development within high and medium flood hazard areas ensures any changes to the depth, duration, velocity of flood waters are contained within the site.

A flood modelling study, completed by a suitably qualified and experienced Registered Professional Engineer of Queensland (RPEQ), in accordance with Attachment 1 - *Guidelines for Preparation of Flood Studies and Reports*, will likely be required.

As a minimum, evaluating the impacts on floods up to the defined flood event will require a flood modelling study to evaluate the minor drainage system capacity event and the defined flood event for the catchment-wide critical duration and the site-specific critical duration. In addition, certain areas of the Townsville Local Government area will require evaluation of other frequency floods to assess adverse impacts on flooding. Attachment 2 – *Adverse Flooding Impacts Assessment – Additional Design Floods for Assessment* outlines areas where impact assessment and flood mitigation works will need to consider additional design floods to the minimum requirements.

To confirm adverse impacts on flood levels/depths, flow velocities and time of inundation are contained to the site; a pre- and post-development scenario will need to be assessed. Where possible, council requires the base-line flood modelling study that was used for deriving the flood hazard overlay to be used for evaluating development impacts. The RPEQ undertaking the impact study will need to determine if there is a need to update the base-line flood modelling with site specific survey/detail to adequately describe the hydrologic or hydraulic controls.

Performance outcome 7

Development within high and medium flood hazard does not directly, indirectly or cumulatively worsen flood characteristics outside the development site, having regard to:

(a) increased scour and erosion; or

(b) loss of flood storage; or

(c) loss of or changes to flow paths; or

(d) flow acceleration or retardation; or

(e) reduction in flood warning times.

To adequately assess the impacts of development on flooding regimes may require a hydrological and hydraulic assessment to be carried out by a suitably qualified and experienced hydrologist or engineer in accordance with Attachment 1 - *Guidelines for Preparation of Flood Studies and Reports.*

As a minimum, evaluating the impacts on floods up to the defined flood event will require a flood modelling study to evaluate the minor drainage system capacity event and the defined flood event for the catchment-wide critical duration and the site-specific critical duration. In addition, certain areas of the Townsville Local Government area will require evaluation of other frequency floods to assess adverse impacts on flooding. Attachment 2 – *Adverse Flooding Impacts Assessment – Additional Design Floods for Assessment* outlines areas where impact assessment and flood mitigation works will need to consider additional design floods to the minimum requirements.

To evaluate the potential for worsening flooding outside the development site; a pre- and postdevelopment scenario will need to be assessed. Where possible, council requires the baseline flood modelling study that was used for deriving the flood hazard overlay to be used for evaluating development impacts. The RPEQ undertaking the impact study will need to:

(a) determine if there is a need to update the base-line flood modelling with site specific survey/detail to adequately describe the hydrologic or hydraulic controls; and

(b) undertake analysis to adequately assess the potential for directly, indirectly or cumulatively impacting on flooding.

Figure SC6.7.1 – Flood modelling study areas of this PSP identifies which flood study has derived the flood hazard overlay in given areas.

Performance outcome 8

Facilities with a role in emergency management and vulnerable community services are able to function effectively during and immediately after flood events.

It is appropriate to have a higher level of flood immunity for critical community infrastructure. Table 8.2.6.3(b) within the Flood hazard overlay code outlines the required immunity for critical community infrastructure with a role in emergency management. The identified flood immunities within Table 8.2.6.3(b) should be used for setting flood levels as well as designing building services associated with the facility.

Performance outcome 9

Public safety and the environment are not adversely affected by the detrimental impacts of flooding on hazardous materials manufactured or stored in bulk.

The delineation of the low, medium and high flood hazard areas are shown the Flood hazard overlay maps OM-06.1 and OM-06.2 and allows for clear identification of areas where performance outcome 9 is applied.

Other than in the medium hazard – further investigation, council will be able to make available the height of the flood level for any particular location, upon request, where flood modelling studies have been undertaken (refer to SC6.7.2.1.1).

Alternatively, council's online flood mapping service can be used to obtain the height of flood levels for any particular locations.

SC6.7.4.1 Introduction

A flood study consists of the following parts:

(1) the hydrological determination to calculate the likely volume of water that results from the storm under consideration;

(2) the hydraulic determination to calculate the inundation levels and flow velocities that will most likely occur from the flow of water determined in the hydrological determination; and

(3) subsequent modelling to determine development impacts for the proposed development along with evaluation of works to mitigate the impacts of development.

Flood studies will be accepted based on approved inundation estimation calculation procedures and on observed historical records that can be quantified and related to an Average Recurrence Interval (ARI) by the use of the appropriate statistical flood frequency analysis procedure. It should be noted, use of historical records may allow for determination of inundation levels, however, will not be able to quantify the impacts on flooding of a development.

For analysis purposes a specific storm event is nominated as the benchmark event or standard to which council requires immunity against inundation for a development. That event is called the Defined Flood Event (DFE).

This guideline provides guidance on the appropriate use of given methods as well as some guidance on parameter values within the Townsville Local Government Area. There are numerous industry technical documents that detail the methods that should be consulted when completing flood studies including:

(1) Australian Rainfall and Runoff (AR&R); and

(2) Queensland Urban Drainage Manual (QUDM).

SC6.7.4.2 Catchment land use

Catchment land use is an important consideration for flood studies. The level of urbanisation within a catchment influences the volume of runoff and magnitude of peak discharges by:

(1) increasing the impervious fraction of the catchment which reduces the volume of infiltration and increases the total volume of runoff; and

(2) decreasing the time to peak discharge due to construction of open drains and stormwater networks which

concentrates flows and may increase the magnitude of peak discharges.

Strategies to avoid and increase in flooding as a result of any works may include:

(1) mitigation of flows at the individual development;

(2) catchment wide approach to mitigation of flows; or

(3) allowance for additional flow capacity within flow paths.

The strategy for accommodating flows will depend on existing land uses within the catchment and the environmental value of the watercourse. In preparing a flood study, **council must be consulted to identify the proposed approach to flood mitigation within the catchment.** The flood study may require assessment beyond the planning horizon in the current planning scheme, and make a determination of potential ultimate possible development or at least into the future for a period of 50 years, and even possibly 100 years.

As a general principle, drains are an opportunity to have several functions including providing flood mitigation for an area, however for the rest of the time they can be quite an effective open space for the community.

SC6.7.4.3 Hydrological determination

SC6.7.4.3.1 General

The hydrological process that is to be used for determining the design flows for the hydraulic modelling is to be cognisant of the proposed land uses. When calibration is being undertaken based on historical events, then the model being calibrated is to be based on the land use at the time of the storm event under calibration.

The choice of hydrologic method must be appropriate to the type of catchment and the required degree of accuracy. Simplified hydrologic methods such as the Rational Method should not be used whenever a full design hydrograph is required for flood mapping or to assess flood storage issues. Instead the more reliable runoff-routing techniques presented in publications such as Australian Rainfall & Runoff (ARR) should be adopted. Chapter 4 of the Queensland Urban Drainage Manual (QUDM) provides detailed guidance on the selection of an appropriate hydrologic method.

SC6.7.4.3.2 Hydrologic method

The hydrologic method adopted for the required analysis should be appropriate to the type of catchment and the design problem being assessed. Designers should be aware of the limitations, for each of the methods.

Approach	Applicability	Notes
Rational method	• Regular shaped catchment; • Homogenous catchments (generally uniform land use within the catchment); • Storage or timing issues are not relevant; • Rural catchments smaller than 25km^2; • Urban catchments smaller than 5km^2; • Time of concentration is likely to be less than 30 minutes; • **Rational method should only be used for drainage design as it is not appropriate for impact assessment at master planning stage.**	An appropriate method for calculating the time of concentration is essential to applying the rational method.
Synthetic unit hydrograph procedure	• Rural catchments; • Larger flood events where overbank flows are developed; • Rainfall can be assumed to be uniform across the catchment; • **Synthetic Unit Hydrograph Procedure has limited practical application in development assessment.**	Use of synthetic unit hydrograph procedures is not preferred and should preferably be undertaken by an experienced hydrologist with an extensive knowledge of the catchment.

Non-linear runoff-routing models (RORB, RAFTS, WBNM, URBS)	• Rural and Urban catchments (Rural only for RORB and all others should be used with caution in urban areas); • Storage or timing issues are relevant. • **Non-linear Runoff Routing Models are appropriate for drainage design or impact assessment at master planning stage, particularly for areas comprising both rural and urban land uses.**	Council uses RAFTS and requires any flood studies completed within the Townsville LGA to be completed using RAFTS. Models should be generally developed by suitably experienced practitioners, with appropriate verification / calibration of the models.
Time area runoff-routing models (DRAINS, ILSAX)	• Urban catchments with significant underground pipe network; • Storage or timing issues are relevant. • **Time Area Runoff Routing Models are appropriate for drainage design or impact assessment at master planning stage, particularly for areas only urban land uses.**	Models should be generally developed by suitably experienced practitioners, with appropriate verification / calibration of the models.
Direct rain on grid application in hydraulic model (MIKE FLOOD, TUFLOW)	• Flatter areas to prevent instabilities forming from flows down steep surfaces; • Study area needs to be small enough so that the model grid cell is not too large. • Storage or timing issues are relevant. • **Rain on Grid approach is appropriate for drainage design or impact assessment at master planning stage, and can represent areas comprising both rural and urban land uses.**	Although these methods are a component of hydraulic determination, they supplement the need for hydrologic determination and are gaining wider acceptance within the industry. Models should be generally developed by suitably experienced practitioners, with appropriate verification / calibration of the models.

Any hydrologic method using emerging technologies needs to clearly demonstrate:

(1) The approach and the principles it employs;

(2) Assumptions and limitations; and

(3) Appropriate calibration or verification.

SC6.7.4.3.3 Catchment parameters

Discussion on catchment parameters is required in particular:

(1) Overall catchment area and sub-catchment areas;

(2) (Sub-) catchment roughness and how the roughness or retardance was developed (may include a photographic record);

(3) Fraction impervious and how values have been derived including reference to what date values represent;

(4) Rainfall losses; and

(5) (Sub-) catchment slopes and how these have been derived.

All information used to define catchment parameters should be clearly referenced. A site assessment in the selection of some parameters is essential.

Catchment roughness

Catchment roughness or surface retardance accounts for the influence of vegetation and surface roughness on the generation of flows from sub-catchments. Ideally, values should be determined from calibration of the hydrological model to stream gauging. Values should be in the ranges presented below:

Catchment land use	Roughness coefficient (n*)
Urban impervious areas	0.010-0.030
Bare soil	0.010-0.050
Sparse vegetation	0.050-0.130
Heavily vegetated areas	0.080-0.200

Note that a sub-catchment may consist of numerous surface types that need to be accounted for in the specification of the catchment roughness.

Rainfall Losses
Rainfall losses account for rainfall which does not contribute to stormwater runoff because of infiltration and storage in surface depressions. Rainfall losses can vary from event to event and depend on antecedent rainfall conditions. Loss values for historical floods should be determined from calibration with loss values within the range of values as follows:

Surface type	Loss values
Pervious	Median initial loss 15 – 35 mm Median continuing loss – 2.5 mm/h Initial loss 0 – 140 mm Continuing loss 0.1 to 8 mm/h
Impervious	Initial loss 1mm Continuing Loss 0 mm/h

It should also be noted that loss values can vary between design storms of different frequencies. Guidance on appropriate loss values for different ARI storms can be obtained by matching peak discharges with peak flows determined from flood frequency assessment.

Sub-catchment slope
Sub-catchment slope can be derived from topographic maps or survey. Slopes applied should be representative of the sub-catchment and the modeller should ensure:

(1) The appropriate slope schematisation is applied when assigning values (equal area slope, vectored slope,); and

(2) Limitations of slope within the hydrological calculation method (i.e. Laurensen's method – minimum slope 0.3-0.5%, maximum slope 15%).

SC6.7.4.3.4 Rainfall intensities
Design Intensity-Frequency-Duration (IFD) Rainfall - IFD relationships shall be derived in accordance with the methodologies outlined in Australian Rainfall & Runoff, for the particular catchment under consideration. Input parameters shall be shown in the calculations submitted to council.

SC6.7.4.3.5 Partial area effects
If the Rational Method is being used, then there should always be checks to ensure that flows of greater magnitude are not apparent for partial catchment areas with faster runoff characteristics. These partial areas should be checked with the higher intensities relating to the shorter times of concentration.

Likewise, when using hydrograph techniques (such as runoff routing or Rain on Grid procedures), a range of storms of different duration for the same ARI should be checked to ensure that the worst event for the ARI is calculated and adopted. It should be noted that a range of storm durations may be required to evaluate sites that cover longer reaches of watercourses or numerous watercourses.

SC6.7.4.3.6 Calibration and verification of hydrological models
Calibration of results based on observed inundation events is desired. There are many pluviograph stations located within and adjacent to the City. Information from these is generally available from the Bureau of Meteorology or relevant Queensland Government department(s). Records from stream gauging stations will be required to match to hydrologic calculations and are generally available from the relevant Queensland Government department(s).

If observed data is not available to assist in the study, then it is suggested that the estimation of discharge flows from several methods will be considered with greater confidence in the result than the estimation of flows from one method alone.

SC6.7.4.3.7 Assessment of development impacts

When undertaking an assessment of the potential for development impacts on flooding, the development must be appropriately accounted for in the hydrological assessment including:

(1) Changes to imperviousness and expected rainfall losses;

(2) Changes to catchment layouts or extents;

(3) Changes to catchment roughness;

(4) Changes to slopes; and

(5) A re-evaluation for the potential for partial-area effects.

SC6.7.4.3.8 Preparation of reports

Reporting requirements

The method chosen should be adequately referenced and values derived should be substantiated by defining procedures used in their derivation. Where parameters are chosen or assumed, references and reasons should be supplied. The preferred method of setting out the hydrology is to describe in the text of the report the method to be used, and then to set the calculations out in a clear and concise table with sufficient data to enable quick verification of the results. The time of concentration or critical duration storm from the hydrological assessment should be clearly identified for areas relevant to the site.

Where computer methods for calculation of flows are used, the text of the report should describe the method that is utilised by the computer programme. Parameters that have been chosen should be referenced with reasons stated for any assumptions. A figure should be used to clearly demonstrate the layout of the model. Output from software should be tailored to produce concise tabular results to enable quick verification of the results. Where recognised computer programmes are utilised, council may require the electronic data files to be provided in acceptable format.

Where insufficient data is supplied then delays will occur while studies are returned to enable the additional data to be provided.

Catchment maps

Most hydrological techniques will require a catchment analysis and stream slope analysis. The catchment analysis should be presented on as large a scale map (smallest reduction ratio) as possible. The following scales for catchment sizes are recommended for use:

Scale	Catchment area
1:1000	up to 0.5 sq. kms (50 ha)
1:2000	up to 1.0 sq. kms (100ha)
1:5000	up to 1.5 sq. kms (150ha)
1:10000	up to 50 sq. kms (5000ha)
1:25000	limited to 300 sq. kms per sheet

Maps should be well presented with catchments contained upon one sheet where possible. Standard sized sheets should be used. Sub-catchments should be boldly defined and the contours should be clearly defined to enable easy verification of the catchments in relation to the contours. Where sub-catchments are not consistent with the contour information then reasons should be stated in the text and clearly labelled on the map. Good drafting standards should be maintained in the presentation of these maps.

SC6.7.4.4 Hydraulic determination

SC6.7.4.4.1 General

The hydraulic determination involves the calculation of flood levels and velocities for the flood flows from the hydrological determination. Australian Rainfall and Runoff and the Queensland Urban Drainage Manual set out

aspects of hydraulic calculations that can be utilised to determine the water levels for design discharges.

Unless the channel consists of long lengths of uniform section and uniform flow, the Mannings equation cannot be used in its simple form. This equation describes flow in a uniform channel at non-varying steady state flow conditions.

Australian Rainfall and Runoff describes methods for flood level determination in gradually varied flow conditions. The method for hydraulic determination will be dependent on the hydraulic controls of the study area. In general, it is appreciated that these methods will use computer applications.

SC6.7.4.4.2 Hydraulic method

The hydraulic method adopted for the required analysis should be appropriate to the hydraulic controls of the study area and the design problem being assessed. Designers should be aware of the limitations, for each of the methods.

Approach	Applicability	Notes
Steady state – one dimensional (HEC-RAS)	• Storage or timing issues are not relevant; and • Flows are one-dimensional, largely within a watercourse and the immediate overbank area.	Generally only suitable for small site scale hydraulic determination.
Fully dynamic – one-dimensional (MIKE11, ISIS, SWMM)	• Storage or timing issues are relevant; • Flows are one-dimensional, largely within a watercourse and the immediate overbank area.	Suitable for smaller onedimensional watercourses. Provides stability advantages over 2D models for steeper areas. Council uses MIKE11 and requires any flood studies completed within Townsville using a fully dynamic – onedimensional model, to use MIKE11.
Fully dynamic – two dimensional (MIKE21, TUFLOW)	• Storage or timing issues are relevant; • Flows are two-dimensional,	Flood maps are generally direct output from models. Council uses MIKE21 and requires any flood studies completed within Townsville using a fully dynamic – two-dimensional model, to use MIKE21.
Fully dynamic–coupled one & two dimensional (MIKE FLOOD, TUFLOW)	• Storage or timing issues are relevant; • Flows are combination of one and two- dimensional; • Large areas need to be represented in combination with fine detail	Council uses MIKE FLOOD and requires any flood studies completed within Townsville using a fully dynamic – one & two-dimensional model, to use MIKE FLOOD.

SC6.7.4.4.3 Topographic data

Topographic data used for the hydraulic determination will be dependent on hydraulic method:

(1) One-dimensional models employ cross-sections along branches to represent the study area topography; and

(2) Two-dimensional models employ digital elevation models to represent the study area topography.

The accuracy of the topographic data governs the accuracy of the hydraulic determination.
The accuracy of the topographic data should be clearly stated.

Cross-sections

Cross-sections are required at representative locations along a stream reach and at locations where changes occur in discharge, slope, shape, or roughness, and at bridges, culverts or control structures such as weirs. Where abrupt changes occur, several cross sections should be used to describe the change in shape regardless of the distance between sections. Cross-section spacing is also a function of stream size, slope and uniformity of cross section

shape. For one-dimensional models, the cross-sections should be wide enough so that the water surface is contained within the extent of the cross-sections. The accuracy of the hydraulic modelling will be dependent upon the spacing of cross-sections and the accuracy of the cross-section survey.

Digital elevation models

Digital elevation models used for two-dimensional models should use a grid spacing fine enough to resolve watercourses within the study area. As a general rule, a watercourse should be represented by a minimum of 5 grid-cells across the width of the watercourse. Coupled models can be used as an alternative to maintain the resolution within the watercourse.

The digital elevation model should be orientated to minimise disturbance of flows by the grid cell orientation. Aligning grid cells with streets (often part of the major drainage system) helps to achieve an appropriate orientation.

Digital elevation models are often captured from aerial surveying methods such as LiDAR or Photogrammetry. These methods can lose accuracy in areas of dense vegetation. It should be clearly demonstrated what steps (including ground survey) have been taken to improve the accuracy in areas potentially obscured by vegetation.

SC6.7.4.4.4 Roughness values

Based on the procedure developed by Cowan (1956), stream roughness values are a combination of influences from:

(1) Bed material;

(2) Surface irregularities;

(3) Variations in channel cross-section;

(4) Obstructions;

(5) Vegetation and flow conditions; and

(6) Meandering.

Different methods for hydraulic determination such as fully dynamic and fully dynamic twodimensional modelling will account for some of these influences within the underlying digital elevation model or solution scheme of the model.

Suggested ranges for roughness values based on the hydraulic method are provided below:

Land use	Roughness values (Manning's n)		
	1D Steady state	1D fully dynamic	2D fully dynamic
Natural watercourse	0.03-0.08	0.025-0.06	0.02-0.05
Riparian corridor	0.15-0.2	0.08-0.16	0.06-0.12
Open grassland	0.04-0.08	0.035-0.06	0.03-0.05
Low density vegetation	0.06-0.12	0.045-0.08	0.04-0.06
Medium density vegetation	0.08-0.18	0.06-0.1	0.05-0.08
High density vegetation	0.1-0.25	0.08-0.15	0.06-0.12
Roads	0.03-0.06	0.025-0.05	0.02-0.04
Open channels	0.03-0.05	0.025-0.05	0.02-0.04
Rural residential	0.06-0.1	0.05-0.08	0.04-0.07
Urban residential	0.06-0.15	0.05-0.12	0.04-0.1
Parks	0.04-0.18	0.035-0.1	0.03-0.08

Where possible, roughness values should be determined from calibration. Often, calibration will not be possible and sensitivity analysis to variations in roughness should be undertaken.

In the case of a one-dimensional model, roughness should be appropriately defined across the cross-sections based on the land use. In the case of a two-dimensional model, roughness should be appropriately defined using a grid to

represent the study area based on the land use.

SC6.7.4.4.5 Bridges and culverts
Australian Rainfall and Runoff and Queensland Urban Drainage Manual provide useful information and references for the determination of afflux levels and water profiles at bridges and other structures.

Head-losses across major drainage structures assessed within fully dynamic models should be verified by hand-calculations or assessment with a steady state model.

SC6.7.4.4.6 Tailwater conditions
Tailwater conditions for hydraulic models will be dependent on the location of the downstream extent of the model. Tailwater conditions may be one of the following:

(1) Sea levels for a coastal boundary;

(2) A gauged rating curve;

(3) Flood levels from the same ARI flood based on a previously accepted flood study; or

(4) Flood levels calculated from simplified means in the absence of other information (e.g. normal depth or critical depth).

In using flood levels calculated from simplified means, the method of calculation should be justified and sensitivity to input parameters should be evaluated. The downstream boundary should be located so that the boundary conditions do not influence results at the study site. Ensuring the boundary is sufficiently far enough downstream from the study site will reduce the impact on results at the site.

Requirements for some specific boundary conditions are discussed below.

Coastal boundaries
When calibrating hydraulic models, tailwater conditions should be based on observed sea levels for the event. Sea-levels are monitored at the Townsville port, with the information available through the Bureau of Meteorology.

To maintain the probability of the assessed flood event for design purposes, the tailwater condition adopted should not have a frequency of occurring any less than once a year. A fixed tailwater condition equal to the height of the Mean High Water Springs (MHWS) tide should be adopted. For storm events greater than 24 hours, a representative tidally varying water surface level between MHWS and Mean Low Water Springs (MLWS) can be adopted.

Backwater effects in tributaries from larger streams
Where a smaller stream discharges into a larger stream, it will be most probable that the larger stream will experience more severe flooding for storms of longer duration and hence lesser intensity for the same average recurrence interval. The tributary is to be checked for a storm of the same duration and intensity as that causing the peak flow in the larger stream.

The hydraulic assessment should assess the flooding for both the storm duration critical for the larger stream and the local tributary. Flood levels in the area will be based on the highest flood level determined from both storm durations. Peak velocities in the area will be based on the fastest velocity determined from both storm durations regardless of whether the storm duration that generates the fastest velocities produced the highest flood levels.

It is acknowledged that runoff routing models combined with fully dynamic hydraulic models will adequately account for these processes.

Estuary boundaries
Sometimes downstream boundary conditions for hydraulic models will be required in reaches of watercourses that are influenced by tides, but are not located at the coastline. In this instance, it is inappropriate to use neither a tidal water level boundary condition nor a rating curve boundary condition alone. The downstream boundary condition must account for both the tidal conditions and the ability for water levels to be elevated due to flood flows. Typically, this would involve the development of a rating curve with flows below MHWS set to zero and flows above MHWS to be calculated based on an appropriate water surface slope.

SC6.7.4.4.7 Impact of climate change

The impacts of climate change on flooding are likely to manifest from increased sea levels and changes in extreme event rainfall intensities. As part of understanding the risk associated with climate change, a sensitivity assessment should be undertaken as part of a flood study. The sensitivity should account for the latest projections in sea-level rise and increased rainfall intensities, specific to the area from leading authorities including relevant Queensland Government department(s), Australian Rainfall and Runoff, Commonwealth Scientific and Industrial Research Organisation, Bureau of Meteorology or Intergovernmental Panel on Climate Change. At the time of preparing this PSP appropriate values were:

Parameter	Value
Sea level rise to 2100	0.88m
Extreme rainfall Intensities to 2100	+15%

The DFE should be assessed in combination with the maximum sea-level rise applied to the MHWS level and the increase in rainfall intensities to evaluate the additional risk associated with climate change. The results from the climate change sensitivity should be assessed with commentary provided about:

(1) Areas where the floor level freeboard above the DFE would be exceeded;

(2) Any new flow paths that are formed; and

(3) What is the AEP of the climate change DFE relative to existing conditions.

SC6.7.4.4.8 Determination of impacts of development

Developments have potential to cause significant adverse impacts on flooding due to:

(1) Increasing the impervious fraction, reducing amount of infiltration and generating a larger volume of runoff;

(2) Providing more efficient conveyance of flows through the site so that flows are concentrated faster at the downstream end of the site producing larger peak flows; and

(3) Removing floodplain storage due to filling which reduces the natural flow attenuation of the floodplain and increases flood levels.

It will be necessary to carry out studies of the catchment in the pre-developed state (base case) and the developed state to determine increased amounts of flow and flood levels. The pre-developed state should represent the state of development within the catchment and floodplain immediately prior to time of construction of the proposed works.

Adverse impacts on flooding may preclude development unless appropriate flood mitigation measures are proposed as part of the development. As a result of developments:

(1) Flood levels should not increase beyond the accuracy of the method of hydraulic determination (generally 0.01 m) either upstream, downstream or adjacent to the site;

(2) There should be no significant change in flow patterns so that new flow paths on adjacent land are formed; and

(3) Any changes in flow velocities should be shown to have minimal impact on erosion potential.

Mitigation works such as levees or detention basins, involving embankments, need to be shown to have a safe overtopping failure. Such works should be modelled for the Probable Maximum Flood (PMF) to demonstrate safe passage of these flows without catastrophic failure of embankments.

Any mitigation measures recommended beyond the subject site will need to undergo the development assessment process including:

(1) Clear identification of the land parcels impacted;

(2) Development applications (material change of use, reconfiguration of a lot or operational works) - as required; and

(3) Identification of maintenance measures including responsibilities and funding sources.

Mitigation measures should generally be on the subject site unless prior discussions have been entered into with council and the landholder and there is an agreement for works outside of the subject site.

Hydraulic modelling of development

When representing development typically the hydraulic model is updated by:

(1) Changing the topography (cross-sections/DEM) to represent the development;

(2) Updating inflows to represent changes in hydrological response; and

(3) Updating roughness to represent the development.

Roughness values should only be changed to reflect the change in land use resulting from the development. These changes need to be clearly identified and justified. In assigning roughness values within new drainage channels or areas impacted by flooding, there should be consideration given to the way regrowth can occur within these areas. Areas below Highest Astronomical Tide (HAT) are likely to have mangrove regrowth occur. In areas further upstream, regrowth by tea-tree is likely to occur and can create a significant impediment to flows. Also, most flood events within Townsville occur towards the end of the wet season (January to March), when earlier rain has enabled grass in drains to grow with minimal ability to mow. Roughness values within drainage corridors for development assessment should be adopted towards the higher end of the range of values to account for regrowth, which may have minimal maintenance.

Freeboard for existing areas

Within some existing urban areas, design criteria have changed over time and have resulted in freeboard to existing buildings being less than is required in new development. To ensure the freeboard for existing areas is maintained, there should be no adverse impacts on flooding for all events floods up to the DFE. As a minimum, the assessment should demonstrate that there are no adverse impacts on flooding for the minor system drainage capacity AEP and the DFE.

SC6.7.4.5 General matters

SC6.7.4.5.1 Presentation of reports

As stated in the previous sections all reports and tabulations are to be printed on A4-sized sheets, and drawings presented on standard size sheets prepared using good drafting standards. The expected content of the reports is as discussed in SC6.7.4.2, SC6.7.4.3 and SC6.7.4.4 above. In summary the contents of a study report must include:

Hydrology section

(1) catchment Map - large as possible;

(2) report on procedure (brief), including hydrologic method, catchment characteristics, assumptions and discussions on results including critical duration /time of concentration as detailed in SC6.7.4.3 above; and

(3) calculations and model results - tabulated where possible and attached in appendix if significant in volume.

Hydraulics section

(1) report on procedure including hydraulic method, stream/floodplain characteristics and assumptions as detailed in SC6.7.4.4 above;

(2) model Results – Clearly presented as maps and tabulated values;

(3) stream Flood profile and bed profile of the study area;

(4) drawings/figures of topographic data used for the model (Digital Elevation Model map or plan of cross-section locations and cross- sections with X and Z coordinates included);

(5) a plan containing the proposed works showing any filling and excavation associated with development; and

(6) model results updated on the basis of including the development with the revised flood extents and impacts on flooding.

General

(1) discussion on sensitivity analysis for critical parameters (e.g. roughness, infiltration etc.);

(2) discussion on accuracy of inundation mapping and the resulting required flood line;

(3) recommendations as to methods of flood mitigation within the site;

(4) recommendations as to method of flood mitigation beyond the site together with development approvals,

construction proposal and funding proposals; and

(5) electronic data for both the hydrology and hydraulics in an agreed format (modelling platforms and GIS).

Drawings should be bound into the report where sizes are A3 or A4. Larger drawings are to be appropriately folded and inserted in a pocket in the back cover.

Recognition by the consultant, that the assignment of data to council, and use of the studies by council for its sole use, is a mandatory requirement before a study is commissioned and/or the results of any study will be accepted by council.

All studies, reports and submissions forwarded to council shall be prepared by, or at least certified by, a Registered Professional Engineer Queensland (RPEQ) who is registered in the specific area of engineering in which the study or report has been prepared e.g. an RPEQ (Structural) shall not certify a stormwater report.

SC6.7.4.5.2 Preference of computer models

It is acknowledged that where no modelling has been undertaken, then any modelling will provide a more accurate estimation of inundation levels than collated levels from observed inundation events.

Modelling studies where the results have been calibrated using observed levels and measured rainfalls will be recognised as providing a more representative result for the study area.

The hydrologic and hydraulic methods adopted should be suitable for purpose as indicated in SC6.7.4.3.2 and SC6.7.4.4.2. Townsville City Council requires that any flood studies completed within the Townsville Local Government Area uses software that is run internally which includes:

(1) Non-linear Routing – XP-RAFTS;

(2) 1D Steady State – HEC-RAS;

(3) 1D Fully Dynamic – MIKE11;

(4) 2D Fully Dynamic – MIKE21; and

(5) Coupled 1D/2D Fully Dynamic – MIKE FLOOD.

SC6.7.4.5.3 Copyright of reports, studies and drawings

Prepared directly for council

It is acknowledged that intellectual capacity has been demonstrated in the preparation of the report. However, the report is prepared and based on accepted engineering fundamentals and principles. In addition, the practices adopted are those developed by the engineering profession through initiative and ingenuity and ratified through the professions recognised body “The Institution of Engineers, Australia” currently trading as “Engineers Australia”.

All reports and studies (including drawings, tables, model files etc.) prepared for council under direct commission will become the sole copyright of council, and those reports will be used by council in a manner that will provide the optimum benefit to the community. All reports adopted by council will also be available for public and professional perusal on council’s website.

In any reference to the report, the author of the report will be acknowledged by council and should be acknowledged by any authorised third party user.

Submitted as part of a development application

Submitted as part of a Development Application and adopted as supporting the application only

When a technical report or study is submitted to council as part of a development application, this report/study, along with all components of the submission, can be made available to the public as part of the notification stage. The report can be provided to anyone seeking the report during this stage and following the approval. Use of the report for any third-party use will be at the complete risk of the third party. It should be noted that it will be only the approved report including any council requested amendments, which should be referred to in future.

Submitted as part of a Development Application and adopted by council as a benchmark report for future development or other purposes

From time to time, reports etc. submitted as part of a development application, or supporting an application, could provide a wider ‘regional’ significance and importance than just the development site for which they were prepared. Council may choose to open discussions with the developer to determine if obtaining all supporting digital and electronic data along with software input/output files would allow the option of adopting the report as a ‘base-line’ report for council. The decision as to whether a report has wider regional significance will be council’s alone.

Once these reports have been adopted by council as a ‘base-line’ report, the report assumes the status as if the report was prepared by or for council, and the copyright previously assigned by the author is released and the copyright provided to council. Council can use the report to achieve optimal outcomes for the wider community.

SC6.7.4 Attachment 2 - Adverse Flooding Impacts Assessment - Additional Design Floods for Asessment

Location	Design flood event
Ross River - Downstream *Within the immediate area around Ross River downstream of Ross River Dam and the lower Ross River Floodplain.*	0.2 % AEP
Ross River Upstream *Upstream of Ross River Dam*	0.5 % AEP

SC6.8 Mitigating bushfire hazard planning scheme policy

SC6.8.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Bushfire PSP.

SC6.8.1.1 Purpose

(1) The purpose of the planning scheme policy is to:

(a) support the outcomes presented in the Bushfire hazard overlay code; and

(b) provide guidance and information relating to the preparation of a Bushfire hazard assessment, and where necessary a Bushfire management plan.

SC6.8.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.8.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan, in particular, the Bushfire hazard overlay code.

SC6.8.1.4 Terminology

Terms used in this planning scheme policy are as defined in Schedule 1 – Definitions. A term used in the planning scheme policy which is not defined in Schedule 1 - Definitions is to be interpreted in accordance with Part 1.3.1 Definitions.

SC6.8.2 Planning scheme policy details

SC6.8.2.1 Bushfire hazard assessment

A Bushfire hazard assessment (and where necessary a Bushfire management plan) may be required as part of an assessable Reconfiguring a Lot or Material Change of Use development application as determined by assessment under the Bushfire hazard overlay code.

Where a Bushfire hazard assessment is required or is submitted, assessments are to be prepared and undertaken by a suitably qualified and experienced professional.

As a guide, the features sought by council to achieve a comprehensive Bushfire hazard assessment are addressed below.

The Bushfire hazard assessment should have regard to the following –

(1) Australian Standard AS3959 - 2009: Construction of buildings in bushfire prone areas.

(2) State Planning Policy and supporting guidelines.

Editor's note—A detailed guide on how to undertake this type of risk assessment is provided in QRA (2012) publication. Although this focuses on flooding the evaluation process can be applied for any natural hazard.

(1) A bushfire hazard assessment should provide:

(a) the name and qualifications or experience of the person(s) preparing the assessment;

(b) the use description;

(c) location of the extent and level of bushfire hazard in relation to the spatial extent of existing and forecasted land uses;

(d) details of the storage of any dangerous or hazardous goods to be kept on the site;

(e) details of existing vegetation, including slope and aspect characteristics of the site;

(f) details of weather conditions that influence bushfire intensity; and

(g) details of existing bushfire records and local knowledge.

(2) Risk appropriate development;

(a) mapping details of the proposed development through GIS overlays or comparison of hard copy mapping;

(b) a determination of the consequence of a bushfire hazard for each lot within the study area, and a qualitive assessment of

  (i) vulnerability;

  (ii) tolerability;

  (iii) a bushfire risk assessment to identify how development mitigation measures will work in conjunction with other risk management measures including building controls, mitigation infrastructure, early warning systems, community awareness and emergency managements to address the risk of bushfire, should it not be classed as a low hazard on the subject site; and

  (iv) recommendations.

SC6.8.2.2 Bushfire management plans

Where a bushfire management plan is required to respond to the risk, these are to be prepared and undertaken by a suitably qualified and experienced professional.

Where required, a Bushfire management plan is to include with the following:

(1) a discussion of proposed mitigation measures, the reduction of the hazard risk and the feasibility and reasonableness of these measures;

(2) identification of the key factors such as vegetation type, slope and aspect and include matters such as: likely direction of bushfire attack, environmental values that may limit mitigation options, location of evacuation routes and/or safety zones;

(3) an assessment of the specific risk factors associated with the development proposal, including matters such as the nature of activities and materials to be conducted or stored on the site, numbers and types of persons likely to be present, particular warning and/or evacuation requirements; and

(4) a plan for mitigating the bushfire risk. The plan should address all of the matters raised and recommend specific mitigation actions for the proposed development including:

  (a) road and lot layout and land use allocations;

  (b) firebreaks and buffers;

  (c) building locations or building envelopes;

  (d) landscaping treatments;

  (e) warning and evacuation procedures and routes;

  (f) firefighting requirements including infrastructure;

  (g) any other specific measures such as external sprinkler systems and alarms;

  (h) purchaser/resident education and awareness programs;

  (i) ongoing maintenance and response awareness programs; and

  (j) a description of the control measures that will be use to ensure compliance.

The level of detail required will vary with the nature of the development proposal and site, and with the type of development application.

The level of detail required to accompany a particular application should be determined in consultation with the assessment manager.

SC6.9 Natural assets planning scheme policy

SC6.9.1 Introduction

Short Title -The planning scheme policy (PSP) may be cited as the Natural assets PSP.

SC6.9.1.1 Purpose

(1) The purpose of the planning scheme policy is to:

- (a) support the use of the Natural assets overlay code;
- (b) provide background information on the derivation of the natural assets overlay maps;
- (c) outline information the council may request for a development application; and
- (d) provide guidance or advice about satisfying assessment benchmarks.

SC6.9.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.9.1.3 Relationship to Townsville City Plan

This planning scheme policy supports the assessment provisions specified in Townsville City Plan. Natural assets PSP specifically relates to the assessment of the Natural assets overlay code.

SC6.9.2 Natural assets

SC6.9.2.1 General guidance - environment protection

A healthy natural environment underpins the social and economic fabric of a sustainable city. Human modification of the natural environment interferes with physical and biological processes, natural cycles and energy flows. Natural systems can tolerate some amount of human modification however when the resilience level is exceeded, natural system break down and life support functions are diminished or damaged. In extreme cases damage may be irreparable as with endemic habitat loss, species extinction and desertification. Protecting the environment from human activities is a prerequisite for achieving ecological sustainability.

SC6.9.2.2 Land use and environment protection

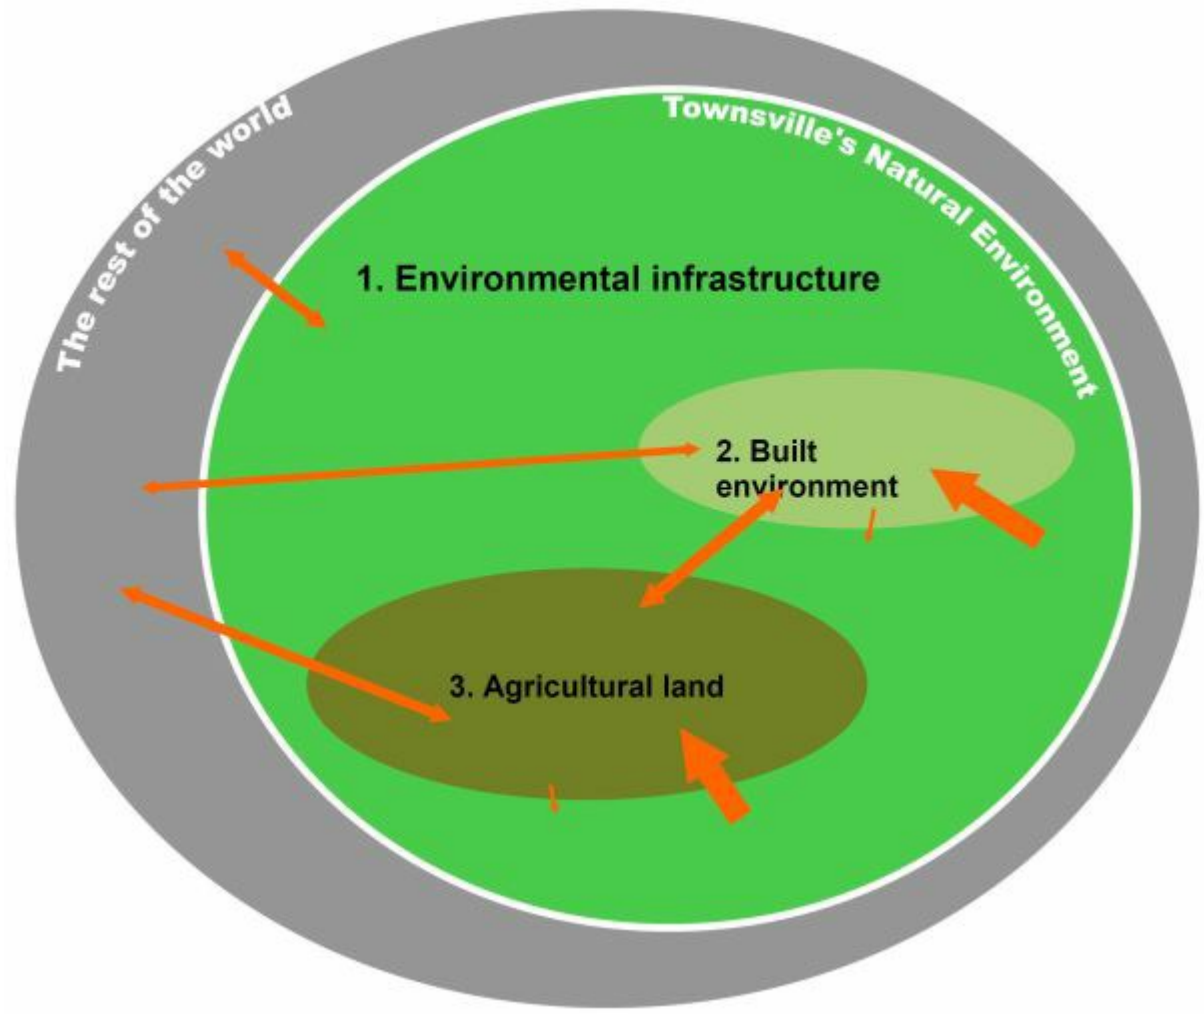
In broad terms, the three main functional land use units are:

(1) Environmental infrastructure;

(2) Built environment; and

(3) Agriculture land.

The three units are overlain on the single pillar of our existence - the natural environment, as illustrated conceptually in the diagram below.



SC6.9.2.3 Ecological planning

To seek to achieve ecological sustainability requires ecologically-based planning solutions. The underlying principle of ecological planning is the maintenance of our quality of life through the protection of our life support systems. This can best be done in a planning context through the recognition and protection of significant environmental areas.

Ecological planning takes an 'organic' approach to planning where the placement of built structures is dictated by environmental features and the need to protect and maintain natural assets and significant environmental infrastructure.

SC6.9.2.4 Environmental infrastructure

Environmental infrastructure is the basic framework or underlying foundation of the natural environment that contains the myriad of life support systems for all forms of life. Environmental infrastructure and function include:

(1) waterways/drainage systems (water drainage, water storage, seed transport, nutrient relocation, soil formation, sediment redistribution, habitat, connectivity, aquifer recharge, recreation, base flow, food source, biodiversity);

(2) wetlands (water filtering, water storage and aquifer recharge, habitat, seasonally high productivity, food source, biodiversity);

(3) riparian vegetation (shading, nutrients, ground cover; bank stabilisation, erosion prevention, water filtering, shelter/refuge, habitat, connectivity, recreation, food source, buffering, biodiversity);

(4) coastal dune systems (first line storm protection, buffering, water filtering, recreation, habitat, biodiversity);

(5) extensive forest in mid and upper catchments slopes >15% (erosion prevention, soil and slope stabilisation, soil formation, habitat, recreation, food source, aquifer recharge/intake, biodiversity, climate stabilisation);

(6) corridors and connections (wildlife movement, seed and vegetation dispersal, habitat, shade, shelter/refuge, food source, buffering, recreation, biodiversity);

(7) habitat/sustainable living space (biodiversity, connectivity, buffering, food source, recreation);

(8) native vegetation (biodiversity, habitat, wildlife movement, buffering, seed and vegetation dispersal, food source, recreation, soil health, shade, shelter/refuge, fuel, timber, erosion prevention;

(9) floodplains (habitat, biodiversity, nutrient and sediment dispersal, food source);

(10) aquifers (water storage, sub surface connectivity, hydraulic pressure); and

(11) protected areas (National Parks, Conservation Parks, Forest Reserves, Fish Habitat Areas and other socially delineated conservation areas).

Environmental infrastructure is unlikely to follow the same lines as appear on cadastral maps.

SC6.9.2.5 Ecosystem services

When planning and designing the built form we need to be aware of the intrinsic value of the surrounding environment and the ecosystem services operating in the background.

These services are provided without the need for any extra mechanical or chemical intervention and operate continually at variable rates determined by environmental conditions and climate. When we 'adjust' the environmental conditions we change the balance of ecological functions and ecosystem services at times beyond the resilience of the system to bounce back. If the change in environmental conditions is exacerbated by climate variability then a system may collapse due to the cumulative combination of natural and human impacts.

A risk management approach is adopted in ecological planning due to the uncertainties about how much of our natural assets (land, vegetation, water, soil, wildlife, soil microbes) is required to sustain an increasing human population and still maintain ecological processes at functional levels.

Determining or estimating the extent and influence of the ecological processes and ecosystem services is necessary in a planning context so that planning policies and intent can be applied to small areas (e.g. a house lot) as well as across broader landscape units such as regional ecosystems and land units.

SC6.9.2.6 Categories and components

The environmental importance ratings depicted on the Natural assets overlay map identify the likely significance of the natural environment and the likely extent of environment protection required to maintain habitat, species, vegetation communities, strategic habitat units, ecological processes, ecosystem services and hydrological function. Each of the three categories (medium, high and very high) are based on a variety of environmental and ecological components. The components associated with each category are listed in Table SC6.9.1—Environmental importance categories and components.

Table SC6.9.1 — Environmental importance categories and components

Category	Environmental importance components	General description
Very High	• Endangered ecological communities − semi evergreen vine thicket* − littoral rainforest and coastal vine thicket − broad leaf tea tree* • Endangered remnant vegetation (VMA vegetation management status) − Brigalow belt north bioregion − sub-regional (<10% left OR <300ha of pre-clearing extent remains) − local government area (<10% left OR <300ha of pre-clearing extent remains) • Remnant vegetation (VMA biodiversity status - endangered (dominant)) • Endangered high value regrowth (VMA) • Non bioregional ecosystems* • GBR wetland protection areas • Main connecting corridors • Mahogany glider habitat • Southern Cassowary habitat • Land units of limited extent* − Alligator Creek delta − *Eucalyptus acmenoides* lowlands − *Eucalyptus brownii* woodlands major occurrence − *Corymbia clarksoniana* alluvial fans − *Eucalyptus platyphylla — Melaleuca viridiflora* alluvial fan complex − *Eucalyptus tereticornis* on holocene deposits − *Grevillea striata* dominant − Land zone 4 grasslands − Pleistocene dunes − Terminal wetlands − *E. platyphylla — C. clarksoniana* woodlands on old levees and prior streams	This category includes endangered species habitat and vegetation communities along with the main connecting corridors (riparian, coastal and biogeographic units), land units of limited extent and Great Barrier Reef (GBR) wetland protection areas. These areas have been allocated as very high priority as they are the last examples of this type of vegetation community and/or habitat (generally less than 10% remains) and are the most vulnerable to loss and/or extinction in the short to medium term. Any further loss of these endangered elements could result in their loss from the landscape with little chance that they will recover or could result in their loss from the landscape with little chance that they will recover or could be restored.

Table SC6.9.1 — Environmental importance categories and components

Category	Environmental importance components	General description
High	• Of concern remnant vegetation (VMA vegetation management status) − Brigalow belt north bioregion − sub-regional (<10% left OR <300ha of pre-clearing extent remains) − local (30-50% of the pre-clearing extent remains) • Remnant vegetation (VMA biodiversity status - Endangered (sub dominant)) • High value regrowth − endangered (sub dominant) − of concern (dominant) • Wetland regional ecosystems (Estuarine, Palustrine, Lacustrine and Riverine) • Black-throated Finch habitat* • Essential habitat (regional ecosystems) • Very high ecosystem diversity (SDI >75% of the maximum value for the Bioregion) • A significant habitat for 'at risk' species • Waterways (buffered as per VMA bioregion codes) • Essential regrowth habitat (VMA)* • Wet tropics corridors* • Statewide corridors (remnant)* • Magnetic Island corridors (remnant)* • Magnetic Island lowland values(remnant)* • Land units of limited extent* − Castle Hill − (Sandy Creek and Double Barrel Creek) floodplain complex − watercourses (and associated areas subject to flooding)	This category includes the next most threatened suite of habitat, species and regional ecosystems (generally less than 30% of these components remaining in the landscape) along with strategically important connecting corridors, essential regrowth habitat, wetland regional ecosystems and endemically important landscape elements. It also includes a significant portion of the network of waterways and buffers (not included in the very high category) that are critical to the maintenance of ecological functions and ecosystem services. This category includes environmental elements close to the probable 'survival edge' as 30% is considered to be at the lower limit of ecological viability and function for habitat and vegetation communities. Any further reduction of extent is likely to result in a downward spiral that could ultimately lead to species endangerment and/or the endemic loss or degradation of vegetation communities and ecological processes. To take into account the relative importance of this category, if there are two or more environmental parameters with a high rating in a given polygon then the polygon was elevated to the very high category.

Table SC6.9.1 — Environmental importance categories and components

Category	Environmental importance components	General description

Medium	• Least concern remnant vegetation (VMA vegetation management status)
	  − Brigalow belt north bioregion
	• Remnant vegetation (VMA biodiversity status — Of Concern)
	• High value regrowth
	  − of concern (sub dominant)
	  − least concern
	• GBR wetland protection trigger areas (buffers)
	• Statewide corridors (nonremnant)*
	• Magnetic Island corridors (nonremnant)*
	• Magnetic Island lowland values (regrowth)*
		This category includes the widest range of environmental values from near threatened (30% remnant vegetation remaining) to relatively stable (100% remnant vegetation remaining). This category also includes some of the less tangible environmental and ecological functions, such as catchment protection, buffers, landscape connectivity and viable- sized habitat and ecosystems.
		
		This is the category that is likely to require the highest level of investigation prior to any development, as it is the least 'certain' in terms of priority for environmental protection. It is likely to have very high and high environmental value features, which have not been identified at the mapping resolution used for the categorisation. It may also include some low value features.
		
		If there are three or more environmental parameters with a medium rating in a given polygon then the polygon has generally been elevated to the high category.

Footnote—SDI is Simpson's Diversity Index

Footnote—*Denotes amendments/additions using DEHP mapping

It should not be assumed that any area has no environmental values. Areas not included in the overlay map (depicted without an infrastructure rating) generally consist of areas that have significantly less environmental value due to the level of disturbance resulting from anthropogenic activities, including clearing of native vegetation and the construction built form. The environmental values of some of these areas could be reinstated.

Applicants and landowners should be aware that other land not included in the overlay map may contain other remnant and non-remnant vegetation or other environmental value that is subject to the requirements of other state and/or federal legislative requirement.

In addition, there are provisions in some zone codes that require applicants to respond appropriately to any localised values that may exist outside the overlay area.

SC6.9.2.7 Mapping limitations

The general mapping resolution used for the environmental importance ratings map (Overlay Map OM-08) is 1:100,000. The Queensland Government's Regional Ecosystem mapping has been used as the base map for the environmental importance rating map and, while being the best available data source for this type of environmental categorisation, it is recognised that there are inaccuracies in the base map and therefore there will be inaccuracies in the resulting product - i.e. environmental importance ratings.

To overcome some of the inaccuracies, a review of the environmental importance ratings has been undertaken for the urban, rural and rural residential areas using 2011 aerial photography (the most recent available at the time of review). Further refinement of the mapping is required, for example, to accurately locate waterways, wetlands, riparian zones and buffers as the current Queensland Government mapping is not accurate at the local/urban scale and especially for order 1 and order 2 streams.

In light of these mapping limitations, it is imperative that an environmental assessment is undertaken for areas mapped with medium, high and very high environmental importance to ensure that development applications are assessed with the benefit of the best available information.

Council will continue to improve its environmental mapping, over time, to more accurately reflect environmental importance across the entire Townsville landscape, to reduce the incidence of unsustainable land use and development, and thereby contribute to the achievement of ecological sustainability and a sustainable Townsville.

SC6.9.2.8 Supporting maps

Supporting maps have been produced to assist applicants in using the Natural assets overlay code. The data presented on each of the supporting maps has been extracted from data contained on map OM-08 and are provided to assist applicants identify environmental and ecological features within the Townsville landscape.

Supporting maps may be used to assist applicants address relevant assessment benchmarks of the natural assets code.

Maps supporting the natural assets overlay code are:

(1) Figure SC6.9.1 – Natural assets – waterways represent the Queensland Government 1:100,000 waterways mapping. Waterways have been mapped to enable identification of stream orders specifically and are designed to allow applicants to identify the relevant stream order that affects a given location.

(2) Figure SC6.9.2 – Natural assets – wetlands include Great Barrier Reef wetlands of high ecological significance (wetland protection areas), riverine wetland regional ecosystems and other wetland regional ecosystems. Ramsar wetlands and wader roosts have also been shown to identify the presence of these areas at their given location.

(3) Figure SC6.9.3 – Natural assets – ecological corridors include:

  (a) priority corridors from the Environment and Biodiversity Study: Final Report (Chenoweth April 2011);

  (b) state corridors from data provided by the Department of Environment and Heritage Protection (DEHP); and

  (c) the state and priority corridors as major ecological corridors and the great eastern ranges conservation corridor. Major ecological corridors shown on the map consist of a 250m core corridor and a 50m buffer either side of the core corridor.

(4) Figure SC6.9.4 – Natural assets – core habitat includes Cassowary, Mahogany Glider and draft Black-throated Finch habitats in addition to essential habitat for other threatened species as mapped by DEHP including declared fish habitat areas.

SC6.9.2.9 Environmental assessments

An environmental assessment may be required to show what impacts the development activity may have on the environment and how potential adverse impacts on the environment can be mitigated. To demonstrate compliance with the Natural assets overlay code, such an assessment may need to include a detailed ecological assessment.

The required assessments should be undertaken by a suitably qualified and experienced professional and provide a site specific investigation of the values present and their significance to ground truth the data reflected on the overlay mapping. The level of investigation required and techniques utilised should be commensurate with the scale and nature of the proposed development and the type of values present on the site. The environmental assessment should provide the appropriate level of information to assess the potential impact of a proposed development on the environment including:

(1) identification of the physical and ecological features of the site;

(2) identification of the ecological processes and ecosystem services associated with the site;

(3) identification of the physical and ecological connections between the site and the surrounding environment, including ecological processes and ecosystem services; and

(4) comparison of the environmental importance components and features identified on OM-08 to on ground findings.

The environmental assessment and reporting process also provides the development proponent with the opportunity to propose potential solutions that prevent or minimise potential environmental harm to natural assets and ecological processes associated with the proposed development. Potential solutions may include:

(1) environmental offsets;

(2) operational environmental management plans;

(3) succession plans and criteria for handover of natural assets to council;

(4) establishment of Nature Refuge areas;

(5) stormwater management plans incorporating water sensitive urban design (WSUD);

(6) resourced rehabilitation plans (in addition to or instead of environmental offsets); and

(7) innovative ideas for the progression of the development and protection of environmental values.

SC6.9.2.10 Environmental assessment report

The environmental assessment report should be set out in accordance with the framework provided below.

Physical and ecological features of the site including:

(1) Introduction providing information about:
   (a) the applicant;
   (b) tenure;
   (c) location; and
   (d) current land use and proposed land use.

(2) Site description including:
   (a) surrounding land use;
   (b) location in the water catchment;
   (c) proximity to HEV waters;
   (d) proximity to World Heritage Areas and other protected areas;
   (e) geology and soils; and
   (f) Regional ecosystems.

(3) Environmental importance components and features identified on OM-08 (Natural assets overlay).

(4) Likely ecological processes and ecosystem services associated with the site and adjoining areas.

(5) Social, physical and environmental constraints identified in other overlays including flooding, fire hazard, slope and visual amenity.

Physical and ecological features of the site (on ground site assessment results):

(6) The physical and ecological features of the site, based on on-ground assessment including:
   (a) soils and their geological derivation;
   (b) drainage and wetland features;
   (c) Other native vegetation and regrowth;
   (d) Regional Ecosystem type and extent;
   (e) habitat type and extent;
   (f) exotic species presence (terrestrial and aquatic – plant and animal); and
   (g) fauna sightings and signs (additional targeted survey work may be required where threatened species and ecological communities are likely to be present).

(7) Ecological processes and ecosystem services associated with the site.

(8) The physical and ecological connections between the site and the surrounding environment including ecological processes and ecosystem services.

Comparison of desktop review features with site assessment features:

(9) Comparison of the environmental importance components and features identified on OM-08 council's Natural assets overlay to on ground findings.

Suggestions for development impact avoidance or mitigation, including, but not limited to the following considerations:

(10) stormwater management including erosion prevention and sediment movement control;

(11) habitat management including weed control;

(12) maintenance of ecological processes; and

(13) maintenance or improvement of connectivity.

Environmental assessments and the preparation of management and rehabilitation plans are to be undertaken by a

person/people/organisation with the appropriate skills and experience. Where a person with less than four years' experience in field work is involved in the assessment, they should be supervised by an experienced environmental practitioner. Regardless of experience and qualifications, all work should be thoroughly reviewed as part of a quality assurance process prior to submission of studies, reports and plans to council.

SC6.9.2.11 Site-based management and rehabilitation plan

Where there is a requirement in the Natural assets overlay code, a site based management plan and/or a rehabilitation plan should be prepared to address the site specific situation. Generally, content should be in a format that identifies:

(1) the physical and biological condition of the site (from the Environmental assessment report);

(2) the issue/s being addressed and their location (from the Environmental assessment report);

(3) how and over what time scale the issue will be addressed (with input from Part 4 of the Environmental assessment report); and

(4) the commitment of resources allocated to implement the plan.

Plans need to provide enough information to show that the performance outcomes in the Natural assets overlay code will be met by the implementation of the plan. The use of maps and accompanying tables with management actions are encouraged to simplify the plan and reduce the size of documents.

SC6.9.2.12 Additional information

Additional material may be required as part of the environmental assessment depending on the environmental importance components and features identified in the Natural assets overlay. This involves proximity to areas of significant ecological or environmental value and requirements for vegetated buffers as well as the proximity to wader roosts. Additional information will be required if the proposed development is within:

(1) 200 metres of a wader roost area as indicated on Figure SC6.9.2 – Natural assets – wetlands;

(2) 200 metres of core habitat and endangered ecological communities;

(3) 200 metres of HEV waters;

(4) 200 metres of a wetland area;

(5) 100 metres of an ecological corridor;

(6) 100 metres of a declared fish habitat area; and

(7) 100 metres of a waterway.

Information derived from on ground investigations will be required to show:

(1) the actual distance from the environmental feature to the edge of the development and a comparison to the Natural assets overlay.

(2) the physical condition of the area between the environmental feature and the development including:

  (a) soils;

  (b) drainage patterns;

  (c) habitat type/s;

  (d) vegetation type and condition;

  (e) presence of exotic species;

  (f) observed fauna and signs of fauna; and

  (g) built infrastructure e.g. fences, drains and roads; and

(3) how buffer areas will maintain natural assets and ecological processes if a proposed buffer area/width is less than that specified in the Natural assets overlay code.

It is the responsibility of the development proponent to provide council with alternative solutions, when digressing from council's acceptable solutions, to ensure natural assets and ecological processes are not degraded as a consequence of the proposed development. Council may adopt the proponent's suggestions as conditions of development approvals.

SC6.9.2.13 Background information to assist environmental assessments

Council has compiled a range of environmental information to assist development proponents with the preparation of their environmental assessments. A list of the information is provided below with associated references:

(1) schedule of locally significant fauna, flora and vegetation/ecological communities along with those scheduled under legislation;

(2) landscaping guidelines expounding the use of local native species and excluding environmental weed species;

(3) local and regional movement requirements of wildlife (refine connectivity corridors based on species habitat location and known ecology);

(4) fauna survey techniques (e.g. types of trapping, call play back etc.) including the most appropriate targeted survey techniques and when these may be required for particular species;

(5) pest species (flora and fauna) specific to Townsville and appropriate management techniques; and

(6) Black Ross (Townsville) Water Quality Improvement Plan

SC6.9.2.14 Terminology

The following table provides a useful compendium of environmental terms, including terms used in this policy.

Word / Term	**Explanation**
Aquatic	Of the water, or living or growing in water.
Arboreal	Tree dwelling. Adapted to living in or among trees. Spending a significant part of the life cycle in trees or relying on arboreal habitats for shelter and/or food.
Avian	Birds. Of or pertaining to birds.
Biodiversity	The variety of all life forms: (1) *genetic diversity*—the variety of genetic information contained in individual plants, animals and other organisms. (2) *species diversity*—the variety of species. (3) *ecosystem diversity*—the variety of habitats, ecological communities and ecological processes. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Biodiversity values	As biodiversity is the variety of all forms of life biodiversity values are difficult to quantify. Biodiversity values are often based on a combination of biological and biophysical parameters including; habitat species richness and endemic anomalies. Some of these parameters have been included in the environmental importance rating map prepared for the Natural Assets Overlay.
Biophysical processes	Processes involving interaction between the biological (organic) world and the physical (inorganic) world e.g. soil formation and nutrient recycling.
Bioregion	As described in the *Vegetation Management Act 1999* (VMA).
BTF is Black-throated Finch	The Black-throated Finch BTF is an Endangered species under the *Commonwealth Environmental Protection and Biodiversity Conservation Act 2000* (EPBC Act) and Queensland's *Nature Conservation Act 1992*. BTF habitat mapping is draft and will require further investigation to determine actual core habitat. A greater level of assessment will be required for development applications in BTF habitat areas.
Buffer	The threat management space between a natural or environmental asset and the threat. Buffers can also act as ecological corridors and provide habitat for wildlife. [anything serving to neutralise the shock of opposing forces (The Macquarie Dictionary (2nd Edition) 1991, p.234)]

Buffering	The practice of providing a managed ecotone between the area of environmental significance and the threatening process/es.
Connectivity	The physical linkages serving to connect dissimilar or separated patches of habitat. The name given to the concept of landscape elements being connected. The capacity of landscapes or aquatic environments to allow ecological movement and function. The broad concept can be considered to have several main elements:*landscape connectivity*—the physical connection between areas with vegetation cover across a landscape. (1) *habitat connectivity*—the connection between patches of habitat suitable to a particular species. (2) *ecological connectivity*—the ecological processes that underpin the function of landscapes; for example, the transfer of pollen or seeds and the sequestration of soil carbon. (3) *evolutionary connectivity*—populations of species are able to interact naturally, sharing genes and adapting to changing environmental conditions. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Core area, core habitat area	An area of habitat that is of a suitable size, shape and condition for an assemblage of species or a single organism. Core habitat provides nutrients and water resources, and supports successful reproduction. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45- 49).
Corridors	Corridors are passageways that facilitate the movement of organisms and serve as habitat. Corridors exist at a range of scales depending on the organism and their ecological requirements. Corridors are not confined to linear strips of vegetation or riparian zones but rather include an interconnected network of native vegetation and habitat across the landscape. Waterways and wetlands provide ecological corridors for aquatic organisms.
Degraded	In a lessor state as a result of human interaction and natural causes e.g. storms.
Ecological communities	Assemblages of species (plants, animals, bacteria and fungi) that interact with each other in a common environment and often as part of a food chain or trophic web.
Ecological functions	Functions and processes involving the interaction of organisms with each other and their environments including , nutrient cycling, pollination, animal and plant breeding.
Ecological significance	The term used to describe areas that are important for maintaining biodiversity and ecological processes.
Ecotone	The gradation or transition zone between different habitats or vegetation communities.
Ecosystem	Ecosystem is “1. a community of organisms interacting with one another and with the environment in which they live.” (The Macquarie Dictionary (2nd Edition) 1991, p.555). A complex network or interconnected system or a biological community of interacting organisms and their physical environment; for example, combinations of plant, animal and other organisms in communities and their non-living environment (soil, water, climate, and so on) interacting as a functional unit, such as forest, wetland or grassland. (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Ecosystem health	A measure of the condition of ecosystems from sustainable to threatened.

Ecosystem processes	Those life processes and interactions between organisms and the environment that (generally) contribute to the overall health of the ecosystem.
Ecosystem services	The multitude of resources and processes that are supplied by natural ecosystems. Collectively, these benefits are known as ecosystem services and include products like clean drinking water and processes such as the decomposition of wastes. The term is generally applied to benefits to human beings as with the Millennium Ecosystem Assessment 2005 definition “the benefits people obtain from ecosystems”. This is a narrow, anthropogenic definition that could restrict the protection of important ecosystem services if they are not seen as beneficial to humans. The definition has been broadened in the National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012 to read; “the processes or materials provided by ecosystems. Ecosystem services benefit biodiversity, humans and society through the provision of essential goods and services such as clean air, water, food, shelter, energy, nutrients, amenity values and cultural resources”. (pp.45-49)
Endemic	Refers to organisms that are native to a particular area or region. Having a limited distribution or habitat extent or confined to a specific area.
Environmental infrastructure	Environmental infrastructure is the basic framework or underlying foundation of the natural environment that contains the myriad of life support systems for all forms of life.
Hydrological function	The function of water moving through the landscape as part of a natural drainage process. Hydrological function is shaped by geological features and influences those features over time e.g. erosion. Hydrological function can be impeded by: (1) the placement of obstacles in waterways, (2) obstructing overland flow e.g. raised roads and rail lines, (3) reduced aquifer recharge.
Migratory species	Animals, especially birds and marine species, that travel significant distances (compared to remaining in a home range) to: (1) avoid climatic extremes and resource (food) depletion, (2) find sufficient resources to maintain physical health, (3) breed in more favourable conditions.
Native habitat	Habitat that is in a relatively natural state with minimal disturbance from human activities with a low incidence of exotic plant species.
Native species	Species (plant or animal) that would normally be found in the (Townsville) natural environment.
Natural areas	Those parts of the environment that have not been significantly altered from their natural state and that retain their ecological processes, biophysical functions and suite of native species.
Naturalised	Non-native species introduced to Australia that flourish and become part of the landscape.
Non-native	Not having evolved in Australia. Introduced into Australia from another country within the last 300 years.
Pest fauna and flora	Introduced species that threaten the viability and/or productivity of native ecosystems.

Refuge/refugia	An area that provides shelter, food or water for organisms when other parts of the landscape are inhospitable. For example, rocky areas can provide shelter during bushfires, while riparian areas might provide food and water during times of drought (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012, pp.45-49).
Resilience	The ability to recover after being impacted by threatening processes.
Riparian areas	Areas of vegetation alongside watercourses, lakes and wetlands. They often contain vegetation that differs from that in the surrounding landscape, providing important habitat and ecological resources (from National Wildlife Corridors Plan: A framework for landscape-scale conservation 2012 pp.45-49).
Significant ecological communities	Those ecological communities that are limited in extent (endemic) or population, confined to specific habitats or have characteristics that result in a vulnerability to environment changes and threatening process.
Threatened species	Threatened wildlife means native wildlife that is prescribed under the *Nature Conservation Act 1992* as— (a) extinct in the wild wildlife; or (b) endangered wildlife; or (c) vulnerable wildlife.
Threatening processes	Human activities that adversely impact the environment, natural values and ecological processes and result in adverse impacts including habitat loss, native vegetation destruction and reduced populations of native and migratory species.
Wader roosts	As defined in the Environment and Biodiversity Study: Final Report (Chenoweth 2011) and represented as a 700 metre buffer trigger area around wader roosts.
Wetland mapping and classification methodology	The "A Method to Provide Baseline Mapping and Classification for Wetlands in Queensland (VERSION 1.2) published by the Environmental Protection Agency, Queensland Government and produced in conjunction with the Australian Government (Department of the Environment and Heritage) in 2005.

SC6.10 Parking rates planning scheme policy

SC6.10.1 Introduction

Short Title – The planning scheme policy (PSP) may be cited as the Parking rates PSP.

SC6.10.1.1 Purpose

The purpose of the planning scheme policy is to:

(1) define the particular rates of parking that provide the relevant acceptable outcome under the Transport impact, access and parking code in the Townsville City Plan.

SC6.10.1.2 Legislative authority

This planning scheme policy is made under Chapter 2, Part 3 of the *Planning Act 2016*.

SC6.10.1.3 Relationship to the Townsville City Plan

This planning scheme policy is to be read in conjunction with the assessment provisions specified in the Townsville City Plan, specifically the Transport impact, access and parking code.

SC6.10.1.4 Terminology

Terms used in this planning scheme policy are defined in Schedule 1 - Definitions. A term which is not defined in Schedule 1 - Definitions is to be interpreted in accordance with Part 1.3.1 - Definitions.

SC6.10.2.1 Planning scheme policy content -parking rates

(1) Parking rates are provided on site in accordance with the following uses or combination of uses.

(2) Where the number of parking spaces calculated in accordance with this table is not a whole number, then the minimum number of spaces to be provided is to be rounded upward to the closest whole number.

(3) The number of car parking spaces required for people with a disability is to be in accordance with Table D3.5 of the Building Code of Australia. There is no requirement to designate car parking spaces for people with a disability where the total number of car parking spaces required is five (5) or less.

Use	Parking rates
Adult store	One (1) space per 25m² of GFA.
Agricultural supplies store	One (1) space per 100m² of total use area, but not less than five (5) spaces.
Air services	One (1) space per 80m² of GFA.
Animal keeping	One (1) space per 10 animals for which accommodation is provided for on the premises, OR 3 spaces, whichever is the greater.
Aquaculture	One (1) space per employee (FTE).
Brothel	One (1) space for each room in the brothel AND one (1) space per two employees (FTE) on the premises at any one time.
Bulk landscape supplies	One (1) space per 100m² of total use area, but not less than five (5) spaces.
Caretaker's accommodation	One (1) space.
Car wash	Two (2) spaces, AND queuing space within the site for 4 vehicles using or awaiting use of each washing bay.
Cemetery	Thirty (30) spaces plus one (1) space per two employees (FTE) on the premises at any one time.
Child care centre	One (1) space for every 6 children, and 1 space per employee (FTE).
Club	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Community care centre	One space per 20m² of GFA
Community use	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Crematorium	Thirty (30) spaces plus one (1) space per two employees (FTE) on the premises at any one time.
Detention facility	One (1) space per 2 employees (FTE); plus a minimum of ten (10) visitor spaces.
Dual Occupancy	Two (2) spaces per dwelling unit, which may be provided in tandem, of which one (1) space is to be covered per dwelling unit.
Dwelling house	Two (2) spaces, which may be provided in tandem, of which one (1) space is to be covered.
Dwelling unit	One (1) space.
Educational establishment	Primary – one (1) space per employee (FTE) AND one (1) space per 10 students for visitor parking AND sufficient spaces for loading and unloading of passengers in addition to other requirements. Secondary – one (1) space per employee (FTE), AND one (1) space per 10 students of legal driving age, AND one (1) visitor space per 50 students, AND sufficient spaces for loading and unloading of passengers in addition to other requirements. Tertiary – point five (0.5) spaces per employee (FTE) PLUS one (1) space per 10 students (FTE), AND sufficient spaces for loading and unloading of passengers in addition to other requirements.
Emergency services	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Environment facility	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Extractive industry	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Food and drink outlet	One (1) space per 10m² of GFA available to the public (including outdoor dining); One (1) space per 50m² of GFA for food preparation; AND One (1) space per 100m² of GFA used for storage.

Function facility	Sufficient spaces to accommodate the amount of vehicle traffic likely to be generated by the particular use.
Funeral parlour	One (1) space per employee; AND One (1) space per hearse; AND One (1) space per 4 persons capable of being seated in any chapel or accommodated in a function area with a minimum of ten (10) spaces.
Garden centre	One (1) space per 100m² of total use area, but not less than five (5) spaces.
Hardware and trade supplies	One (1) space per 40m² of GFA.
Health care services	One (1) space per 20m² of GFA, OR four (4) spaces per medical practitioner, whichever is the greater; AND one (1) space for ambulance vehicle pick-up and set down.
High impact industry	One (1) space per 100m² of GFA.
Hospital	One (1) space for each 4 beds, two (2) spaces for each 3 employees, AND one (1) space for each doctor.
Hostel	One (1) space for every 2 beds provided, one (1) space for every 4 employees (FTE), and an additional one (1) covered space for a resident manager, and a dedicated car washing bay (additional to visitor and tenant parking spaces). A dedicated car washing bay is not required where there are 5 or less dwelling units provided. A dedicated car wash bay may also be integrated with visitor parking to serve both functions.

Appendix 1 Index and glossary of abbreviations and acronyms

Table AP1.1 - Abbreviations and acronyms

Abbreviation/Acronym	Description
AEP	Annual exceedance probability
AHD	Australian height datum
ANEF	Australian Noise Exposure Forecast
ANZSIC	Australia and New Zealand Standard Industrial Classification
ARI	Average recurrence interval
BCA	Building Code of Australia
CASA	Civil Aviation Safety Authority
CBD	Central business district
DARC	Defence (Areas Control) Regulation
DSS	Desired standard of service
DME	Distance measuring equipment
ESD	Ecologically sustainable development
GBR	Great Barrier Reef
HAT	Highest astronomical tide
HES	High ecological significance
HF	High frequency
JCU	James Cook University
LGIP	Local government infrastructure plan
MCU	Material change of use as defined in the Act
NDB	Non-directional beacon
PFTI	Plans for trunk infrastructure
PIA	Priority infrastructure area
PDA	Priority development area
PIP	Priority infrastructure plan
PSP	Planning scheme policy
QDC	Queensland Development Code
QWQG	Queensland Water Quality Guidelines
RAAF	Royal Australian Air Force
ROL	Reconfiguring a lot as defined in the Act
RL	Reduced level
RSTEL	Recommended storm tide event level
SPP	State planning policy
the Act	*Planning Act 2016*
the Regulation	Planning Regulation 2017
UNESCO	United Nations Educational, Scientific and Cultural Organisation
VOR	VHF omni-directional radio range
VMA	*Vegetation Management Act 1999*
WQO	Water quality objective

Appendix 2 Table of amendments

AP2.1–Table of amendments

Date of adoption and effective date	Planning scheme version number	Amendment type	Summary of amendments
13 October 2014 (adoption) and 27 October 2014 (effective)	2014/01	Administrative and Minor	The purpose and general effect of the administrative amendments are to correct errors in explanatory matter, formatting and presentation, spelling and grammar, inconsistent numbering and cross-references. The purpose and general effect of the minor amendments are to: • Remove and amend gross floor area triggers for the uses Food and drink outlet and Community use in Part 5 Tables of assessment, Part 5.5.2 Medium density residential zone and Part 5.5.1 Mixed use zone to better reflect the purpose of the zone; • Amend mapping (Schedule 2 and Schedule 3) to reflect recently created lots and the new use intention; and • Reflect the declaration of the Townsville City Waterfront Priority Development Area.
28 July 2015 (adoption) and 28 August 2015 (effective)	2015/01	Administrative and Minor	The purpose and general effect of the administrative amendments are to correct formatting and presentation, spelling and grammar and mapping errors. The purpose and general effect of the minor amendments are to correct and update minor technical matters with respect to: • local government administrative matters in Part 1; • the levels of assessment tables associated with the Character residential zone, Mixed use zone, Bushfire hazard overlay and Flood hazard overlay in Part 5; • the Low density residential zone and Rural zone codes in Part 6; • the Coastal protection – Coastal hazard areas overlay, Development constraints - Flood hazard overlay and Development constraints - Landslide hazard overlay mapping in Schedule 2; and • the Development manual planning scheme policy in Schedule 6 (SC6.4.4.4 Attachment A).

15 December 2015 (adoption) and 29 January 2016 (effective)	2015/02	Administrative and Minor	The purpose and general effect of the administrative amendments are to correct formatting and presentation, spelling, grammar and mapping errors. The purpose and general effect of the minor amendments are to correct and update minor technical matters with respect to: • Table of assessable building works in Part 1.6; • Amend zoning and precinct maps to reflect existing development approvals in Schedule 2; • Inclusion of mandatory transport and noise corridor maps in Schedule 2; and • Outline requirement for footpath treatments to be approved prior to construction in Schedule 6; • Updated wording and mapping of existing Oonoonba PDA and inclusion of Waterfront PDA under Part 10.
27 September 2016 (adoption) and 12 December 2016 (effective)	2016/01	Administrative and Minor	The purpose and general effect of the administrative amendments are to correct formatting and presentation, spelling, grammar and mapping errors. The purpose and general effect of the minor amendments are to correct and update minor technical matters with respect to: • Local government administrative matters in Part 1 relating to information regarding declared locality and building form for amenity and aesthetic referral agency assessment; • Refinement of the Coastal protection overlay code in Part 8 Table 8.2.3.3(a) relating to the design of buildings; • Refinement of the Cultural heritage overlay code in Part 8 Table 8.2.4.3 relating to elements in the road reserve; • Refinement of the Advertising devices code in Part 9, Table 9.4.1.3(a) relating to clarification of zoning and luminance values at night; • Amend zoning and precinct maps to reflect existing development approvals in Schedule 2; and • Updating the legend of Overlay Map OM-01.4 Australian noise exposure forecast (ANEF) in Schedule 2.

25 October 2016 (adoption) and 12 December 2016 (effective)	2016/01	Major	The purpose and general effect of the major amendment to SC6.4 Development manual PSP is to make improvements to the policy to reflect modern standards and practices. The more notable changes are listed below: • SC6.4.3.2 - Standards relating to building over or adjacent to services; • SC6.4.3.3 - Revised extents of the Footpath treatment policy to strategically align with the Townsville City Plan; • SC6.4.3.8 - Clarification of stormwater management plan requirements; • SC6.4.3.14 - Improvements to the Traffic impact assessment guidelines; • SC6.4.3.20 - Introduction of use of LED public street lights; • SC6.4.3.21 - Revised and improved water design standards; • SC6.4.4.2 - Revised and improved pavement design standards; • SC6.4.4.4 - Revised and improved stormwater design standards; and • General formatting and administrative corrections throughout the policy.
25 October 2016 (adoption) and 12 December 2016 (effective)	2016/01	Major	The purpose and general effect of the major amendment to SC6.10 Parking rates PSP is to correct the anomaly that exists between the definition of a Community care centre and the nominated parking rate for such a use under the Townsville City Plan. The parking rate associated with a Community care centre has been amended to: • One (1) space per 20m2 of GFA.
24 January 2017 (adoption) and 6 March 2017 (effective)	2017/01	Minor	The purpose and general effect of the minor amendment is to update minor technical matters with respect to: Updating of the Australian Noise Exposure Forecast (ANEF) contours on Overlay Map OM-01.4 in Schedule 2.
28 April 2017 (adoption) and 2 May 2017 (effective)	2017/02	Administrative and Minor	The purpose and general effect of the administrative amendments are to correct formatting and presentation and mapping errors. The purpose and general effect of the minor amendments to the planning scheme are as follows: • Update Map SFM-004 to reflect an additional future extractive resource area in Schedule 2. • Update Overlay Map OM-08 to rectify a mapping error in Schedule 2. • Update of Overlay Map OM-10.1 to reflect the most up-to-date noise corridor information in Schedule 2.

27 June 2017 (adoption) and 3 July 2017 (effective)	2017/03	Alignment amendment under section 293 of the *Planning Act 2016*	The purpose and general effect of the alignment amendment is to amend the Townsville City Plan for alignment with the *Planning Act 2016* as by the Minister's rules under section 293 of the *Planning Act 2016*.
25 July 2017 (adoption) and 31 July 2017 (effective)	2017/04	LGIP amendment	The purpose and general effect of the LGIP amendment is to convert the Priority infrastructure plan to a Local government infrastructure plan.
25 July 2017 (adoption) and 31 July 2017 (effective)	2017/04	Administrative	The purpose and general effect of the administrative amendment is to change outdated terms in the planning scheme following adoption of the Local government infrastructure plan.
17 April 2018 (adoption) and 30 April 2018 (effective)	2018/01	Major	The purpose and general effect of the major amendment is to amend the relevant zoning and overlay maps associated with the land parcel at 134 Racecourse Road, Cluden (Part of Lot 21 SP261125). The amendments are: • Schedule 2 – Zoning Map ZM-041 – Part of Lot 21 SP261125 at 134 Racecourse Road, Cluden has been removed from the Open space zone and included in the Low impact industry zone. • Schedule 2 - Overlay Map OM-03.1 and Overlay Map OM-03.2 Coastal hazard areas – storm tide inundation areas and erosion prone areas from sea level rise - Part of Lot 21 SP261125 at 134 Racecourse Road, Cluden has been removed from High hazard and included in the Medium hazard. • Schedule 2 - Overlay Map OM-03.3 Coastal hazard areas – erosion prone areas - Part of Lot 21 SP261125 at 134 Racecourse Road, Cluden has been removed from the Erosion prone area. • Schedule 2 – Overlay Map OM-06.1 and Overlay Map OM-06.2 Flood hazard and Overlay Map - Part of Lot 21 SP261125 at 134 Racecourse Road, Cluden has been removed from the High flood hazard area and included in the Low flood hazard area.

22 March 2018 (adoption) and 30 April 2018 (effective)	2018/01	Administrative and Minor	The purpose and general effect of the administrative amendments are to correct formatting, presentation mapping errors. The purpose and general effect of the minor amendments are to correct and update minor technical matters with respect to: • Part 9 - Refinement of the Landscape code in Table 9.4.3.3 relating to irrigation systems; • Schedule 2 - Updating of Coastal hazard overlay maps OM-03.1, OM-03.2 and OM-03.3 regarding the inclusion of an identified coastline; and • Schedule 2 - Updating of Cultural heritage overlay maps OM-04.1, OM-04.2, OM-04.3 and OM-04.4 regarding State heritage sites.
22 March 2018 (adoption) and 30 April 2018 (effective)	2018/01	Amendment	The purpose and general effect of the amendment is to make improvements to Schedule 6, SC6.4 Development manual planning scheme policy to reflect modern standards and practices. The key amendments include: • SC6.4.3.6.6 Crime prevention through environmental design (CPTED) notes that landscaping design should be considerate of CPTED principles; • SC6.4.3.6.9 Public open space provides greater clarity around levels of public open space embellishment to achieve balance between the needs and wishes of the community and the development industry and more sustainable maintenance outcomes; • SC6.4.3.6.10 Recreation Parks provides further detail to improve identification and classification of the open space and park hierarchy; • SC6.4.3.6.11 Sporting Parks provides further detail to improve identification and classification of the open space and park hierarchy; • SC6.4.3.6.12 Other public open space provides further detail to improve identification and classification of the open space and park hierarchy; • SC6.4.3.6.13 Open space embellishments provides greater clarity around levels of public open space embellishment to achieve a balance between the needs and wishes of the community and development industry and sustainable maintenance outcomes; • Table SC6.4.3.6.1 Public open space embellishment framework provides increased clarity about the level of

			embellishments required for open space areas within the park and open space hierarchy; • SC6.4.3.6.24 Dog off-leash facilities has been added to guide the development of dog off-leash facilities to meet community expectations and needs; • Sub-section SC6.4.3.6.34 – Irrigation design and system requirements provides greater clarity around irrigation construction handover standards; • SC6.4.3.6 Table A – Preferred plant species list includes a small number of new species reflective of industry supply and research; • SC6.4.4 Design specification and standard drawings include changed engineering standards; • SC6.4.5 Construction Management includes changed engineering standards; and • SC6.4.6 Construction Management includes changed engineering standards.
22 January 2019 (adoption) and 4 March 2019 (effective)	2019/01	Major	The purpose and general effect of the major amendment is to include an addition precinct, to be known as the Burdell precinct, within the Emerging community zone in the North Shore master-planned community at Burdell. The key amendments include: • Part 5 Tables of Assessment: Table 5.6.1 – Reconfiguring a lot has been amended to make reconfigurations in the Burdell precinct code assessable; • Part 6 Zones: 6.7.1 Emerging community zone: Section 6.7.1.2 Purpose has been amended to include overall outcomes for the Burdell precinct and Table 6.7.1.3 – Self-assessable and assessable development has been amended to include criteria for assessable development in the Burdell precinct; • Part 9 Development codes: Table 9.3.4.3(c) – Minimum lot size dimensions has been amended to include reference to the Burdell precinct in the Emerging community zone; and • Schedule 2 Mapping: Zoning Map-ZM-026 and Precinct Map-PM-028 have been amended to include the Burdell precinct within the Emerging community zone.
